Gold atoms have extremely high positive electrostatic field effects, more so than any other atom. This is why gold is the most malleable of all substances. This means that soft electrons will have a greater affinity for gold than for any other metal. As a result, abnormally high concentrations of soft electrons will concentrate around gold. This effect is greatly enhanced when gold is in contact with iron. These dissimilar metals produce an EMF which in turn, causes a flow of electricity or eddy currents resulting in the iron being magnetised. The magnetic field produced, captures additional soft electrons. A higher concentration of soft electrons is created by this combination then could be produced by a similar thickness of gold foil alone. It follows that by far the most effective material that could be used for pyramids is gold-plated sheet iron (galvanised iron should not be used).

With everything else being the same, the greater the size of a pyramid, the better the performance. The reason for this is that the thicker the layer of concentrated soft electrons through which the incoming soft particles must pass, the more they are slowed down when passing. This results in a greater back-up of soft electrons and an increase in the concentration inside the pyramid. Another reason is that a large pyramid has a greater ratio of volume to surface area. Soft electrons are continuously leaking away from the surface of the pyramid, the larger the pyramid, the lower the percentage of soft electrons which is lost. Consequently, very small pyramids are ineffective.

The Devices of Pier Luigi Ighina.

Pier Luigi Ighina was a remarkable Italian scientist who died in 2004 at the age of 95. He was a colleague of Guglielmo Marconi who was well-known for his work in the early days of radio. Pier, in common with many famous scientists, had an enquiring mind, major intelligence and a very high level of patience and persistence. He too, discovered the energy flows which affect life on this planet and he had his theories and descriptions for what he observed. From his very wide range of inventions and fields of interest, just two will be mentioned here in this chapter as they relate directly to the energy flows channelled by pyramids and Joe Cells, and whether we call this energy flow ‘orgone’, ‘soft electrons’, ‘OD’, ‘ethers’, ‘ambient background’ or whatever, the effects are the same. Pier describes (very briefly) two important devices which have a direct effect on our health and well-being, and on our local environment generally. The first of these passive devices, he has named “ERIM”.

He describes this device as a small apparatus which concentrates and develops what he calls “the Magnetic Rhythm Solar Earth Energy, which regenerates cells and returns them to their normal functioning”. While I have not seen any specific constructional details for this device we do have a general description and several photographs which show three or four different constructions. On the surface, the device appears to be very simple and straightforward and the photographs give the impression that the construction does not have to be exact in order for it to function correctly. However, it needs to be remembered that these energy flows are directly influenced by the user and just because Pier has had spectacular results with his constructions, some of the performance may well be caused by Pier himself. Having said that, there appears to be very little to be lost by attempting a replication and quite possibly, a major amount to be
gained if the replication is successful. The following four photographs show three different constructions of the device which looks like this:

Or like this:
Photographs 1 and 2 show two different views of one build. The nine spiral coils have seven turns and the narrow end is a flat turn. The gap between the yellow and blue spirals is quite large, appearing to be just under the depth of two turns of the spirals. The base is the same shape and the mounting bolt is not painted, the colour suggesting that it might be a brass bolt. The size of the mounting ring can be estimated from the man in photograph 2 and I would put it at 250 mm (10") as Pier was Italian and so probably used metric units of measurement. I doubt that the dimensions are critical and the spirals appear to be about 100 mm (4") tall with the widest turn being about 45 mm (1.75"). We are not told what metal was used for any of the construction, but as the second of Pier’s devices to be described here specifies aluminium, it can’t be ruled out here, although the metal does look like painted steel.

Both aluminium and copper are generally considered to be non-magnetic because a magnet does not normally attach itself to either of those metals. But, this is highly misleading as both have a major effect when placed in a magnetic field, and the energy flow being channelled by this device of Pier’s is itself affected by magnetic fields, so the use of aluminium is likely to be highly significant. However, that being said, we have no direct information on what is used in this “ERIM” device.

You will notice in photographs 1 and 2, that the lugs on the arms of the bars across the circular mounting are quite short, causing their bolts to be widely spaced, which in turn, causes the outer blue and yellow spirals to be widely separated. Those lugs are longer in the build shown in photograph 3, moving the bolts closer together and bringing the blue and yellow spirals closer together. In photograph 3 the long mounting bolt at the bottom of the ring appears to be thicker and it is painted blue. The spirals have the smallest turn flat across the length of the spiral.

Photograph 4 shows a third build of the device, with an even thicker supporting bolt painted blue, wider spacing between the blue and yellow spirals and this time, the smallest turn of the spiral turned up axially and filed to a point. It appears that the device is assembled and then painted afterwards although the spirals may be dipped beforehand. Photograph 4 shows how the spirals are secured under the head of a bolt which is screwed into a threaded hole in the circular frame. Photograph 3 seems to suggest that constructional accuracy is not critical with the side spirals not aligned correctly (unless the lower spirals are supposed to point slightly inwards which seems unlikely, especially since the top spiral of photograph 3 is not truly vertical and does not align with the other two yellow spirals.

Photograph 4 seems to suggest that the green spirals can be slightly more compact than the others although they have exactly the same number of turns. Every spiral is wound the same way so when viewed from above, the upper spirals move in a counter-clockwise direction as they rise and the lower spirals move in a clockwise direction as they get lower. It might be that the colouring of the components might just be for referencing them, but I do not think that this is so. In the following device, Pier stresses the different colours and considering that different colours radiate different frequencies of light, there may well be significance in the colours. Piers describes the operation in this way:

The properties of the device are determined by it’s shape. The three yellow spirals pointing upwards concentrate Solar Energy while the three blue spirals pointing downwards, concentrate Earth’s bio energy which is the negative reflection from the Earth of the Solar Energy. When these two meet, they produce a wave on the green spirals called the Sun-Earth Magnetic Rhythm (which is the rhythm of everything which exists on Earth - both animate and inanimate). This wave enhances that essential basic rhythm for everything within it’s operating radius, normalising and balancing cells and cleansing the energy of a room.

Ideally, the device should be placed in the bedroom so that it can act during the night, but it can also be effective almost anywhere. It should be positioned about 10-20 cm away from walls. At the beginning, to accelerate the process of cellular balancing, you can place your hands about 10-15 cm from each side of the device, with your palms turned towards the green spirals and at the same level as they are. The time required will depend upon individual sensitivity.

If you have hot water central heating, you can place the device about 10 cm from the boiler with the green spirals parallel to it; the circulating water will carry information throughout the system and cleanse rooms within a few days. To energise water and return it to it’s original, natural state, place a bottle of water at each side of the device, about 10-15 cm from the green spirals. It can also energise foodstuffs such as fruits, vegetables and meats by placing them level with, and about 10-15 cm in front of the green spirals, using a
non-metallic support, if necessary. Flowers placed close by, will keep fresher longer, or will blossom sooner than normal.

The second passive device designed by Pier is what he calls his "Elios" device. It is constructed from a long small-diameter coil of aluminium wire which is snaked backwards and forwards through a circular wooden frame supported on three short wooden legs. The wooden frame is painted as shown here:

![Diagram of Elios device](image)

The aluminium wire coil is fed through the frame using plastic tubular beads. It is not clear if the beads pass the whole way through the frame with the upper bead meeting the lower bead in the centre of the frame, or if the beads are completely external to the wood, or perhaps partially embedded in the wood.

Pier says that the Elios device concentrates the maximum energy output in the cavity. The device is able to destroy every type of toxic pollution, including nuclear radiation. Food exposed to its action changes completely because every chemical added to the food gets dissolved by balancing its own Rhythm (vibration) by a multi-wave signal comprising a full octave of colours. Every type of matter receives a certain type of enhancement from it. For example, our body and all types of biological entities are healed, and growth is boosted by it.

This signal is a stationary type phenomenon of rotating particles which come from the Sun and other stars. These particles strike the Earth, store energy, and return to their sources in a reflected state which is the opposite phenomenon of discharge. Everything which was born or which is growing, changes when inside this column of light-like particles. This phenomenon is called "Solar-Terrestrial Rhythm" and it is the power supply of the Planet, continuously causing balancing and growth. Everything on the planet is continuously bathed in this stream of rotating particles.

Every type of matter has its own basic Rhythm plus the Solar-Terrestrial Rhythm. This rhythm is unique and it represents the state of tension of the specific matter. The matter grows and evolves because of this incoming energy. If you modify the energy with various types of pollution, radiation, or other types of
destructive phenomena, you destroy the normal work of Nature. This device concentrates this phenomenon in its immediate local area and as a result, it improves the Health and Life Energy of that local environment.

The Elios device is only a passive resonator, tuned by its shape to resonate with a harmonic of the cosmic event signal. It consists of a ring of painted wood with seven holes positioned in a heptagon shape in its perimeter. This ring is supported on three legs evenly spaced around the circle. On every hole there is a piece of a coloured plastic tube, each one having a different colour and positioned in a particular order.

The sinusoidal conductor is made of aluminium wire, wound clockwise, and inserted through every hole in a serpentine movement, leaving one end facing upwards and the other end facing downwards, parallel to each other. The signal coming from the sky, moves in a clockwise direction. The two ends of the aluminium wire coil finish in adjacent holes. One end points towards the sky and the other end points towards the ground.

The device should be located on open ground and not on concrete which generates an out-of-phase component of the earth signal which destroys the good rhythm. The phenomenon occurs in the cavity especially, and around the perimeter of the ring. To increase the amplitude of the signal you can put glass bottles filled with water, one inside the cavity and six around the outside in a hexagon shape. Wait some days and observe the environment. Everything changes! There is an explosion of life! Everything which I have described happens, depending only on the length of elapsed time and the amplitude of the signal. The device needs sunlight for its best operation. Take it away from every artificial electrical and magnetic field because this is only a passive resonator and a strong EMF can distort its signal.

Do not try nuclear cleansing with Elios until it is highly charged. The device is a passive resonator and it needs to build up a charge before bringing any isotopes near it. When dealing with isotopes, always use water containers but do not contact the substance with the apparatus as you can destroy the ambient rhythm by doing that, and cause very big trouble in the area. This device has a powerful resonant effect on the surrounding land, influencing the environment up to a kilometre in every direction.

The Joe Cell.
The device called the "Joe Cell" used to be one of the most difficult devices for any experimenter to get operating properly but new design data has changed all that. It is a passive device for concentrating energy
drawn from the local environment and it takes great perseverance and patience to use one to power a vehicle. Here is some practical information on the Joe Cell.

In 1992 in Australia, Graham Coe, Peter Stevens and Joe Nobel developed previously patented units which are now known by the generic name of the “Joe Cell”. Peter introduced Joe to Graham and they rehashed the patented cells which Graham knew about, using materials from the Local Dairy Production Facility NORCO. A two hour long video showing the Joe Cell was produced by Peter and Joe and the unit shown operating in the video was attached to Peter’s Mitsubishi Van. Joe had his equipment stolen and his dog killed, so he decided to keep a low profile, moving out into the wilds and not generating much publicity, in spite of fronting the two hour video recording. A search on the Joe Cell will locate many videos on the subject. This document is an attempt to provide detailed information on a recent Cell built by Bill Williams in the USA and the subsequent constructional advice which has arisen from his experiences.

First, you need to understand that, at this point in time, building and using a Joe Cell of any variety, is as much an art as a science. It might best be explained by saying that creating building plans for it is rather like producing plans for painting a copy of the famous Mona Lisa painting. The instructions for the painting might be:

1. Buy a canvas, if one is not available, then here is how to make one.
2. Buy some oil-based paints, if none are available, then here is how you make them
3. Buy an artists brush, palette and charcoal, if none are available then this is how you make them.
4. Here is how you paint the picture.

Even given the most complete and detailed instructions, many people, including myself, are unlikely to produce a top-quality copy of the Mona Lisa. It is not that the instructions are lacking in any way, it is the skill and ability of the person attempting the task which are not up to the job. It used to be that not everybody who built a Joe Cell had instant success. However, recent advances have changed all that, but let us run through the earlier constructional information as a lead-in to the current technology.

A Joe Cell is capable of powering a vehicle engine without needing to use conventional fossil fuel. So, what does the engine run on? I suggest that it runs on a newly discovered energy field not yet understood by mainstream science. In another couple of hundred years time, it will be a routine subject which every child in school will be expected to understand, but today it looks like the ‘witchcraft’ of the magnifying glass starting a fire.

It is not unusual for newcomers to the subject to get confused by the Cell itself. The Cell consists of a metal container with tubes inside it. The container has what looks like ordinary water in it and it sometimes has a DC voltage applied across it. This causes many people to immediately jump to the false conclusion that it is an electrolyser. It isn’t. The Joe Cell does not convert water to hydrogen and oxygen gasses to be burnt in the engine. The water in a Joe Cell does not get used up no matter how far the vehicle travels. It is possible to run a car on the gasses produced by electrolysis of water, but the Joe Cell has absolutely nothing whatsoever to do with electrolysis. The Joe Cell acts as a concentrator for a new energy field, in the same way that a magnifying glass acts as a concentrator for sunlight, and both have to be done just right for them to work.

At the present time, there are at least fifteen people who have built Joe Cells and managed to power vehicles using them. Several of these people use their Joe Cell-powered vehicles on a daily basis. Most of these are in Australia. The first Cell-powered vehicle was driven some 2,000 kilometres across Australia.

Disclaimer: The remainder of this document contains considerable specific detail on the design and construction of a Joe Cell. This presentation is for information purposes only and must not be construed as a recommendation that you actual physically construct a device of this nature. The author stresses that he is in no way liable for any damage, loss or injury caused by your future actions. It should also be borne in mind that any alteration to an automotive vehicle, such as changing the fuel on which it runs to hydroxy gas, natural gas, Joe Cell energy, or anything else, might void the vehicle insurance unless the insurer is informed beforehand and agrees to continue insurance cover on the modified vehicle.

In broad outline, a Joe Cell is a 316L-grade stainless steel container, with a central cylindrical electrode, surrounded by a series of progressively larger stainless steel cylinders, and filled with specially treated water. This arrangement of steel shells and treated water acts as a focusing mechanism for the energy field used to power the vehicle.
The Cell itself is made up with the battery negative taken to the central electrode. The connection to this stainless steel electrode is made at the bottom with the electrical connection passing through the base of the cell container. This obviously needs careful construction to prevent any leakage of the conditioned water or the energy focused by the Cell.

Surrounding the central electrode are two or three cylinders made of either solid or mesh stainless steel. These cylinders are not connected electrically and are held in position by insulating material which needs to be selected carefully as the insulation is not just electrical insulation but is also energy-field insulation. The outside stainless steel cylinder forms the container for the cell:

The picture above shows the general construction of a cell of this type although, unlike the description below, this one does not have the lip which is used for attaching the lid. It is included here just as a general illustration of how the cylinders are positioned relative to each other.

The following information on constructing a Joe Cell, is broken down into the following sections:

1. The Materials needed for construction.
2. Constructing the Cell
3. Getting the Cell working
4. Installing the Cell in the vehicle
5. Getting the vehicle running
6. Suppliers
7. Workarounds
The Materials needed for Construction.

Various vehicles can be powered by a Joe Cell. If you have not built and used a Joe Cell before, then it is worth using the easiest type to convert. The most suitable is an older type vehicle with no computer control of the combustion, a carburettor and a water-cooled engine. If the engine block is aluminium rather than steel then that is also a slight additional advantage.

The Cell is built from stainless steel pipes. The lower the magnetism of the finished unit the better, so 316L grade stainless steel is preferred. However, there is no need to become obsessed with this as most varieties of stainless steel can be persuaded to operate. The length of the tubing is not critical, but about 8 inches (200 mm) is a reasonable choice for the overall length of the inner tubes. The outer pipe which forms the casing, needs to be about 10 inches in length so that there is clearance above and below the inner pipes.

The innermost pipe diameter is 2 inches (50 mm) and the others can be 3 inch, 4 inch, and 5 inches in diameter as that creates a gap of just under half an inch between the pipes, which is a suitable spacing. The wall thickness of the pipes is not critical but it needs to be a practical size with 1 mm being the minimum thickness with the most common thickness being 1/16 inch (1.6 mm or 0.0625 inch). It is important that the walls of the outermost cylinder are completely rigid, so using a greater thickness for that cylinder is an advantage.

Some stainless steel plate is needed for the ends of the outer cylinder. Ideally, the top and base should not overhang the sides but that is difficult to achieve if the cell is to be airtight, so the end pieces will need to be slightly larger than the outside tube and 1/8 inch (3 mm) thick sheet is suggested. The base size is 5 inch square, or possibly slightly larger to facilitate cutting a circular shape out of it. The lid and lip blanks will need to be 6 inch squares, or again, slightly larger to facilitate cutting circles out of them.

The plinth component at the base of the 2-inch inside tube needs to be cut from a piece of stainless steel. If the option of machining the whole plinth as a single piece is chosen, then the piece of 316L stainless steel needed to do this will be substantial, perhaps a section of solid bar 2.25 inches (57 mm) in diameter and some 3 inches (75 mm) long. If the easier and cheaper option of using a standard half-inch (12 mm) 316L stainless steel bolt (if one is available) is selected, then a piece of 316L stainless steel some 2.25 inches (57 mm), or slightly larger, 2 inch (50 mm) thick will be needed. The exact details of this will need to be discussed with the person who will undertake the machining as practical issues come into play, and the optimum size will depend to a certain extent on the lathe being used. If a screw thread is being machined on the spigot of the plinth, then the thread should match the locally available nuts, unless nuts are also being made up.

Some additional steel will be needed for constructing a mounting bracket inside the engine compartment, also, some double-laminated hessian sacking ("burlap") and about 36 inches (1 m) of half-inch (12 mm) wooden dowel to use in the mounting bracket.

Some Ultra-High Molecular Weight Polyethylene material as found in kitchen chopping boards will be needed to insulate between the engine mounting and the cell and between the inside tube’s plinth and the base plate.

A length of aluminium tubing typically three quarters of an inch (20 mm) in diameter will be needed for connecting the Cell to the engine, and a short length of strong, clear plastic pipe for the actual final connection to the engine, needed to prevent an electrical short-circuit between the Cell and the engine. This plastic pipe needs to be a tight push-fit as clamping clips are not used. A stainless steel compression fitting to fit the pipe is needed to make the seal between it and the lid of the Cell. It is very important that this fitting is stainless steel as other materials such as brass will prevent the cell from operating. The wrong material for this fitting has been the reason for many Cells not operating. Neither brass nor any other material (other than stainless steel) should not be used anywhere in the construction, whether it be for nuts, bolts, fittings, metal connections, or anything else.

Ideally, natural rubber with no additives or colouring, failing that “Buna-n” (nitrile rubber) o-ring, or teflon, is needed for inter-cylinder bracing and some sheet to make the circular lid gasket. Also some white marine-grade Sikaflex 291 bedding compound. Natural rubber with no colouring or additives is the best insulator and should be used if at all possible. After extended use, Bill has found that teflon spacers work better than the rubber and so has switched to teflon.
Seven or eight stainless steel cones will be needed for the water-conditioning process. These are usually manufactured for machines which separate cream from milk and it is possible to buy them via eBay from time to time. If none are available, then it is perfectly possible to construct them yourself.

There will also be minor items like a few bolts, lengths of electrical wire and the like. To summarise this then:

**Stainless steel pipes in 316L grade steel:**
- 5-inch (125 mm) diameter 10 inches (250 mm) long, one off
- 4-inch (100 mm) diameter 8 inches (200 mm) long, one off
- 3-inch (75 mm) diameter 8 inches (200 mm) long, one off
- 2-inch (50 mm) diameter 8 inches (200 mm) long, one off

**Stainless steel plate in 316L grade steel:**
- 5.25 inch (133 mm) square 1/8 inch (3 mm) thick, one off
- 6.25 inch (157 mm) square 1/8 inch (3 mm) thick, two off
- 3 inch (75 mm) strip, 16 gauge thick, two feet (600 mm) long
  One plinth blank as described above, size depending on the lathe and style of construction.

**Stainless steel bolts:**
- 1/4 inch (6 mm) diameter, 3/4 inch (18 mm) long, twelve off with matching nuts
- One 1/2 inch (12 mm) diameter, 2.25 inch (57 mm) long with two nuts and three washers

**Aluminium tubing 3/4 inch (20 mm) in diameter, 3 feet (1 m) long**

**Plastic tubing to form a tight fit on the aluminium tubing and some 4 inches (100 mm) long**

**One stainless steel compression fitting to seal the pipe-to-lid connection**

**Natural rubber with no additives, (or “Buna-n” insulation if natural rubber just cannot be got):**
- O-ring tubing, 3 feet (1 m) long
- Sheet, 6 inch (150 mm) square, one off

**Miscellaneous:**
- White Sikaflex 291 bedding compound (available from ships chandlers), one off
- Double-laminated hessian sacking (“burlap”) 1 foot (300 mm) wide, 6 feet (2 m) long
- Wood (ramin) dowel three quarter inch (18 mm) diameter, 36 inches (1 m) long
- UHMWP plastic food-chopping board, one off
- Sundry connecting wire and ordinary engine compartment mounting bolts, and the like
- Stainless steel cones and canister as discussed below

Don’t polish the tubes and never, ever use sandpaper or wet-and-dry paper on any of these components as the result is scored surfaces and each score reduces the effectiveness of the Cell.

**Constructing the Cell**

The Joe Cell looks like a very simple steel construction which could easily be made by any amateur. While it can be constructed by an amateur, it is not a simple construction as it is important to keep any acquired magnetic properties to a minimum. Consequently, it is suggested that an angle grinder is not used for any of the metalwork, and hand tools used for cutting and shaping. Also, if the cutting tool has previously been used to cut anything other than stainless steel it should not be used, or at the very least, thoroughly cleaned before use as contamination of your Cell components through particles of another material is critical and can prevent the Cell from working. It should be stressed again that the materials used in the construction of a Cell are absolutely critical if success is to be assured. If you have an experienced friend who has made many Cells work, then you can experiment with different materials, but if this is your first Cell and you are working on your own, then use the exact materials shown here and don’t end up with a Cell which doesn’t work.

Bill Williams started building a 5 cylinder cell comprising 1", 2", 3", 4" and outer tube 5" but Peter Stevens later advised him to remove the 1" centre tube and go with only two neutrals being the 3" and 4" tubes as the 1-inch diameter is too small for optimum energy pick-up.
Please accept my apologies if the following suggestions for construction seem too basic and simple. The reason for this is that this document will be read by people whose first language is not English and who will find it much easier if plenty of detail is provided.

The first step is to construct the base plate, used to form the bottom of the container. Cut the largest diameter pipe to a 10-inch (250 mm) length. (If you have difficulty in marking the cutting line, try wrapping a piece of paper around it, keeping the paper flat against the tube and making sure that the straight edge of the paper aligns exactly along the overlap, then mark along the edge of the paper). Place the pipe on one of the end blanks and mark the blank around the bottom of the pipe. Cut the blank to form a circular plate which sits flush with the bottom of the tube:

![Diagram of base plate and largest cylinder](image)

The next step is to mount the innermost 2-inch (50 mm) diameter pipe rigidly to the base plate. Cut the pipe to an 8-inch (200 mm) length. The pipe mounting needs to be exactly in the centre of the plate and exactly at right angles to it. This is probably where the most accurate work needs to be done. To complicate matters, the mounting needs to be connected electrically outside the base, be fully insulated from the base plate, and make a completely watertight fit with the base plate. For that reason, the arrangement looks a little complicated. Start by drilling a three quarter inch (18 mm) hole in the centre of the base plate. Construct and fit two insulating washers so that a half-inch stainless steel bolt will fit through the base plate while being securely insulated from it. The washers are made from Ultra-High Molecular Weight Polyethylene (plastic food-chopping boards are usually made from this material):

![Diagram of Ultra-High Molecular Weight Polyethylene (UMWP) washer and base plate](image)

The washers which fit into the hole in the base plate need to be slightly less than half the thickness of the plate so that they do not actually touch when clamped tightly against the base plate, as shown in the lower
part of the diagram. Cut another washer, using the full thickness of the plastic sheet. This will act as a spacer.

Next, the plinth for the central 2-inch diameter cylinder needs to be made. This is the only complicated component in the construction. It is possible to make this component yourself. The local university or technical college will often be willing to allow you to use their lathe and their staff will usually do the job for you or help you to do it yourself. Failing that, your local metal fabrication shop will certainly be able to do it for you. If all else fails and this equipment is just not available, then the ‘workarounds’ section below shows how to fabricate an alternative version which does not need a lathe.

A large piece of 316L stainless steel needs to be machined to produce the plinth shown below. The actual 2-inch diameter central cylinder needs to be a tight push-fit on the top of this component. To facilitate assembly, the central boss is given a slight chamfer which helps alignment when the tube is forced down on top of it. Peter Stevens recommends that tack welds (in stainless steel using a TIG welder) are used to connect the plinth to the outside of the cylinder. Three evenly-spaced vent holes are drilled in the plinth to allow the liquid inside the Cell circulate freely inside the central cylinder.

An alternative method of construction which does not call for such a large amount of machining is to machine the plinth to take a standard stainless steel bolt as shown here:
When assembled, the arrangement should look like this:
This arrangement looks more complicated than it really is. It is necessary to have a construction like this as we want to mount the innermost tube securely in a central vertical position, with the battery negative connected to the cylinder, by a connection which is fully insulated from the base plate and which forms a fully watertight seal with the base plate, and to raise the central cylinder about one inch (25 mm) above the base plate.

However, as the plastic washers would be affected by the heat when the base plate is joined to the outermost pipe, when all of the components shown have been prepared, they are taken apart so that the base plate can be fuse-welded to the outside tube. Unless you have the equipment for this, get your local steel fabrication workshop to do it for you. Be sure that you explain that it is not to be TIG welded, but fuse-welded and that the joint has to be fully watertight. At the same time, get them to fuse-weld a half-inch wide lip flush with the top edge of the tube. You cut this piece as a 6-inch (150 mm) circle with a 5-inch (125 mm) circular cut-out in the centre of it. When it is welded, it should look like this:
Cut a six-inch (150 mm) diameter lid out of 1/8 inch (3 mm) stainless steel. Cut a matching ring gasket of natural rubber (Buna-n material if natural rubber can’t be obtained), place it on top of the flange with the lid on top of it and clamp the lid firmly down on the flange. Drill a hole to take a 1/4 inch (6 mm) stainless steel bolt, through the lid and the middle of the flange. Insert a bolt and tighten its nut to further clamp the lid in place. An alternative to this for the more experienced metalworker, is to drill a hole slightly smaller than the bolt, and when all holes have been drilled, remove the lid, enlarge the lid holes to allow free passage of the bolts, and cut a thread inside the flange holes which matches the thread on the bolts to be used. This gives a very neat, nut-free result, but it calls for a greater skill level and more tools.

If using nuts and bolts, drill a similar hole 180 degrees away and fasten a bolt through it. Repeat the process for the 90 degree and 270 degree points. This gives a lid which is held in place at its quarter points. You can now complete the job with either four more evenly-spaced bolts or eight more evenly-spaced bolts. The complete bolting for the twelve-bolt choice will look something like this when the cell is installed:

The lid can be finished off by drilling its centre to take the fitting for the aluminium pipe which will feed the output from the cell to the engine. This fitting, in common with every other fitting must be made of stainless steel. Video at http://youtu.be/-7075bVmDQo.

The next step is to assemble the neutral pipes. Cut them to 8-inch (200 mm) lengths. These pipes are held in place by the natural rubber insulators. This material comes in an o-ring strip which is like a hosepipe with a large wall-thickness. The gap between the pipes will be approximately half an inch (12 mm), so cut each piece of pipe to a length which makes it a very tight fit in that gap. Cut six spacers, locate the 3-inch diameter pipe exactly over the inner pipe and push three of them between the pipes, about a quarter of an inch from each end and evenly spaced 120 degrees apart around the circumference of the pipes. The hole through the centre of the insulating strip points towards the centre of the cell and the ends of the insulator pieces press against the cylinder walls. These pieces are not placed lengthwise:

Place similar insulators at the other end of the two-inch pipe, directly above the ones already in place. If you look down the length of the tubes, then only three of the six insulators should be seen if they are correctly
aligned. The spacers will be more effective if the ends are given a thin layer of the Sikaflex 291 bedding compound before the ends get compressed against the cylinder walls.

Do the same for the four-inch pipe, pushing tightly squeezed natural rubber insulators strips between the three-inch and four-inch pipes. Place them directly outside the insulators between the two-inch and three-inch pipes so that when viewed from the end, it looks as if the rubber forms a single strip running through the middle pipe:

Spark off each of the cylinders in the inner assembly. This is done by connecting a 12V battery negative to the inside surface (only) at the bottom of the tube and with a wire from the battery positive, sparking the outside surface of the cylinder at the top of the tube. Give each four sparks in rapid succession.

If you are using a bolt rather than a machined spigot, insert the stainless steel bolt and washer through the bottom of the base to the central pipe. Wedge the bolt in place by inserting a piece of the dowel, or some similar material into the centre of the 2-inch pipe and tape it temporarily in place. Alternatively, force the innermost cylinder tightly over the machined plinth. Turn the inner pipe assembly upside down and place the full-depth UMWP plastic washer on the threaded shaft. Apply a thin layer of white Sikaflex 291 bonding compound to the face of one of the shaped UMWP washers and place it on the threaded shaft with the bonding compound facing upwards.

Carefully clean the surface of the base plate of the outer casing around the central hole, both inside and outside. Under no circumstances use sandpaper or wet-and-dry paper, here or anywhere else, as these abrade and score the surface of the steel and have a major negative effect on the operation of the Cell. Carefully lower the 5-inch outer casing on to the assembly so that the threaded shaft goes through the central hole and the shaped washer fits tightly into the hole in the base of the outer housing. Apply a thin layer of the bonding compound to the face of the second shaped washer, place it over the shaft of the bolt and press it firmly into place to completely seal the hole in the base plate. Add a stainless steel washer and bolt and tighten the bolt to lock the assembly together. If using a bolt, a long-reach box spanner may be needed inside the central pipe for tightening the locking bolt. If one is not available, use a longer bolt through the washers, screw a second nut up on to the shank of the bolt, file two flats on the end of the bolt, clamp them in a vice to hold the bolt securely and tighten the locking nut. When the spare nut is unscrewed, it pushes any damaged fragments of the bolt thread back into place.

Finish the assembly by adding three further rubber insulators between the top of the 4-inch tube and the outer 5-inch casing. Use a thin layer of Sikaflex 291 bonding compound on the cut faces of the insulators as this improves the insulation. Line the new insulators up with the insulators already in place and make them a tight fit. These extra insulators support the end of the tube assembly and reduce the stress on the plinth fitting at the base of the central tube when the unit is subjected to knocks and vibration when the vehicle is in motion.
The construction of the basic unit is now complete, with the exception of the lid fitting for the aluminium pipe which feeds the engine. The construction so far has been straightforward engineering with little complication, but the remaining steps in getting the Cell powering a vehicle are not conventional engineering. If you do not feel confident about this construction, then advice and help can be got from the experienced members at the Yahoo Group http://groups.yahoo.com/group/joecellfreeenergydevice/ or alternatively, the companion Group http://groups.yahoo.com/group/JoesCell2 both of which are very active.

**Getting the Cell working**

The Cell is not just the container and the inner tubes. A major active ingredient of the “Cell” is the liquid placed inside the container. To a casual glance, the liquid appears to be water and loosely speaking it is water. However, water is one of the least understood substances on the planet. It can have many different molecular configurations which give it widely different characteristics. For example, in one configuration, it will actually burn, but this “burning” is nothing like the burning experienced in an ordinary log fire. The water flame is not hot and it is quite possible to hold your hand just over the flame without feeling any heat from it.

We do not want to “burn” the liquid in the Cell. The “conditioned water”, for want of a better description, is not consumed when a Cell powers an engine. Instead, the engine is powered by external energy flowing into it. Here, the Cell acts like a lens, concentrating the external energy and focusing it to flow along the aluminium pipe to the engine. This action is not unlike the way in which a magnifying glass gathers and concentrates the sun's energy into a small area to raise the temperature there. The “conditioned water” in the cell, along with the materials and shapes in the Cell, cause the gathering and concentration of this external energy and channel it into the engine.

At this point in time, nobody knows for sure, what the energy is. Earlier, I called it the Zero-Point Energy field, but I have no direct evidence for that, some people call this energy “orgone”. Nobody knows exactly how this energy makes the engine run. Engines powered by this energy sound pretty much the same as when they are running on fossil fuels but they run a lot colder and it is usually necessary to advance the timing of the spark. These engines can tick over at a much lower rate than normal and they have much greater power than when running on fossil fuels. Bill Williams in America found that when he fitted a Joe Cell to his Ford pickup, the performance suddenly became like a Formula One racing car and very gentle use of the throttle was needed. He says:

"Over the summer, I used the truck to haul firewood for this winter's wood supply. I added 5 gallons of fuel to bring the fuel level to the half tank mark. I ran the truck with the cell which I installed a month earlier. Basically, I tried to forget about the cell being installed in the truck. The Ignition timing was set at about 25 degrees before TDC with no vacuum connect to the distributor. The fuel line was still connected so "shandy"
mode was being used. The surprising thing is that the truck did not use any fuel during the two and a half months of driving in the woods. In fact, when I parked the truck at the end of the wooding season, I physically sounded the fuel tank (it is a 'behind the seat' tank). It was still showing the half full mark. I pulled the cell for the winter and have it sitting on the bench waiting for spring to arrive for it to be installed again. I don't even pretend to understand this technology, but I keep hoping that someone will come up with a viable explanation of how the cell works.

Anyway, how do we get “conditioned water”? It can be generated inside the Cell, but as the conditioning process usually generates an unwanted residue on top of the water and on the bottom of the Cell, there is an advantage to do the conditioning in a separate container. If water conditioning is done in the Cell, then when the residue is removed, the Cell does not have the correct amount of water and needs to be topped up. That has to be done with non-conditioned water which promptly puts the Cell back to square one. So, use a separate conditioning vat which contains considerably more water than the Cell needs. In the documentary video produced by Peter and Joe, the conditioning procedure is described in some detail.

Joe explains that he conditions the water by suspending an electrode array in the water and applying 12 volts DC to it. Using the water found local to Joe, the current is initially about 10 amps and if left overnight the current drops to anywhere between 2 amps and 4 amps. This indicates that his local water contains a large amount of dissolved material since completely pure water will carry almost no current when 12 volts DC is placed across it. It is almost impossible to get pure water as so many things dissolve in it. Raindrops falling through the atmosphere pass through various gasses and some of these dissolve in the droplets. If the pollution in the atmosphere is particularly bad, then the rain can become acidic and this “acid rain” can rot the trees and vegetation on which it falls. Water on and in the ground, picks up chemical elements from nearly everything with which it comes in contact, so water, any water, needs treatment to reach its “conditioned” state.

Joe’s conditioning electrode array is made up from truncated stainless steel cones, positioned vertically above one another. Joe describes it as being made up from seven cones (not strictly true) with the central cone connected to the battery positive and the top and bottom cones connected to the battery negative. That leaves two unconnected cones positioned between the positive and each of the two outer negative cones. His array looks like this:

What Joe does not mention, but what can be seen in the video, is that there is an eighth cone cut-down and tack-welded in an inverted position underneath the bottom cone:
The inverted cone section appears to project underneath the rim of the bottom cone by an amount of about one inch (25 mm), or perhaps slightly less:

The electrical straps connecting to the cones are insulated to prevent contact with either the other cones or the inside of the metal drum which Joe uses to hold the water being ‘conditioned’. He says that if this array is suspended in a tank of water (his happens to be a vertical metal cylinder - a significant shape) and provided with 12 volt DC electrical power for a few minutes, then the water becomes ‘charged’ as he expresses it. Although the water is supposedly clean, Joe gets gas bubbles coming off the surface of the water. These will explode if lit, so it is very important that this process is carried out in the open air and there is no possibility of the gas ponding on a ceiling.

Joe states that the cleaner the water the better the result. Also, the longer the array is immersed and powered up, the better the result. It is likely that the shape of his powered array is causing the energy field to flow through his water in a concentrated fashion. The water absorbs this energy, and the effect increases with the length of time it is being conditioned, until a maximum level is reached. The objective is to achieve unusually pure water in one of its least usual molecular configurations. The overall procedure is as follows:

1. A vertical stainless steel cylinder, with an open top, is obtained and filled with water. Joe uses a steel beer keg but he selects the keg very carefully indeed from a very large choice of kegs, and then cuts the top off it. There is no need to have such a large container, or cones as large as the ones which Joe uses.

2. The array of cones is suspended vertically in the middle of the water and 12 volts applied to it. The Cell is most definitely not any form of electrolyser and should never be confused with one. An electrolyser
operates by breaking water down into hydrogen and oxygen gasses which are then used for combustion inside an engine, and it requires rapid and continuous replacement of the water which gets used up as the engine runs. The Joe Cell never operates in that way, instead it channels outside energy through to the engine and the water inside a Joe Cell is never used up by the engine running. However, in this conditioning process, some hydrogen and oxygen are produced as a side effect of the purification process. Consequently, the conditioning should be carried on out of doors to prevent any hydrogen ponding on the ceiling and forming an explosive mixture there. The more impure the water, the higher the current which flows and the greater the unwanted electrolysis of some of the water.

3. The procedure for applying the 12V supply to the conditioner electrodes is unusual. First, connect the negative supply, and only the negative supply. After 2 to 20 minutes, make the positive connection for just 2 or 3 minutes. A residue of impurities will form from this process. Some, being lighter than water, rise to the surface and form a layer there. Some being heavier than water, sink to the bottom. The surface residue is removed and the process repeated until a surface layer no longer forms. This may take 24 hours. The clean water from the middle section of the container is used to fill the Cell.

Many people are of the opinion that a current of about one amp should flow through the conditioning vat in the early stages of the process. If the current is much less than this, then it may take a considerable length of time to get the processing completed - possibly one or two weeks if the water needs a good deal of work done on it. The process can be speeded up by using higher voltage, 24 volts or 36 volts by adding extra batteries or using an electronics bench power supply. The water can also be pre-processed by placing it in a glass jar in an orgone accumulator for a day or two, but that process is outside the scope of this description.

As the impurities get ejected from the water by this process, the electrolysis element gets stifled progressively and as a consequence, the current drops. As completely pure, molecularly-reconfigured water is the goal, no additives of any kind are normally added to the water used to fill the Cell. However, if citric acid is used to clean the cylinders before assembly, there is no harm in allowing them to be assembled in the Cell with traces of the acid on them.

The Cell is filled to just under the level of the top of the inside tube array. This is very important as we need to have separate cylinders of water divided by the steel cylinders. If the water level is over the top of the cylinders, then the whole charging arrangement is destroyed. Further water conditioning inside the Cell may be needed as the cylinders also need to be conditioned. This is done with an easily removable cover replacing the lid of the Cell. The Cell should be kept covered while it undergoes its further conditioning and the lid only lifted briefly to examine the bubbles (unless a glass lid is used). The positive connection to the cell is made to the outside of the 5-inch cylinder and at the top of the cylinder. A length of copper wire tightened around the top of the cylinder is a convenient way to make the connection to the outside (and only the outside) of the cell. Place the cell on a wooden workbench or failing that, on a sheet of high-density plastic such as a chopping board. Connect the negative wire and wait two minutes before connecting the positive wire.

The Cell is ready for use, when it continues to produce surface bubbles for hours after the 12 volt DC power supply is removed from the Cell. The bubbles produced are not part of the energy-focusing process and are themselves unimportant, but they act as an indicator of the outside energy flowing through the Cell. When the Cell is running correctly, the flow of outside energy is sufficient to keep the water in its conditioned state without the need for any external electrical supply. It also maintains its own energy flow through the Cell. There is no point in proceeding any further until the Cell has reached its self-sustaining condition. If it is not happening for you, check out the information in the “workarounds” section below and if that does not get your Cell operational, ask for advice and assistance through the Yahoo groups mentioned above.

Some people concern themselves with the pH of the water. The pH really is not important as the cell will take up the correct pH as conditioning proceeds. A cell of the type described in this document, will have water which is very slightly acid with a pH of about 6.5, but it is not important to know this or to measure it. Do not put litmus paper in the cell water as that will contaminate the cell. Just rely on the action of the bubbles to determine how the cell conditioning is progressing.

**Installing the Cell in the Vehicle**

When the Cell has reached its self-sustaining condition, it can be mounted in the vehicle. The first step is to insulate the Cell from the engine components. This insulation is not just electrical insulation which is easily accomplished, but it is a case of introducing sufficient separation between the Cell and the engine to stop the
concentrated (invisible) energy leaking away instead of being fed to the engine through the aluminium tube. So, wrap the Cell walls in three layers of double-laminated hessian sacking ("burlap"), pulling it tightly around the 5-inch diameter outer tube. Tie (a minimum of) three wooden dowels along the length of the Cell and bend the mounting bracket around the dowels. The purpose of this is solely to ensure that there is at least a three quarter inch air gap between the walls of the Cell and everything else, including the mounting bracket:

The mounting details depend on the layout of the engine compartment. The really essential requirement is that the aluminium pipe running to the engine must be kept at least 4 inches (100 mm) away from the engine electrics, radiator, water hoses and air-conditioning components.

The last four inches or so, of the tube going to the engine cannot be aluminium as that would cause an electrical short-circuit between the (occasional) positive outer connection to the outside of the Cell and the engine itself which is connected to the battery negative. To avoid this, the final section of the pipe is made using a short length of clear plastic piping, forming a tight push-fit on the outside of the aluminium tube and on the connection to the intake of the engine’s carburettor. There should be a 3/4 inch (18 mm) gap between the end of the aluminium pipe and the nearest metal part of the carburettor. If it is just not possible to get an airtight fit on the intake to the carburettor and a hosepipe clamp has to be used, be sure that the fitting is non-magnetic stainless steel. If such a fitting cannot be found, then improvise one yourself, using only 316L grade stainless steel.
In the installation shown above, you will notice that the aluminium tube has been run well clear of the engine components. A vacuum gauge has been added but this is not necessary. For the early stages of installation, the aluminium pipe runs to the vacuum port of the carburettor but stops about 3/4 inch (20 mm) short of it, inside the plastic tubing. This method of connection is advisable for the initial setting up of the vehicle modification. At a later date, when the engine has been running with the Cell and is attuned to it, the Cell operates better if the pipe is connected to one of the bolt heads on the engine block, again using the plastic tube and a gap between the aluminium tube and the bolt head. Some people feel that a safety pressure-release valve with a safe venting arrangement should be used if the pipe feeding the engine, terminates on a bolt head. If it is still available, the [http://www.youtube.com/watch?v=DexBoYfDoNw](http://www.youtube.com/watch?v=DexBoYfDoNw) video shows Bill Williams operating his Joe Cell.

**Getting the Vehicle Running and Driving Techniques**

The Joe Cell is not a 'turnkey' system. In other words, just building a Cell and installing it in the vehicle is not nearly enough to get the vehicle running without the use of a fossil fuel. Some adjustments need to be made to the timing and the engine has to become 'acclimatised' to the energy.

Mount the Cell in the engine compartment and connect the Cell to the battery negative. After two or three minutes, take a lead from the battery plus and touch it briefly to the lid of the Cell. This should produce a spark. Repeat this until four sparks have been produced. This ‘flashing’ process aligns the Cell electrically and directs the energy to flow in the direction of the metal which has been ‘flashed’.

The next procedure is dangerous and should only be carried out with the greatest of care. The engine crankshaft also needs to be ‘flashed’ four times. This is carried out with the engine running and so can be hazardous - take extreme care not to get caught up in the moving parts. Connect the lead from the battery positive to the shaft of a long-handled screwdriver and keep your hands well clear. The procedure is to get a helper to start the engine, then arc the current to the exposed pulley on the crankshaft (where timing adjustments are made). There should be a total of four sparks to the crankshaft in a period of about one second.

Next, for three or four seconds, flash along the length of the aluminium pipe. This encourages the energy to flow along the pipe, reinforcing the natural attraction between aluminium and this energy. Remove the wire coming from the battery positive as the Cell operates with only the negative side of the battery connected (remember that this is NOT electrolysis and the cell just directs the unseen energy into the engine).

Mark the present position of the distributor cap. Loosen the bolt holding it in place and rotate it to advance the timing by 10 degrees. Disconnect the fuel to the carburettor (do not use an electrically operated valve for this). The engine will continue to run on the fuel left in the carburettor and the engine will start to cough. Turn the distributor cap a further 20 degrees (that is now a total of 30 degrees from its original position) and have your helper use the starter motor to assist the engine to keep turning.

Rotate the distributor cap to further advance the spark until the engine starts to run smoothly. There will be a gasping sound and the engine will slow nearly to a stop, then it will pick up again and then slow down. The action is wave-like, something like breathing. Fine-tune the timing to get the smoothest running and then fasten the distributor cap in place. Do not touch the Cell, but leave it undisturbed. You are now ready to drive away in a vehicle which is not using any fossil fuel.

The procedure described here may not end successfully as just described. Some cars are more difficult to get operating on a Cell than others. Experience helps enormously when getting the vehicle started for the first time. Joe mentions in the video that it has taken him a couple of days of sustained effort to get a particular car going for the first time, which is quite something considering that he has years of experience and has got many vehicles and Cells operational.

When the vehicle has been run and is operating correctly on the Cell, it is time to make the final adjustment to the set-up. For this, the pipe connection to the vacuum inlet of the carburettor is moved from there to terminate on a bolt head on the engine block. The Cell works best when completely sealed off from the air in the engine compartment and as no gas is actually being moved from the Cell to the engine, there is no need for any kind of connection to the carburettor. If the engine is a V-type, then the bolt head chosen should be one in the valley of the V, otherwise, any convenient bolt head on the head of the engine block will be satisfactory. Don’t forget that the connecting pipe must still be kept well clear of the engine’s electrical leads and other fittings as described earlier. Also, the 3/4 inch (18 mm) gap between the end of the aluminium pipe and the top of the bolt head must be maintained inside the clear plastic tube, and the pipe fitting should...
remain airtight. A slight timing adjustment may be necessary with the new connection in order to get the very best running.

The energy which powers the engine has a tendency to run along magnetic fields. Driving under high voltage overhead power lines can position the vehicle in an area where the energy level is not sufficient to maintain the energy flow through the Cell. If the energy flow through the Cell is disrupted, then it is likely to stop functioning. If this were to happen, then the Cell would have to be set up again in the same way as for a newly built Cell which has never been used before. This can be avoided by attaching an AA ("penlight") dry cell battery across the Cell with the battery plus going to the lid of the Cell. A battery of this type has such a high internal resistance and so little current capacity that no significant electrolysis will take place on the very pure conditioned water in the Cell. But the battery will have the effect of maintaining the integrity of the Cell if it is temporarily moved away from its source of power.

**Workarounds**

If it is not possible to get pipes of the desired diameters, then they can be made up by rolling stainless steel sheet and using a TIG welder with completely inert gas, to tack weld at each end and in the middle of each cylinder. Don’t weld along the full length of the join unless it is the 5-inch outer casing.

If it is found to be particularly difficult to make the four circular cuts in 1/8 inch (3 mm) steel using hand tools, then I would suggest using a plasma cutter. Make a template to guide the cutting head and clamp it securely in place. You can hire the cutter and compressor quite cheaply as you will only need them for a very short time. If they are not given to you as a pair and you have to select each from a range, take the smallest cutter and a twin-cylinder compressor rated at nearly double the input quoted for the cutter. This is because the cutter is rated by the volume of compressed air, and the compressors are rated by the volume of their uncompressed air intake as that sounds more impressive.

If no lathe is available for machining the base plinth for the central cylinder, then take a piece of 16-gauge stainless steel sheet and cut the plinth out of it as shown below. Bend the projecting tags upwards by holding each tag in the end of the jaws of a vise and tapping the body section square, with a flat-faced hammer and if you consider it necessary, tack-weld the top of the tags to the outside of the central cylinder to give rigidity to the mounting. Extreme heat such as is generated by welding or cutting tends to create permanent magnetism in any ferrous metal being heated, so avoid high temperature operations such as welding wherever possible. If a tight push-fit can be obtained with the base of the 2-inch cylinder, then I suggest that the optional spot welds are omitted.
If tack-welded cylinders have to be used, then it is usually best to line all of the seams up as the seam area does not work as well as the remainder of the tube, so if the seams are all aligned, then there is only one small line in the Cell which is not operating at its optimum value.

Cylinders are best aligned in the same direction. This sounds odd as they are physically symmetrical. However, these cylinders will be used to channel an energy field and each cylinder has a direction along which the energy flows best. To find this, stand all of the tubes upright in a tight group on a table. Leave them for a minute and then place your hand on top of the whole set. If any tube feels hotter than the others, then it is out of energy alignment with the rest and should be inverted. Repeat this test until no tube feels hotter than the rest.

An alternative way to do this test is to use a pair of L-rods. These can be made from two short lengths of rigid black polythene tubing often found in garden centres for use in garden irrigation. This tubing has 1/8 inch internal diameter and so takes 1/8" brass welding rod very nicely. The welding rods should be bent with a radius as shown here:

![Diagram of L-rod](image)

The curved bend in the brass welding rod helps to prevent the rod fouling the top of the plastic tube handle and it allows free rotation of the brass rod. It is essential that the rod can move completely freely in the handle. If two of these are made up, they can be used to check the cylinders before they are assembled for insertion into the Cell. Place a tube standing vertically on a table well away from all other objects (especially magnetic and electrical items). Hold an L-rod handle in each hand so that the rods are parallel in front of you. The rods must be exactly horizontal so as to avoid any tendency for them to turn under the influence of gravity. Approach the cylinder. The rods should either move towards each other or away from each other as the cylinder is approached.

Repeat this procedure at least three times for each cylinder so as to be sure that a reliable result is being obtained. Invert any cylinder if necessary, so that every cylinder causes the rods to move in the same direction. Then assemble the Cell, maintaining that alignment of the cylinders during the assembly.

If you are having difficulty in getting the Cell operational, then try striking and sparking the cylinders again. This is done as follows:
1. Take a 12V lead-acid battery and position it so that it’s negative terminal is pointing towards East and it’s positive terminal is pointing towards West (i.e. at right angles to the Earth’s magnetic field).
2. Attach a lead from the battery negative to the outside of the base of the tube.
3. Lay the tube on a table and strike it with a hammer along its length. If the tube has a seam, then strike the tube along the length of the seam.
4. Connect a lead to the positive terminal of the battery and spark the inside of the top of the tube. It is essential to spark each tube if they have been polished. It is better not to polish any of the tubes.
5. Repeat this procedure for each tube.
If you consider it necessary to clean the cylinders, then, considering the lengths you went to remove all of the things dissolved in the water, be sure to avoid using any kind of chemical or solvent. You can electro-clean them by using the following procedure:

Starting with the largest cylinder:

1. Put the battery positive on the inside of the top of the cylinder, and the negative on the outside at the bottom, and leave them in place for one minute.

2. Put the negative on the inside of the top of the cylinder, and the positive on the outside at the bottom, and leave them in place for one minute.

3. Repeat step 1: Put the battery positive on the inside of the top of the cylinder, and the negative on the outside at the bottom, and leave them in place for one minute.

Do this for all cylinders, working inwards.

It has been suggested that an improved method of conditioning water to fill the Cell can be achieved if pulsed DC is used instead of straight DC from a battery. This has not been proven but there is a reasonable amount of information to suggest that this is likely. The following, most unusual circuit, has been suggested, but it must be stressed that it is untried and anybody who is unfamiliar with working with electronics should not attempt to construct or use this circuit without the assistance of a person who is experienced in building and using mains equipment.

This is a most unusual circuit. A 12V step-down mains transformer provides 12V AC which is taken through a limiting resistor and a zener diode which would not normally be connected as shown. The really odd thing is that the circuit which contains the secondary of the transformer appears not to be connected. The expected output from this very odd circuit is pulsing DC of odd waveform, all of which is positive relative to the ground connection, which is a literal, physical connection to an earthing rod driven into the ground.

Notes:

Engines running while powered by a Joe Cell act in a somewhat different manner. They can idle at a very low number of revs per minute, the power available on acceleration is much greater than normal and they appear to be able to rev very much higher than ever before without any difficulty or harm.

The type of Cell described in this document was built by Bill Williams in the USA with the help and assistance of Peter Stevens of Australia. Bill describes his first driving experience with his 1975 F 250, 360 cu. in. (5.9 litre) Ford pickup:

Well, all I can say is "who needs an Indy car when you can drive an old FORD" – WOW!!! The first five miles after leaving home were wild. I had to be extremely careful on how I pressed the accelerator. I gingerly crept up to 45 mph and that was with moving the pedal maybe half and inch. The throttle response was very crisp or touchy. With about a 1/8" of movement the next thing I knew I was close to 80 mph. If I lifted off ever so slightly on the throttle, it felt like I was putting the brakes on and the speed would drop down to 30 mph or so. "Very erratic". If I barely even touched or bumped the pedal it felt like I had pushed a nitrous oxide booster button. WOW !!!
As stated earlier, the first 5 miles were wild and things started to change. The engine started to buck or surge with very large rpm changes and literally threw me against my seat belt. It got so bad I just took my foot completely off the pedal and rode the brakes to stop the truck. The truck left skid marks on the pavement every time the engine surged in rpm. Well anyway, I manage to get it stopped and shut it off with the ignition key - thank GOD!

I retarded the timing, turned the gasoline back on, crossed my fingers and hit the ignition key, and the engine took right off, revving to maybe 4,000 rpm and then gradually decreased to 700 rpm. I took a deep breath and put it into drive and the truck responded close to normal again. I made it into work a little late, but late is better than never the way I see it. After working during the day at the job and thinking what I could do to stop this erratic rpm oscillation, I decided to disable the cell and drive home on gas. WOW!!!

Peter Stevens states that the main reason for the erratic behaviour of the Cell was due to outside air leaking into the Cell, and he stresses that Cells need to be completely airtight. It is also clear that the timing was not set in the correct position. All properly built Cells give enhanced engine power.

**Water Conditioning:**

Note: With the Cell design shown later, no water conditioning is needed. Please be aware that water quality and purity varies enormously from place to place. One experienced cell builder says: I use water taken from the start of rivers. Further down the river, the water will have encountered influences which are not helpful. My favourite water catchment area well is outside Melbourne, Australia, where there are no roads, power lines, dams, pipes or any man made intrusions, the water flows how and where it wants to in natural, twisty downhill paths it has created, the whole area is green all year round and you can feel the vitality and Nature at work.

This water has a pH of 6.5. That means it is slightly acidic, and perfect for Joe Cells. I bring this water home making sure that I protect it from excessive sloshing and the heat of the sunlight whilst in the car. At home, I store it in 20 litre Pyrex bottles. Do not store it in plastic containers even if the container is marked “suitable for water”. Earthenware or wood containers would also be very suitable.

I make an electrolyte solution by dissolving 500 grams of food-grade phosphoric acid and 100 grams of sodium perborate, in three litres of de-ionised water or distilled water. Just a few drops of this solution will provide a current of 1 amp at 12 volts in the conditioning vat. An alternative is to use a 90% acetic acid solution which has no stabiliser in it.

When conditioning the water in the cell, you will need a lid, or some way of sealing of the cell from air. A lid loosely sitting on top of your test jar is sufficient. The seeding and breeding process is hampered by having too great an area of the top of the cell being exposed to air. All lids are not the same as regards to being a obstruction to orgone. If the lid does not seem to be working, place a layer of aluminium foil underneath the lid and use the foil and lid as one unit.

The aim is to modify the conductivity of the water by the addition of acid, so as to get a suitable current flow. If we used de-ionised water with a pH of 7.0, we would have a very low current flow for our electrolysis, and would have to add something to increase the conductivity of the water if we wanted observable results in a short period of time. As we lower the pH, the current flow and electrolysis process will increase together with a heat increase.

We are trying to achieve electrolysis action with the minimum heat generation. As the propagation of orgone is reasonably slow, there is not much to be achieved with excessive current. Slow and steady does it. For the patient experimenter or one that is using neat water, i.e. water without electrolyte, excellent results are achieved with currents as low as 50 milliamps.

**The procedure is:**

1. Place your cell on a wooden work bench or on a sheet of plastic type material or, as a last resort, on a newspaper. We are trying to insulate the cell from metal paths that may impede the seeding process. Keep the cell well away from electrical sources such as a television set, refrigerator, electric cooker, etc.

2. With a multimeter, measure the resistance between the innermost and the outermost cylinders of your cell. It should be in the high Megohm range. If not, the insulators are conductive or there is a short-circuit. Check for a short-circuit and if there is none, remove the insulators and reassemble the set.
checking the resistance between the innermost and outermost cylinders as each cylinder is added. The resistance between every pair of cylinders should be very high.

3. When all is okay in the above step, fill the cell using a funnel containing a paper coffee filter. Fill it only to a level just under the top of the cylinders and no more. The effect that we want to create is a set of water cells separated by metal cylinders. These are your alternate organic and inorganic chambers. Of course, the submerged section of your chambers are flooded, but with this simple cell, the top will be doing all the work. This is why the cylinders should be completely horizontal and true at the top, otherwise the meniscus formed by the water would not work and the water would flow from compartment to compartment. This level is only critical during the seeding process, as we require maximum orgone capture to seed the cell. Naturally, with a charged cell, the water is sloshing all over the place whilst you are driving the car.

4. Turn on the power supply, and if it is adjustable, set it to 12 volts. Connect the negative end of your power source to one end of your meter that is set up to read a minimum of 2 amps and connect the other end of the meter to the bottom of the central cylinder. Wait for two minutes and then connect the positive end of your power source to the top of the outer cylinder. What you have done is set up the meter to read any current flow into your cell from the power source.

At this stage, if your water is close to a pH of 7, as previously discussed, the current flow will be zero, or in the low milliamp region. If the current flow is amps, then you are doing something wrong! It is impossible to pass a huge current through ordinary pure water when using 12 volts. Think about it. To draw even 1 amp at 12 volts, the resistance of the water would have to be 12 ohms! No way! You are doing something wrong. Correct the problem and then move on.

5. Presuming that the current is only milliamps, you now want to introduce electrolyte to increase the current flow through the water. The aim is to get a current flow of about one amp. To do this, drip a small amount of your chosen electrolyte into the cell water whilst stirring and watching the current measurement. Use a glass, Perspex or wooden dowel rod as the stirrer - do not use your handy paint-stirring screw driver! Throw away the stirrer when finished as it will have absorbed some of the cell contents. Do plenty of gentle stirring of the water as you add the electrolyte, otherwise you will add too much electrolyte. Stop adding electrolyte when the meter indicates 1 amp. Your water level may rise as a consequence of the addition of electrolyte. Remove some water from your cell. I use a pipette, so as not to disturb the cell. Remove enough water to again just expose the top of the cylinders. At this stage, disconnect your meter and power source and have a bit of a clean up as the next stages are guided by observation.

The charging process is separated into three distinct stages which are called Stages 1, 2 and 3. These stages have both some obvious differences and some subtle ones. For the rest of the charging process, you will be only connecting your power source to the cell for a maximum of 5 minutes at a time. As orgone lags electricity by about 30 seconds, you will know the state of the cell in less than a minute. Do not be tempted to leave the power connected to the cell for long periods! Yes, I know that you are in a hurry and more is better, but in this case you only generate heat, steam, waste power and overheat the cell. You can pick the failures by seeing their cells running non-stop for days with 20 or more amps turning the water to steam, etching the cylinders and ending up with a barrel full of scum. What else would you expect? After all, electrolysis is time and current related. If you have had the misfortune of having your cell left on for a long period with high current, you have probably destroyed your cylinders. You cannot retrieve the situation so throw the cell away and start again! I bet you don't do it next time!

**Danger:** Do not charge any cell that is totally sealed! The cell will explode, with all the resulting consequences. An airtight seal is not required! At no stage do I prescribe any form of airtight container.

**Stage 1:** This stage is plain old electrolysis. Due to passing direct current through a liquid which contains ions, chemical changes will occur. In our case, you will see small bubbles and a cloud of activity that is greatest nearest the outside of the innermost negative cylinder. The important observation points are that the activity is greatest nearest the central cylinder and gets progressively less as we move outward via the different chambers formed by the rest of the cylinders. Also, within a short period of turning the power off, all activity stops, the water becomes clear and the bubbles disappear.

Every fool and his dog can reach Stage 1. The secret for progressing further is to restrain your impatience and not increasing the electrolyte concentration to raise the current (and/or leaving the cell on for days on end). Be patient, leave the cell on for no longer than 5 minutes, turn the power source off, remove the leads to the cell, and put the top on the test cell, or partially block off the exit of the car cell. It does not have to be
ont some web sites. Reich, you may care to make an orgone meter and thus remove all guesswork. This meter is fully described
valuable method in the verification of the efficiency of the cell. If you are conversant with the work of William
has been removed. The bubbles are pulsating and most importantly the surface tension remains days after the power
no way that you can mistake this stage. The bubbles are larger and pure white, the surface tension is
will still be on top of the water as opposed to Stage 1 or Stage 2 where they disappear in minutes. There is

Stage 3: You will now notice on your initial powering up of the cell, that the bubbles are getting larger and
the white cloud of tiny bubbles in the water are much smaller or more transparent. Also in Stage 1, you had
the action occurring mainly near the central cylinder. Now the bubbles form in a regular fashion irrespective
of their location in the cell. More importantly, on turning the power off from the cell, the bubbles do not go
away immediately but stay there for minutes rather than seconds as in Stage 1. Also, the top of the water
assumes a glazed look and the meniscus is higher due to a change in the surface tension of the water. At
this stage you may have some brownish material amongst your bubbles. Don't panic - it is only the
impurities being removed from the cell. I find that if I wipe the top surface of the water with a paper towel,
the bubbles and the deposit will adhere to the paper and can be removed easily. Top up the cell with water
from your charging vat, if required, after the cleaning, so that again, the top edges of the cylinders are just
showing. No more electrolyte is added! In cleaning the top of the cell as described, it has been observed
that some people react unfavourably with the cell. If so, keep that person away, or if it is you, try changing
your hand i.e. use your right hand instead of your left or vice versa. If the presence of your hand seems to
collapse the surface bubbles, I would suggest you get a friend to do the work for you.

Summary of Stage 2: The result is very similar to Stage 1, but now we have a more even bubble distribution
and an increase of surface tension and a longer presence of the bubbles when the power is turned off.
There will be no scum in the bottom of the cell and the water will be crystal clear. At this stage the orgone
has seeded the cell, but as yet, is not "breeding", that is, the orgone concentration is not yet great enough to
attract additional orgone flow to itself. With the right cell, water and operator, it is possible to go straight to
Stage 2 on the first turn on of a new cell.

Stage 3: Not many people get to this stage, or what is worse, get here incorrectly. If you get here following
the above steps, your water is still crystal clear with no deposits in the sump. If you get here by brute force,
you will have stripped appreciable amounts of material from the cylinders and this material will now be
deposited on the insulators and suspended in the water as tiny particles which never settle out, and finally,
the material will form a deposit at the bottom of the cell. The low resistance insulators and the metallic
particles in the water will create a cell which leaks orgone and consequently it will cause endless mysterious
car stoppages or refusals of the car to start.

Right, the miracle of Nature is now breeding in your cell. Upon turning your power on to the cell, within 30
seconds copious beautiful white bubbles will rise from all the surface area of the cell. Before these bubbles
cover the water surface, you will notice a slowly rotating and pulsing front in all cylinders, that is
synchronised and has a regular rhythm of about 2 pulses per second and a clockwise rotation speed of
about 1 revolution every 2 seconds. These effects are very hard to observe for a first time viewer who does
not know what to look for. I find it easier to watch these effects with the aid of a fluorescent light, as the 100
cycles per second pulsations of the light “strobe” the water surface and help the observation.

The bubbles may overflow the container and show great surface tension. One of the definite proofs that the
cell is breeding is that, on turning the power source off and coming back the next day, most of the bubbles
will still be on top of the water as opposed to Stage 1 or Stage 2 where they disappear in minutes. There is
no way that you can mistake this stage. The bubbles are larger and pure white, the surface tension is
greater, the bubbles are pulsating and most importantly the surface tension remains days after the power
has been removed.

I do not recommend any additional tests or measurements. But for those who are incapable of leaving
things be, they may measure the voltage across the cell after it has been left standing with the power off for
at least 24 hours. A Stage 3 cell will have a residual voltage, or more correctly, a self-generated voltage of
around 1 volt. A Stage 1 cell measured under similar conditions will read 0.1 to 0.2 volts. Remember, that
unless you know what you are doing, these voltage measurements can be very misleading due to probe
materials and battery effects that can easily mask your true measurement. As the cell reaches the maximum
density of orgone that it can hold, the result of the breeding process is the conversion of this excess orgone
into the formation of electricity. As such, electrical measurement with the correct instruments is a very
valuable method in the verification of the efficiency of the cell. If you are conversant with the work of William
Reich, you may care to make an orgone meter and thus remove all guesswork. This meter is fully described
on some web sites.
I do not recommend any form of bubble exploding. As noted earlier, noise and vibration are orgone-negative. Therefore, these explosions applied during the delicate seeding period will kill your cell. Apart from a dead cell, the chance of fire igniting other gasses in the workshop and injuries to the ears etc. makes this exercise highly unnecessary. I must admit that I too fell for the "go on, ignite it!" feeling. I had a cell that had been at Stage 3 for seven months. It was my favourite test cell. My hands and matches fought my brain and they won. There was a huge "ear-pulling, implosion/explosion", and yes, I killed the cell. It went back to Stage 2 for four days. I will not do it again.

As all water we are using so far has been electrolysed, this water is not suitable for use in non-stainless steel or glass containers due to reaction with the container and the resultant corrosion, but if you have to, or want to, you can use juvenile water with no electrolyte added and still charge it to Stage 3. As the ion count is much lower, the water is not as conductive, i.e. you cannot get as much current flow with 12 Volts as you would if you electrolysed the water. However, if you obtain a power supply of approximately 60 to 100 Volts at about 1 Amp, you will be able to charge "plain old ordinary water". The down side is the additional waiting, in some cases, over 3 weeks, and the cost of the fairly expensive power supply. The advantage is that you will be able to pour it into the radiator of a car with no increase in corrosion as compared to water containing acids.

Do not at any stage short circuit, i.e. join any of the cell cylinders to each other electrically with your charging leads, wedding ring, etc. If you do, the cell will "die"! Your only option, if this occurs, is to connect the cell to your power source and see if you are still running at Stage 3. If the cell does not revert to running in Stage 3 mode within 1 minute, your only option is to completely dismantle the cell and re-clean and re-charge. Huh???, you are kidding us, right?? No, I am serious, that is your only option! So do not do it, do not short out your cell! You will have similar, but not as severe problems if you reverse your leads to the cell.

When the cell is running at Stage 3, you can tip the charged water out of the cell into a glass container and clean, adjust or maintain your now empty cell. Try to keep all cylinders in the same relation that they were in before you dismantled the cell, i.e. keep all cylinders the same way round and in the same radial alignment. This is mainly relevant when dismantling cells over 6 months old as the metal parts develop a working relationship that can be weakened or destroyed by careless re-assembly.

When finished, pour the charged water back and you are back in business. Of course you can pour this charged water into other cells, or use it as you see fit, but, remember, do not leave it out of the cell for periods longer than 1 hour at a time as the breeding has now stopped and you are slowly losing charge.

**Troubleshooting.**

It is usually quite difficult to get an engine running from a Joe Cell. Many people find it difficult to get their Cell breeding ("at Stage 3"). The following suggestions from various experienced people who have succeeded are as follows:

1. The metal construction of the Cell needs to be of stainless steel and nothing else. Using copper or brass, even for something as simple as the connector between the Cell and the aluminium tube running to the engine is sufficient to cause serious problems as the energy is not directed to the engine and just leaks away sideways.

2. The water is best charged in a separate vat which has a larger capacity than the Cell itself. That way, when the Cell is being conditioned and scum removed from the surface of the water, the cell can be topped up with charged water from the vat. If, instead, ordinary, uncharged water is used, then the whole process is liable to be put right back to square one.

3. Be very sure that the mounting in the engine compartment is electrically insulated from the engine and chassis and be sure that there is serious clearance between the Cell and everything else. Also, the aluminium pipe running to the engine must be kept at least four inches (100 mm) clear of the main engine components. Otherwise, the energy which should be running the engine, will leak away sideways and not reach the engine.

4. It can take up to a month to get a steel engine acclimatised to a Cell. Run the engine as a "shandy" where fossil fuel is still used but the Joe Cell is also attached. This usually gives greatly improved mpg, but more importantly, it is getting the engine metal and cooling water 'charged' up ready for use with the Joe Cell alone. Once per week, try advancing the timing and see how far it can be advanced before the
engine starts to ping. When the timing gets to a 20 or 30 degree advance, then it is time to try running on the Joe Cell alone.

5. Finally, having conditioned the Cell, the water, the engine and the coolant, if there is still difficulty, then it is probably worth conditioning yourself. Both the idea and the procedure sound like they have come from Harry Potter’s classes in Hogwarts School of Witchcraft and Wizardry. However, there is a serious scientific basis behind the method. Use of the Bedini battery-pulsing devices shows that lead/acid batteries act as a dipole for Radiant Energy. Also, the energy flow which powers the Cell appears to move from West to East. Bearing those two facts in mind, makes the following rather bizarre procedure seem slightly less peculiar:

(a) Get a car battery and position it so that it’s terminals line up East/West with the negative terminal towards the East and the positive terminal towards the West (along the main energy flow line)

(b) Stand on the North side of the battery, facing South.

(c) Wet the fingers of your right hand and place them on the battery’s negative terminal (which is on your left hand side).

(d) Keep your fingers on the terminal for two minutes.

(e) Wet the fingers of your left hand. Place your left arm under your right arm and place the fingers of your left hand on the positive terminal of the battery. Do not allow your arms to touch each other.

(f) Keep the fingers of your left hand on the positive terminal for three minutes.

(g) Remove your left fingers from the positive terminal, but keep the fingers of your right hand on the negative terminal for another 30 seconds.

This procedure is said to align your body with the energy flow and make it much easier for you to get a Cell to “Stage 3” or to get a vehicle engine running. In passing, some people who suffer continuing painful medical conditions state that they have got considerable pain relief from this procedure.

**Recent Joe Cell Developments.**

One of the greatest problems with using a Joe Cell has been to get it operational. The reason for this has probably been due to the lack of understanding of the background theory of operation. This lack is being addressed at this time and a more advanced understanding of the device is being developed. These design dimensions cause ordinary tap water to go immediately to the fully functional “Stage 3” and remain in that state indefinitely, the only way of stopping the Cell is to physically take it apart.

While it is still rather early to draw hard and fast conclusions, a number of results indicate that there are three separate, unrelated dimensions which are of major importance in constructing a properly “tuned” Joe Cell. It needs to be stressed that these measurements are very precise and construction needs to be very accurate indeed, with one sixteenth of an inch making a major difference.

The dimensions are specified to this degree of accuracy as they represent the tuning of the Cell to the frequency of the energy which is being focussed by the Cell. The fact that there are three separate dimensions, suggests to me that there are probably three components of the energy field, or possibly, three separate energy fields.

These three dimensions have been assigned names and are as follows:

Golden dimension: 1.89745" (48.195 mm)
Blue dimension: 3.458" (87.833 mm)
Diamagnetic dimension: 0.515625" (13.097 mm)

It is suggested that a Joe Cell should be constructed with cylinder heights which are a multiple of either the ‘Golden’ or ‘Blue’ length. Also, the water height inside the container should be below the tops of the inner cylinders and be a multiple of the basic length chosen for construction. The inner cylinders should be positioned the ‘Diamagnetic’ dimension above the base of the Cell. They should also be constructed from stainless steel of thickness 0.06445" (1.637 mm, which is very close to 1/16") and there should be a horizontal “Diamagnetic” gap between all of the vertical surfaces.
The inner cylinders should be constructed from stainless steel sheet which is tack welded at the top and bottom of the seam, and all of the seams should be exactly aligned. The lid should be conical and sloped at an angle of 57°, with its inner surface matching the inner surface of the housing and the inner surface of the outlet pipe. The outer casing should not have any dome-headed fasteners used in its construction. The length of the outlet pipe should be made of aluminium and should be 15.1796" (385 mm) for 'Golden' height cylinders or 20.748" (527 mm) for 'Blue' height cylinders. That is 8H for Golden and 6H for Blue and should there be a need for a longer pipe, then those lengths should be doubled or tripled as the single dimensions no longer apply (this being a fractal effect). At this point in time, these are only suggestions as the science has not yet been firmly established. One possible arrangement is shown here.

A suggested Joe Cell design is shown below. This diagram shows a cross-section through a Joe Cell with four inner concentric stainless steel tubes. These tubes are positioned 0.515625 inches (13.097 mm) above the bottom of the Cell and the gap between each of the tubes (including the outer casing) is exactly that same 'Diamagnetic' resonant distance.
It should be clearly understood that a Joe Cell has the effect of concentrating one or more energy fields of the local environment. At this point in time we know very little about the exact structure of the local environment, the fields involved and the effects of concentrating these fields. Please be aware that a Joe Cell which is properly constructed, has a definite mental / emotional effect on people near it. If the dimensions are not correct, then that effect can be negative and cause headaches, but if the dimensions are correct and the construction accurate, then the effect on nearby humans is beneficial.

"Golden" Values for $H$
1.89745” (48.195 mm)
3.7949” (96.391 mm)
5.69235” (144.586 mm)
7.5898” (192.781 mm)
9.48725” (240.796 mm)
11.3847” (289.171 mm)
13.28215” (337.667 mm)
15.1796” (385.652 mm)
30.3592” (770.124 mm)

"Blue" Values for $H$
3.450” (87.333 mm)
6.916” (175.666 mm)
10.374” (263.500 mm)
13.832” (351.333 mm)
17.290” (439.166 mm)
20.748” (527 mm)
41.496” (1054 mm)
It should be pointed out that Joe Cells will be constructed with the materials which are readily to hand and not necessarily those with the optimum dimensions. If picking stainless steel sheet which is not the suggested optimum thickness, then a thinner, rather than a thicker sheet should be chosen. In case the method of calculating the diameters and circumferences of the inner cylinders is not already clear, this is how it is done:

For the purposes of this example, and not because these figures have any particular significance, let's say that the steel sheet is 0.06" thick and the outer cylinder happens to be 4.95" in diameter and it is 0.085" thick. People wanting to work in metric units can adjust the numbers accordingly where 1" = 25.4 mm.

Then, the inner diameter of the outside cylinder will be its outer diameter of 4.95", less the wall thickness of that cylinder (0.08") on each side which works out to be 4.79".

As we want there to be a gap of 0.516" (in practical terms as we will not be able to work to an accuracy greater than that), then the outside diameter of the largest of the inner cylinders will be twice that amount smaller, which is 3.758":

And, since the material of the inner cylinder is 0.06" thick, then the inner diameter of that cylinder will be 0.12" less as that thickness occurs at both sides of the cylinder, which works out to be 3.838":

The length of stainless steel needed to form that cylinder will be the circumference of the outer diameter of 3.758" which will be 3.758" x 3.1415926535 = 11.806 inches.

The dimensions of the other inner cylinders are worked out in exactly the same way, bearing in mind that every steel thickness is 0.06". The results for three inner cylinders would then be:
Comments from an expert in July 2012:

That information is really ancient history and it was Dave’s best guess at optimising a cell at that time. Later testing left us disappointed with the ‘Blue’ lengths, however the ‘Golden’ lengths make a very nice cell, but not one which is particularly good with an internal combustion engine but one which is better as a learning tool, or for use in healing.

We are into an entirely different approach now, one which entails introducing specific vibrations into the cell. An optimum implementation involves cutting each tube to a specific length so as to make it self-exciting, but that’s not necessary because the frequencies can be introduced just using a caliper, or a precise length of metal touched against the tubes in a sequence. Since this approach was totally different from traditional Joe Cell work, we set up a discussion group specifically for it: http://tech.groups.yahoo.com/group/vibrational_combustion_technology/

The nice thing about this approach is that it’s ultra stable. Once the vibration is set up the only way to stop it is to take the cell apart. This construction method totally eliminates the human influence factor problem! In fact, a cell can affect the engine even without there being water in the cell. Another nice thing about it is the mathematical design process is implemented in a couple of spreadsheets. My thinking at this time, is that we now need to incorporate specific engine parameters into the design to tune the cell to a particular engine.

We have been a bit sidetracked lately and have been working a lot on the healing aspects of Torsion fields: http://groups.yahoo.com/group/awaken_to_vibration/ but I hope to get back into engine testing soon.

Advances in 2011. In an effort to develop a device to emulate the function of a Joe cell without it’s inherent stability issues, Dave Lowrance came up with the idea of a set of 3 concentrically-wound torsion field coils. In early testing it has become apparent that a field is being generated, as demonstrated by their effect on two test engines, even with no power being applied to the coils.

This is the very early stage of the investigation so this initial design is being released with the hope that others will wind and test similar coils and report their results to the appropriate groups, so that we can learn more about them through further experimenting on a variety of different engines.

The initial set of coils were wound on 7/8” (22 mm) diameter stainless steel tubing which happened to be to hand. The use of stainless steel is not significant and two successful replications have used half-inch (12 mm) PVC plastic pipe, as using a non-ferrous material is the main requirement.
The wire diameter has an effect and while 20 gauge (0.812 mm diameter) enamelled copper wire was used for the coils shown here, coils wound with 12 gauge (2.05 mm diameter) copper wire work much better and it is now thought that the weight of copper in the winding is important.

For the first layer, a length of 311 cm is used and wound on the former in a clockwise direction. The ends of the wire are secured with tape, leaving three or four centimetres of wire exposed at each end of the coil, for connection purposes. This is the first layer wound and secured:

The wire for the second layer is cut to a length of 396 centimetres. This second coil layer will be longer than the first layer, so before winding it, it’s necessary to build up the area at both ends of the first layer with tape:

This is so that the second layer of wire will have the same diameter along it's entire length. It is probably a good idea to completely cover the first layer of wire with tape to ensure good electrical insulation.

The second wire layer is also wound in a clockwise direction:

The wire for the third layer is cut to a length of 313 centimetres. Since it will be covering less length along the former, there is no need to build up the ends of the earlier layers. So, simply cover the second winding with tape, and then wind on the third layer, but this time, the coil is wound in a counter-clockwise direction and then the entire coil is covered in tape to protect it.
To be sure that the second and third layers are centred over the earlier layers, it is a good idea to locate the centre of the wire and start winding from the middle outwards in both directions:

It has been found that one end of the centre winding is similar to the centre tube of the Joe cell, and the opposite end of the outer winding functions like the canister of a Joe cell. In theory, this can be tested by connecting a small capacitor between these two points, and checking for a low DC voltage using a digital voltmeter. Like a Joe cell, polarity is really the important issue to test for, since we do want the positive polarity end to transfer the energy, and the negative polarity end to be connected to engine ground. If the polarity is wrong, simply use the opposite ends of both coils.

In the testing the negative end was connected to chassis ground, and the positive end to a Hull-effect type oil probe already installed in each test vehicle. The oil probe is Robert Hull's contribution to this technology. He found that if you apply a torsion field to the oil, it will charge up an engine in a way similar to a Joe cell, but more consistently than a Joe cell would. There are two basic types of Hull-effect probe - the simplest is just a wire inserted down the dipstick tube. However, the preferred method is to remove the oil-pressure sensor and insert a T-fitting, then slide an insulated stainless steel rod into the high-pressure oil at that point. By using an oil probe, one can eliminate the aluminium transfer tube in favour of a length of wire.

The experimenter who wound the 20-gauge coils then wound a larger diameter set using 12-gauge wire on a 1.5-inch (38 mm) diameter former. He fitted these over the original set and connected just two wires, one end of the innermost of the six coils and the opposite end of the outermost coil. This gave about a 25% reduction in the fuel used by an old Honda Accord car with an Electronic Fuel Injection system.

Fuel-less operation has not yet been achieved, but that could just be a matter of getting the engine set up properly. Some of the issues we need to deal with are things like antifreeze, which destroys the dielectric properties of water, and inhibits it from charging up. This has never been discussed, but it is one of the key things which limited the ability of people to succeed with their cells. Oil is a similar issue. Some oils, particularly the ones with all the additives and detergents, simply won't charge up.

There still needs to be a lot of testing done. For instance, with this setup it might be better to connect one end of each coil to ground. Or possibly the coils would do better if the windings were all connected in series. This is all uncharted territory! Dave's original concept was to use a set of these coils to replace each tube of a Joe cell.

The engine from an old Pinto car is also being used as a test bed. Attempts were made to run it completely fuel-less. It would kick repeatedly, but just wasn't quite there. It would only kick at a very specific timing setting - somewhere between 50-60 degrees before Top Dead Centre. The Pinto has antifreeze and with just water it's more likely to run fuel-less. But that should be a last-resort option, since most people do need antifreeze.

Devices such as the Joe cell tend to work really well on engines which have a carburettor because the spark timing can be adjusted quite easily. They work well on older EFI engines (probably those prior to OBD2) but they can be a real problem on the newer EFI models as they are liable to cause a fuel injection error state to
be reached almost immediately. The newer ECUs control everything so tightly that they are almost impossible to work with (which was probably a design objective of the ECU design).

The Pinto engine had not been started for over six months. No T-field devices were connected to the engine during this period, so we can assume that there was little or no residual charge on the engine. The cooling system had only water in it. The crankcase was filled with NAPA brand 30-weight oil. We fiddled with the engine to get it started. At that time the car had a little motorcycle carburettor on it, rather than the stock carburettor and the timing was set quite a bit advanced.

After just a few minutes of idling we realised that the engine was getting extremely hot with the exhaust manifold glowing red. So we shut it down. Being the optimist that I am, we went ahead and connected the coils at this time.

The next morning I took a little compass and found that it didn’t point to North anywhere within about 2 feet of the car body - a very good sign! So we went ahead and started it up, and carefully monitored the head temperature with an infra-red thermometer. The temperature rose slowly to about 170 degrees F which is a little below normal. After verifying that the temperature held steady at that value, I tested with the compass again, and now it was messed up out to about 10 feet from the body. So the field strength had jumped up about 500% after starting the engine.

We then played with the carburettor and timing to get the smoothest operation at the lowest RPM at which it would idle smoothly. The RPM appeared to be well below a normal idle RPM., and when I went back and checked the timing, it was very close to 60 degrees before Top Dead Centre. At this point everything was looking so good that we tried a few attempts at fuel-less operation, but the engine died each time.

Due to pressure of other work, the car was ignored for a couple of months. When I finally got back to doing a little further testing, I found it surprisingly easy to get it started again. I didn’t have to reset the timing to get it running. It actually started up with little effort, which was amazing, since the timing was still way advanced. It should be nearly impossible to start an engine with the timing set like that. The spark is just occurring at the wrong time in the cycle so it should try to push the pistons in the wrong direction.

Anyhow, it was starting to get cold here, so I decided to install some antifreeze, and that just set everything way back. It reduced the field strength by over 80%.

Since then Dave has come up with a coil-set designed to charge up antifreeze, but I was disappointed when I tried it. It did better with the antifreeze than the original set did, but we came to the conclusion that the antifreeze destroys water’s diamagnetic properties to the point that the mixture is just hard to charge up. Working on this problem is the reason why I didn’t release the coil info sooner. I kept hoping that we might solve this problem as well, but we didn’t. However, this just might not be as big a problem as I thought, because I’ve heard that well-charged water just might have a significantly lower freezing point. This has not been tested yet to verify it.

An interesting side issue is the fact that the water which I drained out when adding antifreeze, showed no sign of rust. It was perfectly clear. Under normal circumstances, with no additives in the cooling system, this water should have been a horrible orange mess. It wasn’t, and that has to be because of the field on the engine.

The Pinto is not roadworthy, so I have no way of knowing what kind of fuel consumption is possible with this setup or what power it might be capable of producing. At this time, I just use it to test different devices, and to try for fuel-less operation. However, if I was to achieve a consistent, repeatable fuel-less operation, it could become roadworthy very quickly, so I could do some actual road testing.

**The Italian B.A.C. Coil.**

In July 2016 I was informed about the Italian BAC coil which I had not heard of before. It’s function is very much like that of the Joe Cell coil described above, but it is much more simple. The video shown at [http://translate.google.com/translate?hl=es&sl=it&tl=es&u=http%3a%2f%2fecocreando.weebly.com%2ffunzioni-bobina-bac.html&sandbox=1](http://translate.google.com/translate?hl=es&sl=it&tl=es&u=http%3a%2f%2fecocreando.weebly.com%2ffunzioni-bobina-bac.html&sandbox=1) describes its construction and uses. This is not a coil which I have tested and so all that I can do is to pass on the information. The coil is a bi-filar coil which is closed off to form a single, continuous loop **but** it is wound in a clockwise direction which is not the usual direction:
The claims made for this coil are quite remarkable and as the coil is so very simple that they are easily checked. The number of turns in the coil is a critical factor, depending on the application. The coil is wound using two wires of 1 sq. mm. diameter copper wire and connected together as shown in the illustration. The coil is said to improve the quality of a wide range of things:

1. Water quality can be improved very substantially as follows:
   a. Water with mild limestone hardness can be improved with one 15-turn coil on the water pipe.
   b. Water with severe limestone hardness can be improved with one 13-turn coil.
   c. For industrial use in a severe hardness area: two separate 13-turn coils on the water pipe.
      Water treated with any of these procedures makes much healthier drinking water

2. Fuel treatment results in improved mpg results:
   a. Petrol: two separate 13-turn coils on the fuel pipe.
   b. Diesel: one 13-turn coil plus one 7-turn coil on the fuel pipe.
   c. LPG: one 13-turn coil plus one 28-turn coil on the fuel pipe.
      Up to 25% fuel reduction can be expected.

3. Natural gas:
   a. one 13-turn coil on the gas pipe OR one 28-turn coil if the 13-turn coil is not effective.
      Up to 25% gas reduction can be expected.

4. On High-voltage cables such as spark-plug leads:
   a. One 13-turn coil on the high-voltage lead.
      A further 15% mpg improvement may result from improved fuel burn.

The web page shown here: 
http://translate.google.com/translate?hl=es&sl=it&tl=en&u=http%3A%2F%2Fecocreando.weebly.com%2Ffunzioni-bobina-bac.html&sandbox=1 mentions these and many other applications, including medical applications. These coils are generally wound using “figure of eight” wire, but there is no reason why two separate strands of single core stranded wire should not be used provided that the two wires are wound side by side as shown in the car fuel line winding below where a green/yellow wire and a white wire are used separately.
Electrets Constructed from Co-axial Cable.
There is a device which is not widely known. It is called an "electret" and I have to confess that my knowledge of them is almost zero. Essentially, an electret is a passive device which pours out electrical energy. I do not know where that electrical energy comes from. The Wikipedia encyclopaedia has some highly technical information on the subject remarking that "tunnel ionisation" is a process in which the electrons in an atom can pass through the atom's potential (voltage) barrier and escape from the atom. In an intense electric field, the potential barrier of an atom is distorted drastically and so the length of the barrier through which electrons have to pass, decreases and electrons can escape quite easily. The atoms spoken of here, might be those of a dielectric which could form an electret.

One method which has been used in the past to make an electret, has been to alter the structure of certain types of wax. A more convenient method is to use a reel of standard co-axial cable which is the sort of cable used to connect television aerials to television receivers:

An electret of that type can produce 10,000 volts at 10 milliamps. The current flow of 10 milliamps sounds trivial and of no consequence, but that is not actually the case as the power of 10 milliamps at 10,000 volts is 100 watts, so imagine a 100 watt light bulb brightly lit and not needing any power input at all to make it shine. That is actually, quite impressive.

PLEASE NOTE THAT 10,000 VOLTS WILL KILL YOU AND INVESTIGATING A DEVICE OF THIS TYPE IS NOT FOR PEOPLE WHO ARE NOT ALREADY FAMILIAR WITH WORKING SAFELY WITH VERY HIGH VOLTAGES. MEASUREMENTS MUST ONLY BE MADE WITH HIGH-VOLTAGE EQUIPMENT. LET ME STRESS AGAIN THAT I AM NOT ENCOURAGING YOU TO MAKE OR EXPERIMENT WITH ANY FORM OF HIGH VOLTAGE DEVICE AND THAT THIS INFORMATION IS FOR YOUR INTEREST ONLY.

The arrangement with a single reel of cable is:

Unfortunately, life being what it is, it has been found that when you try stepping that voltage output down to a more convenient level, there are liable to be losses which can lower the output power to just 50 watts. That sounds disappointing until you put it in perspective. This is a device which has the same output as a 50 watt solar panel in full sunlight, mounted at the optimum angle and positioned near the equator, but a home installation of such a panel gives far lower output, especially so when your home is a long way from the equator. But, note that the electret costs far less, produces that full output at any latitude and at night, while the solar panel is restricted by cloud cover, distance from the equator, needs an expensive mounting system, ideally should rotate to track the position of the sun, and only works when there is a high light level. So, the electret's fifty watts of continuous power is not an insignificant thing when you compare it to the other options available. These electrets can be stacked in parallel and an output in the kilowatts range is possible.

Let me stress that I personally have not yet made or used a co-axial cable electret, and so the information here comes from an experimenter who has done this. Also, while the information here is intended to help anyone who wishes to experiment along these lines, the fact that it is here must not be interpreted as my
encouraging you personally to try to make or use an electret of this or any other type. If you choose to do that, then you do so entirely at your own risk and nobody other than yourself is liable should any mishap occur.

The following procedure has been used to convert a full reel of 1/4", type RG6/U 75-ohms, 18-AWG co-axial cable into an electret:

1. Make sure that neither end of the cable has the screen touching the central core.
2. Make an electrical connections to both the screen and the core at both ends of the cable.
3. Place the whole of the spool of cable inside an oven.
4. Heat the oven (a genuine oven and not a microwave) slowly to 350°F (180°C).
5. Maintain the heat until the inner plastic insulation is so soft that it can be permanently indented. This plastic must not get too soft and reach the flowing stage, nor must it get burnt or develop holes which allow arcing - if that happens, then the reel of cable is a throwaway. The objective here is to get the plastic to lose its polarisation memory.
6. When the inner plastic sleeve has reached this level of softness, apply a steady DC voltage of about 10,000 volts to the connections already made to one end of the cable (to the screen and to the core). Although any voltage from 12V to 20,000V can be used, a 10 mA current draw can be expected when using 10,000V. Maintain this applied voltage at the high temperature for about ten minutes.
7. Turn off the heat and let the oven cool down gradually at its own rate to the 25°C to 30°C region, keeping the high voltage attached to one end of the cable.
8. Disconnect the DC voltage.
9. Connect the cable screen to the central core at both ends of the cable.
10. Leave the cable at room temperature for five to seven days. During this time, the polarisation of the plastic is reorganising. After this time, the electret is ready for use as a power source.

The Devices of Mehran Keshe

In 2015, an Iranian man called Mehran Keshe went public with his latest design of an Orgone concentrator, showing the construction details and offering completed units for sale. This was not a sudden announcement as Mr Keshe had been discussing energy flow for several years and showing how to construct low-power devices.

Faced with the problem which all Orgone builders find difficult, namely, describing a piece of technology in a field where there are no commonly accepted terms, Mr Keshe has invented his own names where none existed. That makes it rather difficult to understand his descriptions, but this is a common problem in this field. The device which we are discussing here is his:
Unfamiliar terms such as “Gans”, “Nano coating” and “Plasma capacitor” do tend to put people off and make them wonder if this design is genuine. That tends to make people decide to wait and see if people can make it work. That waiting time appears to be coming to an end now.

How do we know that this is an Orgone device? In the page displayed above, you will notice that the first step is “Pray”. That makes people with just basic science training, tend to dismiss the entire matter out of hand. But, as you can see in my chapter 10 entry the “Weird Nature of Water” demonstrates clearly that in free-energy designs, the builder has a major influence on the performance of the finished product. In the case of water, the crystal structure of the frozen water is drastically influenced by the mental state of the human involved.

Many years ago there was a report in an electronics magazine about a man attaching a lie detector to the leaf of a plant and then, standing several metres away, he thought of destroying the plant by burning it. The sensitive lie detector equipment displayed major changes caused by his thoughts and the magazine concluded that plants are sentient. Personally, I think that their conclusion is quite wrong and while many plants have protective mechanisms to warn other plants in their species of any immediate threat, I seriously doubt their conclusion. What I think was happening was that the man was transmitting thoughts across the space to the plant leaf which formed a variable resistor sensitive to the thought waves and it was the man causing the lie detector display fluctuations. Either way, it shows the transmitted effect of human thought. The effect is also seen in gardeners who are supposed to have “green fingers”. Those gardeners don’t have special fingers, what they do have is positive mental thoughts about plants and those thoughts influence the plants in a positive way.

Another indicator that the Keshe design operates on Orgone is seen in the instructions which come with the units purchased complete from the Keshe Foundation. The instructions stress that before any electrical load is connected to the unit, that there needs to be a three week to five week period while the immediate surroundings become attuned to the energy field of the unit. Remember that the Joe Cell described earlier in this chapter, when attached to a vehicle, can take a week to get the vehicle attuned to the Cell. These things are all consistent with each other. So when Keshe says “Pray” he is completely serious as prayer is a form of meditation which produces positive brain activity which will help the construction steps which follow. If this is new to you, you will find the concept difficult because it does not fit in with the wholly inadequate
idea of the universe which you have been fed all your life. It would be nice to think of this as a “lunatic” idea, but unfortunately, it is perfectly correct.

Anyway, have we any evidence that the Keshe design can work? The answer is ‘yes’ and we will start with a homemade version as shown by Robert Stubblefield. He shows this electricity bill:

and on 7th January 2016 he comments: This bill is from last month. The reading of 47822 is from 01/02. The reading of 47986 is from 01/07 at about the same time (22 minutes apart). That means I was using an average of 2.875 kilowatts per hour last month (November). Right now (December) I am using 1.366 kilowatts per hour. My savings from using the plasma technology is 1.515 Kilowatts per hour.

The link is https://www.facebook.com/groups/GoldenAgeofGans/?ref=bookmarks. Interestingly, I have seen it said that an Orgone pyramid placed underneath an electricity meter caused a much reduced electrical reading, so much so that the utility company replaced the meter on two different occasions because of the very low readings. In that set-up, there was no connection to the mains. In the Keshe system, there is a connection in one of four different connection methods.
We also have information from John Blanpied of the Volcano Ubuntu Centre in Volcano, CA who shows the initial work on a unit delivered by the Keshe Organisation:

The link is https://www.facebook.com/groups/GoldenAgeofGans/?ref=bookmarks#. This shows that the Keshe Foundation is actually producing devices and shipping them to the people who purchased them. It is too soon to be certain of the genuineness of Keshe or to assess the performance of his designs, but it looks very promising at this point in time.

John Anderson appears to be well informed about the Keshe systems and following some probing questions from Sterling Allan on his PESN website, John provided the following answers:

Q: I've not seen any reports of the performance of this technology by anyone besides Aleks.
A: There are several workshops where the initial testing was performed "on air" over time. There are many knowledge seekers who have built and tested these units in a limited fashion. This is very new technology, but using very old concepts.

Q: But it is a huge problem for most people. How do you plug a little box into your house to run your house off it?

A: I can understand how folks can get confused with the claims. It is necessary to understand, that what this box does is totally different from what folks are used to thinking about. The electricity output is a by-product of the technology and not the primary energy. The primary energy is vastly different from anything conventional physics has worked with in the past.

Q: Do any of you know anyone who has either replicated this for themselves and are now powering their house or car with it, or who has installed one of the Keshe Magrav systems which they bought, and have been powering their house or car with it?

A: I know many people who have replicated this technology in various forms with generally good results. I myself have made limited systems and have tested them, although my understanding of them is not complete. Remember, you cannot compare these systems to a "generator" or electricity supply. They work on an entirely different level.

Q: We have no information about how user-friendly this is. Is it just a matter of plug-and-play, or does it require a specially trained electrician to install it? And once it's installed, is it fully functioning, or is there a period of "conditioning"?

A: This is initially, a plug and play system. You plug one end into a wall socket (or between your electric meter and the circuit breaker box) and it begins to condition what you plug into the other end (or your whole house) to accept and function with the plasma energy. It does take a little while for the system to come to full operation, but even so, some appliances will work off it straight away.

Q: From what I gather from bits and pieces which I have heard, there is a "conditioning" period, and it doesn't power all appliances. For example, if I heard correctly in the previous video, it won't power Compact Fluorescent lights, which almost everyone has in their homes now. So how does that work? How feasible is this for people in the Western world actually using it in their homes right now?

A: The reported limitations of the initial units is with resistive loads. These are loads such as electric heaters, electric stoves, filament light bulbs and such. If I understand it correctly, capacitive or inductive loads operate perfectly. There will be some time of discovery for many to see the precise requirements and limitations inherent in the Keshe plasma system, but the benefits are far beyond the inconveniences. Resistive loads will still be operational, but only to around 3.2 kW. This is due to the nature of the conversion of plasma into resistive capable electron flow.

Q: If it requires input from the mains to produce power, will it work when the grid goes down? Keshe says "Yes". How can that be?

A: The input from the grid is used as a signal for the unit to know what form of electricity to output. Barring using a resistive load on the output there is no energy drawn from the grid. If a resistive load is used, only a small percentage of mains energy is used. The next generation units will not require a mains connection.

Q: The plugs going to and from the Magrav Power system are Italian connectors. Converting that to other similar power systems is just a matter of using the proper adaptor. But what about when converting it to power systems that are different? Keshe says that this is not an issue? Has that been demonstrated successfully?

A: Yes. Again, you need to adjust your thinking away from the limitations of conventional physics. In the conference, both 240 volt 50 Hz "European" and 110 volt 60Hz "North American" devices were plugged into...
the same output socket strip and functioned correctly at the same time. No converter was necessary other than the physical plug connections. It is possible to power a cell phone, an air conditioner and a fridge from different countries from the same plug with this technology. It does not have the limitations of "electricity".

Q: What about vehicle applications? How does that work? What kind of success have people had implementing the Magrav technology in that application? I understand that it is supposed to even work on non-electric vehicles. How does it do that and how well does it perform?

A: The "how" of this question is a bit complicated and does require some relearning of how matter and energy interact. In a very basic explanation, the plasma employs forces identical to how the universe operates. There are no engines on the Earth to keep it spinning and orbiting the Sun. It is the interaction of magnetic and gravitational fields which provides the energy for that system. The plasma is a harnessed and directed combination of these types of fields and that can impart its energy into any "matter" (or non-matter) system. Since everything is made of this same plasma, contrary to what conventional physics would have you believe, it is not difficult to see and plan interactions as needed, once one has surpassed the "matter" limitations.

Q: Do you know of any reports from people who have implemented this technology?

A: There are, to be bold, millions of folks around the globe creating and using plasma based systems for everything from agriculture, food replacement, motive force, healing and pain control, fuel efficiency increases, home heating load reduction, as well as other fields. We are only beginning to see the potential uses and benefits of plasma technology. There are many Facebook groups with folks offering their research and ideas freely and in the spirit of cooperation, in order to advance this technology as quickly and as broadly as possible. On 26th October 2015, the details of the plasma energy unit will be released, barring unforeseen events, in which anyone will be able to replicate the units in their home. It will require no special tools or knowledge, though a basic understanding of the nature of the technology is certainly helpful. It is a very simple technology in practice, once one surpasses the limited thinking of conventional physics. There is even a pre-school girl in China who is creating basic systems on her own. This technology replicates what is done in nature and the universe as a whole. It can be done with simple tools and items scrounged from the forest, junkyards and such. A good training video is at https://youtu.be/Yf_ezDailhI.
**DO’S**

1. Contact a Professional Electrician when connecting to the Main Breaker.
2. Mount MAGRAV POWER on Wall or Table Top
3. Connect Proper Polarity
4. Gradually Load the MAGRAV POWER
5. Allow 3-4 Weeks Use to obtain maximum potential
6. Keep the MAGRAV POWER in a place that is out of reach of children.
7. Send Good Intentions to it.

**DON'TS**

1. DO NOT Wet the MAGRAV POWER
2. DO NOT Overload, Maximum 2KW
3. DO NOT invert Polarity
4. DO NOT send negative intentions to the MAGRAV POWER.

---

**MAGRAV POWER** Power Factor Corrector Device **SAFETY**

**HOW TO IDENTIFY THE LIVE WIRE**

Use a polarity tester device or a phase meter for LIVE wire identification. The LED lights up when it is a LIVE (+) wire.

If LED lights on both sockets, the one with the brightest light is the LIVE (+) wire.

Production of Coils

Keshe Foundation R&D Group
August 30, 2015
Materials
Gauge no. 14 (1.6mm) TW solid copper wire, insulation removed, made into coils.

Insert the small diameter coil in the bigger coil
Coils must be close touching each other and still have room for movement

Bending the longer end of the inner coil, ready for insertion into itself
Insert the longer end of inner coil on the other side all the way through the other side.

Pull all the wire that comes out the other end to form a loop.
Form each loop into a circle

The smaller loop should be placed in the middle of the bigger loop before each individual wires.
For schematics how the coils are connected to each other, please refer to the MG-Energy-Coils-Schematics.pdf file

Nano Coating Process using Fire from butane torch
Start on the wire junction, temperature should be only be right before copper turns red hot.

Move the flame towards the center loop and start moving clockwise slowly maintaining the desired temperature while moving along the coil.
Move the flame up after completing the center loop and start moving counter clockwise around the outer loop.

You'll get consistent bluish black color coating when you maintain a consistent temperature by movement speed. The tip of blue part of the flame should be touching the copper like a paint brush.
Continue along the path. Too cold will result to different colors coating. Copper surface becomes shiny when the right temperature is reached then you move along.

Ideal surface material is ceramic tile while doing this process. Never use metal surface, it will act as heatsink, resulting to inconsistent coating.
Do a similar process on the other side while still warm but of opposite direction on every loop to have a consistent flow of heat and not material movement. An optional double flame opposite each other moving together while the coil is hanging on wire on its two terminals can do a single pass process both sides together, saving production time.

After cooled down by itself, one can make corrections on form then repeat the heating process one last time and it will be ready for use after cooling itself. Just leave it on the same tile while cooling.

Before form correction made.  After form correction made.
Form correction process can be done before a complete nano coating process. Simply preheat all at a lower temperature enough to align the copper material structure and let it cool for handling with gloves. Copper becomes softer after the heating process, one can make the desired shape then proceed to nano coating process.

Coils made from copper wire without insulation should be tightly close to each other, no gaps in between. The nano material created after nano coating will serve as the insulator touching each other.

Coil winding can be done on a coiling setup or machine for faster production.

Please note that not all number 14 gauge wire that is 1.6mm are actually 1.6mm. Every manufacturer output may vary from each other.
Important note on quality of copper:
Not all copper wire are created equal. However, we will use that copper that is soft and not yellowish and hard to bend. Yellowish dull color and hard to bend kind is an indicator of impurities. Hard to bend will only slow down your production process.

Never use this ->

Use this ->

MAGGRAV COIL CIRCUIT CONNECTION

A non polarized AC capacitor C is needed when this circuit is connected in parallel to AC or DC.

No capacitor is needed when this is connected in series on one line of AC or DC circuit.

The negative input should be connected to the negative on DC circuit or facing the source when connected in series on AC.

NOTE:
Magnetical flow should be counter clockwise.
Gravitational flow should be clockwise.
Gravitational coil is inside the magnetical coil.

Drawing Legend:

- Magnetical Coil magnetical loop
- Gravitational Coil gravitational loop
- Magnetical Coil gravitational loop
- Gravitational Coil gravitational loop
- Connection points red on magnetical coil, black on gravitational coil
- Connection lines
- Arrows shows the entry and desired flow.
MAGRAV Power Unit: Build and Grow
Keshe Foundation R&D Group

**Lists of Items**
1. Gauge #14 Solid Copper Wire - about 20-30 meters to make 3 sets of MAGRAV COILS
2. Nano Coating Kit (Refer to Videos of You Tube)
3. Hand Drill with 2 rods for inner and outer coil forming
   or 2 Screw Drivers with different rod diameter that can be inner and outer coils former
4. Gans Mix for Coating the Coils and putting on the Center Gans Container
5. Plasma Capacitor - 2-3 Units
6. A lot of Patience, Prayers and Love in doing your MAGRAV Power Unit

**Coils Specifications**
1. All Coiled Counter Clockwise (use the Right Thumb Rule - by pointing your Right Thumb towards you and curl your 4 fingers to the left going in your palm - The Curl Is the Direction of Turn)
2. Diameter of Loop Coils Varies on tubes use to make the coils.
3. **Magnetic Loop** (Outer) consists of 2 coils Magnetic Coil (outer) and Gravitational Coil (Inner)
   - 140-160 Turns
4. **Gravitational Loop** (Inner) consists of 2 coils Magnetic Coil (outer) and Gravitational Coil (Inner)
   - 70-80 Turns

**Steps**
1. Pray and Make the Coils - 3 sets.
3. Coating the Coils with Gans Mix (Pastel/Liquid) and Dry it properly.
4. Assemble the Coils and Connect properly (make sure to fold the ends of the wires towards itself)
5. Assemble the casing and properly arrange and stack all parts including the Gans Center Container
6. Connect the Plasma Capacitor Properly.
7. Check the Connections again (you can use electrical shrink tape to hold the connections)
8. Install proper Switches or Breakers to the System.
9. Always consult an Electrical Engineer or Technician when connecting to the Main Power Line
10. Build another one for your Neighbor and Relatives

---

MAGRAV Coil Circuit Connection
Keshe Foundation: R&D Group
August 30, 2016

**Specifications:**
- **Gauge #14 Solid Copper Wire**
- **All Coiled Counter Clockwise**
- **Diameter of Loop Coils Varies on tubes use to make the coils.**
- **Magnetic Loop (Outer)** consists of 2 coils Magnetic Coil (outer) and Gravitational Coil (Inner)
  - 162 Turns
- **Gravitational Loop (Inner)** consists of 2 coils Magnetic Coil (outer) and Gravitational Coil
  - 91 Turns
MAGRAV Coil Circuit Stacked & connected in Series

Note:
1. Connecting wires must be nano-coated.
2. Always twist the ends of the wire back to itself.

Circuit/Load

Notes:
1. Discharge the Capacitor to the Ground in few seconds once a month by switching off the system.
2. Magrav Coils and Capacitor can be increased according to the power requirement.
3. This setup is for 2.2kW and can be at power up to 8 kW in the first month of operation.
Dan Davidson has produced a book entitled “Shape Power”. In it he points out that nine wooden chopsticks pushed into a Styrofoam ball produces both an electrostatic field and a magnetic field. This is due to the effect of converging straight lines and it is impressive that these non-magnetic components can produce a magnetic field.

Dan examines the effects of various shapes. The twelve pointed tesseract has an effect on orgone:
A twelve pointed tesseract is a shape where every point is connected to every other point. A circle draws in power and concentrates it at the centre of the circle. Strange as it seems, the orgone energy flow which surrounds us can be affected merely by drawing shapes on paper and the order of making the lines also has a major effect as can be seen in the following diagram which is a shape connected with healing:

A very powerful shape is the vortex. In this arrangement, a circular ring surrounds, but does not touch the wires which form the vortex shape:
This shape forms a powerful jet of concentrated orgone energy projecting out from the central opening and extending for five or six feet (1.5m to 1.8 m) from the shape. The effect can be increased if extra, smaller vortex shapes are placed over the larger, main vortex shape.

Dan also comments on the effect of different materials. He remarks that William Reich stated that while orgone energy passes through everything, the speed of penetration is different for different materials. Reich found that organic materials such as cotton, wool, wood, and silk readily transmit orgone energy. Metals such as iron and aluminium, on the other hand, will first absorb orgone and then repel it. Within each category (i.e., organic and metal) there were varying degrees of conductivity and absorption.

Dan confirms the effects of a pyramid and he states that while the magnetic orientation of a pyramid (typically North-South and East-West for the four sides of the base) is important, that the dimensions of the great pyramid of Gisa are not at all essential and many different side slopes work well. He confirms Joseph Cater’s analysis that the energy flow is concentrated at the five pyramid tips. Dan also says that a very effective way of using a pyramid is to use it to energise a glass of water for an hour or so, as orgone energy is highly attracted to water and drinking that water is beneficial. Using a set of small pyramids in a grid forms a base for supporting the glass of water. Dan also states that it is important to have an opening in every side of a pyramid shape. It is definitely worth reading Dan Davidson’s book “Shape Power”.

Chapter 10: Automotive Systems

Note: If you are not at all familiar with basic electronics, you might find it easier to understand this chapter if you read chapter 12 first.

There are two or three main objectives for people who create automotive devices – increasing the mpg performance and reducing the harmful emissions are the top two priorities, while running the vehicle on water alone is the aim of a few people.

The first two objectives are readily achievable, but running a vehicle on water alone is not going to happen for almost everybody. This idea is peddled by con artists who sell worthless “plans”, claiming that these will run a vehicle on water for anybody who wants to construct these simple devices. This is just not true. You are welcome to download the "HydroStar" and "HydroGen" plans free from [http://www.free-energy-info.com/P61.pdf](http://www.free-energy-info.com/P61.pdf) and [http://www.free-energy-info.com/P62.pdf](http://www.free-energy-info.com/P62.pdf). However, most experienced people looking at these plans are convinced that they could not possibly produce enough hydrogen/oxygen gas mix to run an engine. While I have never heard of anyone, anywhere, ever getting an engine to run on these plans, the present day science of water is so inadequate, that I am not in a position to be certain that they could not work, and so I am just highly doubtful as to them being viable devices.

Just before getting on to explain the construction details of practical systems, let me put the running of an engine on water alone in its proper context. The internal combustion engine which you own has an efficiency less than 50%. This means that at least half of the energy available from the fuel which you use is wasted and does not produce any useful mechanical output power. In many cases, that percentage can be as high as 90% wasted, but let's be generous and assume that your particular engine is especially good and manages 50% efficiency.

The main way of running an engine with water as the only fuel, involves splitting water into hydrogen and oxygen and then burning those gases to power the engine. To be self-sustaining, the splitting of the water has to be done by the electrics of the vehicle and that means that the efficiency of the water splitting has to be more than 200% efficient. That just doesn't happen with simple systems, so please forget the notion of building some device in your garage with a couple of hours work and waving goodbye to filling stations forever – it ain't going to happen.

Just to set the record straight, it is possible to appear to run a car on water alone, but the difficulty level is about the same as building a rocket capable of going into orbit, something well beyond the capabilities of most people, including me. This document does tell you how it can be done, but please understand that it calls for exceptional skills, very considerable expenditure and a great deal of patience, so for the time being, please forget about it.

What can be done quite readily and at low cost, is to construct a device which will raise the efficiency of your engine. This is done by feeding a hydrogen/oxygen gas mix (called “HHO” gas) into your engine along with the air which is drawn in to make the engine run. A device of this type is called a “booster” as it boosts the fuel burn, extracting a greater percentage of the fuel’s available energy. An important side effect of this improvement in the burn quality of the fuel is the fact that unburnt fuel no longer gets pushed out of the exhaust as harmful emissions.

Another effect is that the engine has greater pulling power and runs smoother. Inside your engine, carbon deposits will have built up from previous un-boosted running and these deposits get burnt away when you use a booster and that internal cleaning extends the engine life.

Some people worry about the fact that burning HHO gas produces water and they imagine this water causing rusting inside the engine. What they don’t realise is that the ordinary fuel used in the engine is a “hydrocarbon” which is a compound of hydrogen and carbon and that fuel actually splits up to form hydrogen which the engine burns. Actually, it is the carbon part of the hydrocarbon fuel which is the problem, producing Carbon Dioxide, Carbon Monoxide, and physical carbon deposits inside the engine. A normal fuel burn produces water anyway, but you don’t get rusting inside the engine as the temperature there is so high that any water is in the form of steam or vapour which dry out completely when the engine is switched off. Adding a small amount of HHO gas has no adverse effects at all.

This document describes different types of booster. Let me stress that each engine is different and it depends on how inefficient the engine is to begin with, what sort of mpg improvement is likely to be produced by a booster. Just to make sure that you understand what is involved, a booster is a simple container which holds a set of plates submerged in water which probably has an additive to make the water conduct electrical current better. A pipe from the top of the container feeds the gas into the air filter of the vehicle, via one or two simple safety devices. Adding this gas causes a major improvement in the quality of the fuel burn inside the engine and cuts harmful emission to near zero.
As a consequence of this, it is possible to reduce the amount of fossil fuel being sent to the engine, which is not something which should be done if HHO gas is not being added, as the engine is liable to overheat and some valve damage could occur. It is a completely different matter if HHO gas is being added. However, all recent engine designs have an Electronic Control Unit (“ECU”) which controls the amount of fuel being sent to the engine. The ECU accepts input signals from an “oxygen sensor” placed in the exhaust stream, and often a second sensor after the catalytic converter to make sure that the catalytic converter has not failed.

Unfortunately, the much improved exhaust caused by the better fuel burn caused by the HHO gas, causes the ECU to think that the engine fuel-air mix must be too low, and so it pumps in more fuel in an effort to compensate. Ideally, this can be dealt with by adding a circuit board which adjusts the signal coming from the oxygen sensor so that it is correct for the improved fuel burn. Details of how to do this are in a companion document.

So, to recap, the only practical device which you can build yourself and use to improve automotive performance is a ‘booster’. Using a booster improves the efficiency of the fuel burn inside your engine and that results in more power, better torque, smoother running and vastly improved exhaust emissions. If the ECU is not adjusted or its input signal not controlled, the mpg figures may actually get slightly lower due to unwanted excess fuel being pumped into the engine. If a control circuit is used to correct this ECU error, then mpg gains will be produced.

So, what mpg gains can be expected? The worst I have ever heard of was 8% which is very rare. The lowest likely gain is 20%. Typical gains are in the 25% to 35% bracket. Not particularly unusual is 35% to 60%, while gains up to 100% and over have been achieved but they are rare. A realistic expectation would be a 33% gain.

This chapter is divided up into the following sections:

1. Simple DC boosters, using a 12-volt electrical input.
2. Advanced DC boosters using much higher DC voltages.
3. Water-splitters which use pulsed electrical signals to change water into “HHO” gas.
4. Running engines without fossil fuels.
5. Other useful devices.

One thing which needs to be understood:

Caution: A booster is not a toy. If you make and use one of these, you do so entirely at your own risk. Neither the designer of the booster, the author of this document or the provider of the internet display are in any way liable should you suffer any loss or damage through your own actions. While it is believed to be entirely safe to make and use a properly built booster, provided that the safety instructions shown in this document are followed, it is stressed that the responsibility for doing this is yours and yours alone.

Simple DC Boosters.

It is important that you understand the basic principles of electrolysis if you are to be successful in building and operating a booster, or alternatively, buying and operating a booster. A “DC booster” operates on “Direct Current” which is the sort of electrical power delivered by a car battery.

The method is very simple in basic outline. Two metal plates are placed in water and an electric current is passed between the plates. This causes the water to break down into a mixture of hydrogen gas and oxygen gas (The two components used in the Space Shuttle). The greater the flow of current, the larger the volume of gas which will be produced. The arrangement is like this:

Remembering that the result of doing this is to produce fuel for the Space Shuttle, you should avoid doing this indoors and letting the gas produced by the process collect on the ceiling. There are many videos on the web where people act in a dangerous manner and perform electrolysis indoors using a container which is open at the top as shown above. Please, please don't do that as it is highly dangerous - it is not a party popper which pushes
the Space Shuttle into space! If you were to collect a cupful of HHO gas and light it, the resulting explosion would probably damage your hearing permanently, so don't do it under any circumstances. Just like the fact that a very useful chain saw is a dangerous device which needs to be treated with respect, so too, please understand that the very useful HHO gas mix contains a lot of energy and so needs to be treated with respect.

This style of electrolysis of water was investigated by the very talented and meticulous experimenter Michael Faraday. He presented his results in a very technical and scientific format which are not understood by most ordinary people. But in simple terms, he tells us that the amount of HHO gas produced is proportional to the current flowing through the water, so to increase the rate of gas production, you need to increase the current flow. Also, he found that the optimum voltage between the two “electrode” plates is 1.24 volts.

This sounds a bit technical, but it is a highly useful piece of information. In the arrangement shown above, twelve volts is being connected across two plates in water. Faraday tells us that only 1.24 volts of that twelve volts will go to make HHO gas and the remaining 10.76 volts will act as an electric kettle and just heat the water, eventually producing steam. As we want to make HHO gas and not steam, this is bad news for us. What it does tell us is that if you choose to do it that way, then only 10% of the power taken by the booster actually makes HHO gas and a massive 90% is wasted as heat.

We really don't want a low electrical efficiency like that. One way around the problem is to use two cells like this:

![Diagram of two cells](image1)

This arrangement uses our 1.24 volts twice while the twelve volts stays unchanged and so the electrical efficiency goes up to 20% and the heat loss drops to 80%. That is quite an improvement but even more important is the fact that twice as much HHO gas is now produced, so we have doubled the electrical efficiency and doubled the gas output, giving a result which is four times better than before.

We could go one step further and use three cells like this:

![Diagram of three cells](image2)

This time we are using three of our 1.24 volt sections and this gives us an electrical efficiency of 30% and three times the amount of gas, making the system nine times more effective.

This is definitely going in the right direction, so how far can we take it when using a twelve volt battery? When we use the construction materials which years of testing has shown to be particularly effective, there is a small voltage drop across the metal plates, which means that the very best voltage for each cell is about 2 volts and so with a twelve volt battery, six cells is about the best combination, and that gives us an electrical efficiency of 62% and six times as much gas, which is 37 times better than using a single cell, and the wasted electrical power drops down from 90% to 38%, which is about as good as we can get.
Of course, it would not be practical to have six boxes each as large as a car battery as we would never manage to fit them into most vehicles. Perhaps we could just put all the plates inside a single box. Unfortunately, if we do that, a good deal of the electric current would flow around the plates and not make much gas at all. A top view of this arrangement is shown here:

This is a disaster for us as now we will not get your six times the gas production or our massively reduced heating. Thankfully, there is a very simple fix for this problem, and that is to divide the box up into six watertight compartments using thin partitions like this:

This gives us back our high efficiency by blocking the current flow past the plates and forcing the current to flow through the plates, producing gas between every pair of plates.

In passing, if this booster were to be powered by the electrics of a vehicle, then the voltage although called "twelve volts" will actually be almost fourteen volts when the engine is running so that the "twelve volt" battery will get charged. This would allow us to use seven cells inside our electrolyser, rather than the six cells shown above and that would give us seven times the gas volume that a single pair of plates would give. Some people prefer six cells, and others, seven cells - the choice is up to the person constructing the unit.

We have been discussing the methods of increasing the gas production and reducing the wasted energy, but please don't assume that the objective is to make large volumes of HHO gas. It has been found that with many vehicle engines, very good performance gains can be had with a HHO gas production rate of less than 1 litre per minute ("lpm"). Flow rates of as little as 0.5 to 0.7 lpm are frequently very effective. Remember, the HHO gas from a booster is being used as an igniter for the regular fuel used by the engine and not as an additional fuel.

The big advantage of an efficient booster design is that you can produce the wanted volume of gas using a much lower current, and so, a lesser extra load on the engine. Admittedly, there is not much additional engine load needed by a booster, but we should reduce the extra amount by intelligent design.

In the discussion above, the battery has been shown connected directly across the booster or "electrolyser". This should never be done as there is no protection against a short-circuit caused by a loose wire or whatever. There should be a fuse or a circuit-breaker as the first thing connected to the battery. Circuit breakers are available from any electrician's supply outlet as they are used in the "fuse box" in homes, to provide protection for each lighting
circuit and each power socket circuit. They are not expensive as they are manufactured in very large volumes. They are also available on eBay. The circuit breaker is wired like this:

![Circuit breaker diagram]

A common design (rated at 32 amps) looks like this:

Some would-be constructors feel that some aspects of the construction are too difficult for them. Here are some suggestions which might make construction more straightforward.

Constructing a seven-cell housing is not difficult. Pieces are cut out for two sides, one base, one lid and six absolutely identical partitions. These partitions must be exactly the same so that there is no tendency for leaks to develop. If you decide to use the bent-plate system of electrodes shown on the next few pages, then drill the bolt holes in the partitions before assembling them:

![Partition diagram]

The bottom piece is the same length as the sides, and it is the width of the partitions plus twice the thickness of the material being used to build the housing. If acrylic plastic is being used for the construction, then the supplier can also provide an “adhesive” which effectively “welds” the pieces together making the different pieces appear to have been made from a single piece. The case would be assembled like this:
Here, the partitions are fixed in place one at a time, and finally, the second side is attached and will mate exactly as the partitions and ends are all exactly the same width. A simple construction for the lid is to glue and screw a strip all the way around the top of the unit and have the lid overlap the sides as shown here:

A gasket, perhaps of flexible PVC, placed between the sides and the lid would assist in making a good seal when the lid is bolted down. The gas outlet pipe is located in the centre of the lid which is a position which is not affected if the unit is tilted when the vehicle is on a steep hill.

Years of testing have shown that a really good choice of material for the electrode plates is 316-L grade stainless steel. However, it is very difficult to connect those plates electrically inside the cells as you need to use stainless steel wire to make the connections and bolted connections are really not suitable. That leaves welding the wires to the plates and welding stainless steel is not something which a beginner can do properly as it is much more difficult than welding mild steel. There is a good alternative, and that is to arrange the plate material so that no wire connections are needed:

While this six-cell design may look a little complicated to a quick glance, it is really a very simple construction. Each of the plates used in the central cells is just this shape:
The plate shapes shown above are arranged so that there is access to the bolts from above and they can be reached by a spanner and held steady while the other nut is being tightened.

Unless you are skilled in bending plates, I suggest that you use stainless steel mesh for the plates. It works very well, can be readily cut using tin snips or any similar tool and it can be bent into shape by the home constructor using simple tools - a vice, a piece of angle iron, a small piece of mild steel sheet, a hammer, etc.

You will find a skip outside any metal fabrication shop where scrap pieces are tossed for recycling. There will be off-cuts of various sizes of angle iron and all sorts of other small sections of sheet and strip. They are in the skip mainly to get rid of them as the fabrication business gets paid almost nothing for them. You can use some of these pieces to shape your booster plates, and if you feel bad about costing the business about a penny, then by all means put them back in the skip afterwards.

If you clamp your plate between two angle irons in a vice, then careful, repeated gently tapping with a hammer close to the bend location, will produce a very clean and neat bend in the plate:

The bent sheet can then be clamped between two steel strips and a sharp U-shaped bend produced by tapping with a hammer, again, along the line of the required bend:

The thickness of the steel bar on the inside of the bend has to be the exact width of the required gap between the finished plate faces. This is not particularly difficult to arrange as 3 mm, 3.5 mm, 4 mm, 5 mm and 6 mm are common thicknesses used in steel fabrication, and they can be combined to give almost any required gap.
There are many varieties of stainless steel mesh. The style and thickness are not at all critical but you need to choose a type which is reasonably stiff and which will hold its shape well after it is bent. This style might be a good choice:

Your local steel supplier probably has some types on hand and can let you see how flexible a particular variety is. The shape shown above is for a "three plate per cell" design where there are two active plate faces. Ideally, you want two to four square inches of plate area per amp of current flowing through the cell, because that gives very long electrode life and minimum heating due to the plates.

This style of construction is reasonably easy to assemble as the two bolts which pass through the partitions and which hold the plates rigidly in place, can be accessed from above, two spanners being used to lock them tight. Lock nuts are optional. If you feel that your particular mesh might be a little too flexible or if you think that the bolts might eventually loosen, then you can attach two, or more, separator insulating pieces - plastic washers, plastic bolts, cable ties or whatever to one of the plate faces.

These will hold the plates apart even if they were to become loose. They also help to maintain the gap between the plates. This gap has to be a compromise because the closer the plates are together, the better the gas production but the more difficult it is for the bubbles to break away from the plates and float to the surface and if they don’t do that, then they block off some of the plate area and prevent further gas production from that part of the plate as the electrolyte no longer touches the plate there. A popular choice of gap is 1/8 inch which is 3 mm as that is a good compromise spacing. Circular spacers would look like this:

If the current is low enough, an even more simple shape which has just a single pair of active plate surfaces per cell, can be used as shown here:
Any of these designs can be 6-cell or 7-cell and the plates can be constructed without outside help. You will notice that the electrical connections at each end of the booster are submerged to make sure that a loose connection can’t cause a spark and ignite the HHO gas in the top of the housing. There should be a gasket washer on the inside to prevent any leakage of the electrolyte past the clamping bolt.

If you want to use three active plate pairs in each cell, then the plate shape could be like this:

The electrolyte is a mix of water and an additive to allows more current to flow through the liquid. Most of the substances which people think of to use to make an electrolyte are most unsuitable, producing dangerous gasses, damaging the surfaces of the plates and giving uneven electrolysis and currents which are difficult to control. These include salt, battery acid and baking soda and I strongly recommend that you do not use any of these.

What is needed is a substance which does not get used up during electrolysis and which does not damage the plates even after years of use. There are two very suitable substances for this: sodium hydroxide, also called "lye" or "caustic soda". In the USA, this is available in Lowes stores, being sold as "Roebic ‘Heavy Duty’ Crystal Drain Opener". The chemical formula for it is NaOH.

One other substance which is even better is potassium hydroxide or "caustic potash" (chemical formula KOH) which can be got from soap-making supply shops found on the web. Both NaOH and KOH are very caustic materials and they need to be handled with considerable care.

Bob Boyce of the USA is one of the most experienced people in the construction and use of boosters of different designs. He has kindly shared the following information on how to stay safe when mixing and using these chemicals. He says:
These materials are highly caustic and so they need to be handled carefully and kept away from contact with skin, and even more importantly, eyes. If any splashes come in contact with you, it is very important indeed that the affected area be rinsed off immediately with large amounts of running water and if necessary, the use of vinegar which is acidic and so will neutralise the caustic liquid.

When making up a solution, you add small amounts of the hydroxide to distilled water held in a container. The container must not be glass as most glass is not high enough quality to be a suitable material in which to mix the electrolyte. The hydroxide itself should always be stored in a sturdy, air-tight container which is clearly labelled "DANGER! - Potassium (or Sodium) Hydroxide". Keep the container in a safe place, where it can't be reached by children, pets or people who won't take any notice of the label. If your supply of hydroxide is delivered in a strong plastic bag, then once you open the bag, you should transfer all of its contents to sturdy, air-tight, plastic storage containers, which you can open and close without any risk of spilling the contents. Hardware stores sell large plastic buckets with air tight lids that can be used for this purpose.

When working with dry hydroxide flakes or granules, wear safety goggles, rubber gloves, a long sleeved shirt, socks and long trousers. Also, don't wear your favourite clothes when handling hydroxide solution as it is not the best thing to get on clothes. It is also no harm to wear a face mask which covers your mouth and nose. If you are mixing solid hydroxide with water, always add the hydroxide to the water, and not the other way round, and use a plastic container for the mixing, preferably one which has twice the capacity of the finished mixture. The mixing should be done in a well-ventilated area which is not draughty as air currents can blow the dry hydroxide around.

When mixing the electrolyte, never use warm water. The water should be cool because the chemical reaction between the water and the hydroxide generates a good deal of heat. If possible, place the mixing container in a larger container filled with cold water, as that will help to keep the temperature down, and if your mixture should "boil over" it will contain the spillage. Add only a small amount of hydroxide at a time, stirring continuously, and if you stop stirring for any reason, put the lids back on all containers.

If, in spite of all precautions, you get some hydroxide solution on your skin, wash it off with plenty of cold running water and apply some vinegar to the skin. Vinegar is acidic, and will help balance out the alkalinity of the hydroxide. You can use lemon juice if you don't have vinegar to hand - but it is always a good idea to have a bottle of vinegar handy.

The concentration of the electrolyte is a very important factor. Generally speaking, the more concentrated the electrolyte, the greater the current and the larger the volume of HHO gas produced. However, there are three major factors to consider:

1. The resistance to current flow through the metal electrode plates.
2. The resistance to current flow between the metal plates and the electrolyte.
3. The resistance to current flow through the electrolyte itself.

1. In a good electrolyser design like those shown above, the design itself is about as good as a DC booster can get, but understanding each of these areas of power loss is important for the best possible performance. We were taught in school that metals conduct electricity, but what was probably not mentioned was the fact that some metals such as stainless steel are quite poor conductors of electricity and that is why electrical cables are made with copper wires and not steel wires. This is how the current flow occurs with our electrolyser plates:
and so has to be accepted as an overhead. Generally speaking, the heating from this source is low and not a matter of major concern, but we provide a large amount of plate area to reduce this component of power loss as much as is practical.

2. Resistance to flow between the electrode and the electrolyte is an entirely different matter, and major improvements can be made in this area. After extensive testing, Bob Boyce discovered that a very considerable improvement can be made if a catalytic layer is developed on the active plate surface. Details of how this can be done are given later in the companion "D9.pdf" document as part of the description of Bob's electrolyser.

3. Resistance to flow through the electrolyte itself can be minimised by using the best catalyst at its optimum concentration. When using sodium hydroxide, the optimum concentration is 20% by weight. As 1 cc of water weighs one gram, one litre of water weighs one kilogram. But, if 20% (200 grams) of this kilogram is to be made up of sodium hydroxide, then the remaining water can only weigh 800 grams and so will be only 800 cc in volume. So, to make up a 20% "by weight" mix of sodium hydroxide and distilled water, the 200 grams of sodium hydroxide are added (very slowly and carefully, as explained above by Bob) to just 800 cc of cool distilled water and the volume of electrolyte produced will be about 800 cc.

When potassium hydroxide is being used, the optimum concentration is 28% by weight and so, 280 grams of potassium hydroxide are added (very slowly and carefully, as explained above by Bob) to just 720 cc of cold distilled water. Both of these electrolytes have a freezing point well below that of water and this can be a very useful feature for people who live in places which have very cold winters.

Another factor which affects current flow through the electrolyte is the distance which the current has to flow through the electrolyte - the greater the distance, the greater the resistance. Reducing the gap between the plates to a minimum improves the efficiency. However, practical factors come into play here as bubbles need sufficient space to escape between the plates, and a good working compromise is a spacing of 3 mm. which is one eighth of an inch.

However, there is a problem with using the optimum concentration of electrolyte and that is the current flow caused by the greatly improved electrolyte is likely to be far more than we want. To deal with this we can use an electronic circuit called a "Pulse-Width Modulator" (or "PWM") circuit. These are often sold as "DC Motor Speed Controllers" and if you buy one, then pick one which can handle 30 amps of current.

A PWM circuit operates in a very simple way. It switches the current to the electrolyser On and Off many times every second. The current is controlled by how long (in any one second) the current is On, compared to how long it is Off. For example, if the On time is twice as long as the Off time (66%), then the average current flow will be much greater than if the On time were only half as long as the Off time (33%).
When using a PWM controller, it is normal to place its control knob on or near the dashboard and to mount a simple low-cost ammeter beside it so that the driver can raise or lower the current flow as is considered necessary. The arrangement is like this:

![PWM controller diagram]

There is a more sophisticated circuit controller called a "Constant-current Circuit" and that allows you to select the current you want and the circuit then holds the current at your set value at all times. However, this type of circuit is not readily available for sale although some outlets are preparing to offer them.

Some of the most simple boosters don't use a PWM circuit because they control the current flow through the booster by making the concentration of the electrolyte very low so that the resistance to current flow through the electrolyte chokes off the current and holds it down to the desired level. This, of course, is far less efficient and the resistance in the electrolyte causes heating, which in turn, is an operational problem which needs careful handling by the user. The advantage is that the system appears to be more simple.

**Feeding HHO Gas to an Engine.**

When using a booster of any design you need to realise that HHO gas is highly explosive. If it wasn't, it would not be able to do it's job of improving the explosions inside your engine. HHO gas needs to be treated with respect and caution. It is important to make sure that it goes into the engine and nowhere else. It is also important that it gets ignited inside the engine and nowhere else.

To make these things happen, a number of common-sense steps need to be taken. Firstly, the booster must not make HHO gas when the engine is not running. The best way to arrange this is to switch off the current going to the booster when the engine is not running. It is **not** sufficient to just have a manually-operated On/Off switch as it is almost certain that switching off will be forgotten one day. Instead, the electrical supply to the booster is routed through the ignition switch of the vehicle. That way, when the engine is turned off and the ignition key removed, it is certain that the booster is turned off as well.

So as not to put too much current load on the ignition switch, and to allow for the possibility of the ignition switch being on when the engine is not running, instead of wiring the booster directly to the switch, it is better to wire a standard automotive relay across the oil pressure unit and let the relay carry the booster current. The oil pressure drops when the engine stops running, and so this will also power down the booster.

An extra safety feature is to allow for the (very unlikely) possibility of an electrical short-circuit occurring in the booster or its wiring. This is done by putting a fuse or contact-breaker between the battery and the new circuitry as shown in this diagram:

![Safety feature diagram]

If you choose to use a contact-breaker, then a light-emitting diode ("LED") with a current limiting resistor of say, 680 ohms in series with it, can be wired directly across the contacts of the circuit breaker. The LED can be mounted on the dashboard. As the contacts are normally closed, they short-circuit the LED and so no light shows. If the circuit-breaker is tripped, then the LED will light up to show that the circuit-breaker has operated. The current through the LED is so low that the electrolyser is effectively switched off when the contact breaker opens. This is not a necessary feature, merely an optional extra:
A good source for general components needed in building boosters is The Hydrogen Garage in the USA, website: http://stores.homestead.com/hydrogengarage/StoreFront.bok. A very important safety item for any booster is the “bubbler” which is just a simple container with some water in it. The bubbler has the gas coming in at the bottom and bubbling up through the water. The gas collects above the water surface and is then drawn into the engine through an outlet pipe above the water surface. To prevent water being drawn into the booster when the booster is off for any length of time and the pressure inside it reduces, a one-way valve is placed in the pipe between the booster and the bubbler.

If the engine happens to backfire, then the bubbler blocks the flame from passing back through the pipe and igniting the gas being produced in the booster. A bubbler is a very simple, very cheap and very sensible thing to install. It also removes any traces of electrolyte fumes from the gas before it is drawn into the engine. In practice, it is a very good idea to have two bubblers, one close to the booster and one close to the engine. The second bubbler makes sure that every last trace of electrolyte fumes are washed out of the HHO gas before it enters the engine.

There are various ways to make a good bubbler. In general, you are aimed at having a five-inch (125 mm) depth of water through which the HHO gas must pass before it leaves the bubbler. It is recommended that a bubbler is built inside a strong container such as this one:

These strong containers are generally sold as water filters. They can be adapted to become bubblers without any major work being done on them. At this point, we need to consider the mechanism for moving the HHO gas out of the booster and into the engine.

It is generally a good idea to position the gas take-off pipe in the centre of the lid so that if the booster gets tilted due to the vehicle operating on a sloped surface, then the surface level of the liquid remains unchanged underneath the gas pipe. A common mistake is to use a gas pipe which has a small diameter. If you take a length of plastic pipe of a quarter inch diameter (6 mm) and try blowing through it, you will be surprised at how difficult it is to blow through. There is no need to give your booster that problem, so I suggest that you select a gas pipe of half an inch (12 mm) or so. If in doubt as to how suitable a pipe is, then try blowing through a sample length of it. If you can blow through it without the slightest difficulty, then it is good enough for your booster.
One other thing is how to deal with splashes and the spray from bubbles bursting at the surface of the electrolyte. You want some device which will prevent any spray or splashes caused by the vehicle going over a very rough road, from entering the gas pipe and being drawn out of the booster along with the HHO gas.

Various methods have been used and it is very much a matter of personal choice as to how you decide to deal with the issue. One method is to use a piece of suitable material across the end of the pipe. This is generally called anti-slosh material because of the job which it does. The material needs to let the gas pass freely through it but prevent any liquid getting through it. Plastic pot-scrubbers as a possible material as they have an interlocking mesh of small flat strands. The gas can flow around and through the many strands, but splashes which go in a straight line will hit the strands and drip back into the booster again. Another possible device is one or more baffles which will catch the liquid but let the gas pass freely by:

The HHO gas produced by a DC booster of this type contains about 30% monatomic hydrogen, which means that 30% of the hydrogen is in the form of single atoms of hydrogen and not combined hydrogen pairs of atoms. The monatomic form is about four times more energetic than the combined form and so it takes up a greater volume inside the booster housing.

If the booster is left turned off for a long period of time, then these single hydrogen atoms will eventually bump into each other and combine to form the less energetic diatomic form of the gas. As this takes up less space inside the booster, the pressure inside the booster drops and this has been known to suck water out of the bubbler back into the booster. We don't want this to happen as it dilutes our carefully measured electrolyte concentration and it can make the bubbler ineffective due to lack of water.
To deal with this, a one-way valve is put between the booster and the bubbler, positioned so that it does not allow flow back into the booster. In very cold climates, a 28% by weight potassium hydroxide electrolyte will not freeze until -40°C, it is more difficult to stop the bubblers freezing. While it is possible to have equipment which unplugs and can be taken indoors overnight, an alternative is to use alcohol or paraffin (kerosene) instead of water and they generally do not freeze and their fumes are not harmful to an engine.

The bubbler design is not difficult. Ideally, you want a very large number of small bubbles to be formed and float upwards through the water. This is because it gives the best connection between the gas and the water and so can do a really good job of washing any traces of hydroxide vapour out of the HHO gas before it gets fed to the engine. Small bubbles are also better separated from each other and so there is no real chance of a flame passing through the water where large bubbles might merge together and form a column of gas as they rise to the surface.

In this good bubbler design, the pipe which feeds the HHO gas into the bubbler is bent into an L-shape. The end of the pipe is blocked off, and many small holes are drilled in the horizontal section of the pipe. Only a few holes are seen in this diagram, but there will be a large number in the actual construction. Like the booster itself, the gas outlet pipe needs to be protected from splashes of water caused by the vehicle going over a bump. It is very important to make sure that water is not drawn into the engine along with the gas, so anti-slosh material or one or more baffles are used to prevent this happening. So the overall protection for the gas flow is:
Where the first bubbler is close to the booster and the second one is placed close to the engine. Once in a while, the water from the first bubbler can be used to top up the water inside the booster so that any traces of hydroxide which may have reached the bubbler are returned to the booster, keeping its electrolyte concentration exactly right and making sure that the water in the bubbler is always fresh.

There is one final item which is an optional extra. Some people like to add a gas-pressure switch. If, for any reason, the pressure starts to rise - say that the outlet pipe became blocked - then the pressure switch would disconnect the electrical supply and stop the pressure rising any further:

One decision which has to be made is the rate of HHO gas production which is the best for you. Most people seem to think that the larger the volume of HHO gas the better. That is not necessarily true because a very effective use of the gas is to make it act as an igniter for the engine's normal fuel and very satisfactory results have been achieved with HHO gas flow rates in the range of 0.4 to 0.7 litres per minute. You control the rate of gas production by controlling the current, either by the concentration of the electrolyte or by adjusting the current flow using an electronic circuit.

Each litre of water produces about 1,750 litres of HHO gas, so you can estimate the length of time the booster can operate on one litre of water. If, for example, your booster is producing 0.7 litres of gas per minute. Then, it will produce 1,750 litres in 1,750 / 0.7 minutes and that is 2,500 minutes or 41 hours 40 minutes. As the booster only operates when you are driving, you are looking at 41 hours of driving time and if you drive about two hours per day, it would take three weeks to use one litre of water. The internal dimensions of your booster allow you to calculate how far the electrolyte level will drop if one litre of water is taken out of it.

Generally speaking, it is normally considered that topping up the booster with water by hand every so often, is a perfectly good method of operation. The booster design described above has a good electrolyte capacity in each cell and so topping up with water should not be a major task. As tap water and well water have a good deal of dissolved solids in them, when the water is taken away by electrolysis, these solids drop out of solution and fall to the bottom of the housing, and/or coat the plates with an layer of unwanted material. For this reason, life is so much easier if distilled water is used for making electrolyte and for topping up the booster after use.

It is possible to have an automatic water supply for your booster even though that is probably over-kill for such a simple device. If you decide to do that, then you need a water supply nozzle for each of your six or seven cells. It is not necessary for the electrolyte level to be exactly the same in each cell, but you would normally have them at roughly the same height. Your automated water supply could be like this:
A point which might not be immediately obvious is that because the gas pressure inside the booster is probably about 5 pounds per square inch ("psi"), once the water pump stops pumping, it is possible for the gas pressure to push out the remaining water in the inlet pipes and escape through the body of the pump. To prevent this, an ordinary one-way valve is put in the water supply pipe to prevent flow back towards the pump.

Up to now, the HHO gas feed to the engine has just been indicated in a vague way in spite of the connection point being important. With most engines, the HHO gas should be fed into the air filter where it mixes well and is fully dispersed inside the air being drawn into the engine. You sometimes see diagrams which show the connection point being close to the engine intake manifold. This is not a good idea because the lowered pressure there causes reduced pressure inside the booster which in turn produces more unwanted hot water vapour, so stick with feeding the gas into the air filter. If there is a supercharger on the engine, then feed the HHO gas into the low-pressure side of the supercharger.

**The “Smack’s” Booster.**
The style of booster described above has the advantages of high electrical efficiency, easy construction, very few specialist parts and a large electrolyte volume per cell. There are many other very successful booster designs which have very different forms of construction. One of these is the "Smack's Booster" where electrical cover plates are clamped together and placed inside a length of plastic pipe:
The advantages of this design are the very simple construction, compact size, reasonable performance and the fact that you can buy one ready-made if you want to. You can download a copy of the construction details free from [http://www.free-energy-info.com/Smack.pdf](http://www.free-energy-info.com/Smack.pdf). The electrical efficiency of this design is lowered a bit because only a single body of electrolyte is used and so current can bypass the plates. The overall performance is a respectable 1.3 lpm for 20 amps, though you may wish to lower the current and settle for about half that rate of HHO gas production. The construction of a 5 lpm version is at [http://www.youtube.com/watch?v=cqjn3mup1So](http://www.youtube.com/watch?v=cqjn3mup1So)

### The “Hotsabi” Booster.

Another design which is very easy to build is the "HotSabi" booster, which is a single threaded rod inside a length of plastic pipe with a stainless steel inner lining. It has the lowest possible electrical efficiency, being just a single cell with the full vehicle voltage connected directly across it, but in spite of that, its performance in actual on the road use has been remarkable, with a reported 50% improvement on a 5 litre capacity engine. This excellent performance is probably due to the design having a steam trap which removes the hot water vapour produced by the excessive heating caused by having only a single cell with so much voltage across it (remember, 90% of the power supplied to this booster design goes in heating the electrolyte).

As the designer of this booster has freely shared his design, the free construction plans can be downloaded from [http://www.free-energy-devices.com/Hotsabi.pdf](http://www.free-energy-devices.com/Hotsabi.pdf)

### The “Zach West” Electrolyser.

Zach West of the USA has produced a motorcycle electrolyser. Zach’s 250 cc motorcycle can run on the output of his electrolyser and Zach estimates the output as being 17 litres per minute of HHO gas, which seems to me to be far too high for the current flow. This is not a COP>1 system as the output from the electrical system of the motorcycle is very limited, and so the battery will slowly run down as time goes by. However, Zach’s design of electrolyser is interesting, both for it’s simplicity and it’s high rate of gas output. The increased gas volume which would be produced if this design were adapted for, and driven by, a 12-volt input could be very useful, especially if combined with David Quirey’s system which allows the resulting modified gas to operate in unmodified engines, as shown later on in this chapter.
The method which Zach uses is somewhat unusual as he manages to bleed off and discard most of the oxygen produced. This means that the remaining gas is mainly hydrogen which is far less explosive than HHO which is already in the perfect proportions for combination back into water and so is highly reactive. Instead, the resulting gas can be compressed reasonably well, and Zach compresses it to 30 psi (pounds per square inch) in a storage container. This helps with acceleration from stationary at traffic lights.

Zach uses a simple, modular style of construction where a series of coiled electrode pairs are each placed inside an individual length of plastic pipe. This is a design which is neither difficult nor particularly expensive to build. In overall broad outline, Zach’s electrolyser is fed water from a water tank to keep it topped up. The electrolyser box contains several pairs of electrodes which split the water into hydrogen and oxygen when fed with pulsed electrical current generated by the electronics, which is powered by the electrical system of the motorcycle. The gas produced by the electrolyser is fed to a dual-purpose bubbler, which prevents any accidental igniting of the gases from travelling back to the electrolyser and in addition, removes most of the oxygen from the gas by acting as a gas “separator”. The arrangement is like this:

The hydrogen gas output from the electrolyser is not fed directly to the engine but instead it goes to a pressure tank which is allowed to build up to thirty pounds per square inch before the engine is started. The majority of the oxygen produced by the electrolysis is vented away through a 30 psi one-way valve which is included to keep the pressure inside the bubbler (and the electrolyser) at the 30 psi level. That pressure is excessive for a high-performance electrolyser which produces HHO which is highly charged electrically and so will explode spontaneously when compressed, due to it’s own electrical charge. In this simple DC electrolyser, the HHO gas is mixed with quite an amount of water vapour which dilutes it and allows some compression.

The water supply system operates by having an air-tight supply tank positioned at a higher level than the electrolyser. A small diameter (1/4” or 6 mm) plastic tube coming from the supply tank feeds through the top of the electrolyser and straight down, terminating at exactly the electrolyte surface level wanted in each of the electrolyser tubes. When the electrolysis lowers the electrolyte level below the bottom of the pipe, bubbles of gas pass up the tube allowing some water to flow from the tank to raise the electrolyte surface level back to it’s design position. This is a very neat passive system needing no moving parts, electrical supply or electronics but yet one which accurately controls the electrolyte level. One essential point to understand is that the water tank needs to be rigid so that it will not flex and the filler cap needs to be air-tight to prevent the entire water supply discharging into the electrolyser. Another point to remember when topping up the water tank is that the tank contains a mix of air and HHO gas above the water surface and not just plain air, and that gas mix is at 30 psi pressure.

Now, to cover the design in more detail. This 6-volt electrolyser contains eight pairs of electrodes. These electrode pairs are coiled around in “Swiss-roll” style and inserted into a length of 2 inch (50 mm) diameter plastic pipe, ten inches (250 mm) tall. The electrodes are each made from a 10 inch (250 mm) by 5 inch (125 mm) of 316L-grade stainless steel shimstock which is easy to cut and work. Shimstock is available from a local steel supplier or metal fabrication company and is just a sheet of very thin metal.

Each electrode is cleaned carefully, and wearing rubber gloves, cross-scored using coarse sandpaper in order to produce a very large number of microscopic mountain peaks on the surface of the metal. This increases the
surface area and provides a surface which makes it easier for gas bubbles to break away and rise to the surface. The electrodes are rinsed off with clean water and then coiled round, using spacers to maintain the necessary inter-plate gap, to form the required shape which is then inserted into a length of plastic pipe as shown here:

As the springy metal pushes outwards in an attempt to straighten up again, spacers are used to keep the electrodes evenly separated along their whole length by inserting 1/8” thick vertical spacer strips. The connections to the plates are made by drilling a hole in the corner of the plate and inserting the wire several times through the hole, twisting it back around itself and making a wire-to-wire solder joint on both sides of the steel. The joint is then insulated with silicone or any other suitable material. It is, of course, essential that the joint does not short-circuit to the other electrode even though that electrode is very close by.
It is always difficult to make a good electrical connection to stainless steel plates if space is restricted as it is here. In this instance, the electrical wire is wrapped tightly through a drilled hole and then soldered and insulated. The soldering is only on the wire as solder will not attach to stainless steel.

An unusual feature of this design is that each of the electrode pairs is effectively a separate electrolyser in its own right as it is capped top and bottom, and effectively physically isolated from the other electrodes. The water feed comes through the top cap which has a hole drilled in it to allow the gas to escape. The electrical wires (#12 AWG or swg 14) are fed through the base and sealed against leakage of electrolyte. Each of these units has some electrolyte stored above it, so there is no chance of any part of the electrode surface not being able to generate gas. There is also a large amount of freeboard to contain splashes and sloshing without any being able to escape from the container. The end caps are standard PVC caps available from the supplier of the PVC piping, as is the PVC glue used to seal them to the pipe.

Eight of these electrodes are placed in a simple electrolyser case and connected together in pairs as shown here:

Pairs of pipe-enclosed electrode spirals are then connected in a chain inside the electrolyser as shown here:

Many years of experimentation and testing have shown that 316L-grade stainless steel is the most suitable material for electrodes, but surprisingly, stainless steel is not highly electrically conductive as you would expect. Each electrode causes a voltage drop of nearly half a volt, and so careful surface preparation, cleansing and conditioning are needed to get top performance from the electrodes. This process is described in detail by the very experienced Bob Boyce who says:

The preparation of the plates is one of the most important steps in producing an electrolyser which works well. This is a long task, but it is vital that it is not skimped or hurried in any way. Surprisingly, brand new shiny
stainless steel is not particularly suitable for use in an electrolyser and it needs to receive careful treatment and preparation before it will produce the expected level of gas output.

The first step is to treat both surfaces of every plate to encourage gas bubbles to break away from the surface of the plate. This could be done by grit blasting, but if that method is chosen, great care must be taken that the grit used does not contaminate the plates. Stainless steel is not cheap and if you get grit blasting wrong, then the plates will be useless as far as electrolysis is concerned. A safe method is to score the plate surface with coarse sandpaper. This is done in two different directions to produce a cross-hatch pattern. This produces microscopic sharp peaks and valleys on the surface of the plate and those sharp points and ridges are ideal for helping bubbles to form and break free of the plate.

When doing hand sanding the sandpaper is drawn across the plates in one direction only and not backwards and forwards, as the backwards stroke always destroys the perfectly good ridges created on the forward stroke. Also, you only need two strokes in one direction before turning the plate through ninety degrees and completing the sanding of that face of the plate with just two more strokes (again, with no backstroke).

Always wear rubber gloves when handling the plates to avoid getting finger marks on the plates. Wearing these gloves is very important as the plates must be kept as clean and as grease-free as possible, ready for the next stages of their preparation. Any particles created by the sanding process should now be washed off the plates. This can be done with clean tap water (not city water though, due to all the chlorine and other chemicals added), but only use distilled water for the final rinse.

While Potassium hydroxide (KOH) and Sodium hydroxide (NaOH) are the very best electrolytes, they need to be treated with care. The handling for each is the same:

Always store it in a sturdy air-tight container which is clearly labelled "DANGER! - Potassium Hydroxide". Keep the container in a safe place, where it can’t be reached by children, pets or people who won’t take any notice of the label. If your supply of KOH is delivered in a strong plastic bag, then once you open the bag, you should transfer all its contents to sturdy, air-tight, plastic storage containers, which you can open and close without risking spilling the contents. Hardware stores sell large plastic buckets with air tight lids that can be used for this purpose.

When working with dry KOH flakes or granules, wear safety goggles, rubber gloves, a long sleeved shirt, socks and long trousers. Also, don’t wear your favourite clothes when handling KOH solution as it is not the best thing to get on clothes. It is also no harm to wear a face mask which covers your mouth and nose. If you are mixing solid KOH with water, always add the KOH to the water, and not the other way round, and use a plastic container for the mixing, preferably one which has double the capacity of the finished mixture. The mixing should be done in a well-ventilated area which is not draughty as air currents can blow the dry KOH around.

When mixing the electrolyte, never use warm water. The water should be cool because the chemical reaction between the water and the KOH generates a good deal of heat. If possible, place the mixing container in a larger container filled with cold water, as that will help to keep the temperature down, and if your mixture should “boil over” it will contain the spillage. Add only a small amount of KOH at a time, stirring continuously, and if you stop stirring for any reason, put the lids back on all containers.
If, in spite of all precautions, you get some KOH solution on your skin, wash it off with plenty of running cold water and apply some vinegar to the skin. Vinegar is acidic, and will help balance out the alkalinity of the KOH. You can use lemon juice if you don't have vinegar to hand - but it is always recommended to keep a bottle of vinegar handy.

Plate cleansing is always done with NaOH. Prepare a 5% to 10% (by weight) NaOH solution and let it cool down. A 5% solution ‘by weight’ is 50 grams of NaOH in 950 cc of water. A 10% solution ‘by weight’ is 100 grams of NaOH in 900 cc of water. As mentioned before, never handle the plates with your bare hands, but always use clean rubber gloves.

A voltage is now applied across the whole set of plates by attaching the leads to the outermost two plates. This voltage should be at least 2 volts per cell, but it should not exceed 2.5 volts per cell. Maintain this voltage across the set of plates for several hours at a time. The current is likely to be 4 amps or more. As this process continues, the boiling action will loosen particles from the pores and surfaces of the metal. This process produces HHO gas, so it is very important that the gas is not allowed to collect anywhere indoors (such as on ceilings).

After several hours, disconnect the electrical supply and pour the electrolyte solution into a container. Rinse out the cells thoroughly with distilled water. Filter the dilute NaOH solution through paper towels or coffee filters to remove the particles. Pour the dilute solution back into the cells and repeat this cleaning process. You may have to repeat the electrolysis and rinsing process many times before the plates stop putting out particles into the solution. If you wish, you can use a new NaOH solution each time you cleanse, but please understand that you can go through a lot of solution just in this cleaning stage if you choose to do it that way. When cleansing is finished (typically 3 days of cleansing), do a final rinse with clean distilled water. It is very important that during cleansing, during conditioning and during use, that the polarity of the electrical power is always the same. In other words, don’t swap the battery connections over as that destroys all the preparation work and requires the cleansing and conditioning processes to be carried out all over again.

Using the same concentration of solution as in cleansing, fill the cells with dilute solution. Apply about 2 volts per cell and allow the unit to run. Remember that very good ventilation is essential during this process. As water is consumed, the levels will drop. Once the cells stabilise, monitor the current draw. If the current draw is fairly stable, continue with this conditioning phase continuously for two to three days, adding just enough distilled water to replace what is consumed. If the solution changes colour or develops a layer of crud on the surface of the electrolyte, then the electrodes need more cleansing stages. After two to three days of run time, pour out the dilute KOH solution and rinse out the cells thoroughly with distilled water.

The construction which Zach has used is very sensible, utilising readily available, low-cost PVC piping. The spiral electrodes are inside 2” diameter pipe and Zach says that the bubbler is also 2” diameter PVC pipe. I seriously doubt that a two-inch diameter bubbler could handle a flow as high as 17 lpm which is a substantial amount. Also, you want the bubbles in the bubbler to be small in order that the gas comes into good contact with the water. Consequently, using more than one bubbler where the diagram shows just one, would be sensible.

At this time, Zach only uses one bubbler, but a second one is highly desirable, located between the storage tank and the engine and positioned as close to the engine as possible. This extra bubbler does two things, most importantly, it prevents the gas in the storage tank being ignited by a backfire caused by a valve sticking slightly open and secondly, it removes every last trace of potassium hydroxide fumes from the gas, protecting the life of the engine. This is a big gain for such a simple addition.

The gas storage tank is also made from PVC pipe, this time, 4 inch (100 mm) diameter, 14 inches (350 mm) long with standard end caps fixed in place with PVC glue as shown below. This is a compact and effective arrangement well suited for use on a motorcycle. The majority of this extra equipment can be mounted in bike panniers, which is a neat arrangement.
The electric drive to the electrolyser is from a Pulse Width Modulator ("DC Motor speed controller") which was bought from the Hydrogen Garage as Zach is in America. That particular PWM board is no longer available, so especially for those people in Europe the choice might be rmcybernetics.com, although there are many suppliers and the module should not be expensive.

As this unit was rated at just 15 Amps maximum, Zach added another 15 Amp rated FET transistor in parallel to the output stage to raise the current capacity to 30 Amps. A fuse protects against accidental short circuits and a relay is used to control when the electrolyser is to be producing gas. The connecting wire is #12 AWG (swg 14) which has a maximum continuous current capacity of just under ten amps, so although the current peaks may be twenty amps, the average current is much lower than that.

Two electromagnets outside the bubbler, positioned 2.5 inches (65 mm) above the base, are connected as part of the electrical supply to the electrolyser, and these cause most of the oxygen and hydrogen bubbles to separate and exit the bubbler through different pipes. There is a divider across the bubbler to assist in keeping the gases from mixing again above the water surface. The bubbler also washes most of the potassium hydroxide fumes out of the gas as the bubbles rise to the surface, protecting the engine as these fumes have a very destructive effect on engines.

The objective with any HHO system is to have the minimum amount of gas between the bubbler and the engine in order to block the ignition of the gas in the unlikely event of a backfire. In this system, the gas storage tank contains a very large amount of gas, though admittedly it is not full HHO gas thanks to the electromagnet separation system, but nevertheless, it would be most advisable to have a second bubbler between the gas storage tank and the engine, positioned as close to the engine as possible. HHO gas produces a very high-speed
shock-wave when it is ignited so the bubbler needs to be of strong construction to withstand this. No pop-off bubbler cap or blow-out device acts fast enough to contain a HHO shock-wave, so make the bubbler housing strong enough to withstand the pressure wave.

Zach’s electrolyser arrangement is like this:

It must be realised that the water tank, electrolyser, bubbler/separator and hydrogen holding tank, all operate at thirty pounds per square inch. This means that each of these containers must be robust enough to withstand that pressure quite easily. It also means that the 30 psi one-way check valve on the oxygen venting pipe is an essential part of the design as well as being a safety feature. As a bubble of gas from the electrolyser escapes into the water tank every time a drop of water feeds to the electrolyser, the contents of the water tank above the water surface becomes a stronger and stronger mix of air and HHO. Consequently, it soon becomes an explosive mixture. It is common for static electricity to build up on a tank of this nature, so it will be very important to earth both the tank and it’s cap before removing the cap to top up the tank with more water.

The electrolyser has a potassium hydroxide (KOH) solution in it. The electrolysis process produces a mixture of hydrogen, oxygen, dissolved gases (air) and potassium hydroxide fumes. When the system is being used, the water in the bubbler washes out most of the potassium hydroxide fumes, and in doing so, it gradually becomes a dilute electrolyte itself. Potassium hydroxide is a true catalyst and while it promotes the electrolysis process, it does not get used up during electrolysis. The only loss is to the bubbler. Standard practice is to pour the contents of the bubbler into the electrolyser from time to time, filling the bubbler again with fresh water. Potassium hydroxide has been found to be the most effective catalyst for electrolysis but it has a very bad effect on the engine if it is allowed to enter it. The first bubbler is very effective in removing the potassium hydroxide fumes, but many people prefer to take the scrubbing process a step further by placing a second bubbler in the line, in this instance, between the hydrogen pressure tank and the engine. With two bubblers, absolutely no potassium hydroxide fumes reach the engine.

When running with HHO gas as the only fuel, it is essential to adjust the timing of the spark so that it occurs after Top Dead Centre. The timing on this bike is now set at 8 degrees after TDC. However, if David Quirey’s style of bubbling the HHO through a liquid such as acetone, then no timing alterations would be needed.

This electrolyser is designed to run off the nominal six volts of a motorcycle electrics (about 7.3 volts with the engine running), but increasing the number of tubes, each containing electrode coils, would convert the design to a 12V system and then the electrolyser housing would probably be like this:
It is possible that seven sets of three or four spirals wired in parallel would be used for larger engines with their 13.8 volt electric systems. Zach uses the very simple method of allowing excess gas to be vented via the oxygen valve if gas production exceeds the requirements of the engine. When operating on a twelve volt system it might be more convenient to use a standard pressure switch which opens an electrical connection when the gas pressure rises above the value for that switch:

The pressure switch just mounts on one of the end caps of the pressure tank and the switch electrical connection is placed between the relay and the electrolyser. If the gas pressure reaches its maximum value of 30 psi, then the switch opens, stopping electrolysis until the pressure drops again:
Caution: This electrolyser is not a toy. If you make and use one of these, you do so entirely at your own risk. Neither the designer of the electrolyser, the author of this document or the provider of the internet display are in any way liable should you suffer any loss or damage through your own actions. While it is believed to be entirely safe to make and use an electrolyser of this design, provided that the safety instructions shown below are followed, it is stressed that the responsibility is yours and yours alone.

An electrolyser should not be considered as an isolated device. You need to remember that both electrical and gas safety devices are an essential part of any such installation. The electrical safety devices are a circuit-breaker (as used by any electrician when wiring a house) to protect against accidental short-circuits, and a relay to make sure that the booster does not operate when the engine is not running:

![Diagram of the electrolyser system](image)

However, the system designed by Zach West is almost certainly not self-sustaining and if that is correct, then the battery powering the electrolyser will need to be charged between trips. That does not have to be the situation as high-efficiency electrolyzers are available. First, the Shigeta Hasebe spiral plate electrolyser (shown on page 719 of the Appendix) has produced 7 lpm of HHO gas mix for an input of just 84 watts and while that 84 watts is an inconvenient 2.8V at 30 amps, it should be possible to raise the voltage and lower the current without losing too much of the performance. In my opinion, the electrics of a motorcycle should be able to output 84 watts and so the motorcycle could become self-powered.

Motorcycles can definitely become self-powered as can be seen from the electric motorcycle system of Teruo Kawai’s COP>3 design shown in chapter 2. Teruo went to America and was in a meeting aimed at getting his design manufactured and sold in America when the meeting was interrupted and Teruo intimidated into abandoning his venture.

You must also remember that Steve Ryan of New Zealand demonstrated running his motorcycle on treated water. I suspect that the treated water was water which had been infused by charged water clusters as described by Suratt and Gourley later in this chapter. Their electrolyser has an efficiency of 0.00028 kilowatt-hour or less to generate one litre of gas. Those inconvenient units mean that to produce 1 lpm needs 16.8 watts or 7 lpm needs 118 watts. If cold water mist is added to the air entering the motorcycle engine, then it seems likely that a good deal less than 7 lpm would be needed. If you have a good enough tank which is made of a material capable of containing the very small molecules of this gas, then the gas can be compressed to 1000 psi and that should allow a motorcycle to run for some time on the gas cylinder.

The “DuPlex” Booster designed by Bill Williams.
A fully-submerged design from Bill Williams in the USA is another different style of booster:
The construction details for this booster design, can be downloaded free from the web using the link: http://www.free-energy-devices.com/DuPlex.pdf

There are many other designs, including those with concentric pipes, each having its own advantages and disadvantages, some being commercially available as ready-made devices, and there are links to these boosters on the web sites mentioned above and a general booster forum at http://tech.groups.yahoo.com/group/watercar/ and another at http://tech.groups.yahoo.com/group/HHO/ where people will answer any queries.

One problem with the use of boosters is that if the HHO gas volume is higher than it needs to be, the vehicle's Electronic Control Unit ("ECU") is liable to detect the improved fuel burn and start pumping in excess fuel to offset the improved conditions. How to deal with this situation is covered in the free document which can be downloaded from http://www.free-energy-devices.com/D17.pdf

The "Hogg" Electrolyser from Selwyn Harris.
An interesting design is the Hogg electrolyser as described by Selwyn Harris of Australia. The Hogg cell has two stainless steel mesh electrodes coiled around each other. This gives a large electrode surface area in a very compact container. In this version of the design there are six identical cells which feed into a large bubbler. For clarity, only two of the six electrolyser cells are shown here:
The items marked with a blue dot form just one of three identical sets. That is, three filters feed out from the bottom of the bubbler, the flow through them being caused by three separate pumps and the two electrolyser cells marked “1” and “2” along with their associated pipes and four one-way valves, are replicated to give electrolysis cells “3” to “6” which are not shown in this diagram. Those three identical sets are connected to the central bubbler, spaced around it evenly at 120-degree positions horizontally as shown in rough outline here:

The water is circulated through the set of cells using three small pumps and there are two water collectors built on to the bottom of the bubbler. Also, as the ‘electrolyte’ used is rainwater, and each electrolysis cell is completely full of electrolyte as this is an ‘electrolyte circulation’ style of electrolyser.

Each of the three pumps has it’s own filter to trap any particles coming from the cells as experience has shown that the water can contain a considerable amount of material. The filters are standard irrigation in-line filters made from transparent plastic filled for three quarters of their length with fine plastic sponge material.

A key feature of the cell design is the use of two powerful neodymium magnets per cell. These act directly on the water and that causes a major increase in the gas production rate. The magnets have their North poles facing towards each other.

The two mesh electrodes are made from stainless steel wire of 0.32 mm diameter and woven to give 2 mm holes between the wires and a 0.65 mm overall sheet thickness. These dimensions are important as other mesh sizes and styles do not give so good a performance. The electrodes are wider at one end to form a connection tab which allows easy electrical connection to each electrode and they are then wired in parallel so that each cell gets 12 volts across it as shown here:

The two mesh electrodes are cut like this:
and:

The mesh material looks like this:
The six electrolyser cells and the single large bubbler are constructed using standard plastic plumbing materials:
The connecting pipes are a clear plastic, heat-tolerant type of 12 mm (0.5") diameter. The bubbler is also constructed from plastic pipe fittings:

As some people have difficulty in visualising the way in which the electrodes are combined, this simplified concept sketch may be helpful:

The two electrodes are kept separated by the use of small diameter fibre washers held in place between them at strategic places using super glue. The mesh itself is then treated by being immersed in citric acid in order to make it work well with rainwater.

There are three of these pairs of electrolyser cells, each pair being connected to the upper collector reservoir. The water being pumped out of each cell is passed through one of the three filters before entering the collector reservoir which feeds the small pump which keeps the water circulating which in turn keeps removing any particles which have got into the rainwater.
When used with rainwater from a barrel, this electrolyser is said to draw just 1.4 amps per cell, giving a total input of about 115 watts when run on a 12-volt electrical supply. While rainwater is supposedly pure, the reality is that it seldom is and it’s ability to carry a current varies dramatically from place to place and even more widely from country to country. If you decide to build this electrolyser and find that you do not get anything like 1.4 amps flowing through any one cell, then you may well have to add a small amount of electrolyte to the water in order to get the current flowing. That is, assuming that you want a current flow of 1.4 amps per cell on 12 volts. The output of this electrolyser is said to be capable of running a small electrical generator but that has not been confirmed at this time.

AVA Magnetic Levitation’s Electrolyser

Adam of AVA Magnetics shows a very nicely constructed electrolyser based on an entirely different style of electrode. His video is at https://www.youtube.com/watch?v=Iz8wuUXWuGU and his cell looks like this:

Initially built using stainless steel pipe, the electrical resistance of the long coil proved to be a problem, so Adam overcame the problem by inserting copper pipe inside the stainless steel pipe. Copper carries electrical current very well, while stainless steel has quite a high resistance to current flow, which many people find very strange, having been taught in school that all metals conduct electricity. In a coil like this, electric current has to pass through a considerable length of stainless steel in order to reach the lower turns, and that resistance to current flow is greater than the situation with an electrolyser which uses stainless steel sheets. The copper tube down the inside of the steel pipe makes a major difference because the current flows easily through the copper and then at every point along the tube, the current only needs to flow sideways through a thin layer of stainless steel in order to perform the electrolysis.

The photograph above looks like a very neatly wound coil with twelve turns in it. That is not the case. It is two separate coils with turns 1, 3, 5, etc. being in one coil and turns 2, 4, 6, etc. being in the other coil. That arrangement means that each turn in the coil has a turn with the opposite voltage beside it and the electrolysis takes place between adjacent turns in the coil. The ends of each coil are sealed off carefully to prevent corrosion of the copper pipe by the electrolyte being used. Unfortunately, most of the surface area of the circular pipe electrode is not close to its neighbouring coil surface and that increased distance reduces the rate of gas production for those areas. I suspect that Adam is using a fairly dilute electrolyte in order to keep the heating effect under control and so, better performance may result when using full-strength electrolyte. However, the
HHO production at around 16 amps looks impressive as shown here just before the whole container is obscured by the HHO bubbles coming off the coils:

At full power, the cell draws 18 amps when powered through a Pulse-Width Modulator manufactured by the "HHO Powercell" company using a battery of around 12.5 volts. That 225 watts produces a gas output rate which needs to be measured. In my opinion, the gas output pipe needs to be much larger with an inner diameter of perhaps 15 millimetres as a small pipe hinders the escaping gas. If you don't believe that, then try blowing through a length of 6 millimetre diameter plastic pipe and see how hard that is to do.

Nevertheless, this is a simple, basic electrolyser with just two electrodes, although, possibly because the Pulse-Width Modulator is feeding it a good quality square wave signal, the small bubble size suggests that there is an efficiency gain which makes it perform better than would be expected. A single cell like this will find it hard to escape from the basic fact that 1.24 volts is all that is used in water electrolysis and even with the voltage drop across stainless steel you really do not want more than 2-volts between the plates. In other words, only 2-volts of the battery's 12-volts can actually make gas and so, the vast majority of that 225 watts goes to make heat and not gas. The situation for 1, 2 or 3 single cells is like this:

![Diagram](image)

It is probable that HHO production at 225 watts would be doubled if two of these cells are connected in series, that is, connected in a chain. The performance would probably be tripled at that same 18 amps of current, if three of these cells are connected in series across the voltage source. If that is done, then ideally, each cell needs to be inside its own separate container. Adam suggests that the coil produces a magnetic field which boosts the production of HHO, and considering the effect of the magnets in the Shigeta Hasebe cell, he may well be right.
The arrangement with three cells connected in series and powered through a frequency-adjustable Pulse-Width Modulator would be like this, although the gas outlet pipes need to be connected together with short pipe connections as those pipes will be filled with explosive HHO when in use:

![Diagram of the arrangement](image1)

As always, the battery connects to a circuit breaker “CB” or fuse before anything else is connected. The Pulse-Width Modulator “PWM” is effectively like Dave Lawton's most simple circuit with adjustable frequency, adjustable Mark-Space Ratio (or “Duty Cycle” as it is sometimes called), and a high output current capability. The electrical connections to the cells are done as shown in the diagram and the cells are all positioned the same way round as that allows testing with the cells leads swapped over to see if that makes a difference when the best frequency and Duty Cycle have been found. Please remember that a bubbler is essential on the gas output pipe and the depth of water in any bubbler should be at least five inches which is 125 millimetres.

No measurement of the rate of HHO flow has been made. This can be measured with a cheap gas flow meter from a medical equipment supplier or a result which is easily good enough for our purposes can be determined by using a two litre or other suitable container of known capacity, filling it with water and bubbling the HHO output into the container as shown here:

![Diagram of measuring HHO flow](image2)

The result using this method is got by timing how long it takes for the bottle to be filled with the HHO gas mixture, and from that, working out how many litres are being produced per minute. For example, if it takes one minute to fill a 2-litre bottle, then the flow rate is 2-litres per minute. If it takes two minutes to fill, then the gas output rate is 1-litre per minute. If it takes 2-minutes and 30-seconds to fill, then the rate is 0.8 litres per minute. The result will be altered slightly by the atmospheric pressure which changes from hour to hour, but we only need a rough estimate, especially if we are just comparing performance after some small change to the method of electrolysis.

The [video](https://www.youtube.com/watch?v=YfG6kyifq30) shows methods of winding pipes into helical coils as used here and the plastic spacers needed, but the man posting, ‘ANNMANN’, has a fully equipped workshop and constructional skills not available to most experimenters. Unfortunately, he does not seem to aware of the fact that electrodes need to be very close together for the best HHO production. He has tried using marine cable (used for mast stays) instead of pipe and that is, of course, very much easier to use when making spiral
electrodes, but it is probable that four spacers would be needed rather than just the two used with pipe spirals. There is also, no scope for using copper inside the hawser. Selwyn Harris of Australia, who is a very experienced HHO user, states that it is very difficult to wind stainless steel pipe into an accurate spiral. He wonders if winding the spirals using copper pipe which is very much easier to bend than stainless steel, and then electroplating the spiral with chromium, might not be a better and more practical way of producing good working spiral electrodes.

For me, with my serious lack of accurate constructional skills, another much easier method of construction occurs to me. First, the arrangement of two spirals is not really effective for electrolysis as shown here:

The rate of electrolysis is directly proportional to the area of the electrodes. It is also highly affected by the separation of the electrodes. With the wires or pipes shown on the left, only a small percentage of the surface area is spaced at the best distance which your construction allows (marked by the red arrows). The two plate electrodes shown on the right have their entire surface area at the optimum spacing. So, if we are going to use pipes or wires, then we want to increase the most active surface area, and in fact, increase the electrode area overall. Working with steel is much more difficult than working with plastic, especially since most of us do not have the tools, workspace and skills to help us succeed, using marine-grade stainless steel cable is a very appealing option. This material is shown at [https://www.youtube.com/watch?v=11Qn4CGlZp4](https://www.youtube.com/watch?v=11Qn4CGlZp4) and looks like this:
It is available from ship’s chandleries world wide and is constructed from stainless steel wires. If we use this, then we have to accept the fact that it’s electrical resistance will be high, but the big advantage is that we only have to make the plastic spacers.

This brings us to the problem of increasing the surface area and decreasing the gaps between the wires. While ANN Mann has excellent video presentations, please do not be misled by the excessively large gaps which he had between his wires. The largest gap that we want is 3 millimetres, and ideally, we would like 2 millimetre gaps. So, for this I suggest that a plastic plate is drilled like this:

For this, the hole size matches your cable diameter, say, 6 mm, and the gaps between the holes are 2 millimetres if you are confident, and 2.5 or 3 millimetres if you are not confident of your skill in drilling plastic. This plate will be used to wind four nested spirals. As the cable is flexible, we need to use two additional spacer strips like this:
These are to make sure that the desired gap is maintained along all of the cable length, by threading the cable through these as each turn is made. That way, the cable is supported every quarter turn, maintaining the gap size all the way around every turn.

Although only one type of cable is used, colours are used in the following diagrams merely to make it easier to see where the turns in each winding start and finish. All windings start at the bottom and end at the top. The first winding uses the innermost holes:

This winding is made with two separate lengths of cable, one shown in green and one shown in red. The lower end of the red cable terminates just this side of the plastic sheet. The lower end of the green cable terminates just beyond the other side of the plastic sheet. Unlike the diagram, the cable is NOT cut off short as shown but is left long so that it can be connected outside the plastic cell container.

We now double the electrode surface area by winding a second pair of coils just outside the first one. The arrangement looks like this:
This second layer is wound in exactly the same way as the previous one. The outer cable turns are not exactly above the spiral turns underneath, but they are very close to being directly above. When we connect the cables electrically, we arrange for the cables surrounding any cable to be the opposite polarity, so that the electrolysis is maximised.

The next step is to wind the third layer:

And then the fourth layer is wound using the remaining holes:
Connected electrically as shown, every cable in the first and fourth layers is surrounded on three sides with cables of opposing polarity. The cables in layers two and three have every turn surrounded on all four sides by cables of the opposing polarity. So, this arrangement has overcome the need for difficult pipe bending, has increased the electrode area considerably and has achieved a reasonable gap between the electrodes and has improved the area of best electrolysis by 87%. We now improve matters considerably by using three of these cells in series in order to use the applied power more efficiently.

There is, of course, no reason why there should not be more than three of these cells in series and I would expect five to be the likely maximum due to excessive voltage drop across the stainless steel cable. There is also no reason why there should not be five or more spiral layers in each cell and each additional layer raises the overall efficiency of that set of spirals.

However, while it seems very probable that this construction would yield a good performance, please remember that this is only a suggestion and at time of writing, it has not been built and tested. When first testing the unit, the Pulse-Width Modulator is set to give a low to medium current flow through the cells. Then the frequency control is used to get the maximum gas output without altering the current setting. If the current drops at the point of peak gas production during this test, that is not a problem. With multi-layer spirals of this type, a gas outlet pipe of 20 millimetres would be recommended. Also, the gas outlet should have a baffle plate across it to prevent tiny droplets of electrolyte escaping with the gas, as shown elsewhere in this chapter. That should be done even if the electrolyser is to be used in a stationary location such as feeding a generator. Electrical connections to the ends of the spiral wires can be made with large screw connectors not unlike the ordinary hardware store type but intended for much larger wires. These are also available through ship's chandlers as boats often use high-current twelve volt wiring of large diameter.

**Advanced DC Boosters.**

All of the practical construction details on electrical safety, gas safety, engine connections, type of water, safe mixing of electrolyte, etc. already discussed, apply to all kinds of electrolyzers and boosters of every design. So, please understand that these are universal features which need to be understood when using any design of booster.

It is possible to produce large volumes of HHO gas from a DC booster, enough gas to run a small motor directly on it. For this, we need to pay attention to the efficiency factors already covered in this document. The person
who is outstanding in this field is Bob Boyce of the USA who has kindly shared his experience and expertise freely with people who want to use serious electrolyzers.

Bob's attention to detail when constructing high-performance electrolyzers has resulted in efficiencies which are more than double those of the very famous Michael Faraday whom most scientists consider to be the final word on electrolysis.

**Bob Boyce’s High-Efficiency Electrolyser.**

We are now moving from the "casual" style of booster to the "serious" style of electrolyser. In this category, you will find that the units built are not cheap, weight a considerable amount, require considerable skill to make and usually are quite large physically. I will mention two designs here. First, the very well-known design from Bob Boyce. For this electrolyser, Bob makes solid stainless steel electrode plates act as cell partitions as well as being electrodes. This is a clever technique but it takes a very high level of construction accuracy to make a box with slots in the side and base, so that the stainless steel plates can be slid into the box and when there, form a watertight seal between the cells, preventing electrical current bypassing the places by flowing around them.

The number of cells in the electrolyser depends on the electrical DC voltage supply which is produced from the electrics of the vehicle. This higher voltage is created by using a standard off-the-shelf "inverter" which produces high-voltage alternating current ("AC") meant to be the equivalent of the local electricity mains supply. In the USA, the voltage produced is in the 110 to 120 volt region, elsewhere, it is in the 220 to 230 volt region.

If you are not familiar with electrical jargon, then check out chapter 12 which explains it step by step. The AC output from whatever inverter you buy, is changed back into DC by using a component called a "diode bridge" and a reservoir device called a capacitor. When this is done, the resulting DC voltage is 41% greater than the quoted AC voltage, so a 110-volt inverter will produce about 155 volts and a 220-volt inverter about 310 volts. As you want about 2 volts per cell, the number of cells would be about 80 or 150 depending on which inverter is used. This large number of stainless steel plates each sized at six-inches (150 mm) square, creates a substantial weight which then is increased by the weight of the case, and the electrolyte. The overall arrangement (without the capacitor) is like this:

A very high-precision box for this style of electrolyser can be had from Ed Holdgate of Florida who has also shared the construction methods if you fancy yourself as a skilled fabricator:

Ed's website is at [http://www.holdgateenterprises.com/Electrolyzer/index.html](http://www.holdgateenterprises.com/Electrolyzer/index.html) and each case is hand-made.
The gas production rate is so high that the gas outlet pipe has to have holes drilled along the top in order to try to exclude spray and moisture from the massive rate of bubbles bursting at the surface of the electrolyte. The high efficiency of Bob's electrolysers is due to his meticulous preparation and construction methods. You will notice that Bob recommends the use of a particle filter with a 1-micron mesh, between the engine and the HHO system. Apart from ensuring that everything entering the engine is very clean, the particle filter with a mesh of that small size, also acts as a flashback-preventer as flame can't pass through it.

Firstly, the stainless steel plates are cross-scored with sandpaper to create a specially shaped plate surface which helps high-speed bubble release. Secondly, the plates are put through a rigorous "cleansing" process where they are subjected to repeated periods of electrolysis followed by rinsing particles off the plates and filtering the electrolyte solution. When no further particles break free from the plates, they are then put through a "conditioning" process which develops a catalytic layer on the plate surfaces.

This processing and the various construction details are provided in the following free download document, thanks to Bob's generosity in sharing his experience with us: http://www.free-energy-info.com/D9.pdf and there is a forum for Bob's design: http://tech.groups.yahoo.com/group/WorkingWatercar/ where questions are answered. Here are the main details:

Bob Boyce is a most experienced and knowledgeable series-cell designer, and sincere thanks are due to him for sharing his design freely with everybody and for his continuous help, advice and support of the builders of electrolysers. Bob achieves a massively increased gas production rate by using an electrolyser with a large number of cells in it. Bob's electrolyser is easily the most effective available at this time. It uses one hundred cells (101 plates) and applies a sophisticated pulsing waveform which raises the operational efficiency far above that envisioned by the science textbooks available today. Units with just 60 cells are inclined more to brute-force DC electrolysis, tending to mask the gains produced by pulsing. As there is a voltage drop across each stainless steel electrode plate, it is usual to allow about 2 volts across each cell for DC operation. However, Bob finds that for high-efficiency pulsing, the optimum voltage for each cell with 316L-grade stainless-steel electrode plates is about 1.5 volts. This means that a voltage of about 1.5 x 100 = 150 volts is needed to power it to its maximum pulsed output.

To get this higher voltage, Bob uses a 110 Volt inverter. An inverter is a common, commercially available electronic circuit which usually has a 12 Volt DC input and generates a 110 Volt AC output. These are readily available for purchase as they are used to run (US) mains equipment from car batteries. The output from the inverter is converted from Alternating Current to pulsing Direct Current by passing the output through four diodes in what is called a ‘Diode Bridge’. These are readily available at very low cost from electronic component suppliers.

Obviously, it would not be practical to use a hundred self-contained cells daisy-chained together to act as the series-connected electrolyser cell. There would not be enough physical space in the engine compartment for that, so a different style of cell construction is needed. The view looking down on several separate electrolyser cells could be represented something like this:

Here the plus side of each cell is connected to the minus side of the next cell to provide a set of six interconnected cells acting in series. The current flowing through the electrolyser goes through each cell in turn and so each cell receives exactly the same current as the other cells. This is the same sort of arrangement as using six self-
contained cells in a daisy-chain. To reduce the physical size of the unit, it is possible to construct the electrolyser as shown here:

In this arrangement, the individual cells have just one positive plate and one negative plate. The plates slot into the sides and bottom of the housing so that the electrolyte is trapped between the plates and an air gap is formed between the plus plate of one cell and the minus plate of the next cell.

These air gaps are wasted space. They contribute nothing to the operation of the electrolyser. Each consists of a metal plate, a gap and a wire connection to the next metal plate. From an electrical point of view, the two metal plates at the opposite ends of these gaps, being connected by a wire link, are effectively the same plate (it is just a very thick, hollow plate). These air gaps might as well be eliminated which would save one metal plate and one wire link per cell. This can be difficult to visualise, but it produces an arrangement as shown here:

The only air gaps remaining are at the ends of the electrolyser. The plates in the middle are notionally touching each other. The positive plates are marked in red and the negative plates are shown in blue. In reality, there is only one metal plate between each cell and the next cell - the red and blue marking is only a notional device to try to make it easier to see that the diagram actually shows six separate cells in a single housing. They are separate cells because the metal electrode plates extend into the base and sides of the housing, thus isolating the six bodies of electrolyte from each other. It is very important that the different bodies of electrolyte are fully isolated from each other, otherwise the electrolyser will not act as a series-connected unit and most of the current will skip past the middle plates and just run from the first plate to the last plate around the sides of the other plates. So, the plates need to be a fairly tight push-fit in grooves cut in the sides and base of the housing. The electrolyte level must always be below the top of the plates as shown here:

An electrolyser with a hundred cells, built in this style will have 101 metal plates and 100 separate bodies of electrolyte. In spite of these large numbers, the size of the overall unit does not have to be excessive. The spacing between the plates is set to, say, 3 mm (1/8 inch) and the plate thickness might be 16 gauge (1/16 inch), so the width of a 100-cell electrolyser is about 20 inches. In actual practice, the gaps at the end of the electrolyser may also contain electrolyte although that electrolyte takes no part in the electrolysis process.

The size of the plates may be determined by the space available in the engine compartment. If there is a large amount of spare space, then the plate size may be selected by allowing from two to four square inches of area on both sides of each plate, per amp of current. Each side of every plate is in a different electrolysis cell so a 6-inch
by 6-inch plate will have 36 square inches on each face and so would carry between $36 / 4 = 9$ to 18 amps of current. The choice of current is made by the builder of the electrolyser and it will be influenced by the size and cost of the inverter chosen to drive the electrolyser and the allowable current draw from the battery. This is for straight DC electrolysis where the battery is connected directly across the electrolyser. Using Bob’s triple-oscillator electronics pulser card, the electrolyte level has to be kept down to about three inches from the top of the six inch plate because the gas production rate is so high that there has to be substantial freeboard to stop the electrolyte being splashed all over the place.

Bob usually uses a 6” x 6” plate size. It is essential that every item which contains HHO gas is located outside the passenger compartment of any vehicle. Under no circumstances should the electrolyser or bubbler be located in the passenger area of the vehicle, even if pop-off caps are provided and a second protective outer housing is provided, as the explosive force is so great that permanent hearing damage would be a serious possibility.

For straight DC operation of an electrolyser of this type, the circuitry is very straightforward. The inverter should be mounted securely, preferably in the stream of air drawn in to cool the radiator. Using a diode “bridge” of four diodes converts the stepped up AC output of the inverter back into pulsing DC and produces the electrical arrangement shown here:

![Electrolyser circuit diagram]

As mains voltage is quoted as an average figure (“root-mean-square”) it has a peak voltage of 41% more than that. This means that the pulsing DC has a voltage peak of just over 150 volts for the nominal 110 volt AC output from the inverter.

The one-way valve shown between the two bubblers, is to prevent the water in the bubbler mounted beside the electrolyser, being driven into the electrolyser in the event of an explosion in the bubbler mounted beside the engine. The bubblers and the particle filter remove all traces of electrolyte fumes from the gas as well as protecting against any accidental igniting of the gas caused by the engine misfiring.

The very famous Michael Faraday who was an exceptionally gifted experimenter, placed two electrodes in water and determined how much gas was produced per amp of current. Using an electrolyte and recent technology when running on DC, Bob Boyce would not consider an electrolyser properly constructed, cleansed and conditioned until it was producing more than double Faraday’s gas production rate. A typical working electrolyser made by Bob would have about 216% of Faraday’s result. People taught in universities and unaware of current technology, use Faraday’s result in calculations and those calculations indicate that it would take more energy to produce HHO gas than could be produced by then burning the hydrogen produced. Their calculations are wrong. The energy in freshly made HHO gas is typically four times more energetic than hydrogen is and so those calculations are too low by a factor of more than eight times. Also, the majority of energy from burning HHO comes from “charged water clusters” (see chapter 10) and not from the hydrogen, and most of these good people doing the calculations have never even heard of charged water clusters, and so, they accept the “can’t be done” verdict without thinking about it.

**Pulsed Operation**

If you have already read chapter 10, you will know that the next step forward in raising HHO production is to apply a suitable pulsed waveform to the electrolyser terminals rather than just a straight DC voltage. Doing this with the design of Bob Boyce raises the cell efficiency to around ten times the result produced by Michael Faraday. Bob Boyce’s highly efficient pulsed electrolysis system has been very generously shared freely by Bob so that anyone who wishes may construct one for their own use without the payment of a licence fee or royalties. Just before presenting the details, it should be stressed that in order to get Bob’s performance of up to 1,000% of the Faraday...
Maximum gas output, each step needs to be carried out carefully exactly as described. Much of the following text is quoted from Bob’s forum posts and so should be considered as his copyright, not to be reproduced without his permission.

Your Responsibility:
If you decide to construct an electrolyser of this, or any other design, you do so wholly on your own responsibility, and nobody is in any way liable for any loss or damage, whether direct or indirect, resulting from your actions. In other words, you are wholly responsible for what you choose to do. I say again, this document must not be construed as an encouragement for you to construct this or any other electrolyser.

Bob’s electrolyser splits water into a mixture of gases, mainly hydrogen and oxygen. That gas mixture, which will be referred to as “HHO” is highly explosive and must be treated with respect and caution. A fairly small volume of HHO gas exploded in air is quite liable to cause permanent hearing loss or impairment due to the shock waves caused by the explosion. If HHO gas is ignited inside a sealed container, then the resulting explosion is liable to shatter the container and propel shrapnel-like fragments in all directions. These fragments can cause serious injury and every precaution must be taken to ensure that an explosion of that nature never happens. Bob uses two bubblers and a one-way valve to protect against this occurrence, and details of these are given in this document.

To make the water inside the electrolyser carry the necessary current, potassium hydroxide (KOH) is added to distilled water. This is the best electrolyte for an electrolyser of this type. Potassium hydroxide is also known as “caustic potash” and it is highly caustic. Consequently, it needs to be handled carefully and kept away from contact with skin, and even more importantly, eyes. If any splashes come in contact with you, it is very important indeed that the affected area be immediately rinsed off with large amounts of running water and if necessary, the use of vinegar which is acidic.

This electrolyser design uses a toroidal transformer to interface the electronics to the electrolyser cells. It is vital that this transformer be used very carefully. Under no circumstances may this transformer be powered up by the electronics when connected to anything other than the filled electrolyser cells as they act as a safety buffer. When driven by Bob’s electronics, this transformer draws additional energy from the environment. While this is very useful for electrolysis, there are sometimes unpredictable energy surges which can generate as much as 10,000 amps of current. If one of these should occur when the transformer is not connected to the electrolyser which is able to soak up this excess, the resulting electrical conditions can be very serious. If you are lucky, it will just burn out expensive components. If you are not lucky, it can cause a lighting strike which is liable to hit you. For that reason, it is absolutely essential that the toroid transformer is never powered up with the secondary winding connected to anything other than the filled electrolyser.

Patenting:
It should be clearly understood that Bob Boyce, has released this information into the public domain and it has been displayed publicly since early in 2006. It is not possible for any part of this information to be made part of any patent application anywhere in the world. This prior public disclosure of the information prevents it being patented. It is Bob’s intention that this information be freely available to people world-wide. It should also be emphasised that all of the quotations of Bob’s words which is a very extensive part of this document, remain the copyright of Bob and may not be reproduced for display or sale without his prior written permission.

The Objective:
This is a “HHO-On-Demand” (“HOD”) system. It is very difficult indeed to generate HHO gas fast enough to power an internal combustion engineered vehicle under all road conditions. Moving from standstill to rapid acceleration causes such a massive sudden requirement for additional volumes of HHO gas, that it is difficult to provide that volume instantly.

A better solution is to use an electric engine for the vehicle. This can be an electric vehicle which was designed from scratch as such, or it can be a standard vehicle which has been adapted for electric engine use. These electric vehicles are usually limited in how far they can travel, but a good solution to this is to use an electrical generator to charge the batteries, both when the vehicle is in use and when it is parked. This electrolyser can be used to run such a generator on water as shown in chapter 10. With this arrangement, there are no CO₂ emissions and the vehicle is very environmentally friendly. The batteries provide the necessary sudden acceleration demands and the generator recharges the batteries during normal driving.

Overview:
Bob’s pulsed system has the following components:
1. An electrical connection to the vehicle’s electrical system (with safety features built in).
2. An “inverter” which raises the electrolyser voltage to about 160 volts.
3. Bob’s specially designed circuit board which generates a complicated water-splitting waveform.
4. Bob’s specially designed toroidal transformer which links Bob’s circuit board to the electrolyser.
6. A dual-protection system for linking the electrolyser safely to the internal combustion engine.

None of these items is particularly difficult to achieve, but each needs to be done carefully and exactly as described, paying particular attention to the detailed instructions.

**Building the Case:**

The case needs to have very accurate slots cut in it. If you do not have a milling machine, then you might consider getting a fabrication shop to mill the slots for you. The case has two ends, two sides, one base and one lid. Of these, the two sides and the base need 101 accurate grooves cut in them. The grooves are there to hold the electrode plates securely in position, and have to be cut extremely accurately. The groove width is set at 0.0003" less than the actual, measured plate thickness. This prevents any electrical flow around the plates. If you do not have the equipment to do this, then there is an enthusiast who is willing to do the cutting for people in the USA (and possibly elsewhere) at reasonable price. To contact him for pricing and delivery details, send an e-mail to eholdgate@tampabay.rr.com.

Many people ask about moulding the slotted sides but this is physically impossible to do to the accuracy needed and the cell performance depends on plate spacing to very high accuracy and slot width to even higher accuracy. This is not a backyard construction quality job and there are very, very few people with both the equipment and skill to complete the construction to this degree of accuracy.

The base and two sides of the cell could have grooves cut in them to take the plates. This is not a good idea for various reasons, including the fact that the steel plates expand when they warm up and are liable to crack the acrylic case unless the slots are cut deeper than normal. Also, it is difficult to cut very accurate slots in acrylic due to the heat of the cutting blade causing the acrylic to deform in the immediate area. Grooved acrylic is very much weaker and breaks easily due to the planes of weakness introduced into the material.
Using Ultra High Molecular Weight Poly Ethylene or High Density Poly Ethylene (food chopping-board material) strips is a much better technique as that material does not have the same cutting heat problem and it can also take the plate expansion much better, so it is the construction method of choice. It is also a cheaper material.

The grooves which are cut for the plates should be three thousandths of an inch wider than the thickness of the plates. A good plate thickness is 16 gauge sheet which is one sixteenth of an inch thick or 0.0625 inch (1.5875 mm), so the recommended groove width for that is 0.0655 inches which is not a convenient fraction being about four and one fifth sixty-fourths of an inch. The grooves are 1/8" (3 mm) deep.

The supplier of the acrylic sheet needed for making the case, will be able to supply “glue” specifically designed for joining acrylic sheets together. This glue actually welds the plates together so that the sheets become one continuous piece of acrylic along the joint. Start by mating the sides and the base. Insert two or three plates into the slots to be quite sure that the alignment is spot-on during the joining process. Line the ends up during jointing to be sure that the sides are completely square when being joined to the base.

Concerns have been expressed about the strength of the acrylic casing under severe road conditions. So it has been suggested that the acrylic components be constructed from sheet which is 3/4” to 1” thick (18 mm to 25 mm) and the corners reinforced with angle iron secured with bolts tapped into the acrylic as shown below.
Here is a photograph of a 101-plate housing built by Ed Holdgate who works to a very high standard of accuracy and who prepares and sells these housings to anyone who is in the process of constructing a Bob Boyce electrolyser (Ed’s web site accepts orders for these ready-made electrolyser housings and is at http://www.holdgateenterprises.com/hydrogen.htm):

This housing looks very simple and straightforward, but this is highly misleading and the materials are very expensive, so any error is costly. The construction accuracy needed is very high indeed with many opportunities for a total and expensive disaster. Ed Holdgate has built several custom fixtures to ease the construction, but construction is still very difficult even with these specialist fittings and his years of experience. “Sikaflex 291” or “Marine Goop” marine bedding compound can be used to seal between the two slotted sides and the slotted
base, and between the slotted sides and the two end inserts, in order to prevent any leakage between the acrylic and any of these inserts.

The accuracy required for the slots to hold the stainless steel plates is 0.0003” and the plates are tapered with a belt sander on both sides along all four edges so that when they are forced into the slots they will not cut into the sides of the slots. This produces excellent leakage characteristics, but don’t lose sight of the very high accuracy of the slot cutting needed for this. The edges of the slotted inserts receive a bead of Sikaflex marine bedding compound attaching them to the acrylic box and the compound is allowed to cure before construction is continued.

The end plates with the stainless steel straps welded to them are used to connect the electrical supply to the plates, keeping any connection which could possible work loose and cause a spark, completely outside the housing. Even though the straps are welded and there is no likelihood of them coming loose, the welds are still kept below the surface of the electrolyte.

**Getting and Preparing the Plates:**

A set of 101 plates is needed for the electrolyser. The material used when making the plates is very important. It should be 16-gauge 316L-grade stainless steel as it contains a blend of nickel and molybdenum in the correct proportions to make it a very good catalyst for the pulsing technique. You can try your local steel stockists to see if they can supply it and what their charges would be. One satisfactory stainless steel supplier which Bob has used is Intertrade Steel Corp., 5115 Mt. Vernon Rd SE, Cedar Rapids, IA 52406. Do not buy from eBay as you have no real comeback if the plates supplied are dished due to having been flame cut.

It is very important indeed that when asking for a quote that you make sure that the supplier is aware of the accuracy you require. The plates need to be flat to a tolerance of +/- 0.001 inch after cutting and this is the most important factor. That level of accuracy excludes any kind of flame cutting as it produces inevitable heat distortion. With shearing, expect +/- 0.015 inch on the cuts and +/- 0.001 inch on flatness. Laser cutting produces much higher accuracy and you can expect as good as +/- 0.005 inch on cuts and there is no spec needed for flatness since laser cutting does not distort the edges like shearing does.

The plates are square: 6 inches by 6 inches, but that does not represent 36 square inches of active surface area as some plate area is inside the grooves and some of each plate is above the surface of the electrolyte. Another point to remember is that 101 steel plates this size weigh a considerable amount and the completed electrolyser with electrolyte in it will weigh even more. It is essential therefore to have a case which is strongly built from strong materials, and if a mounting bracket is to be used, then that bracket needs to be very robust and well secured in place.

The preparation of the plates is one of the most important steps in producing an electrolyser which works well. This is a long task, but it is vital that it is not skimmed or hurried in any way. Surprisingly, brand new shiny stainless steel is not particularly suitable for use in an electrolyser and it needs to receive careful treatment and preparation before it will produce the expected level of gas output.

The first step is to treat both surfaces of every plate to encourage gas bubbles to break away from the surface of the plate. This could be done by grit blasting, but if that method is chosen, great care must be taken that the grit used does not contaminate the plates. Stainless steel plates are not cheap and if you get grit blasting wrong, then the plates will be useless as far as electrolysis is concerned. A safe method which Bob much prefers is to score the plate surface with coarse sandpaper. This is done in two different directions to produce a cross-hatch pattern. This produces microscopic sharp peaks and valleys on the surface of the plate and those sharp points and ridges are ideal for helping bubbles to form and break free of the plate.
Bob Boyce uses a specially widened 48-inch belt sander which is good for preparing the plates using 60 or 80 grit. However, most people don't have this equipment and do the sanding by hand. Bob stresses that when doing hand sanding the sandpaper is drawn across the plates in *one* direction only and not backwards and forwards, as the backwards stroke always destroys the perfectly good ridges created on the forward stroke. Also, you only need two strokes in one direction before turning the plate through ninety degrees and completing the sanding of that face of the plate with just two more strokes (again, with **no backstroke**). Most people want to sand the plates far too much and if overdone to a major degree, that can reduce the plate thickness and cause electrolyte leakage through the slots around the plates. So, to say it again, to sand one face of a plate, use just two strokes in one direction, turn the plate through ninety degrees and finish that face with just two more strokes, both in the same direction.

Always wear rubber gloves when handling the plates to avoid getting finger marks on the plates. Wearing these gloves is very important as the plates must be kept as clean and as grease-free as possible, ready for the next stages of their preparation.

Any particles created by the sanding process should now be washed off the plates. This can be done with clean tap water (not city water though, due to all the chlorine and other chemicals added), but only use distilled water for the final rinse.

A point which is often missed by people constructing electrolyzers is the fact that electrolysis is not just an electrical process, but it is also a magnetic process. It is important for maximum operating efficiency that the plates are aligned magnetically. In theory, stainless steel is not magnetic, but much of the stainless steel actually supplied to builders is slightly magnetic. When the plates arrive from the supplier each plate may have random magnetic characteristics. The easiest way to deal with this situation is to try to give the plates a mild magnetic orientation. This can be done quite simply by wrapping a few turns of wire around the stack of plates and passing some brief pulses of DC current through the wire.
Obviously, the plates need to be kept in the same direction when being slotted into the case. The next step in the preparation process is to make up a weak solution of potassium hydroxide. This is done by adding small amounts of the potassium hydroxide to water held in a container. The container must not be glass as that is not a suitable material in which to mix the electrolyte.

Potassium hydroxide, also called KOH or “Caustic Potash”, which can be bought from various suppliers such as:  
http://www.essentialdepot.com/servlet/the-13/2-lbs-Potassium-Hydroxide/Detail  
http://www.organic-creations.com/servlet/the-653/caustic-potassium-hydroxide-KOH/Detail or  
http://www.nuscentscandle.com/ While Potassium hydroxide (KOH) and Sodium hydroxide (NaOH) are the very best electrolytes, they need to be treated with care. The handling for each is the same:

Always store it in a sturdy air-tight container which is clearly labelled "DANGER! - Potassium Hydroxide". Keep the container in a safe place, where it can’t be reached by children, pets or people who won’t take any notice of the label. If your supply of KOH is delivered in a strong plastic bag, then once you open the bag, you should transfer all its contents to sturdy, air-tight, plastic storage containers, which you can open and close without risking spilling the contents. Hardware stores sell large plastic buckets with air tight lids that can be used for this purpose.

When working with dry KOH flakes or granules, wear safety goggles, rubber gloves, a long sleeved shirt, socks and long trousers. Also, don't wear your favourite clothes when handling KOH solution as it is not the best thing to get on clothes. It is also no harm to wear a face mask which covers your mouth and nose. If you are mixing solid KOH with water, always add the KOH to the water, and not the other way round, and use a plastic container for the mixing, preferably one which has double the capacity of the finished mixture. The mixing should be done in a well-ventilated area which is not draughty as air currents can blow the dry KOH around.

When mixing the electrolyte, never use warm water. The water should be cool because the chemical reaction between the water and the KOH generates a good deal of heat. If possible, place the mixing container in a larger container filled with cold water, as that will help to keep the temperature down, and if your mixture should “boil over” it will contain the spillage. Add only a small amount of KOH at a time, stirring continuously, and if you stop stirring for any reason, put the lids back on all containers.

If, in spite of all precautions, you get some KOH solution on your skin, wash it off with plenty of running cold water and apply some vinegar to the skin. Vinegar is acidic, and will help balance out the alkalinity of the KOH. You can use lemon juice if you don't have vinegar to hand - but it is always recommended to keep a bottle of vinegar handy.

Plate Cleansing:

Plate cleansing is always done with NaOH. Prepare a 5% to 10% (by weight) NaOH solution and let it cool down. A 5% solution 'by weight' is 50 grams of NaOH in 950 cc of water. A 10% solution ‘by weight’ is 100 grams of NaOH in 900 cc of water. As mentioned before, never handle the plates with your bare hands, but always use clean rubber gloves. Put the sanded and rinsed plates into the slots in the electrolyser case, keeping them all the same way round so that they remain magnetically matched. Fill the electrolyser with the NaOH solution until the plates are just covered.

A voltage is now applied across the whole set of plates by attaching the leads to the outermost two plates. This voltage should be at least 2 volts per cell, but it should not exceed 2.5 volts per cell. Maintain this voltage across the set of plates for several hours at a time. The current is likely to be 4 amps or more. As this process continues, the boiling action will loosen particles from the pores and surfaces of the metal. This process produces HHO gas, so it is very important that the gas is not allowed to collect anywhere indoors (such as on ceilings).

After several hours, disconnect the electrical supply and pour the electrolyte solution into a container. Rinse out the cells thoroughly with distilled water. Filter the dilute NaOH solution through paper towels or coffee filters to remove the particles. Pour the dilute solution back into the electrolyser and repeat this cleaning process. You may have to repeat the electrolysis and rinsing process many times before the plates stop putting out particles into the solution. If you wish, you can use a new NaOH solution each time you cleanse, but please realise that you can go through a lot of solution just in this cleaning stage if you choose to do it that way. When cleansing is finished (typically 3 days of cleansing), do a final rinse with clean distilled water. It is very important that during cleansing, during conditioning and during use, that the polarity of the electrical power is always the same. In other words, don’t swap the battery connections over as that destroys all the preparation work and requires the cleansing and conditioning processes to be carried out all over again.

Plate Conditioning:

Using the same concentration of solution as in cleansing, fill the electrolyser with dilute solution up to 1/2” below the tops of the plates. Do not overfill the cells. Apply about 2 volts per cell and allow the unit to run. Remember
that very good ventilation is essential during this process. The cells may overflow, but this is ok for now. As water is consumed, the levels will drop. Once the cells stabilise with the liquid level at the plate tops or just below, monitor the current draw. If the current draw is fairly stable, continue with this conditioning phase continuously for two to three days, adding just enough distilled water to replace what is consumed. If the solution changes colour or develops a layer of crud on the surface of the electrolyte, then the cell stack needs more cleansing stages. Do not allow the cells to overfill and overflow at this point. After two to three days of run time, pour out the dilute KOH solution and rinse out the electrolyser thoroughly with distilled water.

**Cell Operation:**
Mix up a nearly full-strength solution of potassium hydroxide (280 grams of KOH added to 720 cc of water) as it is 20% more effective in use than is sodium hydroxide. The filling of the electrolyser depends on whether straight DC electrolysis is to be used, or resonant electrolysis is to be used.

For straight DC electrolysis, fill the electrolyser to about one inch below the tops of the plates. The DC voltage applied to the electrolyser will be about 2 volts per cell or a little less, so this 100-cell electrolyser will have 180 to 200 volts applied to it. This voltage will be generated with an inverter.

For resonant operation, fill the electrolyser to only half the plate height because the HHO gas production is so rapid that room has to be left for the gas leaving the plates. With resonant operation, about 1.5 volts per cell is used.

**Troubleshooting:**
1. Abnormally low current is caused by improper plate preparation or severe contamination. Take the plates out of the electrolyser and start over again from plate preparation.

2. Abnormally high current is caused by high leakages between cells. This will require re-building or re-sealing of the electrolyser case.

3. If current starts higher then drops off, this means that the plates are contaminated. Take the plates out of the electrolyser and start over again from plate preparation.

**Building the Electronics:**
Resonant operation of the electrolyser requires the use of a DC pulsing system. Bob has designed an advanced system for this, consisting of a sophisticated electronics board and a finely-tuned toroidal transformer which interfaces and matches the electronics to the electrolyser. These are available in kit form from The Hydrogen Garage in America: [http://hydrogengarage.com/home.html](http://hydrogengarage.com/home.html) and these electronics boards produce three separate frequencies which are combined together to give a rich and complex output waveform further modified by the toroidal transformer:
In Bob’s electrolyser build, those frequencies were about 42.8 KHz, 21.4 KHz and 10.7 KHz but please don’t get the wrong impression here, there is no single exact frequency or set of frequencies which should be used. The size and shape of your cell, the electrodes spacings, electrolyte density, electrolyte temperature and operational pressure are all factors which affect the tuning of the electronics. With Bob’s large marine-duty cells with square twelve-inch plates, he found the base resonance point using his original, modified inverter, to be at least 100 Hz lower than that of the prototypes with smaller plate sizes. The triple-oscillator board can be tuned with an oscilloscope but if one is not available, then the preset resistors are set to their mid-point and then the 42,800 Hz frequency is adjusted very slowly to find the point of maximum gas output. This is a very precise point and it is essential to use high-quality preset resistors which vary their resistance very accurately. The aim is to adjust the frequency by as little as 1 Hz at a time. When the optimum point is found, then the procedure is repeated with the 21,400 Hz frequency generator, and finally the 10,700 Hz frequency adjustment. Last of all, the Mark/Space ratio presets are adjusted to give the lowest pulse width which does not reduce the rate of gas generation.

When he tried separate flooded cells connected in series, he was not able to get anything more than a marginal rise in performance over a broader range. He felt that this was due to each cell in the set having a slightly different resonant point which did not match very well with the other cells. Bob had to go to the series plate design with accurate spacing and tight tolerance on slots and plates in order to get the resonant responses to line up on all cells. Also, he found that some choices of electrolyte would not produce resonance at any frequency, though he is not sure why. Some worked well while others worked marginally, so Bob stuck with what worked the best for him - sodium hydroxide (NaOH) and potassium hydroxide (KOH).

It needs to be stressed here, that every electrolyser build is slightly different from all others, even though they may have been meant to be exactly the same. There will be small differences between the plates in one electrolyser and the plates in other electrolyser. The electrolyte concentration will be slightly different, the plate preparation will be slightly different and the overall magnetic characteristics will be unique to each actual build. For that reason, the tuning of the completed electronics board and the construction of the best possible transformer to match the electronics to the electrolyser, is always different for each electrolyser built.

The completed third-generation Boyce board looks like this:
It is not too difficult to assemble this board as the printed circuit board can be purchased ready-made and a complete set of components can be ordered using the ordering system set up in the WorkingWatercar forum.

You should notice here, that the whole of the aluminium case is being used as a “heat-sink” to dissipate the heat generated in the FET driver transistors. These transistors are all bolted to the case and each has its own rectangle of mica “washer” between the transistor and the case. These pieces of mica pass heat very readily to the case, while at the same time, isolating the transistors electrically so that they will not interfere with each other.

Notice too, the plastic support columns at each corner of the printed circuit board. These are used to mount the printed circuit board securely, while holding it away from the metal case and so preventing any possibility of the connections on the underside of the board being short-circuited by the case itself.

In some of the builds of the electronics board, it has been found that it is sometimes difficult to get the highest frequency oscillator operating correctly at around 42.8 KHz due to some NE556 chips being out of specification. Even though they should be the same, chips from different manufacturers, and even the same branded chip from different suppliers, can have slightly different actual specifications. On both the PWM3E and PWM3F boards, C4 has now been changed from 0.1 microfarad back to 0.047 microfarad to accommodate the corrected specs of the newer Texas Instruments NE556N chip (the one marked with MALAYSIA on top). The earlier versions of the NE556N chip had required a change to 0.1 microfarad to correct for specifications that were sub-standard.

Depending on which chip you actually use in the “U1 - U3” board positions, you may have to adjust the value of C1, C3, and C4 to compensate for variations from the original 556 chip specification, or adjust some of the other
Setting up the completed board:

**Jumper J1:** If this is short-circuited it disables all three Pulse-Width Modulators, for oscillator outputs only.

**Jumper J2:** If this is short-circuited it connects the MOSFET Gate Supply TB3 to +DC for a single supply.

**Jumper J3:** If this is short-circuited it connects the MOSFET Source to -DC for a common ground.

**Jumper J4:** If this is short-circuited it enables the input of the Auxiliary TTL Inputs 1, 2 and 3. This is a convenient test point for measuring the outputs of each of the three signal generator stages.

To enable the auxiliary inputs, the on-board generators must be disabled with SW1 switches 1, 2 and 3 as shown here:

**Switch SW1:**
- Switching 1 on disables the Pulse-Width Modulation of oscillator 1
- Switching 2 on disables the Pulse-Width Modulation of oscillator 2
- Switching 3 on disables the Pulse-Width Modulation of oscillator 3
- Switching 4 on disables the Pulse-Width Modulation of all three oscillators
Terminal Block TB1: is the DC Power Input & MOSFET Source Ground

Terminal Block TB2: is the MOSFET Drain/PWM Outputs & MOSFET Gate Supply Input

This board has been superseded

In more detail:

J1 is for the connection of an optional external control or safety shutdown device, such as a pressure or temperature limit switch. J1 is shorted to shut down waveform generation. For normal operation, J1 is left open.

J2 and J3 are for optional voltage modification support. For normal operation, both J2 and J3 are shorted with 2 position jumper shorting blocks.

J4 is for the connection of optional auxiliary inputs. For normal operation, nothing is connected to J4. J4 can also be used to connect an oscilloscope to view the Pulse-Width Modulator generator waveforms of channels 1, 2, and 3.

SW1 is for disabling PWM generator channels 1, 2, and 3 via switches 1, 2, and 3. Switch 4 is a master disable that turns off all 3 channels. For normal operation, all 4 switches are switched OFF.
Terminal Block TB1 has 4 connections as follows;

1. DC Input + is connected to the 13.8 V DC power supply positive connection via a 2-amp fuse or circuit breaker.

2. DC Input - is connected to the 13.8 V DC power supply negative connection. If a shorting plug is installed at J3, this wire is optional.

3. and 4. Ground is connected to the 13.8 V DC power supply negative connection via heavy gauge wire. There are two wire connection terminals available so that two equal length wires may be used to reduce wire resistance losses.

Terminal Block TB2 has 4 connections which are connected as follows:

Gate + is not normally connected when a shorting plug is installed at jumper J2.
Output 1 is connected to the “cold” side of primary 1 of the toroidal transformer.
Output 2 is connected to the “cold” side of primary 2 of the toroidal transformer.
Output 3 is connected to the “cold” side of primary 3 of the toroidal transformer.

The “hot” sides of primaries 1, 2, and 3 are brought together, and connected to the 13.8 V DC power supply positive connection via heavy-gauge wire and a 60-amp fuse or DC circuit-breaker.

Note: These fuses are for short circuit protection, and are not an indication of system power consumption.

Testing the completed board:
Do NOT connect the PWM3F outputs to a powered transformer until after the unit tests show it to be fully functional. You may pull the 60-amp fuse out, or trip the DC circuit-breaker, while testing and tuning.

Power up the PWM3F board and check the indicator LEDs for proper operation:

LED 1 - the Channel 1 output - should be lit in normal operation, off if disabled.
LED 2 - the Channel 2 output - should be lit in normal operation, off if disabled.
LED 3 - the Channel 3 output - should be lit in normal operation, off if disabled.
LED 4 - the PWM channel 1 disable - should be off in normal operation, on if disabled.
LED 5 - the PWM channel 2 disable - should be off in normal operation, on if disabled.
LED 6 - the PWM channel 3 disable - should be off in normal operation, on if disabled.
LED 7 - the 12 volt supply - should be lit in normal operation, off when powered down.
LED 8 - the 8 volt supply - should be lit when the power is connected and off when powered down.

If all indicators check out, then start the tuning procedure. If everything checks out ok except the output indicators, then try tuning first then test again. Failures may indicate component or soldering problems.

Tuning the board:
Adjust all 3 of the “DC” marked (Duty Cycle) potentiometers (R25, R27, R29) fully clockwise, for minimum pulse width.

Connect a frequency counter or oscilloscope to Jumper J4 pin 1 (Aux Input 3) and adjust the channel 3 "Hz" marked potentiometer (R28) for a reading of 10.7 KHz.

Connect a frequency counter or oscilloscope to Jumper J4 pin 2 (Aux Input 2) and adjust the channel 2 "Hz" marked potentiometer (R26) for a reading of 21.4 KHz.

Connect a frequency counter or oscilloscope to Jumper J4 pin 3 (Aux Input 1) and adjust the channel 1 "Hz" marked potentiometer (R24) for a reading of 42.8 KHz.

Note: If channel 1 shuts down while tuning towards 42.8 KHz, replace U1 with a different brand of NE556 type timer chip. Many of these chips, like those marked as made in Taiwan, do not fully meet the NE555 spec and will shut down with the output turned on solid. If this occurs while loaded, the output FET for that channel may be
quickly destroyed. The Texas Instruments 556 chips marked as made in Malaysia have typically been tested to work ok at up to 45 KHz.

Once the board has been tuned as described above, verify output at the Terminal Block TB2 Outputs with an oscilloscope. Without a transformer connected, the indicator LEDs only lightly load the FETs, but enough to verify operation during testing. If all checks out ok up to this point, you should be ready to connect the transformer primaries and apply power.

Note: If you experience heating issues with any of the Metal Oxide Varistors M1, M2, and M3, they may be safely removed and left out, or replaced with slightly higher voltage MOVs. There have been some Metal Oxide Varistors that work properly, and some that do not. It seems to be a batch related issue.

Bob also says: The most common mistake that I see made is that when tuning for the common narrow (approx 2.5 uS) pulse width on all channels, most tend to tune for narrow POSITIVE going pulses at the FET outputs. That is totally inverse to proper pulse polarity for the PWM3 series boards. These boards use N channel FETs, so the proper pulses are narrow NEGATIVE going pulses. FET off condition results in a positive state on each of the outputs, proper FET switching pulls that positive state to ground as very narrow pulses.

The result of tuning inverse can be extreme overheat of the 556 chips, extreme overheat of the 8V regulator, and excessive primaries current in the toroid. This can overheat the toroid, burn traces on the board, and/or destroy the FETs, etc.

If the channel goes into frequency division when adjusting pulse width, then you have gone too far in your adjustment. These boards are not using the typical dual 555 (556) PWM coupling because that limits pulse width adjustment to 10% - 90%. This application requires much less than 10% pulse width.

Please remember that J1, J2, and J3, are only used to pull the FETs high through the indicator LEDs during preliminary adjustment. During operation, those jumpers must be removed to prevent interference to primaries operation.

Winding the Transformer:
The transformer in Bob’s system is a very important component. It is an inductor, a transformer, and a source of energy-form conversion, all rolled into one. The transformer has been successfully duplicated and used by others, driven with Bob’s triple-oscillator board, to achieve a resonant drive to the cells which results in a performance which is well beyond the maximum stated by Faraday.

The reason there are no step-by-step instructions for constructing the transformer is because it must be wound to match the load/impedance of the cells it will be driving. There is no “one-transformer-fits-all” solution for this. Bob uses a powdered iron core of 6.5” diameter for units up to 100 cells. The larger the diameter, the greater the power. Ferrite is fine for lower frequencies, but for this application, a powdered iron toroid core is essential. The MicroMetals core, part number “T650-52” is a suitable core and is available from http://www.micrometals.com/pcparts/torcore7.html and can be purchased in small quantities via their “samples requests”, which can be submitted at http://www.micrometals.com/samples_index.html

The Micrometals T650-52 Toroidal Core

The primary of the transformer is 3-phase, while the secondary is single-phase. As most current flows along the outside of wires rather than through the middle of the wire, the choice and size of the wire chosen to wind the transformer is most important. Bob uses solid teflon-covered silver-plated copper wire. It is very important that
this wire is solid core and **not stranded** as stranded wire does not work here (due to the generation of inter-strand, phase-differential induced eddy currents). At this time, a supplier of this wire is [http://www.apexjr.com](http://www.apexjr.com). Before any winding is done, the toroid is given a layer of tape. And the materials to be used are collected together, namely, the tape, the wire, the beeswax and the heat gun:

Of paramount importance with the toroid is that unlike traditional transformer design, the secondary is wound first, and the windings must be evenly spaced where they fan out from the center of the core. This means even though they are tightly packed right up against one another at the center hole, they must not be wound so that they bunch up and gap open around the periphery. Mistakes here will cause field errors that will lower the overall efficiency.

As you can see here, Bob uses short lengths of plastic strimmer cable as spacers for the outside of the toroid, though the picture above has been taken to show what a partially prepared secondary winding looks like when its windings are being moved into very accurate positions.
You will notice that Bob has wrapped the toroid in tape before starting the secondary winding:

Bob also uses a jar to assist in applying beeswax to the accurately positioned turns of the toroidal transformer:

When the windings are completed, correctly spaced and encased in beeswax, each layer is finished off with a layer of tape. Bob says: “I use a single wrap of PVC electrical tape stretched very tightly over the secondary winding. But be aware, that the tension in the tape has a tendency to make it unwrap. A layer of the yellow 1P802 winding tape secures the electrical tape and holds it firmly in place, bridging the triangular gaps between adjacent turns. Big warning here !!!! DO NOT USE FIBERGLASS WINDING TAPE !!!! A big box of 3M winding tape was ordered by accident so I tried it to see if it would work. It not only suppressed the acousto-resonance response of the entire wound toroidal core, but for some strange reason it also caused the electrostatic pulse response of the secondary to reverse polarity and reducing the signal amplitude to a mere 10% of what it was !! It totally negated the benefit of the teflon insulation. I had to unwrap it and rewrap it with the yellow 1P802 winding tape. We had to return a whole box of this 3M winding tape and order more of the “right stuff” in bulk from
Lodestone Pacific. So be warned, the 3M fibreglass winding tape will totally ruin the behaviour of the toroidal windings. So, to recap, the toroid is wrapped in tape, the secondary wound extending the entire way around the toroid, the windings carefully spaced out so that the gaps around the outer edge of the toroid are exactly equal, the winding encased in beeswax, and then the beeswax covered with a thick layer of tape:

For the great majority of systems, the secondary winding is a tightly wound, single layer, full-fill wrap of 16 gauge, single-core, silver-plated, teflon-insulated copper wire. There will be about 133 turns in this winding, though it can vary from 127 to 147 turns due to manufacturing tolerances in the insulation. This will need a wire length of about 100 feet, and the whole of the toroid is covered by this ‘secondary’ winding. Count the exact number of turns in your actual winding and make a note of it. This secondary winding is held in place with melted beeswax, and when that has hardened, the winding is then wrapped tightly with a good quality tape. This makes a good base for the primary windings which will be wound on top of the tape layer.

Please note that every winding starts by passing over the toroid, proceeds in a counter-clockwise direction, and finishes by passing under the toroid. Every winding is created in this way and the quality of workmanship is very important indeed when making these windings. Each winding needs to be tight and positioned exactly with turns touching each other in the centre of the toroid and positioned on the outer edge with exactly equal spaces between each turn. Your construction work has to be better than that of a commercial supplier and needs to
reach the quality demanded by the military, which would cost thousands of dollars for each toroid if it were to be made up for you by professionals.

The three primaries need to be wound on top of the tape wrapping which covers the secondary winding. These three windings are spaced out equally around the toroid, that is, at 120 degree centres and the leads of the secondary winding exit through the gap between two of the primary windings and **not** in the middle of a secondary winding. The primary windings are held in place with beeswax, and then tightly taped. The primaries may need more than a single layer, and they are wound with the same direction of winds as the secondary, and the same care for even winding spacing as the secondary needed. Tape the entire core well with tightly-stretched PVC electrical tape after winding, to ensure that the primary windings do not move and then add an outer layer of winding tape. Bob uses the 1P802YE type on 3 inch rolls, both the 1 inch and 2 inch widths from: http://www.lodestonepacific.com/distrib/pdfs/tape/1p802.pdf

This is where the generic information ends. The exact details of the primary windings must be determined from the operational characteristics of the cells. This means that you must build, cleanse and condition your cells prior to making the operational measurements. This is done as follows: After full plate cleansing as described earlier, condition the plates until the cell stack reaches at least 150% but ideally 200% or more of Faraday's maximum power efficiency (2.34 Watt-Hours per Litre per Hour). Then, allow the cell stack to cool to room temperature. The cell stack is then powered up with a variable-voltage power supply and the voltage adjusted until the cell current is exactly 2 amps. Write down the voltage needed to give this 2 amp current flow, and do it promptly before the cell starts to warm up again.

The objective here is to have the complex waveform generated by the electronics, produce voltages of about 25% of this measured voltage, so divide your measured voltage by four. The output from the electronics board is about 12.5 volts, so divide again by 12.5 to get the turns-ratio for the toroidal transformer. This is normally in the range of 3.0 to 3.5 and that means that the secondary winding needs to have that times as many turns in it as each primary winding does.

For example, *(and example only)* say your measured voltage happens to be 155 volts. Then the turns ratio would be 155 divided by 4 which is 38.75, and then divide that by 12.5 which gives 3.1 which is the turns ratio. If your secondary winding has, say, 134 turns in it, then the number of turns in each of the three primary windings would be 134 / 3.1 which is 43.23 turns. Round this upwards to give 44 turns.

If the number of turns which you use is off by one turn, then the tuning of the electronics board can compensate for it. If the number of primary turns is off by two turns, then it is possible that you might just be able to compensate for the error by tuning the board, but it is unlikely that you will. If the number of turns is three or more away from the optimum number calculated, then the impedance of the primary windings will be too far out for the board to tune it.

Normally, the diameter of the wire used in the primaries will be greater than that of the secondary because it will be driven by a much lower voltage and so will need a much higher current, but that is not the case here. Now that you have cleansed and conditioned the plates in your electrolyser, power up your inverter with your vehicle engine running at 2000 rpm or so, and measure the DC current taken by the inverter. This is the level of current which the primary windings have to carry, so the wire size can be selected from this measurement. Each primary winding is pulsed, so it is not carrying current all of the time, also, the final primary current is the sum of the three pulsing signals, so a reduction can be allowed for that. While the wire diameter for the primary windings of each toroidal transformer need to be calculated separately, a common diameter turns out to be AWG #20 (21 SWG). The wire length for the primaries will be greater per turn as the turns are now being made over the secondary winding. Forty-eight turns of #20 wire are likely to require at least thirty-five feet and that is for each of the three windings, assuming that all turns can be laid flat side-by-side. If it is necessary to make each a two-layer winding, then the wire length will increase further.

If you would like a 360 degree template for marking the positions of the primary windings, then there is one available at http://www.thegsresources.com/files/degree_wheel.pdf
Power Limits:
At the present time, the largest available iron-powder toroid commercially available is the Micrometals 6.5” unit. This sets the upper power limit for a Bob Boyce design electrolyser at 32 square inches of plate area. Bob’s present design uses six inch square plates, but the electrolyte level is maintained at just three inches and some area is effectively lost where the plates enter the walls and base of the housing. This 101-plate unit, when built with precision and conditioned and tuned correctly, can generate 50 lpm continuously and short bursts of up to 100 lpm. That is about one litre per minute of HHO gas per cell. This should be sufficient to run an internal combustion engine with a one litre engine capacity, but engines vary so much, that there can be no rule of thumb for the gas production rate needed for a given engine size.

The optimum operating voltage for his 101-plate electrolyser has been established by Bob as being 1.5 volts per cell. However, the power limitation of the 6.5 inch toroid does not prevent the voltage being raised. So, if we opt for using a 220 volt inverter rather than the 110 volt one already described, then the number of cells can be doubled. This extends the case from about twenty inches in length to around forty inches. This might be suitable for use with vehicles up to two litre engine capacity and the unit can be located on the flatbed of a truck or the boot (trunk) of a car or beside a generator if it is being used to power an electrical generator. Electrical generator engines are usually incredibly inefficient with an overall efficiency of as little as 10% when the generator is considered. Consequently, running a generator on HHO gas alone is by no means as easy as it looks on the surface. If an electrolyser is installed in a vehicle, it is very important that no pipe carrying HHO gas is routed through any passenger area and a bubbler positioned close to the engine. The number one priority must always be safety.

Increased gas output can be got by increasing the width of the plates while maintaining the plate area covered by the electrolyte. One possibility is to make the plates nine inches wide and keeping the electrolyte at a four-inch depth, giving thirty-six square inches of plate area. The plate size would then be 9” x 6” or any other height up to 9” x 9”.

The reason why a Boyce electrolyser can give 1,200% of the maximum possible gas output determined by Michael Faraday, is that this unit pulls in large amounts of additional power from the environment. So, the vehicle electrics is used primarily to power the pulsed toroidal circuitry which taps this energy, and the conversion of water to HHO gas is performed primarily by energy drawn from the environment.

Plate surface preparation is very important and is described in detail. However, the way that the plates operate when used for straight DC electrolysis is quite different from the way that they operate when being used in high-efficiency pulsed-mode:
With straight DC-electrolysis, the bubbles of HHO gas form on the face of the plates and break away, helped by the thousands of microscopic, sharp-peaked mountains created on the face of every plate by the two-direction scoring with sandpaper. With the pulsed technique, the HHO bubbles form in the electrolyte itself, between the plates and give the visual impression of the electrolyte boiling.

It should be realised that with the large gas volumes produced with the 101-plate and 201-plate electrolysers, that a considerable pipe diameter is needed to carry the gas, and even more importantly, the two bubblers used need to be a considerable size. It is important that the bubbles streaming up through the water in the bubbler do not form a continuous column of HHO gas as that could carry a flame straight through the bubbler and defeat the protection which it normally provides. A good technique to combat this and improve the scrubbing of electrolyte fumes out of the gas, is to put a large number of small holes in the sides of the pipe carrying the gas down into the water in the bubbler. This creates a large number of smaller bubbles and is much more effective.

**Connecting the Electrics:**

Bob has specified that the primary windings are connected between the board outputs and the positive supply for the board like this:

It is important to include heavy-duty chokes (coils) in both sides of the high voltage power supply and in the 13.8 volt positive lead coming from the vehicle electrics. The recommended choke cores are the MicroMetals T157-45 and these are wound with 15 turns of AWG #16 (SWG 18) enamelled copper wire, through it is perfectly ok to wind these chokes on laminated iron pieces taken from an old mains power transformer frame. The fifteen turns of wire produce a choke of 29.5 microhenrys.

If all is well and the 20-amp contact-breaker (or fuse) is not tripped, the electrical power passes through to the gas-pressure switch mounted on the electrolyser. If the gas production rate is greater than the engine requirement and as a result, the gas pressure inside the electrolyser gets above 5 psi, then the gas pressure switch disconnects the electrical supply which in turn, cuts off the generation of more gas until the pressure inside
the electrolyser drops again as the engine uses the gas. If all is well, the gas-pressure switch will be closed and the electrical power is then passed to the relay’s switch contacts. The relay is wired in such a way that the relay will be powered up if, and only if, the engine is running. If all is well and the relay contacts are closed, then the power is passed through to both the inverter and the electronics board. The inverter output is 110 volts AC so it is passed through a diode bridge which converts it to pulsing DC with a peak value of about 155 volts. This voltage and the output of the electronics board toroidal transformer are passed to the electrolyser to break down the water and generate HHO gas. The wire connecting the vehicle negative to the electronics board should be very heavy duty as it is carrying a large current.

There is a lot of power stored in a charged battery. It is important therefore, to protect against short-circuits in any new wiring being added to a vehicle, if this electrolyser is to be used with a vehicle. The best overall protection is to have a circuit-breaker or fuse connected in the new wiring immediately after the battery. If any unexpected load occurs anywhere in the new circuitry, then the circuit will be disconnected immediately.

It is also important that the electrolyser is only connected and operating when the engine is running. While the gas-pressure switch should accomplish this, it is no harm to have additional protection in the form of a standard automotive relay in the power supply line as shown in the diagram above. This relay coil can be connected across the electric fuel pump, or alternatively wired so that it is powered up by the ignition switch being turned on.

**Positioning the Electronics**

The descriptions and diagrams have been presented with the objective of helping you understand in broad outline, what Bob Boyce’s electrolyser is and very roughly speaking, how it operates. There are practical details which you should discuss in the WorkingWatercar forum as there experienced people there who will help builders get the details right.

It should be realised that the strong, rapidly pulsing currents generated by the electronics, cause very powerful magnetic fields. These magnetic fields can disrupt the operation of the circuitry. These fields flow around inside the toroid core and this creates an area of very reduced magnetic activity in the space in the centre of the toroid. For that reason, it would be ideal if the circuit board were placed in that area with the toroid surrounding it. However, the electronics board size does not allow this at the present time, so instead, Bob places the toroid inside a custom, circular housing, something like a biscuit tin made of aluminium which operates as a “Faraday Cage” to protect against the magnetic fields produced:
Supplying the Water
The potassium hydroxide is not used up when the electrolyser is operated. A small amount leaves the electrolyser in the form of vapour but this is washed out of the gas in the first bubbler. Two bubblers are used, the first is located beside the electrolyser and connected to it via a one-way valve. The second bubbler is located close to the engine. From time to time, the water in the bubblers is poured back into the electrolyser and that prevents the loss of any potassium hydroxide. Not only does this conserve the potassium hydroxide, but it also protects the engine as potassium hydroxide has a very bad effect inside the engine itself.

The overall water system is like this in broad outline, omitting the electrical safety devices:

A probe inside the electrolyser senses when the average level of the electrolyte has dropped and powers up the water pump to inject more water into the electrolyser. The rate of gas production is so high with the pulsed system that the electrolyte level is placed at about half the plate height. That is some three inches below the tops of the plates. Because of this violent action, the water-level sensor needs to be operated from the electrolyte outside the plates where the surface of the electrolyte does not move so violently.

A serious issue with an electrolyser of this type is dealing with water loss. As the plates have to be spaced closely together and the since the electrolyte between the cells is effectively isolated from the electrolyte in the other cells, driving a mile down the road is liable to lower the water level by half an inch (say, one centimetre). It is essential to keep replacing the water which is used.

Two things have to be dealt with:
1. Sensing when the electrolyte level has fallen, and
2. Creating some device for getting extra water into each cell

Simple electronics provides the answer to sensing the level of the electrolyte, and a windscreen-washer water pump can be used to inject the additional water.

A sensor for the water in the cells can be on just one cell. If the water level of any one cell falls below the level in the other cells, then the gas produced in that cell will be slightly less than the other cells, so it will lose less water until the water levels match again. Also, Bob recommends cutting the slots which hold the plates, 3 thousandths of an inch (0.003 inch or 0.075 mm) larger than the actual thickness of the metal plates. This effectively blocks electrical leakage between adjacent cells but does allow a very gradual migration of water between the cells to help maintain an even water surface across the cell.

The water-level sensor can be just one stiff stainless steel wire run down each side of any cell. These wires should be insulated to make sure that they do not short-circuit to either (or both) of the plates on each side of them. They should be set so that their tips are at the intended surface level of the electrolyte.

If the electrolyte level drops below the tip of the wire sensors, then the resistance between the wires will fall, indicating that more water is needed. This can switch the water pump on, which will raise the water level until the electrolyte level reaches the tip of the wire again. A possible circuit for doing this is shown here:
When the level of the electrolyte falls, the sensor wires come clear of the liquid and the voltage at point ‘A’ rises. Provided that this situation remains for a second or two, capacitor C2 charges up and the voltage on the base of transistor Tr1 rises, causing it to switch on. Transistors Tr1 and Tr2 are wired as a Schmitt trigger, so transistor Tr2 changes state rapidly, raising the voltage at its collector, and causing transistor Tr3 to power the relay on. The relay contacts switch the water pump on, which raises the level of the electrolyte until it reaches the sensor wires again. This flips the circuit back into its standby state, powering down the water pump. Resistor R1 feeds capacitor C1 to reduce the effects of variations of voltage reaching the sensor circuit. The components shown here are not critical and there must be at least twenty alternative designs for this circuit.

A possible physical layout for this circuit is shown here:

The build is based on using the standard 10-strip, 39-hole strip-board. For convenience in drawing, the holes are represented as the points where the lines cross in the diagram shown here:

The horizontal lines represent the copper strips and the intersections with the vertical lines represents the matrix of holes. Many different layouts could be used for this circuit, so the following diagram is only a suggestion:
Components:

R1 100 ohms   C1 1000 microfarad 35 volt or higher
R2 1,000 ohms  C2 330 microfarad 16 volt or higher
R3 10,000 ohms
R4 1,800 ohms  D1 1N4001 or similar 100 volt or higher 1 amp
R5 18,000 ohms
R6 18,000 ohms  Tr1 to Tr3  2N2222 or 2N2222A or similar
R7 3,900 ohms         40V, 800 mA, 500 mW, gain 100 - 300
To combat splashing of the electrolyte, a layer of aquarium matting is placed over the tops of the plates. In the diagram above, only a few of the 101 plates are shown, in order to keep the drawing narrow enough to fit on the page. The plates at each end have a stainless steel strap welded to them in order to allow for simple and robust electrical connections to be made through the case.

The water supply is arranged to feed equal amounts of water to each cell. The design for this supply pipe has recently been improved by Ed Holdgate and Tom Thayer and Ed now supplies one along with the precision housings which he makes for Bob’s design. The new design has a water-supply pipe with very accurately cut slots in it. The lengths of the slots are directly related to how far along the pipe they are positioned. The objective is to have the same amount of water coming out of each slot even though the water pressure drops the further along the pipe the slot is located.

That water supply pipe is then housed in an outer pipe which has a hole drilled in it exactly above each of the bodies of electrolyte trapped between the plates (a 3/16" spacing):

This water supply pipe arrangement works well in practice and it looks surprisingly like the gas take-off pipe which has a series of holes drilled along the top of it:

This arrangement works well as it allows large volume gas flow out of the cell and yet makes it difficult for any splashes of electrolyte to make it into the pipe.

**Connecting to the Engine:**
The Bob Boyce HHO gas system produces such a very high gas output that one inch (25 mm) pipes are needed to carry the gas from the electrolyser to the engine. Because of the speed of the pressure wave caused if HHO gas ignites, no pop-off or shatter-disc system has sufficient time to operate. In addition, Bob’s system produces the top grade of HHO gas and as that has the highest energy level possible, it explodes spontaneously at a
pressure of just 15 psi. To deal with this situation, and the very high rate of gas flow which has to be handled, two very robust bubblers and one particle filter need to be used on the output of the electrolyser as shown here:

For those people living in America, Bob recommends the use of this bubbler:

This is a bubbler constructed from "Whole Household Prefiltration" units supplied by Home Depot, which unfortunately, may cost more than US $100 each.
These units come with a domed cap which needs to be drilled out with a large number of 1/16" holes like this:

Drill out bottom of pipe cap 1/16" holes. (LOTS OF THEM)

DO NOT USE "FLAT BOTTOMED" PIPE CAP!

An important point with this unit is that the flow through the bubbler is in the opposite direction to the arrows moulded on the outside of the unit:
Also, the pressure at which it operates needs to be dropped from normal household water pressure to the 0.5 psi. gas pressure needed for use as a bubbler. This is achieved by replacing the ball valve inside the unit with a much weaker version available from the KBI company, reference code KC1000 and costing about US $10. If you get one, be sure to specify a 0.5 psi pressure version as they have more than one type.

It is important that the end cap be a domed variety as shown above. This is necessary as it prevents bubbles joining together before streaming upwards through the water.

The particle filter housing is a French-made unit sold by Home Depot under the name of "SmartWater" and reference number GXWH04F and it costs under US $20. As the filter supplied with the unit is not fine enough, so a 1-micron filter needs to be bought from Ace Hardware to replace the standard 4-micron filter supplied with the filter housing. This 1-micron adapted filter also acts as a back-flash preventer:
**Practical Issues**

No matter which variety of electrolyser cell is used, it is essential to put a bubbler between it and the engine intake. This is to prevent any accidental ignition of the gas reaching the electrolysis cell. Also, no electrolyser should be operated or tested indoors. This is because the gas is lighter than air so any leak of gas will cause the gas to collect on the ceiling where it can cause a major explosion when triggered by the slightest spark (such as is generated when a light switch is turned on or off). Hydrogen gas escapes very easily indeed as its atoms are very, very small and can get through any tiny crack and even directly through many apparently solid materials. Testing electrolyzers should be done outdoors or at the very least, in very well-ventilated locations. Using at least one bubbler is an absolutely vital safety measure. A typical bubbler looks like this:

Bubbler construction is very simple indeed. It can be any size or shape provided that the outlet of the entry tube has at least five inches (125 mm) of water above it. Plastic is a common choice for the material and fittings are easy to find. It is very important that good sealed joints are made where all pipes and wires enter any container which has HHO gas in it. This, of course, includes the bubbler. Bob Boyce’s 101-plate units produce up to 100 lpm of gas, so these need large diameter gas piping to carry that substantial volume and the bubblers need to be big as well. It is also a good idea to drill additional holes in the entry pipe from half way down below the surface of the water, in order to create a larger number of smaller bubbles.

The anti-slosh filling or a baffle plate in the cap is to prevent the water in the bubbler from splashing up into the exit pipe and being drawn into the engine. Various materials have been used for the filling including stainless steel wool and plastic pot scourers. The material needs to prevent, or at least minimise, any water passing through it, while at the same time allowing the gas to flow freely through it.

Let me stress again, that this document does NOT recommend that you actually build any of the items of equipment discussed here. The ‘HHO’ gas produced by electrolysis of water is extremely dangerous, explodes instantly and cannot be stored safely, so this document is strictly for information purposes only.

However, to understand the process more fully, the following details would need to be considered carefully if somebody decided to actually build one of these high-voltage series-cell devices.

There is a considerable difference between a mixture of hydrogen and oxygen gases (‘HHO’) and petroleum (gasoline) vapour. While they both can serve as fuel for an internal combustion engine, they have considerable differences. One major difference is that HHO gas burns very much faster than petrol vapour. That would not be a problem if the engine was originally designed to burn HHO gas. However, most existing engines are arranged to operate on fossil fuels.

If using HHO gas to improve the burn quality and improve the mpg of a vehicle, no timing adjustments are normally necessary. However, all recent cars in the USA are fitted with an Electronic Mixture Controller and if
nothing is done about that, a decrease in mpg may actually occur as the Controller may start pumping more fuel into the engine when it sees a change in the quality of the exhaust. Good information on how to deal with this problem can be found at the web site http://better-mileage.com/memberadx.html which includes details of how to deal with the Controller or in the previous document in this Appendix.

If an engine is run without any fossil fuel at all, then timing adjustments need to be made. Hydrocarbon fuels have large molecules which do not burn fast enough to be efficient inside the cylinder of an engine. What happens is that for the first fraction of a second after the spark plug fires, the molecules inside the cylinder split up into much smaller particles, and then these smaller particles burn so fast that it can be described as an explosion:

Because of the delay needed for the conversion of the hydrocarbon molecules to smaller particles, the spark is arranged to occur before the Top Dead Centre point. While the molecules are splitting up, the piston passes its highest point and the crankshaft is some degrees past Top Dead Centre before the driving pressure is placed on the head of the piston. This driving force then reinforces the clockwise rotation of the crankshaft shown in the diagram above and the motor runs smoothly.

That will not happen if a HHO gas/air mix is substituted for the petrol vapour. HHO gas has very small molecule sizes which do not need any kind of breaking down and which burn instantly with explosive force. The result is as shown here:
Here, the explosion is almost instantaneous and the explosion attempts to force the piston downwards. Unfortunately, the crankshaft is trying to drive the piston upwards past the Top Dead Centre ('TDC') point, so the explosion will not help the engine run. Instead, the explosion will stop the crankshaft rotating, overload the crankshaft and connecting rod and produce excessive pressure on the wall of the cylinder.

We do not want that to happen. The solution is to delay the spark until the piston has reached the position in its rotation where we want the explosion to take place - that is, in exactly the same place as it did when using petrol as a fuel.

In the example above, the spark would be retarded (delayed) from 8 degrees before TDC to 10 degrees after TDC, or 18 degrees overall. The spark is 'retarded' because it needs to occur later in the rotation of the crankshaft. The amount of retardation may vary from engine to engine, but with HHO gas, the spark must never occur before TDC and it is preferable that the crankshaft has rotated some degrees past TDC so that most of the push from the piston goes to turn the crankshaft and as little as possible in compressing the crankshaft.

**Diesel Engines**

Diesel engines do not have spark plugs and so there is no timing alterations needed with them. Any booster volume of HHO gas up to 80% of the cylinder contents can be added into the air entering a diesel engine and it automatically helps the mpg performance. If a really large volume of HHO gas is available, then the diesel engine is set to tick over on diesel and HHO gas is then added to rev the engine up and provide the power. The amount of HHO gas should not exceed four times the amount of diesel as engine overheating will occur if it does.

Roy McAlister has been running internal combustion engines on hydrogen and many mixtures of hydrogen and other fuels for forty years now. He advises anybody interested in implementing a system like this, to start with a single-cylinder engine of five horsepower or less. That way, the techniques are easily learnt and experience is gained in tuning a simple engine running on the new fuel. So, let us assume that we are going to convert a small generator engine. How do we go about it?

First, we obtain our supply of the new fuel. In this case, let us assume that we will produce HHO gas using a multi-cell high-voltage series electrolyser as described earlier. This unit has an electrical cut-off operated by a pressure switch which operates at say, five pounds per square inch. Assuming that the electrolyser is capable of producing a sufficient volume of gas, this is roughly equivalent to a hydrogen bottle with its pressure regulators.

In broad outline, the gas supply would look like this:
The physical connection to the engine is via a 6 mm (1/4 inch) stainless steel pipe, fitted with a standard knob-operated needle valve. The carburettor is removed altogether to allow maximum airflow into the engine, (or failing this, the throttle valve of the carburettor is opened wide and secured in that position). The stainless steel gas pipe has its diameter reduced further by the use of a nozzle with an internal diameter of 1 mm or so (1/16 inch or less), about the size of a hypodermic needle used by a vet. HHO gas has very small molecules and will flow very freely through tiny openings. The nozzle tip is pushed close to the intake valve and the gas feed pipe is secured in place to ensure no movement:

When the engine is about to be started, the needle valve can be hand-adjusted to give a suitable level of gas flow to maintain tick-over, but before that can happen, the timing of the spark needs to be adjusted

There are two main ways to adjust the timing. The first is mechanical, where an adjustment is made to the mechanism which triggers the spark. Some small engines may well not have a convenient way to adjust the timing by as much as is needed for this application. The second way is to delay the spark by an adjustable electronic circuit (for instance, an NE555 monostable driving a FET). This can either be built or bought ready made. One supplier which offers a dashboard-mounted manually controlled ready-built ignition delay unit is http://www.msdignition.com/1timingcontrols.htm and there are others.

**Waste spark.**

As already discussed in chapter 10, there is one other very important consideration with small engines and that is the way in which the spark is generated. With a four-stroke engine, the crankshaft rotates twice for every power stroke. The spark plug only needs to fire every second time the piston approaches its highest position in the cylinder. This is not particularly convenient for engine manufacturers, so some simplify matters by generating a spark on every revolution. The extra spark is not needed, contributes nothing to the operation of the engine and so is called the "waste spark". The waste spark does not matter for an engine running on fossil fuel vapour, but it does matter very much if the fuel is switched to HHO gas.

As has been shown in the earlier diagrams, it is necessary to retard (delay) the spark by some eighteen degrees or so when using HHO gas, due to its very much faster ignition rate. Delaying the HHO fuel ignition point until
after Top Dead Centre sorts out the situation in an entirely satisfactory manner for the Power Stroke of the engine. However, if the engine generates a spurious ‘waste spark’ that waste spark does cause a serious problem.

In the case of the fossil fuel, any waste spark will occur towards the end of the Exhaust Stroke and it will have no real effect (apart from wasting electrical power). In the case of the HHO fuel, the engine has completed the Exhaust Stroke, the outlet valve has closed, the intake valve has opened and the gas is being drawn through the open inlet valve into the cylinder in the Intake Stroke. At that instant, there is an open passage from the spark plug, through the cylinder, through the open intake valve, to the gas supply pipe and through it to the bubbler between the electrolyser and the engine. If a waste spark takes place, it will ignite the gas:

The gas ignition is highly likely if there is a waste spark in an engine using HHO fuel and (the necessary) retarded ignition. Trying to eliminate the unwanted spark by using a ‘divide-by-two’ electronic counter circuit is not likely to be successful unless there is some mechanically certain way of triggering the counter circuit at start-up. The best way of overcoming a waste spark, if the engine has one, is to use a 2:1 gearing arrangement on the output shaft of the motor and using the slower shaft to trigger the spark. Multi-cylinder engines do not usually have a waste spark. It is also possible to operate a contact from either the camshaft or directly from one of the valve stems. It has also been suggested that using a pressure-operated switch on the exhaust system would be effective, and another suggestion is to delay the opening time of the intake valve until after waste spark has occurred, though this may create a good deal more engine noise.

Once some experience has been gained in operating a single cylinder engine on HHO gas, the move to a full-sized engine is not very difficult. Each cylinder of the large engine is pretty much the same as the small engine. Instead of running a small tube down the carburettor intake of each cylinder, it is more convenient and economic to use the existing intake manifold, leave the throttle wide open and run the HHO gas pipe into the manifold. A flexible stainless steel pipe section should be used to absorb the vibration of the engine relative to the electrolyser. Roy McAlister suggests using a knob-operated needle valve to set the idling speed to about 1,000 rpm and placing a throttle-operated lever valve in parallel with it for applying more power to the engine:

It is not immediately clear to me why this arrangement is recommended as the knob-operated needle valve use to set the idling rate appears to be redundant. There appears to be no particular reason why a screw adjustment could not be used on the lever valve linked to the accelerator pedal of the vehicle. If that were done, then the throttle screw could be used to set the idle rate and the screw locked in position. That way, the needle valve and two Y-connectors could be dispensed with. The only possible reason which suggests itself is that there is slightly less physical construction needed for the recommended way shown here:
One supplier of flexible tubing suitable for this sort of work is [http://www.titeflexcommercial.com](http://www.titeflexcommercial.com) but there will be many others.

**Engine Size Limits**

A 101-plate Boyce electrolyser accurately built, properly cleansed and conditioned, produces about 50 litres per minute of HHO gas continuously, when tuned properly and can sustain short bursts of 100 lpm. It is really not possible to say how much HHO gas is needed to operate any particular engine as the energy requirement varies so much from engine to engine even though they may have the same engine capacity. However, very rough ball-park figures, it would not be unusual for a 2 litre capacity engine to run satisfactorily on 100 lpm of HHO gas. Please remember that when flow rates like 100 lpm or more are being dealt with, that it is essential to use a large-diameter pipe (say, one-inch diameter) from the electrolyser onwards. Also, the bubblers need to be physically larger. It is essential to avoid any possibility of large HHO gas bubbles forming a continuous path through the water in the bubbler as that would allow a flame-front to pass directly through the water in the bubbler which is exactly what the bubbler is there to prevent, so don’t skimp on the size of the bubblers, especially as they will only be half-filled when the gas flow rate is very high. Bob Boyce explains the present limits on gas production as follows:

The impedance of the “MicroMetals T650” toroidal core reaches a maximum at 36 square inches per plate, it is possible to use one long 201-plate electrolyser, powered with double the voltage. The problem is that we can’t increase the current density as it would increase the toroid temperature which would cause the permeability to decrease. However, we can increase the voltage without worrying about increasing the toroid temperature, so going to 240 volts AC is not a problem.

A 201-plate electrolyser could achieve 200 lpm which would be able to power a 3 to 4 litre engine. Ideally, an electrolyser of that type would have a microprocessor controller circuit board, as that should generate faster pulse transition speeds than the present circuit board. An electrolyser of that type would need a revised case design to take stainless steel plates which are 9 inches wide and 6 inches tall. The electrolyte level would then be set to a 4 inch depth, giving the same 36 square inches of active plate area.

A 101-plate electrolyser measures about 20 inches in length. A 201-plate unit would be about 40 inches long and so would fit into the boot (trunk) of a car or the back of a pick-up. This means that there is still more potential left in the “T650” toroid before there is any need to find a larger toroid.

An 8 inch toroid with a 101-plate unit could fuel an engine of up to 4 litres capacity. A 10 inch toroid driving a 101-plate unit could fuel a 5 litre engine. In these cases, the plate areas would be larger than 6” x 6” because with a larger toroid, the current can be increased without overheating the toroid and lowering it’s permeability.

The information from Micrometals is that their hydraulic press can make toroids up to 8 inches in diameter, but the success rate diminishes as the diameter increases. As it is, the success rate for making the 6.5 inch diameter is their best economical rate. For larger diameters, the cost of the increased failure rate is passed on to the buyers.

There is word of a small private Canadian outfit that is working with 5 gallon pails of mining tailings to extract high-permeability materials which can be used to make larger toroids. They crush the tailings into fine powder with a huge milling stone, then pass the powder under a magnet to collect the magnetic material. They do this several times and then mix the remaining material with a binder to form a toroid.
Every company in the toroid making industry has their own proprietary formula for making toroids. This particular Canadian company's 6.5 inch toroid matches the Micrometals T650 pretty well. If there is enough interest, they can quote a quantity rate for a larger toroid.

Stationary Applications

Some people wish to try home applications with an electrolyser of this type, and they ask about powering the unit directly from the mains, rather than from the electrical system of a vehicle. This is a practical proposition and it has the advantage that size and weight are no longer of any great importance. The circuit would alter very slightly for this application as shown here:

Here, instead of an inverter to create 110 volts AC, a car battery charger or mains Power Supply Unit is needed to provide the same voltage that the vehicle electrics would have provided. It would probably be worth putting a large value capacitor across the output of the car battery charger to help smooth out the voltage ripple which it will produce. Don’t forget that it needs to be able to supply considerable current and so it will be rated as a “heavy-duty” battery charger. If a 200-cell unit is to be used, then a 1:2 mains step-up transformer will also be needed to raise the mains voltage to 220 volts.

In countries which have a 220 volt mains supply, then a 2:1 step-down mains transformer would be needed for a 100-cell unit but not for a 200-cell unit. The circuit would then be:
Bob Boyce’s Experiences:

Bob had an electronics business down in south Florida where he owned and sponsored a small boat-race team through his business, starting in 1988. He had a machine shop behind his business, where he did engine work. He worked on engines for other racers and a local minisub research outfit which was building surface-running drone type boats for the DEA. He delved into hydrogen research and started building small electrolysers using distilled water mixed with an electrolyte. He then resonated the plates to improve the efficiency of the units. He discovered that with the right frequencies, He was able to generate ‘monatomic’ Hydrogen and Oxygen rather than the more common ‘diatomic’ versions of these gasses. When the ‘monatomic’ gasses are burnt, they produce about four times the energy output produced by burning the more common diatomic version of these gasses.

About 4% of diatomic Hydrogen in air is needed to produce the same power as petrol, while slightly less than 1% of monatomic Hydrogen in air is needed for the same power. The only drawback is that when stored at pressure, monatomic hydrogen reverts to its more common diatomic form. To avoid this, the gas must be produced on-demand and used right away. Bob used modified Liquid Petroleum carburettors on the boat engines to let them run directly on the gas produced by his electrolysers. Bob also converted an old Chrysler car with a slant six-cylinder engine to run on the hydrogen set-up and tested it in his workshop. He replaced the factory ignition with a high energy dual coil system and added an optical pickup to the crankshaft at the oil pump drive tang to allow external ignition timing adjustment. He used Bosch Platinum series spark plugs.

Bob never published anything about what he was working on, and he always stated that his boats were running on hydrogen fuel, which was allowed. Many years later that he found that he had stumbled on was already discovered and known as "Browns Gas", and there were companies selling the equipment and plans to make it.

Bob’s electrolysers is fairly simple to make but it requires a lot of plates made of 316 stainless steel able to withstand the more exotic electrolytes which are more efficient, a plastic box to contain the plates, 1/8” spacers to keep the rows of plates apart, the electrolyte, and an adjustable-frequency modified pseudo-sinewave inverter for the drive electronics. A total of 101 plates 6 inches square are used to give a large surface area. These have their surfaces scoured with coarse sandpaper in an "X" pattern to give a fine crosshatch grain which added fine sharp points to the surfaces.

This is found to improve the efficiency of the electrolysis. The box has two threaded ports, a small one for injecting replacement distilled water, and a larger one for extracting the HHO gas. Under the top cover is a piece of plastic matting to prevent sloshing. It is very important to keep the electrolyte level below the tops of the plates to prevent current bypassing any cells and creating excessive water vapour.

Bob places a 5 Pounds per Square Inch cut-off switch in a tee on the water injection port that shut the drive electronics down when the pressure in the unit hit 5 PSI. This allows the unit to be able to supply on demand without building up too much pressure in low-demand situations. He builds a bubbler from a large home cartridge type water-filter housing to prevent any backfire from travelling back up the gas feed pipe to the electrolyser. Without some sort of bubbler there is the risk of the electrolyser exploding if a flame front from the engine flows back to it.

The copper mesh screens designed for welding gasses will not work as hydrogen has a much higher flame propagation speed which passes straight through the copper mesh. The bubbler should be placed close to the engine so as to limit the amount of recombination of the gasses from monatomic to diatomic varieties. The HHO gas should be fed to the vapour portion of a Liquid Petroleum Gas carburettor system. The carburettor will have to be modified for hydrogen use (different mixture rate than propane) and adjusted for best performance with the system running.

Bob found that the best electrolytes to use were Sodium Hydroxide (NaOH) and Potassium Hydroxide (KOH). While Sodium Hydroxide works well and is much easier to get (‘Red Devil’ lye found in most department stores) than the slightly more efficient Potassium Hydroxide. Whatever is used, be very careful what construction materials are used. Make absolutely sure that they are compatible with the chosen electrolyte (Plexiglas acrylic sheet was what Bob used). Never use glass containers for mixing or storing Potassium Hydroxide.

Bob never had the chance to drive the test Chrysler on the road with this system. Instead, he placed the rear end up on jack-stands and ran the engine under no-load conditions in drive just to test and tune the system and get an idea of how well the engine held up on the hydrogen fuel. The vehicle was run for a kilometer recorded distance of one thousand miles in this set-up with the hydrolysis being fully powered by the alternator of the vehicle. With the vehicle running at idle, the drive electronics consumed approximately 4 to 4.3 Amps @ 13.8 V DC. With the rear wheels off of the ground, and the engine running with the vehicle speedometer registering 60 mph, the drive electronics drew approximately 10.9 to 11.6 Amps @ 13.8 V DC.
The unit does not use "normal brute force" electrolysis when operating in high efficiency mode. It relies mainly on a chemical reaction that takes place between the electrolyte used and the metal plates, which is maintained by electrical energy applied and stimulated into higher efficiency by the application of multiple harmonic resonances which help to "tickle" the molecules apart. Multiple cells in series are used to lower the voltage per cell and limit the current flow in order to reduce the production of water vapour. It relies on the large surface area of the total number of cells to get the required volume of fuel vapour output.

In the first prototype of this design, Bob used a custom built controller/driver which allowed a lot of adjustment so that performance could be tested using different frequencies, voltages, and waveforms individually. The result was a pattern of 3 interwoven square waves rich in harmonics that produced optimum efficiency. When Bob had the basics figured out he realised that he could just replace the custom controller/driver unit with a modified inverter (much easier than building a unit from scratch). He experimented using a 300 watt pseudo-sine wave inverter that had been modified so the base frequency could be adjusted between 700 and 800 Hz. The stepped sine wave output was fed through a bridge rectifier which turned each stepped sine wave into two positive stepped half waves. Each of these half waves had 8 steps, so a single cycle was turned into 16 steps. The resulting output, while not consisting of intermixed square waves, was still rich in harmonics, and it was much easier to adjust to the point of resonance than trying to tune 3 separate frequencies. Please note that these inverters are no longer available for purchase and that Bob's triple oscillator board design is far superior, giving more than double the output produced by the old inverter and is definitely the board to use with Bob's electrolyser.

The frequency range can change depending on the number of steps in the pseudo-sine wave of the inverter you choose since not all inverters are created equal. The desired effect is caused by the multiple harmonic resonances in the inverter output at higher frequencies. You will know when you hit resonance by the dramatic increase in gas output. The frequency does vary a bit depending on what electrolyte is used, the concentration of the electrolyte solution, the temperature of the electrolyte, water purity, etc.

Bear in mind that Bob’s electrolyser tank was large enough to hold 61 plates of 316 grade stainless steel which were 6" X 6" each, spaced 1/8" apart, to create 60 cells in series, with the 130 V DC power from the inverter, through the bridge rectifier, applied to the end plates only. That gave 4,320 square inches of surface area, plenty of surface area to produce enough fuel for a vehicle engine. The best electrolyte for efficiency was Potassium Hydroxide, and the electrolyte level must be kept below the tops of the plates to prevent any current from bypassing the plates and creating excess water vapour through heating. Distilled water was used to prevent contamination of the electrolyte which would result in reduced performance and efficiency.

The unit had 316 grade stainless steel wires welded to the tops of the end plates. The other ends of the wires were welded to 316-grade stainless steel bolts which passed through holes in the ends of the container, with rubber o-ring gaskets inside and out, located above the liquid level.

There was a PVC spray bar attached on the inside of the chamber to the water injection port with tiny holes drilled along its length on the underside to supply replacement water evenly to the cells when the water pump was switched on. A backflow-prevention valve on top of the tee was used to keep the gas from flowing back into the water lines. There was a mat of interwoven plastic fibres (air conditioner filter material) cut and fitted on top of the plates to help prevent sloshing. Do not use fibreglass mat, which could cause a severe reaction with some electrolytes, like Potassium Hydroxide.

It is very important to understand that unless an engine is originally designed for, or later modified for, running on vapour fuel such as Liquid Petroleum Gas (natural gas), that water mist injection be added. Unless the engine has the proper valves for vapour fuel, the stock valves will not survive for extended run times on vapour fuel of any kind without additional cooling of some sort. This is an issue of valve design by the vehicle manufacturers, not something detrimental because of HHO gas combustion. The manufacturers want to prevent their cars from being adapted to high mileage operation without adverse effects, so they designed the valves to fail if not cooled by excess raw fossil fuel.

Pulsed Water-Splitters.

There is a much more efficient way of converting water into a HHO gas mix. Unlike the electrolysis devices already described, this method does not need an electrolyte. Pioneered by Stanley Meyer, pulse trains are used to stress water molecules until they break apart, forming the required gas mix. Henry Puharich also developed a very successful system with a somewhat different design. Neither of these gentlemen shared sufficient practical information for us to replicate their designs as a routine process, so we are in a position today where we are searching for the exact details of the methods which they used.
Dave Lawton’s Replication of Stan Meyer’s “Water Fuel Cell”.
The first significant replication of which I am aware, came from Dave Lawton of Wales. By using very considerable tenacity, he discovered the practical details of how to replicate one of Stan Meyer's early designs which is called by the rather confusing name of the "Water Fuel Cell". Dave's work was copied and experimented with by Ravi Raju of India who had considerable success and who posted videos of his results on the web. More recently, Dr Scott Cramton of the USA has adapted the design construction slightly and achieved very satisfactory rates of electrical efficiency, producing some 6 lpm of HHO gas for just 3 amps of current at 12 volts.

Dave Lawton

The video of Dave Lawton’s replication of Stanley Meyer’s demonstration electrolyser (not Stan’s production system) seen at [http://www.free-energy-info.com/WFCrep.wmv](http://www.free-energy-info.com/WFCrep.wmv) has caused several people to ask for more details. The electrolysis shown in that video was driven by an alternator, solely because Dave wanted to try each thing that Stan Meyer had done. Dave’s alternator and the motor used to drive it are shown here:

The technique of DC pulsing requires the use of electronics, so the following descriptions contain a considerable amount of circuitry. If you are not already familiar with such circuits, then you would be well advised to read through Chapter 12 which explains this type of circuitry from scratch.

The field coil of Dave's alternator is switched on and off by a Field-Effect Transistor (a “FET”) which is pulsed by a dual 555 timer circuit. This produces a composite waveform which produces an impressive rate of electrolysis. The tubes in this replication are made of 316L grade stainless steel, five inches long although Stan’s tubes were about sixteen inches long. The outer tubes are 1 inch in diameter and the inner tubes 3/4 inch in diameter. As the wall thickness is 1/16 inch, the gap between them is between 1 mm and 2 mm. The inner pipes are held in place at each end by four rubber strips about one quarter of an inch long.

The container is made from two standard 4 inch diameter plastic drain down-pipe coupler fittings connected to each end of a piece of acrylic tube with PVC solvent cement. The acrylic tube was supplied already cut to size by Wake Plastics, 59 Twickenham Road, Isleworth, Middlesex TW7 6AR Telephone 0208-560-0928. The seamless stainless steel tubing was supplied by: [http://www.metsalsontheweb.co.uk/asp/home.asp](http://www.metsalsontheweb.co.uk/asp/home.asp)

It is not necessary to use an alternator - Dave just did this as he was copying each thing that Stan Meyer did. The circuit without the alternator produces gas at about the same rate and obviously draws less current as there is no drive motor to be powered. A video of the non-alternator operation can be downloaded using this link: [http://www.free-energy-info.co.uk/WFCrep2.wmv](http://www.free-energy-info.co.uk/WFCrep2.wmv).

Dave’s electrolyser has an acrylic tube section to allow the electrolysis to be watched, as shown here:
The electrolysis takes place between each of the inner and outer tubes. The picture above shows the bubbles just starting to leave the tubes after the power is switched on. The picture below shows the situation a few seconds later when the whole of the area above the tubes is so full of bubbles that it becomes completely opaque:

The mounting rings for the tubes can be made from any suitable plastic, such as that used for ordinary food-chopping boards, and are shaped like this:

And the 316L grade stainless steel, seamless tubes are held like this:
Here is the assembly ready to receive the inner tubes (wedged into place by small pieces of rubber):

The electrical connections to the pipes are via stainless steel wire running between stainless steel bolts tapped into the pipes and stainless steel bolts running through the base of the unit:
The bolts tapped into the inner tubes should be on the inside. The bolts going through the base of the unit should be tapped in to give a tight fit and they should be sealed with Sikaflex 291 or marine GOOP bedding agent which should be allowed to cure completely before the unit is filled for use. An improvement in performance is produced if the non-active surfaces of the pipes are insulated with any suitable material. That is, the outsides of the outer tubes and the insides of the inner tubes, and if possible, the cut ends of the pipes.

**Stan Meyer’s Style of Construction.**

While Dave’s style of construction is simple and straightforward, recently, a copy of one of Stan Meyer’s actual construction drawings has surfaced. The image quality of this copy is so low that much of the text can’t be read, so the replication presented here may not be exact or might be missing some useful item of information. Stan’s construction is unusual. First, a piece of plastic is shaped as shown here:

![Diagram of Stan Meyer’s Style of Construction](image)

The size of this disc is matched exactly to the piece of clear acrylic used for the body of the housing. The drawing does not make it clear how this disc is attached to the acrylic tube, whether it is a tight push fit, glued in place or held in position with bolts which are not shown. The implication is that a ring of six bolts are driven through the top and tapped into the acrylic tube, as these are shown on one of the plan views, though not on the cross-section. It would also be reasonable to assume that a similar ring of six bolts is also used to hold the base securely in position. There is a groove cut in the plastic base to take an O-ring seal which will be compressed tightly when the disc is in place. There are either two or three threaded stud recesses plus two through holes to carry the electric current connections. The pipe support arrangement is unusual:
A ring of nine evenly-spaced inner pipes are positioned around the edge of a steel disc which is slightly smaller than the inside dimension of the acrylic tube. The pipes appear to be a tight push-fit in holes drilled very accurately through the disc. These holes need to be exactly at right-angles to the face of the disc in order for the pipes to be exactly aligned with the acrylic tube – definitely a drill-press job. The disc is mounted on a central threaded rod which projects through the plastic base disc, and a plastic spacer is used to hold the disc clear of the studs positioned at ninety degrees apart around the outer edge of the base disc.

The mounting for the outer tubes is also most unusual. A piece of steel plate is cut with nine projecting arms at evenly-spaced positions around a circular washer shape as shown here:

This piece has four holes drilled in it to match the stud positions of the plastic base piece. The number of studs is not specified and while I have shown four, the plate resonance might be helped if there were just three. The size is arranged so that when the arms are bent upwards at right-angles, they fit exactly against the inner face of the acrylic tube.
These arms get two bends in them in order to kink them inwards to form mounts for the outer tubes. The degree of accuracy needed here is considerable as it appears that there are no spacers used between the inner and outer tubes. This means that the very small gap of 1.5 mm or so has to be maintained by the accuracy of these mounts for the outer tubes.

It should be noted that the inner tubes are much longer than the outer tubes and that the outer tubes have a tuning slot cut in them. All of the inner tubes are mechanically connected together through their steel mounting disc and all of the outer tubes are connected together through the ring-shaped steel disc and its kinked arm mounts. It is intended that both of these assemblies should resonate at the same frequency, and they are tuned to do just that. Because the inner tubes have a smaller diameter, they will resonate at a higher frequency than a larger diameter pipe of the same length. For that reason, they are made longer to lower their natural resonant frequency. In addition to that, the slots cut in the outer tubes are a tuning method which raises their resonant pitch. These slots will be adjusted until every pipe resonates at the same frequency.

Looking initially at the mechanical design, suggests that the assembly is impossible to assemble, and while that is almost true, as it will have to be constructed as it is assembled and it appears that the inner and outer pipe assembly can’t be taken apart after assembly. This is the way they are put together:

The ring support for the outer pipes is not bolted securely to the plastic base but instead it is spaced slightly above it and mounted on just the stud points. This ring is underneath the slightly smaller diameter disc which holds the inner pipes. This makes it impossible for the two components to be slid together or apart, due to the length of the pipes. This suggests that either the inner pipes are pushed into place after assembly (which is highly unlikely as they will have been assembled before for tuning) or that the outer pipes are welded to their supports during the assembly process (which is much more likely).

One of the “studs” is carried right through the plastic base in order that it can become the positive connection of the electrical supply, fed to the outer pipes. The central threaded rod is also carried all the way through the plastic base and is used to support the steel plate holding the inner pipes as well as providing the negative electrical connection, often referred to as the electrical “ground”.

Another plastic disc is machined to form a conical lid for the acrylic tube, having a groove to hold an O-ring seal and the water inlet for refilling and the gas output tube. The drawing mentions the fact that if tap water is used, then the impurities in it will collect in the bottom of the electrolyser when the water is removed by being converted to HHO gas. This means that the cell would have to be rinsed out from time to time. It also draws attention to the fact that the gasses dissolved in the tap water will also come out during use and will be mixed with the HHO gas output.

When these various components are put together, the overall cell construction is shown like this:
This cross-sectional view may be slightly misleading as it suggests that each of the nine outer pipes has its own separate bracket and this is probably not the case as they are connected together electrically through the steel ring-shaped disc and should vibrate as a single unit. It is tempting to use separate brackets as that would allow the assembly to be taken apart quite easily, but the electrical contacts of such a system would be much inferior and so it is not to be recommended.

Because of the way that all of the inner pipes are connected together and all of the outer pipes are connected together electrically, this form of construction is not suited to the three-phase alternator drive shown below, where the nine pipes would have to be connected in separate sets of three. Instead, the solid-state circuit is used, which is very effective and which does not have the size, weight, noise and increased current of the alternator arrangement.

If accuracy of construction is a problem, then it might be possible to give the outer pipes a deliberate slope so that they press against the inner pipes at the top, and then use one short spacer to force them apart and give the desired spacing. It seems clear that Stan worked to such a degree of constructional accuracy that his pipes were perfectly aligned all along their lengths.

Dave Lawton points out that the connection point of the brackets for the outer pipes is highly critical as they need to be at a resonating node of the pipes. The connection point is therefore at 22.4% of the length of the pipe from the bottom of the pipe. Presumably, if a slot is cut in the top of the pipe, then the resonant pipe length will be measured to the bottom of the slot and the connection point set at 22.4% of that length.

**Dave Lawton’s 3-Phase Circuit.**
Dave Lawton’s pipe arrangement can be driven either via an alternator or by an electronic circuit. A suitable circuit for the alternator arrangement is:
In this rather unusual circuit, the rotor winding of an alternator is pulsed via an oscillator circuit which has variable frequency and variable Mark/Space ratio and which can be gated on and off to produce the output waveform shown below the alternator in the circuit diagram. The oscillator circuit has a degree of supply de-coupling by the 100 ohm resistor feeding the 100 microfarad capacitor. This is to reduce voltage ripple coming along the +12 volt supply line, caused by the current pulses through the rotor winding. The output arrangement feeding the pipe electrodes of the electrolyser is copied directly from Stan Meyer’s circuit diagram.

It is not recommended that you use an alternator should you decide to build a copy of your own. But if you decide to use one and the alternator does not have the windings taken to the outside of the casing, it is necessary to open the alternator, remove the internal regulator and diodes and pull out three leads from the ends of the stator windings. If you have an alternator which has the windings already accessible from the outside, then the stator winding connections are likely to be as shown here:
The motor driving Dave’s alternator draws about two amps of current which roughly doubles the power input to the circuit. There is no need for the size, weight, noise, mechanical wear and current draw of using a motor and alternator as pretty much the same performance can be produced by the solid-state circuit with no moving parts.

Both circuits have been assessed as operating at anything from 300% to 900% of Faraday’s “maximum electrical efficiency”, it should be stressed that the inductors used in this circuit, form a very important role in altering and amplifying the voltage waveform applied to the cell. Dave uses two “bi-filar wound” inductors, each wound with 100 turns of 22 SWG (21 AWG) enamelled copper wire on a 9 mm (3/8”) diameter ferrite rod. The length of the ferrite rod is not at all critical, and a ferrite toroid could be used as an alternative, though that is more difficult to wind. These bi-filar coils are wound at the same time using two lengths of wire side by side. The solid-state circuit is shown here:

Dave Lawton's Single-Phase Circuit:
Circuit operation:
The main part of the circuit is made up of two standard 555 chip timers. These are wired to give an output waveform which switches very rapidly between a high voltage and a low voltage. In this particular version of the circuit, the rate at which the circuit flips between high and low voltage (called the "frequency") can be adjusted by the user turning a knob. Also, the length of the ON time to the OFF time (called the "Mark/Space Ratio") is also adjustable.
This is the section of the circuit which does this:

![Circuit Diagram]

The 100 ohm resistor and the 100 microfarad capacitor are there to iron out any ripples in the voltage supply to the circuit, caused by fierce pulses in the power drive to the electrolysis cell. The capacitor acts as a reservoir of electricity and the resistor prevents that reservoir being suddenly drained if the power supply line is suddenly, and very briefly, pulled down to a low voltage. Between them, they keep the voltage at point "A" at a steady level, allowing the 555 chip to operate smoothly.

The very small capacitor "B" is wired up physically very close to the chip. It is there to short-circuit any stray, very short, very sharp voltage pulses picked up by the wiring to the chip. It is there to help the chip to operate exactly as it is designed to do, and is not really a functional part of the circuit. So, for understanding how the circuit works, we can ignore them and see the circuit like this:

![Simplified Circuit Diagram]

This circuit generates output pulses of the type shown in green with the voltage going high, (the "Mark") and low (the "Space"). The 47K variable resistor (which some people insist on calling a "pot") allows the length of the Mark and the Space to be adjusted from the 50 - 50 shown, to say, 90 - 10 or any ratio through to 10 - 90. It should be mentioned that the "47K" is not at all critical and these are quite likely to be sold as "50K" devices. Most low cost components have a plus or minus 10% rating which means that a 50K resistor will be anything from 45K to 55K in actual value.

The two "1N4148" diodes are there to make sure that when the Mark/Space 47K variable resistor is adjusted, that it does not alter the frequency of the output waveform in any way. The remaining two components: the 10K variable resistor and the 47 microfarad capacitor, both marked in blue, control the number of pulses produced per
The larger the capacitor, the fewer the pulses per second. The lower the value of the variable resistor, the larger the number of pulses per second.

The circuit can have additional frequency tuning ranges, if the capacitor value is altered by switching in a different capacitor. So the circuit can be made more versatile by the addition of one switch and, say, two alternative capacitors, as shown here:

The capacitors shown here are unusually large because this particular circuit is intended to run relatively slowly. In the almost identical section of the circuit which follows this one, the capacitors are very much smaller which causes the switching rate to be very much higher. Experience has shown that a few people have had overheating in this circuit when it is switched out of action, so the On/Off switch has been expanded to be a two-pole changeover switch and the second pole used to switch out the timing elements of the 555 chip. The complete version of this section of the circuit is then:

which just has one additional switch to allow the output to be stopped and the 12-volt supply line to be fed instead. The reason for this is that this part of the circuit is used to switch On and Off an identical circuit. This is called “gating” and is explained in Chapter 12 which is an electronics tutorial.

The second part of the circuit is intended to run at much higher speeds, so it uses much smaller capacitors:
So, putting them together, and allowing the first circuit to switch the second one On and Off, we get:

The final section of the circuit is the power drive for the electrolyser cell. This is a very simple circuit. Firstly, the output of the second 555 chip is lowered by a basic voltage-divider pair of resistors, and fed to the Gate of the output transistor which while it can run on the 12 volts which the pulse-generation circuit needs, Dave does prefer to run on 24 volts as that generates a greater gas flow:
Here, the 555 chip output voltage is lowered by 220 / 820 or about 27%. When the voltage rises, it causes the BUZ350 transistor to switch on, short-circuiting between its Drain and Source connections and applying the whole of the 12-volt supply voltage across the load, which in our application, is the electrolyser cell:

The transistor drives the electrolysis electrodes as shown above, applying very sharp, very short pulses to them. What is very important are the wire coils which are placed on each side of the electrode set. These coils are linked magnetically because they are wound together on a high-frequency ferrite rod core and although a coil is such a simple thing, these coils have a profound effect on how the circuit operates. Firstly, they convert the 555 chip pulse into a very sharp, very short, high-voltage pulse which can be as high as 1,200 volts. This pulse affects the local environment, causing extra energy to flow into the circuit. The coils now perform a second role by blocking that additional energy from short-circuiting through the battery, and causing it to flow through the electrolysis cell, splitting the water into a mix of hydrogen and oxygen, both gases being high-energy, highly charged atomic versions of those gases. This gives the mix some 400% the power of hydrogen being burned in air.

When the transistor switches off, the coils try to pull the transistor Drain connection up to a voltage well above the +12-volt battery line. To prevent this, a 1N4007 diode is connected across the cell and its coils. The diode is connected so that no current flows through it until the transistor Drain gets dragged above the +12-volt line, but when that happens, the diode effectively gets turned on and as soon as 0.7 volts is placed across it, it starts to conduct heavily and collapses the positive-going voltage swing, protecting the transistor. You can easily tell that it is the environmental “cold” electricity which is doing the electrolysis as the cell stays cold even though it is putting out large volumes of gas. If the electrolysis were being done by conventional electricity, the cell temperature would rise during the electrolysis. A John Bedini pulser circuit can be used very effectively with a cell of this type and it adjusts automatically to the resonant frequency as the cell is part of the frequency-determining circuit.

The BUZ350 MOSFET has a current rating of 22 amps so it will run cool in this application. However, it is worth mounting it on an aluminium plate which will act as both the mounting and a heat sink but it should be realised that this circuit is a bench-testing circuit with a maximum current output of about 2 amps and it is not a Pulse-Width Modulation circuit for a high-current DC electrolyser. The current draw in this arrangement is particularly interesting. With just one tube in place, the current draw is about one amp. When a second tube is added, the current increases by less than an amp. When the third is added, the total current is under two amps. The fourth and fifth tubes add about 100 millamps each and the sixth tube causes almost no increase in current at all. This suggests that the efficiency could be raised further by adding a large number of additional tubes, but this is actually not the case as the cell arrangement is important. Stan Meyer ran his VolksWagen car for four years on
the output from four of these cells with 16-inch (400 mm) electrodes, and Stan would have made a single larger cell had that been feasible.

Although the current is not particularly high, a five or six amp circuit-breaker, or fuse, should be placed between the power supply and the circuit, to protect against accidental short-circuits. If a unit like this is to be mounted in a vehicle, then it is essential that the power supply is arranged so that the electrolyser is disconnected if the engine is switched off. Passing the electrical power through a relay which is powered via the ignition switch is a good solution for this. It is also vital that at least one bubbler is placed between the electrolyser and the engine, to give some protection if the gas should get ignited by an engine malfunction.

Although printed circuit boards have now been produced for this circuit and ready-made units are available commercially, you can build your own using stripboard if you want to. A possible one-off prototype style component layout for is shown here:
The underside of the strip-board (when turned over horizontally) is shown here:
Although using a ferrite ring is probably the best possible option, the bi-filar coil can be wound on any straight ferrite rod of any diameter and length. You just tape the ends of two strands of wire to one end of the rod and then rotate the rod in your hands, guiding the strands into a neat side-by-side cylindrical winding as shown here:

Dave, who built this replication, suggests various improvements. Firstly, Stan Meyer used a larger number of tubes of greater length. Both of those two factors should increase the gas production considerably. Secondly, careful examination of video of Stan’s demonstrations shows that the outer tubes which he used had a rectangular slot cut in the top of each tube:
Some organ pipes are fine-tuned by cutting slots like this in the top of the pipe, to raise its pitch, which is its frequency of vibration. As they have a smaller diameter, the inner pipes in the Meyer cell will resonate at a higher frequency than the outer pipes. It therefore seems probable that the slots cut by Stan are to raise the resonant frequency of the larger pipes, to match the resonant frequency of the inner pipes. If you want to do that, hanging the inner tube up on a piece of thread and tapping it, will produce a sound at the resonant pitch of the pipe. Cutting a slot in one outer pipe, suspending it on a piece of thread and tapping it, will allow the pitch of the two pipes to be compared. When one outer pipe has been matched to your satisfaction, then a slot of exactly the same dimensions will bring the other outer pipes to the same resonant pitch. It has not been proved, but it has been suggested that only the part of the outer pipe which is below the slot, actually contributes to the resonant frequency of the pipe. That is the part marked as “H” in the diagram above. It is also suggested that the pipes will resonate at the same frequency if the area of the inside face of the outer pipe (“H” x the inner circumference) exactly matches the area of the outer surface of the inner pipe. It should be remembered that as all of the pipe pairs will be resonated with a single signal, that each pipe pair needs to resonate at the same frequency as all the other pipe pairs.

It is said that Stan ran his VolksWagen car for four years, using just the gas from four of these units which had pipe pairs 16-inches long. A very important part of the cell build is the conditioning of the electrode tubes, using tap water. Ravi in India suggests that this is done as follows:

1. Do not use any resistance on the negative side of the power supply when conditioning the pipes.
2. Start at 0.5 Amps on the signal generator and after 25 minutes, switch off for 30 minutes.
3. Then apply 1.0 Amps for 20 minutes and then stop for 30 minutes.
4. Then apply 1.5 Amps for 15 minutes and then stop for 20 minutes.
5. Then apply 2.0 Amps for 10 minutes and afterwards stop for 20 minutes.
6. Go to 2.5 Amps for 5 minutes and stop for 15 minutes.
7. Go to 3.0 Amps for 120 to 150 seconds. You need to check if the cell is getting hot...if it is you need to reduce the time.

After the seven steps above, let the cell stand for at least an hour before you start all over again.

You will see hardly any gas generation in the early stages of this conditioning process, but a lot of brown muck will be generated. Initially, change the water after every cycle, but do not touch the tubes with bare hands. If the ends of the tubes need to have muck cleaned off them, then use a brush but do not touch the electrodes! If the brown muck is left in the water during the next cycle, it causes the water to heat up and you need to avoid this.

Over a period of time, there is a reduction in the amount of the brown stuff produced and at some point, the pipes won’t make any brown stuff at all. You will be getting very good gas generation by now. A whitish powdery coat of chromium oxide dielectric will have developed on the surfaces of the electrodes. Never touch the pipes with bare hands once this helpful coating has developed.

Important: Do the conditioning in a well-ventilated area, or alternatively, close the top of the cell and vent the gas out into the open. During this process, the cell is left on for quite some time, so even a very low rate of gas production can accumulate a serious amount of gas which would be a hazard if left to collect indoors.

Further Developments

When producing HHO gas from water, it is not possible to exceed the Faraday maximum unless additional energy is being drawn in from the surrounding environment. As this cell runs cold and has substantial gas output, there is every indication that when it is running, it is drawing in this extra energy.

This idea is supported by the fact that one of the key methods of tapping this extra energy is by producing a train of very sharply rising and sharply falling electrical pulses. This is exactly the objective of Dave’s circuit, so it would not be too surprising if that effect were happening.

The additional energy being accessed is sometimes referred to as “cold” electricity, which has very different characteristics to normal conventional electricity. Where normal electrical losses cause local heating as a by-product, “cold” electricity has exactly the opposite effect, and where a normal electrical loss would take place, an extra inflow of useful "cold" energy enters the circuit from outside. This flow causes the temperature of the circuitry to drop, instead of increase, which is why it is called “cold” electricity.

This remarkable occurrence has the most unusual effect of actually reducing the amount of conventional power needed to drive the circuit, if the output load is increased. So, increasing the load powered by the circuit causes additional energy to flow in from the environment, powering the extra load and as well, helping to drive the original circuit. This seems very strange, but then, “cold” electricity operates in an entirely different way to our familiar
conventional electricity, and it has its own set of unfamiliar rules, which are generally the reverse of what we are used to.

To test his cell system further, Dave connected an extra load across the electrodes of his cell. As the inductors connected each side of the cell generate very high-value, sharp voltage spikes, Dave connected two large value capacitors (83,000 microfarad, 50-volt) across the cell as well. The load was a 10-watt light bulb which shines brightly, and interestingly, the current draw of the circuit goes down rather than up, in spite of the extra output power. The gas production rate appears undiminished.

This is the alteration to that part of the circuit which was used:

It has also been suggested that if a BUZ350 can't be obtained, then it would be advisable to protect the output FET against damage caused by accidental short-circuiting of wires, etc., by connecting what is effectively a 150-volt, 10 watt zener diode across it as shown in the above diagram. While this is not necessary for the correct operation of the circuit, it is helpful in cases where accidents occur during repeated testing and modification of the cell components.

**Dr Scott Cramton's Cell Construction.**
Dr. Cramton and his team of Laesa Research and Development scientists have been investigating and advancing this technology and they have reached an output of six litres per minute for an electrical input of 12 watts (1 amp at 12 volts). In addition, Dr. Cramton's cell has stable frequency operation and is being run on local
well water. The objective is to reduce the amount of diesel fuel needed to run a large capacity standard electrical generator.

The style of design is similar to Stan Meyer’s original physical construction although the dimensions are slightly different. The cell body is transparent acrylic tube with end caps top and bottom. Inside the tube are nine pairs of pipes, electrically connected as three sets of three interspersed pipe pairs. These are driven by a three-phase pulsed supply based on a replication of Stan Meyer’s original cell. It consists of a Delco Remy alternator driven by a 1.5 horsepower 220 volt AC motor. This arrangement is, as was Stan Meyer’s, for demonstration purposes. In a working application, the alternator is driven by the engine being supplied with the HHO gas. The 120 degree phase separation is the critical component for maintaining the resonant frequency. It should be noted that the alternator must maintain a rate of 3,600 rpm while under load.

It needs to be stressed that Dr. Cramton’s cell is very close in construction principles to Dave Lawton’s cell and the quality of construction is very important indeed. The first and foremost point which can be easily missed is the absolutely essential tuning of all of the pipes to a single, common frequency. This is the equivalent of tuning a musical instrument and without that tuning, the essential resonant operation of the cell will not be achieved and the cell performance will not be anything like the results which Dr. Cramton and his team are getting.

Dr. Cramton is using 316L-grade stainless steel pipes 18 inches (450 mm) long. The outer pipes are 0.75 inches in diameter and the inner pipes 0.5 inches in diameter. This gives an inter-pipe gap of 1.2 mm. The first step is to get the pipes resonating together. First, the frequency of an inner pipe is measured. For this, a free internet frequency-analyzer program was downloaded and used with the audio card of a PC to give a measured display of the resonant frequency of each pipe. The download location is http://www.softpedia.com/get/Multimedia/Audio/Other-AUDIO-Tools/Spectrum-Analyzer-pro-Live.shtml

The method for doing this is very important and considerable care is needed for this. The quarter-inch stainless steel bolt is pressed into the inner pipe where it forms a tight push-fit. It is very important that the head of each nut is pressed in for exactly the same distance as this alters the resonant frequency of the inner pipe. The steel connecting strip is then bent into its Z shape and securely clamped to the bolt with a stainless steel nut. The assembly of pipe, steel strip, nut and bolt is then hung up on a thread and tapped gently with a piece of wood and its resonant frequency measured with the frequency analyzer program. The frequency is fed into the program using a microphone. All of the inner pipes are tuned to exactly the same frequency by a very slight alteration of the insertion length of the bolt head for any pipe with a resonant frequency which is slightly off the frequency of the other pipes in the set of nine inner pipes.

Next, the outer tubes are slotted to raise their resonant frequency to match that of the inner pipes. Their frequency is also measured by hanging them up and tapping them gently with a piece of wood. If the frequency needs additional raising, then the tube length is reduced by a quarter of an inch (6 mm) and the testing continued as before. Adjusting the width and length of the slot is the best method for adjusting the resonant frequency of the tube. A small file can be used to increase the slot dimensions. This procedure is time consuming and tedious but it is well worth the effort. The average finished length of the outer pipes is 17.5 inches (445 mm) and the slot dimensions 0.75 inch long and 0.5 inch wide (19 mm x 13 mm).

When setting the resonant frequency of the outer pipes, it is important to have the clips in place. These "hosepipe", "jubilee" or "Terry" clips are used to make electrical connections to the outer pipes as shown in the diagrams and they do have an effect on the resonance of the pipes, so fit them before any tuning is done. The pipe arrangement is shown here:
The outer pipes are drilled and tapped to take either a 6/32" nylon bolt available from Ace hardware stores in the USA, or alternatively, drilled and tapped to take a 4 mm nylon bolt. Three of these bolt holes are evenly spaced around the circumference of each end of all of the outer pipes.

These nylon bolts are used to adjust and hold the inner pipe gently in the exact centre of the outer pipe. It is very important that these bolts are not over tightened as that would hinder the vibrations of the inner pipe. The bolts are adjusted so that a feeler gauge shows that there is exactly the same 1.2 mm gap all round, both top and bottom. The weight of the inner pipe is carried by a 3/4 inch (18 mm) wide strip of stainless steel bent into a Z-shape, and none of the weight is carried by the nylon bolts. Dr Cramton describes this Z-shaped steel strip as a
“spring” and stresses its importance in constructing a set of resonating pipe pairs. The arrangement is shown here:

The supporting springy strip of steel is shown in blue in the above diagram as it also forms the electrical connection for the inner tubes. The outer tubes are held securely in position by two plastic discs which form a tight push-fit inside the 6” (150 mm) diameter acrylic tube which forms the body of the cell. The cell is sealed off with plastic caps (ideally, the upper one being screw threaded for easy maintenance) and the electrical connections are carried through the lower cap using 1/4” (6 mm) x 20 stainless steel bolts. The bolts are sealed using washers and rubber O-rings on both sides of the cap.

For clarity, the diagram above shows only the electrical connections for the inner pipes. The electrical connections for the outer pipes are shown in the following diagram. The connections are made at both the top and the bottom of each outer pipe by attaching a stainless steel hose clamp with a stainless steel bolt attached to each clamp. The wiring is then carried across inside the cell so that all six connection points (three at the top plus three at the bottom) for each set of three pipes are carried out through the base of the cell with just one bolt, again, sealed with washers and rubber O-rings. The nine pipe pairs are electrically connected in three sets of three, and each set is fed with a separate phase of a 3-phase waveform. This sets up an interaction through the water and produces a complex pulsing waveform with each set of pipes interacting with the other two sets. The sets are arranged so that the individual pipes of each set are interspersed with the pipes of the other two sets, making the sets overlap each other as shown in the next diagram. For clarity, the diagram does not show the electrical connections for the inner pipes and it omits the pipes of the other two groups of three, the water-level sensor, the gas take off pipe and the gas-pressure sensor.

At this time, Dr. Cramton is driving the pipe arrays with the circuit shown below. It uses an AC sinewave generated by a pulsed alternator. The current fed to the motor driving the alternator accounts for about 24 watts of power while the current drive to the alternator winding is just 12 watts. It should be realised that the alternator can easily drive many cells, probably without any increase in power required. Dr. Cramton is investigating methods of producing the same waveform without the need for an alternator and while that would be useful, it should be realised that a gas output of six litres per minute for a power input of only 36 watts is a very significant result. Others have shown that it is possible to power a 5.5 kilowatt electrical generator on HHO gas alone with a flow rate of this sort of magnitude, and obviously, the 36 watts can very easily be provided from that 5.5 kilowatt output.

It is absolutely essential that the pipe pairs are “conditioned” as there will be very little gas production until the white conditioning layer is built up on the active surfaces of the pipes. As has already been described, one
method is by powering the cell up for a few minutes, and then letting it rest unused for a time before repeating the process. Dr. Cramton emphasises that at least a hundred hours of conditioning will be needed before the gas output volume starts to rise, and it will be three months before the white conditioning layer reaches its full thickness and the gas production rate increases dramatically.

Dr Cramton stresses that it is the mechanical construction which will make the difference in the gas production rate. The inner and outer pipes must be tuned to a common frequency. It is vital that the pipe pairs must be conditioned, which can be done through repeated use over a period of time. A very important alternative to this long conditioning process is coating the whole of the pipe surfaces with the insulating material "Super Corona Dope" (http://www.mgchemicals.com/products/4226.html) as this gives immediate conditioning of the pipes. When a complete set of tuned tubes has been achieved, then the electronics must be built and tuned to the resonant frequency of the tube sets. Voltage builds up on the pipes from the repeated pulsing of the low voltage circuit and the action of the bi-filar wound coils each side of each pipe set and allowed by the insulation of the pipes. With Super Corona Dope this voltage has been measured at 1,480 volts but with the insulating layer from a local water supply, that voltage is around 1,340 volts.

It should be understood that the bi-filar wound coil (that is, wound with two strands of wire side by side) generates very sharply rising, very short voltage spikes, typically in excess of 1,000 volts in spite of the electrical supply being less than fourteen volts. The coils used by Dr Cramton are wound on ferrite rods, 300 mm (11.8") long and 10 mm (3/8") in diameter. As only 100 mm long rods were available, these were constructed by placing three inside a plastic tube. The coil winding is of enamelled copper wire and to allow sufficient current carrying capacity, that wire needs to be 22 swg (21 AWG) or a larger diameter, that is, with a lower gauge number such as 20 swg. These coils are wound to give an inductance of 6.3 mH on each of the two windings.

The circuit below is the one being used at this time. You will notice that an additional pole has been added to the Gating On/Off switch so that the timing components are switched out when the gating signal is turned off. This gives added protection for the Gating 555 chip in the circuit, preventing overheating when it is running but not being used. The frequency used with Dr. Cramton’s cell is 4.73 kHz although this is not the optimum frequency for the cell. The alternator imposes a certain limitation on the highest possible frequency, but the frequency used
10 - 106

(has been shown to be the most effective and it is a harmonic of the optimum frequency. This is a bit like pushing a child on a swing and only pushing every third or fourth swing, which works quite well.)
Dr. Cramton says: “I would like people to know that the scientific community is working on these projects and this technology is now a fact of science and not conjecture”.

Dr Cramton has performed repeated performance tests on a 40 kilowatt diesel generator and the results were highly consistent, coming in within 1% each time on ten successive tests. Here is his graph of the results of this preliminary work:

![Graph of 40 Kilowatt Generator Tests](image)

The gains at full 40 kW load are about 35%, representing a reduction of 1.4 gallons of diesel per hour. As the generator is part of the equipment of a major power supplier, it is likely that the number of generators will be manipulated in relation to the demand and so the continuous overall gain is likely to be about 33% even with such a low HHO input as 6 lpm. The investigation and development is continuing.

**Bob Boyce’s High-Gain Toroidal System.**

Bob Boyce has recently released a different method for water-splitting using his flat-plate electrolyser-style construction and pulsed with just twelve volts as in the above water-splitter designs. Bob’s circuit is:

![Bob Boyce’s High-Gain Toroidal System Diagram](image)

Here, the electronics board produces three separate, tuneable, very sharp square waveforms as described in the D9.pdf document mentioned earlier. These three waveforms are integrated into a single complex waveform when each is fed into a separate high-precision, high-specification winding on an iron-dust toroidal transformer core. This signal is stepped up to a higher voltage in the secondary coil of the transformer and then applied to the electrode plates via a choke coil on each side of the unit in exactly the same way as in the previous designs.
Resonance.
Water-splitters only operate properly if are held on their resonant frequency. Stan Meyer has a patent on his electronics system which would locate, lock on to and maintain the electronic pulsing at the resonant frequency of his cell. Unfortunately, Stan's patent just gives broad outlines for the methods used.

The John Bedini battery-charging pulse circuits have been very successfully applied to water-splitter cells. Here, the cell itself is part of the frequency control of the oscillator circuit and the arrangement might look like this:

![Diagram of the oscillator circuit](image)

This idea is advocated on a YouTube video put up by a user whose ID is "TheGuru2You" where this arrangement is suggested:

![Alternative circuit diagram](image)

TheGuru2You states that he has built this circuit using a capacitor instead of the water-splitter and he says that he can confirm that it is self-powering, something which conventional science says is impossible (unless perhaps, if the circuit is picking up radiated power through the wiring of the circuit). Once a twelve volt supply is connected briefly to input terminals, the transistor switches on powering the transformer which feeds repeating pulses to the base of the transistor, sustaining the oscillations even when the twelve volt supply is removed. The rate of oscillation is governed by the resonant frequency of the water-splitter unit. Consequently, as the resonant frequency of the cell alters because bubbles form, the pressure changes, the temperature changes, or whatever, the circuit automatically tracks and maintains that optimum frequency.
Dave Lawton’s Auto-Tune Circuit.

Dave Lawton uses a different method as he has designed and built a Phase-Lock Loop (“PLL”) circuit which does the same thing that Stan Meyer’s automatic circuit did. This is Dave’s circuit:

This circuit has been used very successfully by a number of people. One experimenter had the circuit built by a friend as he is not very confident with building electronic circuits. The construction looks like this:

Capacitors are tantalum 35V. Resistors are carbon film 5% 0.33Ω. Variable resistors are presets (RadioSpare: 154-2072 and 154-2094)

Radiospares Part Numbers: LTC1049 545-5807, HEF4046BP 306-645, HEF4001B 333-3303, HEF4066BP 333-1470, 2N3904 294-312, 2N3906 294-323, 62NIF SP 194-315, 1N4148 446-9501, 1N4007 346-5997,
The two air-core coils are wound separately rather than bi-filar wound, and some experimentation with different types will be undertaken to see the effect on overall gas production. This circuit is shown in the following video, driving a 2.6 inch long pair of electrodes with a 2 mm gap between them, sitting in a test cell. The electrodes have seams and are made of an unknown quality of stainless steel and can be seen at the top of the photograph above. The video: [http://youtu.be/XMizRAYdGwA](http://youtu.be/XMizRAYdGwA) shows considerable gas production with almost no current draw and the cell staying completely cool.

Running Electrical Generators on Water Alone.
After many decades of being lied to, most people believe that it is necessary to burn a fuel (typically, a ‘fossil fuel’ such as petrol or diesel) in order to make an engine run. ‘Scientific experts’ demonstrate their ignorance by proclaiming that their calculations show that there is just not enough energy in hydrogen released through electrolysis, to provide enough power to run an engine which can provide sufficient electrical energy to perform the electrolysis in the first place.

Their calculations are completely wrong as they are based on a major level of ignorance of the real facts:

1. Ignoring HHO altogether, engines can run extremely well on environmental energy channelled through a Joe Cell as shown in chapter 9, and when doing that, no fuel at all is consumed.
2. They are not aware that properly made HHO has typically four times the energy content of hydrogen gas.
3. They are not aware that a properly built electrolyser running on DC has more than double the efficiency that Faraday considered to be the maximum possible production rate of HHO for any given current flow.
4. They are not aware that resonant pulsed electrolysis has several times the water-to-HHO conversion efficiency that straight DC can produce, resulting in more than ten times the Faraday ‘maximum’ conversion rate.
5. They are not aware that the majority of the energy produced by HHO being converted back into water does not come from the hydrogen but instead comes from charged water clusters. It is likely that they have never even heard of charged water clusters.
6. They are probably not aware that introducing cold water mist to the air entering an internal combustion engine, makes that engine operate as an internal combustion steam engine as the mist gets converted into flash-steam, raising the pressure inside the cylinder and boosting the engine efficiency very considerably.
Because of these things, the calculations of the ‘scientific experts’ produce completely wrong results due to lack of knowledge and the flawed assumptions on which the calculations are based.

Interestingly, quite apart from the fact that generators running on water as the only visible fuel, have been powering off-grid locations 24 x 7 for many years now, and ignoring that little detail, check out this newspaper comment:

**US Navy will turn seawater into fuel**

THE US Navy claims it has found a way to turn seawater into fuel, having spent decades conducting scientific experiments.

If true, the development could see military ships developing their own fuel and staying operational 100% of the time. Navy scientists say they have already used the new fuel to fly a model aircraft.

Calling it “a huge milestone”, Vice Admiral Philip Cullom pointed out that “in the Navy, we have some pretty unusual kinds of challenges.”

One of these is the need at present to refuel from an oil-tanker. But “developing a game-changing technology like seawater-to-fuel reinvents a lot of the way we can do business when you think about logistics, readiness,” said Cullom.

The US Navy has 289 vessels and most rely on oil-based fuel, apart from some aircraft carriers and 72 submarines that use nuclear power.

The breakthrough came after scientists found a way to extract carbon dioxide and hydrogen gas from seawater. The gasses are then turned into a fuel with the help of catalytic converters.

“We are in challenging times where we have to think in new ways to look at how we create energy, how we value energy and how we consume it,” said Cullom.

“We need to challenge the assumptions that of the last six decades of constant access to cheap, unlimited amounts of fuel.”

This is a very interesting comment from Vice Admiral Cullom. Firstly, he confirms that the Navy’s massive engines can be powered by gas produced by electrolysis. Second, he implies very strongly that refuelling with oil-based consumables is no longer needed, and that means that the electrolysis is well in excess of 100% efficient, making those massive engines self-powered. Third, it seems reasonable to presume that if those massive engines can be self-powered through electrolysis, that the very much smaller engines in cars could also be run on electrolysis, even if the same method of electrolysis were not used. Anyway, we have to deal with the tiny, very inefficient motors which are used in generators which normally use petrol as the fuel:

In the UK, three men managed to run a generator on water alone, using just simple things which are within the scope of the average handyman in his workshop. They bought a standard petrol-driven electrical generator off eBay and managed to run it without using any petrol. They used a HHO gas flow which they measured at just 3 lpm and they test loaded the 5.5 kilowatt generator with 4 kilowatts of equipment. Afterwards they abandoned the generator and moved on to a much bigger engine as their plans are to sell electricity to the local power company.

Their representative said: the equipment was put together by my associate, who supplied the water/electrolyte (not a standard electrolyte, 0.4% by volume). It was a 5 kW petrol generator (about 300cc). We attached a Chevrolet alternator which constantly charges a 12-volt 55 Amp-Hour battery, which in turn powers six HHO tubes, each of which draws 6 watts, for a total of 30 watts. The outputs of these electrolyseres are connected in series and they feed the gas into a low-pressure butane gas “camping” tank which has an 18 psi pressure release valve. This tank feeds the air intake of the generator which is adjustable with a choke. We loaded the 30-amp
socket of the generator with various drills, heaters etc. working, for more than four hours. The maximum load which we tried was 4 kilowatts, being a bar heater, a kettle and two drills. The electrolyser tubes are heavy-duty plastic (rated for 80 psi pressure). Inside are 4 tubes of stainless steel (3 positive and 1 negative). Each tube created 1 litre of gas every two minutes which is a total of 3 litres per minute. They eventually become warm to the touch, but they do not get hot.

Running an Electrical Generator without Fossil Fuel

In Broad Outline

In order to achieve this objective, very much like Stan Meyer, we need to feed the engine three things:

1. Air - this is fed in as normal through the existing air filter.
2. HHO gas - how to make this has already been explained in considerable detail.
3. A mist of very small water droplets, sometimes called "cold water fog".

Also, we need to make two adjustments to the engine:

1. The spark timing needs to be retarded by about eleven degrees.
2. If there is a "waste" spark, then that needs to be eliminated.

To summarise then, a good deal of work needs to be done to achieve this effect:

1. An electrolyser needs to be built or bought, although the required gas production rate is not particularly high.
2. A generator of cold water fog needs to be made or bought.
3. Pipes need to be installed to carry these two items into the engine.
4. The engine timing needs to be retarded.
5. Any waste spark needs to be suppressed.
6. Water tanks are needed for the cold water fog and to keep the electrolyser topped up.
7. Ideally, some form of automatic water refill for these water tanks should be provided so that the generator can run for long periods unattended.

If we omit the electrical safety equipment which has already been explained in detail, and omit the HHO gas safety equipment which has already been explained in detail, and skip the automated water supply details and the starting battery, then, a generalised sketch of the overall arrangement looks like this:
Here, they have opted to feed the HHO gas into the air system after the air filter (a thing which we normally avoid as it is not helpful for the HHO gas production efficiency, but the first step is to reproduce their successful method exactly before seeing if it can be improved further). Also fed into this same area is the cold water fog which is comprised of a very large number of very tiny droplets. The air enters this area as normal, through the existing air filter. This gives us the three necessary components for running the generator engine without using any fossil fuel.

Creating the cold water fog

There are three different ways to generate the spray of very fine water droplets which are a key feature of the success of this way of running the engine. One way is to use a Venturi tube, which, while it sounds like an impressive device, is actually very simple in construction:

It is just a pipe which tapers to a point and which has a very small nozzle. As the engine draws in the air/HHO mix on its intake stroke, the mixture rushes past the nozzle of the Venturi tube. This creates an area of lower pressure outside the nozzle and causes water to exit through the nozzle in a spray of very fine droplets. Some perfume spray bottles use this method as it is both cheap and effective.

An alternative method of making the cold water fog is to use one or more "pond foggers". These are small ultrasonic devices which are maintained at the optimum operating depth in the water by a float. They produce large amounts of cold water fog which can be fed into the engine like this:
A third method is to use a small carburettor of the type used with model aircraft. This does the same job as a regular engine carburettor, feeding a spray of tiny water droplets into the engine air intake. The physical arrangement of this option depends on the construction of the air filter of the generator being modified. You will notice that the people in the UK who did this, used a small gas tank with an eighteen pounds per square inch pressure release valve. This is not possible with the highest quality of HHO gas as it cannot be compressed that much. However, with a lower grade of HHO which has some water vapour mixed in with it, it is possible to have a gas reservoir with that sort of pressure in it. In this case, except possibly for starting, their gas production rate is probably not high enough to allow much raised pressure inside the tank. Obviously, the gas-pressure switch on the electrolyser and the one on the gas storage tank will have similar operational pressures.

**Some Safety Features**

Up to this point, the electrolyser has been shown in bare outline. In practice, it is essential that some safety features are incorporated as shown here:

These safety devices should be familiar to you by now as they have already been explained earlier in this document.

**The Reason for Changing the Timing**

The fuels used with most internal combustion engines are either petrol (gasoline) or diesel. If you are not interested in chemistry, then you are probably not aware of the structure of these fuels. These fuels are called "hydrocarbons" because they are composed of hydrogen and carbon. Carbon has four bonds and so a carbon atom can link to four other atoms to form a molecule. Petrol is a long chain molecule with anything from seven to nine carbon atoms in a chain:
Diesel has the same structure but with eleven to eighteen carbon atoms in a chain. In a petrol engine, a fine spray of petrol is fed into each cylinder during the intake stroke. Ideally, the fuel should be in vapour form but this is not popular with the oil companies because doing that can give vehicle performances in the 100 to 300 mpg range and that would cut the profits from oil sales.

The petrol in the cylinder is compressed during the compression stroke and that reduces its volume and raises its temperature substantially. The air/fuel mix is then hit with a powerful spark and that provides enough energy to start a chemical reaction between the fuel and the air. Because the hydrocarbon chain is such a large molecule, it takes a moment for that chain to break up before the individual atoms combine with the oxygen in the air. The main engine power is produced by the hydrogen atoms combining with oxygen, as that reaction produces a large amount of heat. The carbon atoms are not particularly helpful, forming carbon deposits inside the engine, not to mention some carbon monoxide (CO) and some carbon dioxide (CO2) as well.

The key factor here is the slight delay between the spark and the combustion of the fuel. The combustion needs to happen a few degrees after Top Dead Centre when the piston is about to start its downward movement in the power stroke. Because of the delay caused by the hydrocarbon chain breaking down, the spark occurs a few degrees before Top Dead Centre:

If you were to replace the petrol vapour with HHO gas, then there would be a major problem. This is because HHO gas has very small molecule sizes which do not need any kind of breaking down and which burn instantly with explosive force. The result would be an explosion which occurs far too soon and which opposes the movement of the rising piston as shown here:
The forces imposed on the piston's connecting rod would be so high that it would be quite liable to break and cause additional engine damage.

In the case of our electrical generator, we will not be feeding it a mix of air and HHO gas, but instead, a mix of air, HHO gas and cold water fog. This delays the combustion of the HHO gas by a small amount, but it is still important to have the spark occur after Top Dead Centre, so the ignition of the generator needs to be retarded by eleven degrees.

Engine design varies considerably in ways which are not obvious to a quick glance at the engine. The timing of the valves is a big factor here. In the smallest and cheapest engines, the engine design is simplified by not having the spark timing taken off the cam-shaft. Instead, production costs are cut by taking the spark timing off the output shaft. This produces a spark on every revolution of the engine. But, if it is a four-stroke engine, the spark should only occur on the power stroke which is every second revolution of the output shaft. If the fuel is petrol, then this does not matter as the extra spark will occur near the end of the exhaust stroke when only burnt gasses are present in the cylinder.

Some people are concerned when they think of HHO gas burning and producing water inside the engine. They think of hydrogen embrittlement and rusting. However, because of the nature of the hydrocarbon fuel already being used, the engine runs primarily on hydrogen anyway and it always has produced water. The water is in the form of very hot vapour or steam and the engine heat dries it out when the engine is stopped. Hydrogen embrittlement does not occur as a result of using a HHO gas booster.

Anyway, if we were to delay the spark until after Top Dead Centre as we must, then the situation is quite different as the waste spark will also be delayed by the same amount. With most engines, at this point in time the exhaust valve will have closed and the intake valve opened. Our very flammable gas mix will be being fed into the engine on it's intake stroke. This means that our gas supply system is openly connected to the cylinder through the open intake valve, and so, the waste spark would ignite our gas supply system (as far as the bubbler which would smother the flashback). The situation is shown here:
we definitely do not want that to happen, so it is very important that we suppress that additional "waste" spark. So, this leaves us with two engine adjustments: timing delay and waste spark elimination. There are various ways in which these can be done and as each engine design is different, it is difficult to cover every possibility. However, there is a technique which can be used with many engines and which deals with both issues at the same time.

Most engines of this type are four-stroke engines with intake and exhaust valves, perhaps something like this:

The intake valve (shown on the right in this illustration) is pushed down by a cam shaft, compressing the spring and opening the inlet port. The exact arrangement will be different from one engine design to the next. What is fixed is the movement of the valve itself and that movement only takes place every second revolution. There are various ways of using those movement to eliminate the waste spark and retard the timing. If a switch were mounted so that it opens when the intake valve opens and closes when the intake valve closes, then the switch closure shows when the piston starts upwards on its compression stroke and a simple electronic circuit can then give an adjustable delay before firing the coil which produces the spark. This, of course, involves disconnecting the original electrical circuit so that no waste spark is generated. The current flowing through the switch contacts can be arranged to be so low that there will be no sparking at the contacts when the circuit is broken again. The switch positioning might be like this:
An alternative is to attach a strong permanent magnet to the rocker arm, using epoxy resin, and then position a solid state "Hall-effect" sensor so that it triggers the delay before the spark is generated.

If the engine did not have a waste spark, then in theory, the timing mechanism of the engine could be used to retard the spark. However, in practice, the timing mechanism is almost never capable of retarding the spark to the position that is needed for running without fossil fuel, and so, some kind of delay circuit will be needed anyway.

The sort of delay circuit needed is called a "monostable" as it has only one stable state. A basic circuit of that type is:

![Monostable multivibrator circuit](image-url)

If you are not at all familiar with electronic circuits, then take a look at the beginner's electronics tutorial found in the Chapter12.pdf document on the [http://www.free-energy-info.co.uk](http://www.free-energy-info.co.uk) website as that explains how circuitry works and how to build any simple circuit from scratch. We can use two of these circuits, the first to give the adjustable delay and the second to give a brief pulse to the ignition circuit to generate the spark:
Making the HHO gas

When the generator is running, we have a ready supply of electrical energy, coming from a piece of equipment which has been specifically designed to supply large quantities of electricity for any required application. We are not dealing with the spare capacity of some low-grade alternator in a car, but we have substantial electrical power available.

Having said that, the electrolysers described at the start of this document are efficient and it is unlikely that an excessive amount of power would be needed when using one of those designs. Another convenient factor is that this is a stationary application, so the size and weight of the electrolyser is not at all important, and this gives us further flexibility in our choices of dimensions.

As this is an application where it is highly likely that the electrolyser will be operated for long periods unattended, an automated water supply system should be provided. The main details of such a system have already been covered, but what has not yet been dealt with is the switching for the water pump. The water pump itself can be an ordinary windscreen-washer pump, and we need some form of switch which operates on the electrolyte level inside the electrolyser. It is sufficient to sense the level in just one of the cells inside the electrolyser as the water usage will be pretty much the same in every cell. If you make the electrolyser in a suitable size or shape, then a simple off-the-shelf miniature float switch can be used. If you prefer, an electronic level sensor can be operated, using two bolts through the side of the electrolyser as the level sensor. A suitable circuit for this simple switching task could be:

When the electrolyte level inside the electrolyser is in contact with the upper bolt head, the circuit is switched off and the water pump is powered down. The electrolyte has a low resistance to current flow, and so it connects the 4.7K resistor through to the base of the BC109 Darlington pair (as described in Chapter 12). This keeps the two transistors switched on to the base of the BC109 Darlington pair. If you are concerned about the ZTX6533 transistor being partially on, then resistor "R" could be added, although the prototype did not need one. The value would be about 2K. When the electrolyte level falls below the upper bolt head, the first two transistors switch off, and the ZTX6533 transistor is then powered fully on by the 4.7K resistor and the 8.2K resistor in series, providing the 150 mA needed for the relay to be switched fully on. The circuit draws about 5 mA in its standby state. The numbers on the relay symbol correspond to the numbers on a typical automotive 12 volt relay. Using two BC109 transistors as the front end allows this circuit to be used with tap water if you wish. However, the water-level control for the water supply to the pond fogger or Venturi tube misting device does not need any form of fancy mechanism. The standard ballcock valve mechanism which is used with toilets is quite adequate, especially if a floating pond fogger is being used as it maintains its own optimum depth below the surface and so the overall depth is not in any way critical provided, of course, there is sufficient depth for the fogger to float correctly.

Starting:

When left for any length of time, the gas pressure inside the electrolyser will drop because the nature of the HHO gas alters. This means that there will not be sufficient HHO gas available to start the engine and no more gas will be generated until the engine drives the generator. So, to deal with this situation, a lead-acid car battery is included so that it can be switched in to replace the generator for a brief period before the engine is started. That inclusion gives this overall arrangement:
This arrangement is perfectly capable of running a standard generator without the use of any fossil fuel. It should be noted that while no fossil fuel needs to be bought to run this generator system, the electrical output is far from free and is actually quite expensive as there is the purchase cost of the generator, the electrolyser and the minor additional equipment. Also, generators have a definite working life and so will need to be refurbished or replaced.

It might also be remarked that if a generator of this type is going to be used in an urban environment, then the addition of sound-reducing baffles and housing would be very desirable. At this point in time I am aware of nine different electric generators which have been adapted to run on water. At least four of these are from different manufacturers. The method of altering the timing and dealing with the waste spark is different from one adaption to the next. One user has altered the spark timing of his generator to after Top Dead Centre by rotating the timing disc to a position not envisaged by the manufacturer. The timing disc is held in place by a locking ("key") bar which fits into a channel cut in the shaft of the engine, matching it to a similar channel cut in the disc. The alteration was achieved by cutting a new channel in the shaft, allowing the timing disc to be positioned further around the shaft, producing the required timing delay. This arrangement also makes the waste spark ineffective and so it can be ignored. While this method requires the cutting of a slot, it does away with the need for any electronics and it is a very simple solution.

If you feel that the construction of a suitable electrolyser would be a problem or that the amount of electric current needed to operate it would be excessive, let me show you the actual figures involved:

Michael Faraday was an exceptional and highly respected researcher who investigated the electric current needed to convert water into hydrogen gas and oxygen gas by electrolysis. His results are accepted by pretty much every scientist everywhere. While he expressed the results of his work in terms which would be meaningless to the average person, his result is that an electrical input of 2.34 watts produces one litre of HHO gas in one hour.

In practical terms, that means that a current of 0.195 amps at 12 volts will produce 1 litre of HHO gas in one hour. In passing, only a nearly discharged lead-acid battery would have a voltage of 12 volts as the fully charged state is 12.85 volts and a vehicle alternator produces about 14 volts in order to charge the battery.

It is easier then, to compare the gas output of electrolysers directly to the figures produced by Faraday as shown here, based on a gas output of 15 litres per minute which is 900 litres per hour:

Faraday: 900 litres in one hour, takes 2,106 watts or 100% Faraday
Boyce: 900 litres in one hour, takes 998 watts or 211% Faraday without pulsing
Boyce: 900 litres in one hour, takes 180 watts or 1,170% Faraday with pulsing
Cramton: 900 litres in one hour, takes 90 watts or 2,340% Faraday

Much of this is not very important as it has been demonstrated that a gas production rate of around 3 lpm (180 lph) is sufficient to run a generator which produces 5,500 watts. Let us assume that the measured figure is 100% wrong and that it takes 360 lph of HHO gas, plus cold water fog, plus air, to run the generator, then:

Faraday would need 843 watts
Boyce would need 400 watts without pulsing
Boyce would need 72 watts with pulsing
Cramton would need 36 watts

None of these figures are important for running a generator because with an electrolyser efficiency of only 50% Faraday still leaves a massive generator excess of nearly 4 kilowatts on a 5.5 kilowatt generator. The gain is in running a generator as an internal combustion steam engine and not in the great efficiency of the electrolyser. It is distinctly possible that the pessimistic figures shown above are twice what is actually needed, but who cares? - the facts speak for themselves, with several people scattered around the world, already running generators on water. Many different generator designs have been adapted, typically, by modifying the flywheel, filling in the keyway and cutting another one to give a spark 2 degrees after TDC. Experience has shown that the 6.6 kVA Honda V-twin petrol motor generator and the Vanguard V-twin work very well long-term when adapted to run on water only.

**Wear and Tear Issues**

A man who lives in Alaska is very experienced in the use of renewable energy sources and unconventional fuel systems. His experiences are likely to be helpful for anyone who intends to use an electrical generator, whether running on water or on a fossil fuel. He recalls the experiences of a friend:

He decided to live off-the-grid because it was going to cost him $20,000 to get connected to the grid and as his house was not that large, he decided to go the alternative route. We designed a system which would use a 4 kW inverter and have an 8 kW Briggs & Stratton generator with a 13 kW surge capacity, for back up. The system has 6 solar panels and a 24 volt battery bank with 400 amp capacity. Having long summer days here in Alaska, the solar panels have more than enough capacity for charging the battery bank on sunny days. However, but when the day is overcast or when it is winter when there are only six hours of sunlight, the battery bank does not get charged fully. At these times, the generator is used to top up the battery bank.

American generators normally have either two or four 120-volt outputs each rated at 15 amps, plus one 240-volt output rated at 33 amps. If one of the two 120-volt outputs is used to charge the battery bank, then you get left with just the other 120-volt output for any other power needs during the time when the battery bank is being charged. This is not a satisfactory arrangement as operating with one field at maximum power and the other one lightly loaded or unused, causes a field imbalance in the generator, engine crank imbalance and ring or regulator failure within six months. It also causes noisy running and excessive fuel consumption.

Run in this way, providing a 60-amp charge rate, the generator ran hard and loud for two to two and a half hours per day, and running it was costing $350 per month for gasoline. The generator failed after four months.

In order to balance the loading on the replacement generator, a 15 kVA step-down transformer costing less than $1000 was purchased so that the 240-volt output could be used to drive 120-volt equipment. A transformer to be used for this needs to have a power-handling capacity which is greater than the surge capacity of the generator. A major advantage is that the generator current is halved for any given level of equipment current drawn because the equipment is running at only half of the generator voltage.

Using this transformer made a massive difference, giving a balanced output and providing a 90-amp charging rate for the battery bank as well as having ample power to run other household equipment when the battery bank was being charged. The result was a charge time of just one hour twenty minutes per day, with the generator running quietly and smoothly. The fuel consumption also dropped to just $70 per month which is just one fifth of what it was, covering the cost of the transformer in under four months. This generator has been running now for two years without any problems at all.
The Step-by-Step Conversion of a Generator

Selwyn Harris of Australia has kindly agreed to share detailed information on how he performs the conversion of a standard electrical generator to enable it to run on water alone. The generator which he uses as an example for this tutorial is a GX4000i generator:

The supplier is AGR Machinery which is an Australian company on eBay which buys up stock from collapsed companies and resells the equipment. The supplier says: GX4000i portable type generators have smoother output power, comparable to public utility sources. Ideal for powering medium loads such as:

- Power tools - Both Single & 3 Phase
- Game consoles, Digital Cameras
- Laptops, Camcorders
- Lighting and Microwave Ovens
- Drills, Grinders
- Resistive Load Kitchen Appliances (i.e. Coffee Maker, Toaster)
- Emergency Home Back up power where 240v power is required

Also, these units are significantly quieter than others due to refined engine technology

Features:

- Commercial Grade Engine: 196 cc 4-stroke, 7 horsepower, overhead camshaft, T.D.I. ignition
- Maximum output 4.0 kVA at 240 or 415V AC (Rated output: 2.7 kilowatts)
- Quality Heavy-Duty Construction
- AVR (Auto Voltage Regulator)
- Three 240V and one 415V Protected Outlets
- 100% Pure Copper Core
- Gearless direct drive
- Robust Square frame Design
- Easy – Recoil Start
- Oil capacity: 0.7 litres
• Powder Coated Finish
• Light and Compact for easy manoeuvrability (38.5 Kg)
• Noise level: 69 dB

The first step of the conversion is to remove the fuel tank which is held in place with four bolts:

This allows access to the carburettor which is then removed as it will not be used:

The next step is to construct a pressure-release valve mechanism which will protect the equipment from damage in the unlikely event of a major, sudden rise in pressure caused by the unwanted ignition of the HHO gas mix used to power the generator. For this, parts are purchased from the local hardware store. The brass fittings are a 12mm barrel, a 12mm female T-fitting and a 12mm to 9mm hose reducer as shown here:
The PVC plastic fittings are a ½” to 1-1/4” reducer and a 1-1/4” End Cap, along with the roller ball from an old-fashioned mouse and a relatively weak compression spring to hold the ball in place during normal operation where the gas pressure is low:

These components are then assembled to produce the pressure-release valve:

The inside of the flash-arrestor looks like this:
The ball is held in place by the spring allowing the HHO to flow past it, but if a sudden increase in pressure should occur, then the ball is forced upwards, opening a path to the many holes drilled in the plastic fittings:

When the gas pressure drops again, the spring pushes the roller ball down to seal off the pressure-release holes.

However, Selwyn adds an additional spring-loaded valve to the arrangement. This one is there in case the electrolyser fails to produce a sufficient volume of gas in the event of a sudden increase in demand. This valve is marked as a “vacuum-relief” valve although, strictly speaking, it deals with reduced pressure rather than an actual vacuum. The arrangement is shown below. Please take note of the fact that Selwyn uses the Hogg style of electrolyser and that design has a bubbler built into it, so if you are using some other design of electrolyser, please be very sure to use at least one bubbler between the electrolyser and the engine, in spite of the fact that there is very little chance of the engine mis-firing and igniting the HHO gas in the electrolyser. For an engine of this size, an electrolyser which produces 4.5 or 5 lpm of HHO should be adequate.

The addition of cold water mist through a Venturi tube as shown, both lowers the engine temperature and increases the engine power as the mist converts instantly to flash-steam when the HHO gas ignites, raising the pressure inside the cylinder and boosting the power output.
Next, a piece of ¼" (6 mm) thick aluminium plate is cut and shaped to the size of the carburettor gasket which is not a symmetrical item. This is done by tracing the gasket and transferring it on to the aluminium plate, drilling the holes and then cutting out the outline shape. The edges are then filed to create a nice fit on the engine port.
The pipes, backing plate, pressure-relief, vacuum-relief, gaskets, nuts and bolts are then assembled as shown above. Most of the pressure-relief valve components shown in the photograph have been painted, which happens to conceal the different materials being used.

At this point an electrolyser of any design which can produce at least 4.5 litres of HHO gas mix per minute is connected to the intake. The electrolyser most often used by Selwyn is the Hogg design disclosed by him earlier in this chapter.
The manual Pull-start and the generator cover are now removed. It is only necessary to remove four of the bolts to take the cover off:

This is the engine with the starter pull and the blower cover removed. At “A” you can see the magnetic pulse type Transistor Discharge Ignition pick-up in its original position, bolted in place at 8 degrees before Top Dead Centre. This needs to be removed and an aluminium plate inserted to allow the TDI to be mounted in its new position. Because of the new fuel, it is necessary to retard the ignition system. This can be done in one of two ways, neither of which is particularly easy, so you may need the help of an engineering shop. The easiest way is to modify the installed ignition to Top Dead Centre. This is Selwyn’s aluminium TDI adaptor plate which he made from 2mm thick aluminium sheet:

In this picture, the outline of the fuel intake port is obscured due to it having been temporarily blocked off during the construction. The tools required for constructing these components are a drill press and a jig saw fitted with a metal blade. Selwyn used this timing alteration method on his own smaller generator which has run trouble-free
for a year. The objective is to delay the ignition spark from 8 degrees before Top Dead Centre to either Top Dead Centre or to 1 degree after TDC. This allows for a good spark on the compression stroke and when the waste spark occurs, the inlet valve has not yet opened and so there is no HHO is in the ignition area. That is to say, the exhaust valve has just closed and the inlet valve has not yet opened. This results in a good compression stroke for the HHO and does not try to send the piston backwards due to premature ignition of the gas mix. The above picture shows the aluminium plate mounted and ready to accept the pick-up. This plate needs to have air holes drilled in it in order to allow cooling air to flow over the engine fins behind it.

The TDI adaptor plate looks like this:

And as shown below, the support plate is drilled with the ventilation holes. In this photograph the adaptor plate is just resting on the support plate. Later, when the TDC timing position is established, the adaptor plate will be bolted to it using the three holes top and bottom on the white plate. This locks the timing to that setting and the timing is never changed. In 2010, when adapting a previous generator, an experienced mechanic was asked to establish the TDI plate position and he charged sixty Australian dollars for doing that.

Finally, the covers and the Starter handle need to be bolted back in place.

Instead of paying somebody else to set the new spark timing, it is perfectly possible to do that yourself. One effective method is as follows:
1. Mark the casing of the engine in a convenient location as shown in yellow in this photograph:

2. Remove the spark plug and insert a long screwdriver until the top of the piston is felt. Manually rotate the engine (clockwise for this generator as can be seen from the curved fan pieces on the flywheel) until the screwdriver is no longer pushed upwards. It may take more than one rotation to find this point accurately. When that point is found, mark the flywheel directly in line with the casing mark which you just made. This marking needs to be very accurate.

3. Continue rotating the flywheel very slowly until the screwdriver starts to go down again and mark that point on the flywheel. Again, this marking needs to be very accurate.

4. Measure the distance along the flywheel between the two flywheel marks which you have just made and then make a larger mark on the flywheel exactly halfway between your two marks. If accurately done, this new point is where the flywheel is when the piston is exactly at Top Dead Centre, which is where we want the spark to occur. This marking on Selwyn’s flywheel is like this:
5. Next comes a bit of arithmetic. The diameter of the flywheel is 180 mm which means that it's circumference is 
3.14159 x 180 = 565.5 mm and as there are 360 degrees in each rotation of the flywheel, then the outside 
edge of the flywheel will move 1.57 mm for each of those degrees.

The engine specification states that the spark timing is 8 degrees before Top Dead Centre and we want the 
spark to occur exactly at TDC, which means that we want 8 x 1.57 = 12.5 mm of the flywheel circumference to 
have passed by before the spark occurs.

6. To achieve this delay in the spark timing, the TDI needs to be moved 12.5 mm in the direction which the 
flywheel rotates. You will notice that for this major timing change, the TDI adjustment is very small, only half an 
inch.

7. When the TDI adjustment has been made, the timing can be checked using an automotive timing light 
connected to the spark plug lead. The engine can be spun using an electric drill. As the flywheel is spinning 
fast and the flash of light from the timing light is very short, it makes the flywheel mark appear to be stationary 
in spite of the fact that it is passing by very rapidly. If the TDI adjustment is correct, then the central mark made 
on the flywheel will appear to be stationary and exactly aligned with the mark made on the casing.

This is exactly what happened when Selwyn's motor had it's timing adjusted, but the important factor is to have 
the spark close to the Top Dead Centre point to make sure that the inlet valve is fully closed before the spark 
occurs. Two degrees after Top Dead Centre is a popular point for the spark with many of the existing 
generator conversions which I have been told about, possibly to reduced the loading on the piston's connecting 
rod. Here is a photograph of Selwyn's latest generator conversion having it's new spark timing checked out:
8. Most small petrol engines have the spark timing set between 8 degrees and 10 degrees before Top Dead Centre. If it so happens that you do not know what the timing of your particular generator is, then complete the flywheel marking procedure of step 4 above, but make three additional marks on each side of the TDC mark. Space those marks 1.5 mm apart as they will then make a scale which shows each degree from 3 degrees before TDC to 3 degrees after TDC. When the timing light is used, it then shows exactly where the spark occurs and if the engine had an original spark timing which was not 8 degrees before TDC, then the scale shows immediately how much further the TDI needs to be moved to set the spark exactly where you want it to occur.

The Cold Water Mist.
Getting the fine droplets of water into the engine can be done two different ways. The first way is to use a Venturi tube which generates a fine spray of droplets when air moves rapidly past a small water-filled hole. You may not have noticed, but this method has been used extensively in perfume sprays and it is very effective. Selwyn describes how he constructs a Venturi tube:

A short length of 1/4" (5 or 6 mm) diameter copper tubing is used. This is generally available as central heating supplies and if there is any difficulty in finding some, then your local garage can probably direct you to a supplier (if they don’t just give you a short length from their own supply).
The copper pipe is then heated with a plumber’s gas torch and bent very slowly and carefully to the shape shown above. Some people find it helpful to insert a length of suitable flexible material into the pipe before starting the bending – something like the coiled steel spring material used to support net curtains – as that helps to keep the copper pipe from kinking when being bent.

Next, the end of the copper pipe which will form the nozzle, is filled with silver solder and the end filed flat. Then, a small hole is drilled through that silver solder plug. The smallest possible drill bit should be used for this, although the hole may need to be drilled out to a slightly larger diameter, depending on what the engine requires (which is found by successive trials):

This Venturi tube is to be inserted into the last brass fitting before the engine, so a 1/4” hole is drilled through the brass and then the drill is removed very slowly at a slight angle, the angle of drag being down the axis length of the brass fitting. The copper Venturi tube is then inserted through the hole and positioned so that the Venturi hole is aligned up exactly with the centreline of the brass fitting and positioned exactly in the middle of the cross-section of the brass fitting and then soldered in place:
The method which Selwyn uses to block off the end of the copper tube with silver solder is to seal the far end of the tube with tape and fill the tube with fine-grained sand like this:

And then the tube is heated with the gas torch flame and the solder run into the top part of the tube. When the solder has cooled, the tape is removed and the sand removed by tapping the tube. When the hole has been drilled through the solder, air is blown through it to dislodge any remaining sand, and then water is forced through the hole. As the tube is short, any remaining sand can be removed with a pipe-cleaner or any similar slender cleaning device. The installed Venturi tube can be seen here:

The second way to introduce cold water mist into the airstream entering the engine is to use a commercial “pond fogger” which can be bought at pet supplies outlets. These have to be powered electrically and housed in their own water container. Some of the more advanced versions float on the surface of the water so that the fog-generating section is always submerged to the ideal operational depth below the surface of the water.

The generator should run well with 5 lpm of HHO gas plus cold water mist. Any design of electrolyser can be used. However, when used with rainwater, the Hogg electrolyser will draw about 1.4 amps per cell, giving a total input of about 115 watts when run on a 12-volt electrical supply. While rainwater is supposedly pure, the reality is that it seldom is and it’s ability to carry a current varies dramatically from place to place and even more widely from country to country. However, regarding the water, Selwyn says:

The water I use is treated in a special way to make sure that the electrolyser runs at the lowest temperature and amperage possible. For this, using rain water is a must and the rain water coming off a steel roof is the best.
The water is then treated by inserting a double coil of stainless steel wire into a volume of about 5 litres of water. A supply of 12-volts DC is applied to the coils, and the resulting current allowed to run through the coils for about 5 hours. This results in hot and very dirty water. The water is then filtered using a 0.5 micron filter making the water ready for use in the electrolyser. If more water is needed, say 30 litres, then leave the coils running for at least 24 hours.

I use an old 35 litre beer keg and prepare 30 litres at a time. A major reason for doing this is to remove all the solids suspended in the water so that they will not clog up the stainless steel mesh inside the electrolyser.

After the construction of the Hogg electrolyser is completed, then the stainless steel mesh electrodes need to be treated and cleaned. For this I use distilled water and fill the electrolyser enough to cover all the plates, and then add 1 packet of citric acid for each 3 litres of water used to fill the electrolyser. I got the citric acid from www.hho-research.com.au which is an Australia-only supplier and each packet has about 22 grams of citric acid in it:

The pumps are then run for about an hour after which the Hogg tubes are washed out completely with distilled water and then allowed to dry completely. This removes any residue from the stainless steel mesh electrodes, making the gas production rate much greater.

I use an ordinary car battery to generate the HHO gas needed to start the generator running, after which, a standard battery charger powered by the generator output is used to keep the starting battery topped up.

**Please Note:** This document has been prepared for information purposes only and must not be construed as an encouragement to build any new device nor to adapt any existing device. If you undertake any kind of construction work, then you do so entirely at your own risk. You, and only you, are responsible for your own actions. This document must not be seen as an endorsement of this kind of generator adaption nor as providing any kind of guarantee that an adaption of this kind would work for you personally. This document merely describes what has been achieved by other people and you must not consider it as being a foolproof blueprint for replication by anyone else.

There are YouTube videos which show generators being operated on what appears to be just HHO gas alone and while the operation does not appear to be anywhere close to full power, the addition of cold water mist would probably make a major difference to the performance, but it does demonstrate that a generator can certainly be run without using any fossil fuel. The spark circuit in the first video appears to be powered by a small mains unit, but as the generator is lighting a powerful lamp, that electrical input could almost certainly be met by the output from the generator when it is running.

**Running an Unmodified Generator on HHO**

The reason for the modification of standard generators as shown above is due to the fact that the HHO gas mix produced by an electrolyser, ignites about a thousand times faster than a hydrocarbon fuel, and because of that, the spark which ignites the fuel needs to be delayed. That mechanical adaption of the generator can be avoided if the HHO gas mix is modified so that it ignites more slowly. This can, and has been done.

David Quirey of New Zealand has been operating an unmodified generator and a welding torch on the HHO output from his 6 lpm own-design of electrolyser, for many years now. Henry Paine's US Letters Patent No. 308,276 dated 18th November 1884, states that HHO gas can be converted into a more convenient gas which is much easier to handle, by the simple process of bubbling it through a suitable liquid such as turpentine or linseed oil. Although unaware of Henry Paine's patent, David discovered the technique independently and he has extended the technology further so that the gas ignition speed can be set manually.
One important point which David stresses is that it is essential that the HHO coming from the electrolyser is passed through an ordinary bubbler containing water, before it passes through the second bubbler containing the modifying liquid. David finds that the lighter liquid, acetone, works better than the liquids suggested by Henry Paine although white spirit, carbon tetrafluoride, aviation fuel, hexane or even petrol can be used and any of them will slow the flame speed right down to that of butane. If the flame is being used for a specialist task such as jewellery making or glass blowing, then there may be an advantage in using one particular modifying liquid. Please note that the bubbler holding the acetone needs to be made of stainless steel as acetone can dissolve some plastics.

David has further modified the characteristics of the output gas by adding in a percentage of the unmodified HHO gas. Although it is actually, subtle and sophisticated, David’s overall system is easy to understand. The ratio of the two gasses is adjusted by the settings of the two control valves as shown here:

Adjusting the ratio of modified HHO to unmodified HHO allows a high degree of control over the characteristics of the resulting gas mix. Added to that, David has developed an electronic control system which oversees and manages the gas flow rate according to the user’s needs at any given moment. The result is a system which allows water and electricity to be the means of supplying a gas which can be used as a safe, general purpose fuel. If it is used to run a generator, then the system appears to become self-powered if part of the generator output is used to drive the electrolyser. It should be possible to substitute the modified gas mix for propane or butane and so operate a wide range of existing equipment for heating, cooking and/or lighting.

David runs a 4 horsepower Honda generator using this system:

The generator runs very well for David, however, I suspect that if cold water mist were introduced into the incoming air, then the power output would be increased due to the mist turning into flash-steam and providing...
greater pressure on the piston during it's power stroke. Alternatively, it might be possible to match the present performance with a lesser gas flow rate, possibly powering a much larger generator if that were a requirement.

It needs to be understood that David uses electronics which manages and controls the gas flow volume, suiting it to whatever the needs are at any given moment. Consequently, it is probable that the six litres per minute which David’s electrolyser can produce, is not actually used for most of the time. David also does welding, brazing and cutting with the same modified electrolyser gas mix which can provide adjustable flame heat and a flame length of anything up to two feet in length:

![Image of welding process]

It is a good idea to use a proven design with full control electronics. David can help here with detailed step by step construction plans and instructional videos.
You can contact David at dahq@clear.net.nz for information on what is available to help you at the present time.

When using the system for welding, David uses the mains to power the electrolyser, the arrangement being like this:

The flashback arrestors are a sand-filled design and so are mounted vertically. The gas production rate is knob controlled using this circuit:
The first part of David Quirey’s circuit acts very much like a dimmer light switch. The 230-volt AC mains is fed through an On/Off switch and then an ordinary mains fuse. The current flow on through the circuit is blocked by the BT139 triac until it receives a pulse from the db3 diac (which is a component specifically designed to feed pulses to a triac).

As the voltage builds up on the 68 nanofarad capacitor it eventually reaches the point at which it triggers the triac, which then switches on and remains on until the mains voltage drops down to zero again. The 500K variable resistor sets the rate at which the capacitor charges up, and so it controls the length of time that the triac is on in any given second (and so, the level of power fed onwards to the rest of the circuit). This happens on both the positive-going half of the AC waveform and the negative-going half of the mains sinewave voltage supply. Both the diac and the triac operate with AC and trigger either 100 or 120 times per second depending on the frequency at which the local mains runs.

The current flow is then passed to a bridge rectifier in order to convert the AC into pulsing DC and the capacitor C1 which is 400-volt rated, smoothes the resulting DC. David’s cell has a large number of plates and so, operates off the 300 volts produced by this system. The ammeter between the diode bridge and the cell indicates the current flow and so, the amount of gas being produced at any given moment.

The flashback arrestors are constructed as shown here:

Sincere thanks are due to David Quirey for freely sharing his design and experiences, and for his willingness to provide direct additional support and further details should they be needed.

**Stan Meyer’s Water Injection System.**
While the above simple adaption will work for an electrical generator which is stationary and which is designed to provide large amounts of electrical power, some of which can be used for producing HHO gas from water, it is much more difficult to run a large capacity petrol/gasoline engine continuously with just water as the “fuel”.

---

Sincere thanks are due to David Quirey for freely sharing his design and experiences, and for his willingness to provide direct additional support and further details should they be needed.
For larger engines aimed at producing mechanical output, we need a more powerful system, such as that developed by Stan Meyer of America. Although many years have passed since the sudden, highly suspicious death of Stan Meyer, as far as I am aware, his design has not been replicated, mainly because people do not understand the information which he left behind. However, recently, a man whose forum ID is "H2Opower" has helped explain what Stan meant, and much of the following description is down to his sharing his understanding publicly and freely.

Stan's Canadian patent 2,067,735 has an arrangement where the injector schematic shows the injection into the engine of three separate components:

One component is described as ionised gas and ambient air is mentioned. The second component is part of the exhaust gas which is hot water vapour fed through a limiting valve, referred to as "inert gas". The third injection component is a very fine spray of water droplets or cold water "mist". This three-component mixture is passed between high voltage electrodes and if the mix does not ignite spontaneously, then it is ignited with a spark.

One version of Stan's recommended injectors for an existing engine are shown like this:

This is a cross-section which only shows two of the three gas inputs flowing through this injector/spark plug. Each gas input has it's own feed passage which leads out between the central electrode and the circular outer electrode, and each feeder tube has it's own one-way valve to prevent the power stroke from forcing the incoming fuel back up it's feed tube.

This is only one of the ways that Stan shows that it can be done. Here is his diagram for a two cylinder engine fuel input, although it applies equally as well to any number of cylinders:
Let me stress that this is just an explanatory diagram and you do not have the intake and exhaust valves open when the spark plugs fire. Also, the pistons do not go up and down together but their movement is staggered to give a less uneven drive to the crankshaft. The point to note here is that the fuel intake is through standard valves and ordinary spark plugs are shown. However, this diagram for US Patent 5,293,857 is based on the use of an electrolyser and Stan found a way to avoid the need for an electrolyser.

For this, Stan's "Gas Processor" is a really key device in spite of it being what appears to be a fairly simple construction. It operates by pumping light energy into the fuel components. This may not sound like a big deal but it most definitely is, in fact, it is the heart of Stan's system. In addition to the extra energy, the fuel components are also stressed by high-voltage pulsed DC applied in such a way that it tends to pull the molecules apart as they flow past into the engine.

The Gas Processor is constructed from two highly reflective metal cylinders, 96 Light-Emitting Diodes ("LEDs") and a carefully adjusted high-voltage pulsed DC source. The reflecting tubes are used to make the light bounce backwards and forwards indefinitely until it is absorbed by the passing molecules. The choice of LEDs is very important as the wavelength of the light needs to be matched to the resonant frequencies of the fuel components passing by. Laser LEDs can be used but they need to be angled slightly in order for them to bounce and completely fill a section of the Gas Processor gas passage.

The operation is simple in concept. Six banks of sixteen LEDs are installed in the outer cylinder which has a polished inner surface. To see the effect of each LED, consider just one LED on it's own:

The LED light shines on to the inner tube which has a highly polished outer surface. In the diagram above, the light is shown in red, and the uppermost LEDs of the six columns of LEDs can be seen. The light is then reflected back to the outer cylinder again:
The reflected light is shown here in yellow although it is identical in wavelength to the section shown in red. This reflected light is again reflected by the outer tube and that repeats over and over again until the whole of the area between the two tubes is completely filled with the light. This will happen with just one LED, and that light will continue to be reflected backwards and forwards indefinitely if it does not collide with a gas molecule. That is the effect of just one LED, but there are six LEDs at that level, each producing light of the same frequency and reinforcing the power of each of the other five LEDs, producing a very powerful overall band of light.

The same thing happens in the vertical plane with the light bouncing all the way down the tubes, and as the LEDs at different levels generate different wavelengths, there is a powerful interaction between the different frequency waves, producing intermediate frequencies by a process with the technical name of "heterodyning":

In this diagram it has not been possible to show the way in which the reflected light from each LED interacts with the light from all of the other LEDs, but there is a complete intermixing of the beams. The LEDs are shown with greatly exaggerated size and spacing in order to give a reasonably understandable diagram.

The diagram above, barely indicates the level of light intensity inside the Gas Processor, and that is from only six of the ninety six LEDs actually installed. It is a little difficult to visualise this device, but the gas (of whatever type) flows up through a circular doughnut-shaped space between two pipes and is hammered by a very high level of light energy of the appropriate frequency. "H2Opower" believes that the optimum LED frequencies are as shown here:
and while, not surprisingly, I have not been able to find an LED supplier for these exact frequencies, most LEDs emit a band of frequencies rather than just a single frequency, so the working LEDs need to include the frequencies shown here.

The operation of the Gas Processor is further enhanced by applying a pulsed high-voltage between the inner and outer metal cylinders. This voltage stresses the molecules of the gas flowing between the two cylinders and because it is pulsed, it applies a tugging action on the molecules, tending to pull them apart:

As with all high-power free-energy systems, having the device operate in resonance is very important. If it is still available, the excellent video: http://www.youtube.com/watch?v=kQdcwDCBoNY shows what resonant circuit operation is all about. Briefly, the frequency of the driving waveform passing through winding "A" in the diagram above, is adjusted until almost no current flows through that winding. This is the same as tuning a radio to a particular radio station - in both cases, the signal at that frequency finds it almost impossible to drive any current through the winding. This would make you suspect that almost no current would flow in the output winding, but that is not the case because that current flows into the secondary winding from the local environment (after all, here is no electrical connection between the two windings, so common sense tells you that the electrons flowing in winding "A" do not flow out of the other winding). This resonant operation gives you a major energy gain courtesy of the local environment.

The objective of the Gas Processor is to modify whatever gas is flowing through it, air, water vapour, HHO, or whatever, to one of its highly charged, highly energetic states. The high voltage applied to the metal cylinders of the Gas Processor does not flow through the gas between the cylinders. Instead, it provides a very high electrostatic Plus charge on the outer cylinder and a very high Minus charge on the inner cylinder, and these two opposing charges pull the charged parts of each molecule towards themselves. The positively charged gas ions get pulled towards the Negative inner cylinder and the negatively charged gas ions get pulled towards the Positive outer cylinder. Stan uses this technique on the incoming air when he uses an electrolyser to power an engine.
However, Stan's preference is to use air, water mist and some of the exhaust gas from the previous power stroke to power his engines. This is an effective method as "H2Opower" states that he has blown part of a car engine clean through the bonnet of the car, and that indicates that there is plenty of power available from those three components (although, ideally, you want to get the timing right and not over-stress the engine!).

One thing that "H2Opower" points out is that the injectors supplied for converting any car to run on alternative fuels such as natural gas, can be adapted to be the equivalent of Stan's specialised injectors, if a pair of high-voltage electrodes are added to each injector and fed from a pulsed circuit such as Stan's "Voltage Intensifier Circuit". The arrangement would then be like this:

A 220-page "Technical Brief" from Stan Meyer at [http://www.free-energy-info.co.uk/MeyerData.pdf](http://www.free-energy-info.co.uk/MeyerData.pdf) can be downloaded free, although it may well provide you with more information than you ever wanted to know about the subject.

**Peter Lindemann's Lawnmower Running on Water Alone.**
Peter Lindemann has shown that a much simplified version of Stan's injection system can operate small engines directly on water alone. Let me suggest that it is not the water which causes the explosion, but instead, that the high-power spark causes disassociation of some of the water vapour, producing hydrogen and oxygen which then ignite, turning the remainder of the water vapour into flash-steam, making the engine operate as an internal combustion steam engine. The [http://www.youtube.com/watch?v=p3NE8P0sPS8](http://www.youtube.com/watch?v=p3NE8P0sPS8) video shows a lawnmower engine operating on a spark which occurs ten or eleven degrees before Top Dead Centre:
Developed in conjunction with the EnergeticForum, the technique is based on the Aaron/Gotoluc style of operation with the circuitry shown in this video: [http://www.youtube.com/watch?v=vOhNtRhJ5Rw](http://www.youtube.com/watch?v=vOhNtRhJ5Rw) although the “DirectHits” spark-booster shown at [http://www.pulstar.com/directhits.cfm](http://www.pulstar.com/directhits.cfm) might well make the circuitry easier. Obviously, using this technology to operate a standard electric generator would be a major objective, especially since there appears to be little need to adjust the existing spark timing much.

**Peter Lowrie’s High-Current Electrolyser System.**

Peter Lowrie of New Zealand developed an electrolysis system for use with internal combustion engines. Like the previous systems, Peter feeds a spray of fine water droplets into the engine, using a carburettor, supplied by a water tank. He also feeds in some exhaust gas and heated HHO gas, which is a technique which is almost identical to Stan Meyer’s method.

Peter also produces a very large volume of HHO gas with a most unusual method. He uses a delta-wound, GEC marine alternator (though he says that the alternator from a truck would do). He modifies the alternator by removing the diodes inside it and leading each of the three phase-windings out to his electronics. He uses each of the three phase-windings to power one electrolysis cell. He applies only 2 volts or so, to the DC winding of the alternator, which is about the minimum which allows the alternator to work.

The DC current supplied is less than one amp while the pulsed current to the electrolysis cells is much higher. When a snap-on ammeter surrounds the wires to the cells, a current of at least 800 amps is displayed. A point of particular interest is the inductor (coil) placed between the electrolysis cells and the windings of the alternator. Peter describes this as a choke out of a 3-phase industrial power supply. It is comprised of a laminated steel core with a sheet of copper wound around it. This is remarkably like the arrangement used by Stan Meyer and already described earlier in this document.

Peter has run a 1,600 cc car engine at 5,500 rpm with the gas output from his cells. He believes that his method of cascading the gas output from the cells through each other, produces a more active form of HHO gas. He also uses a heat-exchanger which allows the exhaust to pre-heat the HHO gas before it is passed to the engine (a method also used by Stan Meyer for running a car on water alone). Peter also uses impulse-operated valves to control the flow of gas to the engine as shown here:
The Use of Water in Engines.
I can fully understand someone having difficulty with accepting the idea that water can be used as part of the fuel inside an internal combustion engine. However, there is an old saying that "fact is stranger than fiction" and that certainly appears to apply in this case. First, it is essential to accept the fact that it can be an important component inside the engine, as this has been demonstrated by several different people who do not know each other and who live in different countries around the world. Second, having accepted that fact, the next step is to ask what exactly happens with the water.

I have come across an interesting document dated May 2009. I have been unable to trace its origin in order to ask permission to reproduce it here, so if you know how to contact the author, then please let me know. This is a report on an actual experimental tests on an internal combustion engine:

Ambient heat into work conversion.

**Water-steam car, simple concept:** simple Otto engine running from water mist using standard off-the-shelf ultrasonic humidifier (4 stroke diesel engine will work as well...could even perform better).

Replication log: Ultrasonic humidifier 0.25 litter water vaporisation per hour was set to 1/3 of its power. Use the water humidifier at air intake. Remove carburettor (or injection stuff if any) and filter for first. The way from duster to the engines air intake should be as short as possible to avoid the micro water droplets created by the humidifier collecting on the inside of the tube which feeds the water mist to the engine air intake. The engine used was a 1-cylinder 200 cc
electrical generator. The engine ran very slowly at first. In the case of a 4-stroke Otto engine, it is possible to speed it up using a propane cartridge. The engine then tends to "lock" into a higher rpm band, where the propane can be cut off permanently. The air going into the engine has a temperature of 22°C, while on average the air temperature leaving the engine was -16°C (a 38°C drop).

This is amazing – but this concept really does work!

You can make the car engine idle using this method. The water may need to be a bit warm. Ignition is not needed but it does facilitate the engine running. You may need to “turn the key” several times (based on this replication test). In the case of a diesel engine, you may need to replace the injectors with some kind of spark plug like on an A.E.R.O.P.S engine or use Firestorm plugs or any other stuff which is able to give the water an additional blast via plasma discharge, to increase performance further. You can make a gasoline generator work with water steam, also a lawn mower, etc.

Now – when it idles you have gone ‘over the edge’ so you need to add some more power, possible options are: adding hydrogen or HHO, preheating the water (possibly with solar energy), adding some fuel or spirit, powerful ignition or maybe some magnetic polarisation. This concept is now public and you can experiment with it on your own. Follow safety precautions and use common sense.

Do not expect high rpm results on the very first test run. Its a very basic concept which shows just one kind of transformation of environment heat into pressure and usable work. Also, do not pre-heat the engine before using it. The engine must not be hot!

A bit of physical background:

During the first stroke of a 4-stroke Otto engine, the piston moves down and sucks ambient air into the cylinder. During the second stroke, the piston moves up and compresses this air to a pressure of 25 bar (atmospheres). According to the “ideal gas law”:

\[ p \times V = n \times R(m) \times T \]

the temperature rises due to compression above its initial ambient temperature. The compression ratio of the engine will boost the temperature, typically up to 450°C to 500°C. This second stroke of an Otto engine NEEDS ENERGY FOR COMPRESSION! Now consider what will happen to microscopic water droplets contained in the air inside the cylinder. If the water converts instantly to flash-steam, then its volume increases dramatically, boosting the pressure inside the cylinder and powering the piston during its power stroke and storing energy in the flywheel.

Please note, that the water mist isn’t water vapour…it’s not a gas! It is still a liquid! The important DIFFERENCE becomes evident during the compression stroke! As the piston starts to move upwards to compress air which contains the water droplets, pressure AND HEAT, as described before, start to rise. BUT the compression itself is NOT able to raise the water temperature directly, as the water is still a LIQUID and therefore the temperature of the water isn’t affected from higher pressure! So initially, only the air temperature rises due to compression. But tiny water droplets are present inside the cylinder, and as the air temperature gets greater and greater than the temperature of the water droplets, heat starts to flow from the air into the water droplets, heating them up! But as long the water temperature does not reach its boiling point, the droplets will not expand due to this rise in temperature and they will simply keep the same volume.

So the water droplets acting as a heat-absorber during the compression stroke! Lower heat implies lower pressure, and lower pressure during the compression stroke implies ENERGY SAVING DURING THE COMPRESSION STROKE!

Please have a look at the following graph (no losses are included in the calculation):
The graph shows the pressure within a 4-stroke engine cylinder in respect of time, starting from the beginning of the compression stroke (second one), ending with the end of the power stroke (third one). The work that is needed for the compression stroke is represented by the integral of the graph, from the very left to the yellow marker. The work which is done by the piston during the power stroke is represented by the integral of the graph from the yellow marker to the very right of the graph (20,000 at the time scale).

Let's assume that engine is an ideal one (loss-less). The red graph line represents the pressure within engine cylinder, if no water is present, and no ignition occurs. The graph is symmetrical to the Top Dead Centre (the yellow marker in the middle), so we put in energy at compression and we get the same amount back during the 3 stroke (power stroke). No loss, no gain. We get plus and minus zero.

The blue graph line shows what happens, if microscopic water droplets are present. The pressure does not rise as much as in case without water droplets, because the water works as a heat absorber during the compression stroke, and this lowers the pressure as well. The shape of the graph changes, so that symmetry of the compression and power strokes isn't there any longer, resulting in a gain of energy.

Factors which affect this process include the water droplet diameters, droplet distribution, the engine's rpm which controls the length of time, the ambient air temperature, the engine's compression ratio and even the water hardness and it's physical properties. It is certainly not a simple case where you can say “more water, means higher revs giving more power”. For example, if the water droplets are too large, then there will be too little conversion to steam and insufficient power will be produced. Alternatively, if there are too few water droplets, then there may be no effect at all or the conversion to steam may take place too early to provide useful power.

The theory given here is a very simplified one, but should suffice for the first steps towards a better technology and a better understanding of the concepts of “energy from the environment”.

It is tempting to conclude that the power gained from water droplets inside an engine cylinder are caused by the water turning into flash-steam and nothing else. However, that is probably not the case, nor is it the case that energy placed in the water by the sun heating it is extracted (which does happen) and that is the only additional source of energy.

In the scientific paper entitled "Possibility of Liberating Solar Energy via Water Arc Explosions" by George Hathaway and Peter Graneau, they discovered that when they produced an electric arc discharge in cold water fog: "The principal discovery made in the past two years was that it is a collection of fog droplets in the water which explodes and not the liquid water itself. The term 'fog' is meant to include not only the tiny droplets which float in air but also larger droplets which fall in the atmosphere and would be more correctly described as 'mist'.

10 - 148
The sole explanation of the explosions so far put forward contends that the intermolecular bonding energy in fog is less than 540 cal/g, the latent heat of bulk water. The bonding energy difference is then liberated in a quantum jump when the fog is formed in micro-seconds. Summing up their experiments, they conclude that "virtually all the kinetic energy developed by the explosion must be internal water energy".

In the earlier scientific paper "The Anomalous Strength of Cold Fog Explosions Caused by High-Current Water Arcs" by N. Graneau, he comments: "The unusual strength of explosions caused by a pulsed current flowing through water plasma was first noticed in 1907 by Trowbridge in his early high-voltage laboratory at Harvard University. When he passed as arc through a spray of water, the resulting explosion was louder than in ordinary laboratory air. During the Second World War, Früngel measured the strength of water arc explosions and published his results in 1948. He concluded that they were not caused by heat and steam and freely admitted that he was unable to explain the phenomenon. In 1969, the US Bureau of Mines issued a long report on their investigation into using water arc explosions for rock fragmentation. In one experiment, the investigators at the Twin City Mining Research Centre noticed that the energy output was apparently 156% of the input. This result was reported but treated as an experimental error".

The bottom line appears to be that using cold water mist droplets in an internal combustion engine has a minimum of the following energy additions:

1. Reduction of the energy required during the compression stroke due to the water droplets absorbing some of the heat generated by the compression and so reducing the increase in air volume during the compression.

2. On ignition, the very rapid conversion of the droplets to steam, caused by their massive surface area, produces a very rapid rise in pressure inside the cylinder.

3. The internal energy of the water caused by absorbing energy from the sun before entry into the engine may well be contributed to the power generation process.

4. Surprisingly, it has been shown that under these conditions, at the moment of explosion, the water itself contributes energy, and this process is one which most people are at a loss to explain, in spite of observing and measuring it happening.

The conclusion has to be that it appears possible that an internal combustion engine could be made to operate using cold water mist as the fuel, if a sufficiently powerful ignition plasma spark is provided using something like one of Robert Krupa's "FireStorm" spark plugs described below. Alternatively, with a lesser spark from an ordinary spark plug and the addition of quite a modest amount of a gas mix of hydrogen and oxygen from the electrolysis of water, the same effect can be produced. Consequently, although it appears so unlikely to a quick glance, that an internal combustion engine could be run on a mix of HHO gas, air and cold water mist, the reality is that the process is actually based on sound scientific principles and readily understood processes.

There is at the present time, a video of a car that runs effectively on just water, using aluminium plates: http://www.youtube.com/watch?v=g_2tlnf6y_k.

5. Other Useful Devices

The Panacea series on improving engine running is highly recommended. You can view that information here: http://www.panacea-bocaf.org/fuelsaving-pollutionreduction.htm

Ted Ewert’s “Vortex” Air-Feed System.

Ted Ewert has developed and tested a very effective and simple device which can improve the running of some vehicles. This device works best with four-cylinder vehicles because the pulsed air intake of vehicles with fewer cylinders, enhances the beneficial effect.

This is a silent, simple and cheap device which enhances the airflow into the engine. This can have a dramatic effect on the performance of the engine. For example, Ted has an old Datsun 310 which has been sitting unused for years. Petrol ("gasoline") loses its lighter fractions in six months or so and that makes it far less volatile and more difficult to burn. Ted’s Datsun has gasoline in the tank which is five years old and the car will not run on that fuel with its normal air intake. However, when Ted put one of his turbines on it, it starts immediately and runs fine with that old fuel. That particular vortex turbine has been dubbed "The Respirator". The Datsun has a carburettor which shows that this turbine works well with carburettors.

Ted Ewert’s “Vortex” Air-Feed System.

Ted Ewert has developed and tested a very effective and simple device which can improve the running of some vehicles. This device works best with four-cylinder vehicles because the pulsed air intake of vehicles with fewer cylinders, enhances the beneficial effect.

This is a silent, simple and cheap device which enhances the airflow into the engine. This can have a dramatic effect on the performance of the engine. For example, Ted has an old Datsun 310 which has been sitting unused for years. Petrol ("gasoline") loses its lighter fractions in six months or so and that makes it far less volatile and more difficult to burn. Ted’s Datsun has gasoline in the tank which is five years old and the car will not run on that fuel with its normal air intake. However, when Ted put one of his turbines on it, it starts immediately and runs fine with that old fuel. That particular vortex turbine has been dubbed "The Respirator". The Datsun has a carburettor which shows that this turbine works well with carburettors.
The “Respirator”

This simple device is a vortex tube made from a short piece of PVC pipe which has been slotted and shaped. It fits between the air filter and throttle body, or carburettor, and causes the incoming air to spin at a relatively high rate, creating a vortex. Angular velocity is crucial in the formation of a strong vortex and the air entering the Respirator from the air filter, arrives at right angles to the turbine slots, giving an immediate and powerful spin inside the tubing.

Ted says: “Most people think of a spinning air mass as having no particularly unusual properties. This is not correct. A spinning air mass has some very unique and useful properties. Standard aerodynamics, and linear Newtonian physics are unable to explain the properties of a flow of air spinning at high speed. In fact, when compared to a static flow of air within a pipe, a vortex behaves in almost completely the opposite way.

All spinning objects, whether they are solid, liquid or gaseous, contain two opposing forces: centrifugal and centripetal. Centrifugal is the expanding force travelling away from the centre axis, and centripetal is the contracting force pulling in towards the centre. This concept of dual forces is key to understanding a vortex. “Modern” physics has decided that the centrifugal force doesn't exist and now refers to it as a ‘false’ or ‘phantom’ force. This illustrates how detached from the real world academia has become and why it has stagnated.

The combination of these two forces, acting together in a vortex, create some unique conditions. One of these conditions is a laminar configuration. Co-axial laminations form throughout the vortex, creating numerous layers of air spinning virtually independently of each other. These layers are separated by zones of extremely low, virtually zero, friction and this allows them to spin at different rates.

As the vortex spins faster, the two opposing forces become stronger. This further laminates the flow as well as compressing the layers. The low-friction zones allow the compressed central air mass an unimpeded pathway for it’s axial flow through the pipe. This is the reverse of the flow conditions for a straight, non-coherent air mass which has a tendency to develop friction and resistance, due to turbulence, in direct proportion to its velocity through a pipe.

Spin rate determines the degree of air compression and the linear flow rate of the mass. The faster that the vortex spins, the more it does just what we want, which is to create a dense, compressed and fast-moving flow. This is why we take the flow of air from the air box and use its speed and direction (90 degrees) to initiate the spin in our tube. This is by far the simplest and most efficient way to get the air spinning fast. The properties of a vortex are increased in step with the angular velocity. Just as a top wobbles and falls when spun slowly, so a vortex will not exhibit any strong properties until spun really fast.

As you may know, an important part of supplying air to an engine is the ability to supply a lot of air in a short burst.
This turbine creates a spinning air mass which is uniquely able to supply this air due to its virtually frictionless laminar composition and pressure built up through compression. The vortex provides compressed, dense air to the cylinder, which takes significantly less energy to draw in due to its stored inertial energy, and it's ability to move freely in the direction of it's axis of rotation.

Between engine cycles, when air is not needed, the vortex continues to spin and build up additional pressure. This spinning air mass acts like a flywheel and stores energy which is put to use on the next intake stroke. A static air flow has no such stored energy and has to be accelerated by the engine intake stroke every time air is needed, thereby wasting energy. This flywheel property is key to understanding why the vortex works as well as it does. Unless the vortex is pulsed, or modulated, no extra energy can be developed.

In a multi-cylinder car the flow of air becomes so steady that no effect is produced with just the turbine because there is no pulsing in the airflow into the engine. The rapidly rotating air within the turbine acts as a flywheel. When it is pulsed by the cylinder on the intake stroke, force is applied to the vortex as air is sucked down the pipe and into the cylinder. As soon as the intake valve closes, the pulse ends, the air stops its linear movement, but increases it's angular spin velocity. This is where the extra power is generated. While the intake valve is closed, the vortex continues to draw more air into the pipe, where it is accelerated and compressed, until the intake valve opens again.

Power cannot be accessed until the pulse ceases. In a steady flow this never happens. Force has to be alternately applied and relaxed. To help visualise this imagine a coil spring attached to a shaft. When a sharp pulse is applied to the shaft, the spring expands. Only when the pulse ceases, and the spring starts to contract does the power get translated into movement. This also applies to a flywheel. You can also see with the coiled spring that the pulse must be timed to coincide with the resonant frequency of the spring for the highest efficiency. Random pulses, or pulses that are badly timed, will not have nearly the effect that correctly timed pulses have.

The air turbine doesn't rely as much on resonance as it does on large, well spaced pulses. This is because the power of the pulse is huge in comparison to the inertia of the air. Resonance is essential for anything that has a fair amount of mass - solids or liquids. In the case of a multi-cylinder engine, the pulses become less distinct the greater the number of cylinders. A six-cylinder vehicle barely sees any gain from the turbine, and an eight-cylinder little to none. With this type of engine the vortex needs to be modulated to gain energy.

This enhancement can be done through manipulating the shape of the intake tube. A round tube gives no gain but if the tube is "egg shaped" it produces an alternate centripetal / centrifugal pulse which imparts extra energy to the vortex. Just as the Earth draws energy from it's elliptical orbit, so in the same way, the vortex gains energy with each rotation it makes through an elliptical, or egg shaped tube.

I put a slice of a smaller diameter pipe along the inner top of my tube. This small addition accomplished a noticeable increase in performance for the unit in my car. A curve in the pipe will also act like an ellipse since the rotation is compressed on the inside of the curve and expanded around the outside. Another interesting thing with the turbine is that it works much better when the engine gets hot. I notice a large increase in power in my bike as soon as the engine gets hot. This is because the heat adds energy to the vortex, just like a hurricane travelling across warm water. The heat added by the intake tube adds velocity and compression to the vortex as it spins waiting for the intake valve to open".
The vortex is created by cutting angled slots into a piece of PVC piping as shown here:

The air enters through each of six tapered slots cut parallel to the axis of the pipe. These give the air an initial spin inside the pipe and the pulsating intake of the engine, combined with the oval shape of the PVC exit T-piece, accelerates the air into a serious vortex which improves the intake to the engine, raising it's efficiency and giving more engine power.
Ted created the egg-shaped part of the final PVC T-piece by adding an extra cut section of PVC pipe to a standard T-piece as shown here:

The turbine which Ted put on his bike works outstandingly well. The torque curve is extended well below it's former efficiency range. It is possible to substantially enrich the fuel / air ratio and still maintain the same mpg results as before. When the turbine is removed, both the mpg and the engine performance go way down. The turbine adds more air to the engine. To take full advantage of the possible increase in performance, the mixture should to be enriched.

Ted also put one in his 1995 Toyota Corolla car which has an 1800 cc 4 cylinder engine and a 5 speed gearbox and he is getting over 40 mpg on the open road and the low 30s around town. Originally, those figures were 34 on the open road and 27 around town. The performance has also increased very noticeably. Another nice feature is the lack of knocking and pinging under load. Performance in the mountains at high altitude is also significantly improved.

Ted has spent only a couple of months testing and evaluating this device on his cars and bike. A problem with this device is that it cannot be run directly through a carburettor, as it can with a fuel injection system. A carburettor works with a venturi which develops a low pressure zone in the throat with respect to the float bowl pressure. A vortex has no respect for a venturi and creates it's own pressure gradient which screws up the fuel metering. Ted has somewhat solved this issue by diffusing the vortex just before it enters the carburettor. Pressure and velocity are built up before the carb then sent through a diffuser.

There is still plenty of research to do with this device. And there will be many improvements and beneficial modifications still to be made to it. Ted remarks that he does not have access to any engine test facilities and that makes it difficult for him to assess accurately the results of any design variations which he may make. Ted is hoping that someone will take his design and improve it further. There is great potential in this little piece of plastic pipe.
Cam-Timing Issues in America.
A deceptively simple way of improving mpg performance has been discussed recently in the watercar forums, and that is the adjustment of the cam settings on American cars made since 1971. This sounds most unlikely, but it is a proven fact. For example, a 2004 Jeep Wrangler 2.4 litre received a 10 degree advancement on both cams, and that gave a 70% improvement on the mpg, much more engine power and an exhaust which runs much cooler.

Over the years, one man experienced a 50% to 100% improvement in mpg over a range of personally owned cars and trucks, and the emissions were improved by nearly 90%. It is not suggested that everybody should make a cam adjustment, just to be aware that an adjustment of that nature can have a dramatic effect.

Another example: “Advancing the cam timing will make the engine run cooler. I have been messing with cam timing for about 25 years. I had a 1985 Ford Ranger with a 2.8 litre engine - it was a dog. The same engine used in the 1970 Mercury Capri had lots of power. The Ranger was a dog because the cam timing was set almost 10 degrees retarded. I gave it an 8 degree advance and the Ford Ranger came to life and hauled ass. Also, aftermarket ratio-rocker arms help a lot on late model cars. I changed the cam timing on my 1998 Chevy truck by 10

Ted has fitted a different style of his turbine to his Toyota as shown here. The turbine section is marked “PMT” which stands for “Poor Man’s Turbo”, though obviously, you don’t need to be poor to benefit from a turbine system like this which has no moving parts:
degrees. With it's 350 cubic inch engine and ratio rocker arms installed, it gained almost 90 horsepower and brought the power band lower giving more torque because the rocker makes the cam have higher lift and longer duration on the cam which makes it breath better."

Comment from a man with 25 years experience in this field: “Cam timing is when the valves open and close in relation to the crank shaft and piston movement. The number 1 piston is set at true Top Dead Centre. At this point the degree wheel is set to the front of the engine against the front pulley at the zero degrees mark and you install a pointer mounted to the engine block pointing at the zero mark on the wheel. When the crank is turned to about the 108 to 112 degree mark, the intake valve is fully opened. That is where most engines are set nowadays. This what I call retarded cam timing. The engine seems to run well but doesn't really to seem to have much low and mid-range pulling power. When racing, you would retard a cam for high RPMs, they also could breath and had no restriction in the exhaust. The power may come in at, lets say, 3000 - 6500 RPM and advancing a cam for more torque and power, that same cam may produce power at 1000 - 4000 RPM and after all, who drives over 4000 rpm on the road?”

Another comment: “Our jeep has twin overhead cams. Advancing them does not make them stay open longer, they just open and close sooner. My reason for advancing both cams was, if I only advance the intake cam, the intake would open earlier causing more overlap if the exhaust wasn't advanced. Normally the intake valve closes after Bottom Dead Centre. Just by looking at the piston, sometimes it's almost one quarter of the way up on the compressing stroke before the intake closes. By advancing the cams, the intake closes closer to BDC. This produces higher compression. Years ago, when I did this to some of the V8s, I would switch to adjustable rocker arms and a solid lifter cam. I was able to adjust the overlap by backing off on the rockers. On an engine with one cam, advancing the cam will adjust both the intake and the exhaust. Rule of thumb is: lets say most engines are retarded by 4 degrees or more, you really don't want to advance the cams more than 4 degrees advanced. I sometimes push this as far as 6 degrees advanced for improved mpg. That is a total difference of 10 degrees from 4 degrees retarded to 6 degrees advanced. This works well with low compression engines. I also don't see a need to go to a higher compression ratio. Think about it: if you had a compression ratio of 12 to 1 and the intake closes a quarter of the way up the compression stroke, how much compression will there be, compared to a 8 to 1 compression ratio where the full stroke compresses the mixture? If you had a engine that made it easy to get to the cam or cams by just removing a dust cover, like on our Jeep 4-cylinder, I would say to install adjustable timing gears. Then you could just remove the cover and play with the cam timing until you came up with the best power and mileage

Robert Krupa’s “FireStorm” Spark Plug.
The “FireStorm” plug was developed by Robert Krupa and it is an innocuous looking spark plug which can be used to replace a standard spark plug in an ordinary production engine:

![](image)

However, this plug is far from ordinary. The central electrode has been changed from a cylindrical post to a hemispherical dome, surrounded by four arched electrodes, each of which being positioned at a constant distance from the hemisphere. This allows a much greater spark area and results in very much improved performance.

The fuel/air mixture can be made leaner without any harmful side effects. If this is done using standard plugs, then the engine will run at a much higher temperature which can damage the engine. But when using FireStorm plugs, a leaner fuel/air mix actually results in the engine running at a lower temperature. Robert has measured this effect and found that under identical running conditions, the engine exhaust was 100°F cooler when using FireStorm plugs. A mixture ratio of 24:1 is used rather than the current 14.7:1 mix and polluting emissions are very much reduced by the use of this plug design. Mixtures of up to 40:1 can be used with this plug.

Robert has been awarded two patents for this plug design: US 5,936,332 on 10th August 1999 and US 6,060,822 on 9th May 2000. These show variations of the basic dual arch electrodes, two of which are shown here:
It was hoped that these plugs would go into production early in 2008 but there is no word of manufacturing starting. Robert gave Bosch of Germany a set of FireStorm plugs to test. After ten weeks of testing, their response was “This is unbelievable - we have never seen anything like this in all the time we have been building sparkplugs”. When standard spark plugs fire for a long time, the spark gap increases and the spark is weakened. Bosch ran an eight-week endurance test on the FireStorm plugs and found that there was zero gap growth. They concluded that FireStorm plugs would never wear out (which may well be why they are not yet in production - after all, who wants to manufacture something which never wears out?).

Robert’s first FireStorm plug was made in 1996 and he has encountered strong opposition to their introduction and manufacture ever since. This plug will not be popular with the oil companies as less fuel is burnt. This is probably a fallacy because, human nature being what it is, people are likely to keep spending the same amount on fuel and just drive more. For the same reason, the plug will not be popular with governments who tax fuel. The companies who make spark plugs will not like it as it does not wear out like standard plugs do. It uses less fuel and cuts harmful emissions dramatically, so it will be popular with motorists and environmentalists, if Robert can get it into production.

**Plasma Ignition.**

If any form of construction work with a vehicle is beyond your abilities, then the plasma ignition system offered through the [http://www.bluephoenixignition.com/products.htm](http://www.bluephoenixignition.com/products.htm) web site may be of interest to you. The company offers a system which can be used with any cheap non-resistor spark plugs and they claim a 40% improvement in mpg performance.

The video at [http://www.youtube.com/watch?v=gYCr4p5QDEA](http://www.youtube.com/watch?v=gYCr4p5QDEA) explains the details of the system and claims that the resulting plasma from the plugs is so powerful that it can ignite cold water mist. Also, because of the very much improved fuel burn, the engine timing can be adjusted closer to the Top Dead Centre position, increasing the engine efficiency further. The very cheap spark plugs are liable to need replacing after five thousand miles or so, but that is hardly a serious overhead. The system can be used with 6-cylinder vehicles, 4-cylinder vehicles and electrical generators with one or two cylinders, and with outboard engines.
Roger Maynard’s Water Vapour Injection System.
Fifty years ago car engines were not nearly as powerful as they are now. In those days it was quite common for a driver to remark that his car ran smoother and more powerfully on wet days. This was not imagination as water vapour drawn into the engine along with the air, turned to steam at the moment of ignition, and expanding provided additional thrust to the pistons while lowering the running temperature slightly.

This fact was utilised in World War II when units which were effective standard bubblers used with HHO boosters were added to the vehicles. Roger Maynard has built and used these units extensively since 1978, and my thanks goes to him for providing this information and illustrations.

The unit is attached to the air intake of the vehicle, between the air filter and the engine. A small diameter plastic pipe is lead from there to a glass or plastic container holding water. In the above picture Roger is using a glass Mason jar with a screw-on metal lid which has a seal. Sometimes called a preserving jar, these jars are very convenient.

The air feed into the jar is by a length of the same plastic piping and terminated with a standard air-stone or “soap-stone” as used in a home aquarium, as this causes a large number of separate bubbles. It is good practice to glue the plastic fittings to the lid of the jar, but this can make the jar too airtight and if that happens it may be necessary to remove the rubber seal which is around the neck of the jar.
A glass jar has the advantage of not being affected by the heat produced by the engine. This is a very simple unit and it uses ordinary water which is not exactly a hazardous substance. The effect of using it is far greater than would be imagined. On Roger's 4-cylinder KIA car, the mpg rose from 320 miles per tank full of fuel to 380 miles around town (18%) and 420 miles on the open road (31%) which is a very marked improvement. On his 6-cylinder Tacoma shows an 8% increase around town and a 12% increase on the open road. The water is topped up every 1200 miles or so.

However, some engines are suited to the air-stone and some are not. Smaller engines may work much better if a stainless steel screw is used instead of the air-stone:

Just to clarify the operation of the device:

![Diagram of air-stone device](image)

The container has a plastic elbow connection in the lid through which the outside air is drawn into the container. The air flows down through a plastic tube to either an air-stone from a pet shop, or a loose bolt in the end of the plastic tube. The air-stone has many small holes in it and these break the incoming air up into many streams of small bubbles.

There is a second elbow in the lid and the air, which is now very damp, is drawn out through it by the reduced pressure in the normal air intake of the engine. The lower pressure there is caused by the intake strokes of the engine and the air going to the engine now comes from two sources – the normal path through the air filter, and the new path through the bubbler. Most of the air flows through the air filter as normal, but there is now a small percentage which flows through the water, adding cold moisture to the airflow.

Some people feel that this couldn’t possibly make any difference, but experience has shown that the addition of this extra stream of damp air can and usually does have a beneficial effect, improving the mpg, making the engine run a little cooler and generally improving the operation of the engine. It is a very simple low-tech device which does not cost much, so if you feel inclined, then try it out and see what effect it has on your vehicle, after all, if it does not provide a useful improvement, then you can easily remove it.
“Fuelsavers” Streamlining Fins.
A similar system used to be on offer from the website [http://www.fuelsaver.com.au/](http://www.fuelsaver.com.au/) where they offered small aluminium fins which mount on top of the trailing edge of the bodywork of a vehicle. The devices are reckoned to save some 10% to 12% on fuel consumption, they can be home-made, nine per vehicle is the recommended number. The device and mounting look like this:

[Image of a “Fuelsaver”]

Robert Patterson’s “Ram Implosion Wing” Streamlining System.
The next device may not be a “free-energy” device as such, but if not, it is very close to being such. It is a structure, which when mounted on top of a motor vehicle, improves the airflow to such an extent that the fuel consumption is said to be reduced by a major factor. The device was invented by Robert Patterson and is said to create a vortex which not only decreases wind resistance but may also create a forward propulsion force.

[Image of the Ram Implosion Wing]

It is claimed that the effect created by one of these wings reduces the amount of dust stirred up when driving along a dirt road and if there is a paper bag sitting in the middle of the road, it is left unmoved when the vehicle passes over it at high speed. About a dozen people are testing this device at the present time. The biggest effect is at speeds of 60 mph or more. One researcher states that he installed the wing on the roof of his Lincoln Town car using a roof rack which allowed the wing to hang over the rear window by some six inches. He states that his fuel consumption has improved from 17 mpg to 56 mpg.

Positioning of the wing, texturing of the wing surface, and the speed of the vehicle appear to be important factors in gaining an improvement. There is a research group and the website is: [http://www.pureenergysystems.com/news/2005/03/08/6900067_RamWingUpdate/](http://www.pureenergysystems.com/news/2005/03/08/6900067_RamWingUpdate/)

High-mpg Carburettors.
The very poor mpg figures produced by most US vehicles is a quite deliberate arrangement forced on drivers by the oil companies. In 1997, an engineer working at a US Ford company plant witnessed a 351 CID V8 started at about 4:30 pm. with a 1 litre bottle of fuel as an exactly measured amount. The next morning when he went to the factory floor, that engine was still running and had only consumed about one third of the one litre bottle. On asking about the fuel consumption, he was shown a display that read, “248.92 mpg”. He was shocked and said, “This must be a mistake” but the engineer said that it was true. He then asked when they would have it ready to be put in a new Ford, he was told that he would not see it in his lifetime. This is company policy and has nothing to do with engineering which is easily capable of this level of performance. That 249 miles per US gallon is 298 miles per European gallon since the European gallon is 20% bigger than the US gallon.
There have been more than 200 patents granted for high-mpg carburettors. These designs all give between 100 and 250 mpg on a US gallon of fuel. Not a single one of these designs has made it to the marketplace due to the fanatical opposition of the oil companies. Last year, the Shell oil company posted typical earnings for the year, which showed that they had made US $3,000,000 profit per hour for every hour of every day of the entire year. Did you enjoy contributing to that profit every time you bought fuel to burn?

Nearly all of these high-mpg carburettor designs convert the fuel to vapour form before it enters the engine. There is no magic about this performance, just good engineering practice. It will probably come as a great surprise to you that the oil companies now put additives into the gasoline sold in the USA. They have 103 varieties of additives and I expect that they will explain that these are used to reduce evaporation in summer (as if they care about that!) and combat freezing in the winter. An “unfortunate” side effect of these additives is that they clog up any carburettor which converts the fuel to vapour form. Instead of 200 mpg, it is now quite common for US vehicles to have a 15 mpg performance and that effectively increases the cost per mile by more than ten times.

I am confident that it would be possible to design a high-mpg carburettor which deals with the additive sludge left over when the fuel is converted to vapour. In passing, the present situation gives added encouragement to stop burning oil-based products and switch to electric, compressed air, or water-powered vehicles. That is a perfectly viable option technically, but it would create frantic opposition from the oil companies and most governments which raise massive revenues from taxing oil products. The energy problem is not technical, it is financial and political.

Bob Boyce in America was handed a 3.5 year jail term for “running a vehicle on an unapproved fuel”. Bob was testing a car engine on HHO in his workshop behind his house and not on the road. Bob beat the charge in court. Since then, Bob has been told by the US Military that it is ok for him to build and use HHO boosters but he must not run a car on water alone. Guess who gives the US Military orders. Guess who does not care about the American people. A book on building your own high-mpg carburettor written by Larry D. Wagner can be downloaded from http://www.free-energy-info.com/Wagner.pdf but please be aware that thirty years has elapsed since it was written and gasoline in the USA is liable to be contaminated by additives which were not used thirty years ago and so, some variations may be needed. Wagner remarks that Pogue said that the new additives prevented him getting the same high mpg figures that he used to get.

In the Appendix, you will find eight out of the many high-mpg carburettor patents. The most famous of these are the three patents by Charles Pogue:

www.free-energy-info.com/PatCarb1.pdf
www.free-energy-info.com/PatCarb2.pdf
www.free-energy-info.com/PatCarb3.pdf

It would never have occurred to me that a carburettor could be used for anything other than feeding an engine, but a very experienced and practical man who lives in Alaska has used them for other things. He says:
I started out in 1976 when the first oil crunch came along and the Pogue system seemed to make the most sense at the time. We were looking to get a system started for making alcohol fuel and we were looking to develop a continuous-batch alcohol plant. This can produce feed for animals, fertilizer for the farms and fuel for vehicles or houses. It was based around growing barley and as barley is not good animal feed when grown, it needs to be cracked in some form and it was learned that this was a suitable method which had been used throughout Europe in ancient times. Two years later, the state passed a law banning alcohol fuel production. However, some of us wound up making heaters to use the alcohol produced in this way and those heaters were very efficient and they helped a lot of people, so something good did come of it anyway.

It was about this time that I met a man who had done research on the Pogue carburettor for the Sun oil company in 1928. He was very knowledgeable and helpful and in his 80's at the time. He agreed that going to alcohol, would be a better idea as it would solve many of the problems which had been engineered into gasoline fuels.

If you look at present day engines, they are as far as possible from what is needed for using this method. High compression engines will fire from heat generated under compression before top dead centre and will knock the top out of the pistons as it is an explosion rather than a burn. So, low compression engines are preferred, and firing at least 10 degrees after top dead centre. A long-stroke engine is best and some added flywheel weight increases the engine power. The incoming air needs to be pre-heated to reduce the amount of heat drawn from the combustion by the nitrogen in the air. It is the nitrogen heat content that suppresses the burn of any open fuel.

The GEET system is very similar to what we did with a few exceptions. We heated a small amount of fuel using an electric element, converting the fuel to vapour, pressurising it using the exhaust which made controlling the amount of vapour much easier. All the rest is basic GEET or Pogue.

There are many devices which I have made over the years, including the Pogue carburettor which can get very good energy efficiency from burning fuels. It is used by many industries from smelting furnaces to trains for transporting goods but it is not used by car manufacturers.

I like to study industry, because they use what works in the real world, even if they refuse to share the knowledge with others. Our group built a few metal smelters for cleaning aluminium and casting ingots. They use waste oil and roar like mad, smelting 50 lb engines in 15 minutes or less, burning less than a pint (half a litre) of oil to do it.

**Allen Caggiano**

If you think that this is exaggeration, take the case of Allen Caggiano whose high-mileage carburettor patent and constructional details are at [www.free-energy-info.tuks.nl/Caggiano.pdf](http://www.free-energy-info.tuks.nl/Caggiano.pdf).

Allen is an inventive and stubborn man not readily blackmailed or browbeaten. In 1978 he produced the design for his first high-mileage carburettor, assembled the prototype and installed it in a 1973 Dodge Coronet station wagon. This gave spectacular results of 111 miles per gallon. Unfortunately, it failed after a short time. In 1979, he installed the second generation device on a 318 cubic inch (5.2 litre) Dodge V-8 engine and called it the “FIVS Gen II” standing for “Fuel Implosion Vaporisation System Generation 2”. This second prototype proved very reliable and produced results as remarkable as the first, getting as much as 113 miles per US gallon (European gallons are 20% larger than US gallons so 113 miles per US gallon is 135 miles per European gallon).

The installation of the ‘FIVS Gen II’ required modifications to the carburettor and the removal of the catalytic converter. This was prohibited by EPA regulations. It was therefore a violation of Federal Law. Al ignored the
regulations because he knew tail pipe emissions from his FIVS vehicle were much lower than the law required. He was upholding the spirit of the law, and he was willing to argue his case in court if it came to that. He wanted a confrontation, he wanted a chance to tell the world that his FIVS made pollution control devices obsolete. He painted the station wagon bright yellow and in bold black letters along the sides he wrote: "This Car Gets Over 100 Miles Per Gallon and Doesn't Pollute the Air".

On the third day of his new campaign, as Al got into the station wagon he noticed a car pulling up behind him. He got out to greet two men in suits flashing FBI credentials. While he spoke to one, the other slipped away, climbed in to his station wagon, and drove it off. Astonished, he turned to watch his vehicle going down the street. Then he heard the FBI car pulling out behind him. Al just stood there watching the two vehicles disappear around the corner. An old friend, his attorney, later called the FBI office. The FBI denied any knowledge of the incident. Angry and frustrated, but undaunted, Al said good-bye to the Dodge Coronet, and found another similar Dodge station wagon and set to work installing another FIVS system. He painted this one yellow, too, with bold black lettering.

Not long after the first car was stolen, he received an interesting offer from a California based corporation. This corporation wanted to purchase exclusive rights to his FIVS Gen II. Al asked his attorney to check it out. The corporation turned out to be a subsidiary of several other corporations, all of which were owned by an oil company. This arrangement is typical of the way contemporary monopolies are structured. Al had been doing some reading about other inventors in the past and other fuel saving devices that had never seen the light of day and he was determined that he would never allow the oil companies get control of his device.

After he refused the offer, two different FBI agents came calling. He was careful not to leave keys in his unattended vehicle this time. They informed him that he was violating Federal laws and should cease and desist. Defiant and excited that he might soon make his case in court, he told his wife, Deb, not to worry. A couple of weeks after the second FBI visit, unmarked brown paper envelopes began arriving, containing 8" x 10" photographs of the children and Deb. A child on the playground at school. A child getting off the school bus. Deb in the supermarket, and so on. She was terrified and the marriage broke up.

The FBI was behaving like the Mafia. He wrote on the side of his Dodge: "The Big Boys Are Trying To Make Me And This Car Disappear! HELP ME!". One his oldest friends, his attorney, who was like a brother, refused to have anything else to do with him: "Wake up!" his attorney said, and then abruptly hung up the phone.

The Feds weren’t going to give him his day in court to defend his FIVS. They had stolen his first prototype vehicle and they knew it worked as claimed. He had refused to relinquish his control, so they were going to send him to prison, but not for violating federal emissions regulations. On the face of it, the Environmental Protection Agency appears to be imposing regulations on the auto makers and the oil companies in the public interest of protecting the quality of the air we breathe, and the quality of the air we breath is improved over what it used to be. But in fact, these special interests often write the legislation themselves. The regulations then create a profitable new area of business which allows the special interests to increase their control over the market. The public interest is best served by creative innovation in a free market. Al was learning Politics 101 the hard way. In the business of vehicles and oil, there IS no free market. In a monopoly-controlled market, there are anti-competitive regulations, dirty tricks, and active suppression. The Big Boys protected their turf and took control of or destroyed any potential competition in the hallowed tradition of John D. Rockefeller Snr. and the Robber Barons of the past. That wasn’t hard to understand. But he was unprepared for the sophisticated tactics of today’s faceless Robber Barons.

The Chief of Police for Brockton, planted stolen cocaine in Al’s home during a drug raid that ultimately put Al in prison in 1986, for 15 years on a cocaine trafficking conviction, in spite of the fact that Al didn’t use drugs, nor associate with those who did. He fought back. In prison, he fashioned a key in the prison shop and simply let himself out. He contacted a friend on the police force and then turned himself in on the same day. This police officer friend was able to uncover evidence of the chief’s corruption. Two days later, the Chief was arrested for stealing cocaine from the evidence locker, most of which he had taken home to feed his addicted wife. He went to prison himself, which led to the reversal of over 300 drug convictions that had been decided during his tenure. The Massachusetts Supreme Court of Appeals overturned Al’s conviction. For a moment, he thought he’d beaten the Big Boys and was a free man again.

But then the Federal Prosecutor stepped in and indicted him on new charges relating to the seizure of two shot guns during the phoney drug bust. A spurious interpretation of the US Code was applied. Al was sentenced to a total of 30 years in Allenwood Federal Prison, without parole.

Al’s time in Allenwood was not wasted in self-pity or bitterness towards the Big Boys or the corrupted system that put him there. He was popular in Allenwood right away because of his role in exposing the dirty cop that overturned so many drug convictions. He developed a good relationship with the warden of facilities. As a licensed HVAC contractor, Al was able to fix the prison heating and cooling system that had never worked
properly, saving the government a large amount of money. Honeywell Corporation trained him in the use of computers so that he could operate and maintain the system. The prison had an excellent machine shop which allowed him to continue working with his FIVS devices. He designed small FIVS for the prison lawn mowers and produced numerous FIVS GEN II's, with the collaboration of the warden of facilities, that were secretly distributed outside.

Al made many useful contacts, one of whom helped him secure US Patent 5,782,225, awarded July 21, 1998, for the FIVS Gen II. He designed a new FIVS, the "Gen III", which did not violate any Federal regulations, and he put together a plan to manufacture and distribute the Gen III. And then one day he was out, free for real in 1997. Sentenced to 30 years without parole, he was suddenly released after ten years with five years parole. The Federal appeals court had finally ruled that his possession of two shotguns was legal and that it had no jurisdiction over the matter in the first place. Several years later, because he was curious, he asked a police officer friend to do a background check on him. No record of his conviction and incarceration in Allenwood was found. The stain of systemic corruption had been discretely removed.

He didn't look back and went to work to develop a prototype Gen III device, applied for his new patent, and implement the strategy he had dreamed up in prison. He was no longer politically naive, no longer the blindly patriotic American he'd once been. He did not believe it would be possible to build the Gen III in the home of the brave and the land of the free, so he made arrangements to manufacture parts in the Ukraine, a former satellite of the defunct Soviet Union. He would then assemble the devices in Mexico. He had developed a global perspective in Allenwood. His network of supporters and investors was now called: "FIVS Gen III International" and he set up a website which was generating 70,000 hits a month from all over the world. He also offered the complete blue prints for manufacturing the earlier FIVS Gen II as a free download from his site so that anyone who wanted to could build their own. He thought this might distract the Feds and tie up their manpower as he implemented the Gen III strategy.

By 2002, the delivery date for the first beta testing group was set. The parts were shipped from the Ukraine to Mexico where they were assembled. It was necessary for Al to travel South of the border to oversee the operation. He made the punishing drive from Massachusetts to Mexico several times in his FIVS equipped Pontiac Catalina and it functioned flawlessly, delivering more than 70 mpg with its 400 cubic inch engine. His friends warned him not to drive alone, but he made the last trip by himself and on the return leg of the journey, he noticed an 18-wheel truck following him. The intentions of this truck were soon obvious when it overtook him and forced him off the road. Al anticipated the manoeuvre, however, and was able keep control of the Pontiac. He breathed a sigh of relief and continued on, believing he'd outwitted them once again. He made it all the way to Massachusetts and was nearly home again before the truck found him a second time and caught him unawares. The Pontiac rolled over several times, but landed upright. The driver's side door was crushed and the roof caved in, but the car still ran and Al was able to drive it home without further incident in spite of his injuries. He had to be cut out of the car with a torch. He had several broken ribs and a punctured lung and was immediately rushed to hospital.

The Gen III's for the first group of licensees were shipped from Mexico on time, however, by means of several different shippers. Some devices for US licensees were shipped via United Parcel Service. A total of 137 units were shipped around the world. Only those that went UPS in the continental US and Canada, a total of 44 units, did not arrive at their destinations. Every shipped item has a tracking number, of course, and when Al inquired about the missing 44 units and provided the tracking numbers he'd been given, he was informed the numbers he had did not exist.

The attempt to turn him into road kill was not completely unexpected, but Al was shaken just the same. He maintained his bravado, however, while friends and sympathisers reacted more predictably. When the intent of the suppression escalated from malicious to deadly, most began to slip quietly away and it was 'High Noon' again. Another complicating and aggravating factor was the appearance of a discussion group at the Yahoo website called “Get 113to138mpgNOT”. This Yahoo Group was established by an individual calling himself "David Another complicating and aggravating factor was the appearance of a discussion group at the Yahoo website the suppression escalated from malicious to deadly, most began to slip quietly away and it was 'High Noon' again. Another complicating and aggravating factor was the appearance of a discussion group at the Yahoo website called “Get 113to138mpgNOT”. This Yahoo Group was established by an individual calling himself “David

Al was fully recovered from his “accident” by this time and had repaired the Pontiac. He was feeling every day of his 59 years, but he soldiered on with a grim determination towards whatever final confrontation awaited him. When a careful, bloodless voice on the phone proposed a compromise one day, he felt ready to bargain. His website was experiencing growing traffic. The voice told him that if he would just remove the Gen III from his site he would be left alone. It felt like a small victory, but he didn’t relish the idea of backing down. If Gary Cooper had received such an offer in High Noon, he would have taken it.
He knew a bargain with the devil could never work in his favour, but he had to catch his breath, so he played along and removed the Gen III from his web site. It was a strategic retreat. If they would leave him alone, the beta testing of units already out there could go forward. The program was smaller than he had originally intended, but it was a start and if he could relax and gather his data, then he might ultimately win the game. However, a careful examination of the FIVS in his Pontiac one afternoon made his heart jump into his throat. He found a tiny hairline crack in the aluminium/titanium alloy canister. This Gen III unit had many thousands of miles on it. It presaged a potential disaster and he immediately notified all the licensees of the problem and recalled the units. He worked feverishly and discovered that he didn't have to redesign the canister. A simple alteration appeared to be the solution.

Al was then told that he required immediate surgical treatment. After the fact, this prognosis was shown to be false. While the surgery was underway, Al suffered a stroke. His heart stopped and he was technically dead on the operating table. In addition, the surgeon had damaged nerves in his spinal column. It was not his time to go, however, and he revived, but then lay in a coma for 30 days. When he finally came around in his hospital room, feeling more dead than alive, he was astonished to discover that he could not move his legs. It is possible, that Al's medical experience was not accidental.

On the local TV noon news on a sunny day in the spring of 2003 he watched a dramatic live report of a SWAT team in action. They were closing in around a familiar looking building. He thought to himself: "Hey! That's looks like my condo! Hey! That IS my condo!". He watched the police seizing his yellow Pontiac in the parking lot as the Channel 7 reporter explained that Chelmsford, Massachusetts, resident, Allen Caggiano, had defrauded investors in a fuel saver scam and then fled the country. He didn't see how that could be true since he was in the Intensive Care ward of the local hospital, not 20 miles away.

Meanwhile "David Rodale" at Yahoo Group "Get 113to138mpgNOT" had found 20 disappointed Gen III licensees and was patiently building consensus for legal action at the state level in Massachusetts. It wasn't easy to turn disappointment into outrage and a desire for revenge. In spite of the resources available to the Big Boys, they hadn't been able to otherwise identify most of the testing program licensees. Al returned home to his condo to find his Pontiac with the repaired Gen III's in the trunk gone from its parking space. His premises had been ransacked, his computer hard drives removed. With his mind foggy from pain killers, Al tried to concentrate on getting used to a wheelchair. Nurses from the Visiting Nurses Association were with him around the clock. Gradually he stopped using the pain killers. He began to notice sensation returning to his legs.

Even as he felt himself improving, his diabetic condition inexplicably worsened. Twice he was rushed to the hospital in a comatose state. The third time this happened, a nurse checked his pill box and discovered insulin pills that should not have been there. He was now taking insulin through injection, but the old insulin pills were still in the medicine cabinet and had been put in his pill box with his other medications. The result was insulin shock. The nurse, Michele, who had done this, not once, but three times, did not again appear for her shift. Al tried to reach her to ask for an apology for her mistakes, but she had vanished. The Visiting Nurses Association denied having any record of her employment.

"David Rodale" was having success convincing the disappointed licensees to file suit, and with the newly acquired information about the FIVS Gen III International operations taken during the SWAT assault, a postal inspector launched a preliminary inquiry into the feasibility of action at the federal level for mail fraud. Rodale was confident that the threat to society posed by Allen Caggiano was now neutralised. He announced to the Yahoo Group members that he'd done his best and there was nothing more to do. He would leave the Yahoo Group in place for a while, but he planned to take it down in a couple of months. He was sorry that so many people had been taken in, and he hoped they'd be less gullible in the future. He was glad he could help.

That summer, the judge dismissed the charges against Al in the Massachusetts court. His lawyer petitioned for the return of his property, the Pontiac the local police had seized a year earlier. He was told it had been taken to Washington, DC, and was being examined to determine if it violated any Federal regulations. A grand jury in DC was convened to investigate the Federal charges of mail fraud, but it failed to return an indictment. The licensees who had paid their money and signed their licensing agreements had agreed to assume the risks of a testing program and most of them did understand that part of the risk involved the historical efforts of the oil/auto cartel to suppress new technology that could affect their profitability or control over the markets which they ruthlessly dominate.

Through his attorney, Al received an offer for exclusive rights to the Gen III. The amount of money involved beggars belief, and suffice it to say that Al again refused, as he had done in the early 80's when an offer was made for the Gen II device. The Big Boys have never attempted to prosecute him for the violation of Federal Emission Control regulations. He is clearly guilty on this score so far as the Gen II is concerned. To do so would result in the exposure of the fraud they are perpetrated on the public. Their technology is obsolete. As Al has pointed out on his website, they do not want a reduction in the demand for oil. This would mean a reduction in oil company profits. If the consumer used half or less of the oil now being used, government tax revenues would be

10 - 164
reduced accordingly. If the Gen III were to become available the public interest in fuel economy and clean air would be served and Allen Caggiano would become rich beyond wild imaginings, but the oil/energy cartel and its partner in government would suffer. Therefore, the Big Boys will continue to do all that they can to stop Al and his FIVS and to keep the public ignorant of any technology they do not themselves control. If they don’t control it, and if you don’t buy it from them, then it doesn’t work, or it’s a fraud.

The “FIVS Gen III International” enterprise has been successfully suppressed. Al’s fight to manufacture and distribute his invention and enjoy the great wealth it would have given him is over. The Big Boys have broken his bank, and his health. The struggle has nearly destroyed him. The money would have been nice, but it never was the money that kept him going. He is now donating his work of a lifetime to the American people. The Big Boys can harass, intimidate, and attempt to kill one man and his American Dream, but can they do the same to many thousands of Americans and others around the world? Al now gives away his “FIVS Gen III” plans free.

Al will allow his patent application for the Gen III to expire. He can no longer afford the large investment required for a patent here and in other countries. His main concern now is to prevent the FIVS from being patented by anyone and to keep the device “open source”, so to speak, so that it cannot come under the control of the Big Boys and will remain freely available to the public. Though Al will not profit from his invention through licensing fees or royalties, there is considerable satisfaction for him in knowing that the Big Boys have not and will not ultimately win this game and destroy the work of a lifetime.

**Fuel Vapouriser Bubbler.**

There is one technique originally from [www.alternativefuelsnow.com](http://www.alternativefuelsnow.com) and reproduced here by kind permission, which appears to be effective in spite of the additives. The method is very much like the technique used by Roger Maynard for adding moisture to the incoming air as described above. The difference is that instead of using water in the container, petrol is used. Improved performance of up to 60% has been achieved and experiments are continuing. The general arrangement is like this:

![Fuel Vapouriser Bubbler Diagram](image-url)
You will notice that the fuel level inside the container is kept fairly low in order to allow considerable space to contain the bubbles, allowing them to pop and not be drawn into the air tube which feed the engine.

**Vortex Fuel Reforming.**

This is a very important technology which has been around for more than a hundred years. The objective is to increase mpg not just by the vaporisation of the fuel but also by "cracking" the water / fuel mixture into smaller molecules before being fed into the engine. This is more advanced than the fuel ‘conversion-to-vapour’ technique of the high-mpg carburettors. To get a better understanding of this, you can try a Google search for "fuel reformer" or "steam reforming" which will provide additional information which may help you to understand the basic principles.

The fuel-reforming method can be highly effective and its effectiveness has been proven beyond all doubt with designs from Cal-Tech, Philips Petroleum, Nissan Motors, NASA, universities and other very serious contributors. Some years ago Cal-Tech spent millions proving that on board fuel reformers would give us all better fuel economy and cleaner air. They did long-term testing on buses and cars to provide proof. They teamed up with the very large auto-parts supplier Arvin Meritor to put them in production vehicles. Then "One Equity Partners" bought out Arvin Meritor's division that did all the final work to get fuel reformers in all our vehicles. They created a new company, EMCON Technologies, and that company dropped the fuel reformer from their product line, not because it did not work but because it did work.

There are various techniques for achieving this process. One which is easy to understand is shown here:

Here, the standard exhaust pipe is given a kink to move it clear of its normal run in order to allow an extra straight pipe of smaller diameter to be positioned inside it so that the hot exhaust gases are used to heat the incoming fuel.
flow. This is a useful energy gain as it uses some of the waste heat, raising the overall efficiency of the engine very considerably.

This extra fuel-flow pipe has a solid magnetised ferromagnetic metal rod mounted inside it, blocking off most of the pipe area. This change in available flow area causes the fuel flow inside the pipe to speed up, and as well as that, it causes the flow to spiral around the rod in a vortex flow:

![Vortex Flow Diagram](image)

However, the magnetism of the solid rod, causes a most unusual effect and instead of the helical gas flow being as shown above, a highly uneven flow pattern is created. This causes the fuel flow to bunch up in the centre of the tube, generating a hot spot which creates quite unexpected results:

![Flow Bunches into a Hot Spot Diagram](image)

The really incredible result of this peculiar effect is that the fuel mix exiting from the tube, contains chemical components which did not enter the tube - impossible according to present day physics. This goes to demonstrate once again, that we really don’t yet understand the world in which we live.

The fuel mix for use in this system is best provided by two tiny carburettors, one feeding a fine mist of water droplets and the other a fine mist of fuel droplets. These are fed directly into the intake of the fuel reformatter tube. These carburettors are of the miniature type used for radio control model aircraft and their venturi intakes are blanked off with a plate with a small hole in it. Air is not fed into the reforming tube – after all, this is a fuel reforming system. The air is mixed in with the reformatted fuel after it exits from the reformatter, as shown below. Some of the hot exhaust gas is fed into both of the carburettors in order to help prepare the mixture for the reformating process. The blanking plates on the carburettors are there in order to reduce the amount of the exhaust gas being drawn in with the fuel:

![Carburettor Diagram](image)

The use of carburettors is important since using a bubbler as suggested in the free plans on the internet, creates problems as the lighter fractions of the fuel get taken first which is exactly what we don’t want to happen. The
Carburettors have the massive advantage that they feed all fractions of the fuel together and so the remaining fuel is always in the correct proportions.

The ratio of water to fuel (typically gasoline or diesel) can be adjusted over a very wide range, with some people using 90% water. Actually, there have been claims of running on 100% water, using multiple reactors in parallel with energy being drawn either from transmutation of elements or perhaps spin interactions with the local environment. Jean Chambrin's patent give details of running only on water.

There are several forums where members are researching and using various designs of fuel reformers, with the GEET designs being popular. The http://tech.groups.yahoo.com/group/VortexHeatExchanger/ forum is one such research forum and one of the files there lists 214 different patents for these devices. There are several different types of reformer. Another forum is http://alternativefuelsnow.com/vehicles/geetsystem. Also, check out http://www.teslatech.info/ttstore/articles/geet/geet.htm.

Almost any hydrocarbon fuel can be used - vegetable oil, old motor oil, etc. the normal fuels are the most popular. A forum member named 'bryishere' says in a YouTube video comment: "Everyone should really try this. IT WORKS. I have spent a lot of time on this device. It's very simple. Just follow the plans and experiment as much as you can. Currently I am using 90% water and 10% crude oil/waste oil on a 1-ton, 1969 Chevy truck ....... Get out in your shop !!!!!"

These devices are often used on stationary generators. These devices have been popular in France for some years now. Jean Chambrin found that the gases needed to swirl inside his reactor in the same direction that the crank was turning.

There is a massive 175 Mb file called ‘FuelReformerTechnology.zip’ which you can search for and download from the internet if you are very enthusiastic. That file contains the contents of more than 220 patents and applications. These patents are also listed in the 'Files' section of the Yahoo VortexHeatExchanger forum mentioned above.

In February 2015, Paul Pantone said: “The GEET Fuel Processor (GFP) is an on-board compact plasma fuel refinery that renders just about any liquid into usable and highly volatile fuel by cultivating electro-magnetic and other energy fields. And, YES! We believe It is healthy for you and your engine too! The GFP-retrofitted engine requires only a fraction of the fuel, as the non-GFP-retrofitted engine, to pull the same load for the same duration of time. The exhaust from GFP-retrofitted engines reduces pollution, and in some cases has added oxygen to the environment. The GFP works with any equipment that uses fuel. For information about GEET classes, Contact paul.pantone (at)yahoo (dot) com or visit www.geetinternational.com"

Electric Power.
We have been talking about internal combustion engines as there are so many of them around the world, but electric power is an alternative. One hi-tech option is a Chinese SUV-style 5-seat saloon car which has a top speed of more than 120 mph, a range of 250 miles per charge and a re-charging time of just one hour, thanks to newly developed iron batteries which can be recharged up to 2000 times before they start to degrade. Also, these new vehicles look perfectly normal. I suspect that the cost of such a vehicle may prevent most people from buying one.

However, low-tech solutions can work well for some people. For example, Nader Hoville in Hawaii has adapted a truck for electric operation. He uses a battery bank of eighteen 8-volt Exide golf-cart batteries of 150 AHR each, giving a 144-volt 150 AHR bank. This provides a forty mile journey in fairly flat terrain and twenty-five mile range in hilly country and while that would not suit many people, it suits places like Hawaii where travel distances are not normally very great.

Running costs are lowered still further because Nader has a solar panel array of ten 250-watt panels which provide more than enough electricity for his house. As his solar system has larger capacity than is needed for household equipment, the additional capacity can be used to charge his truck’s battery bank for free. Nader sometimes charges his truck’s battery bank from the 120-volt AC mains when he is away from home, and to do this he uses an ultra-low-tech charging system which does not use a mains transformer. If, like Nadir, you are not familiar with electrical circuitry, then reading chapter 12 may help. The circuit is like this:
This is an unusual voltage-doubler circuit where the mains input has an average of 120 volts and a voltage peak of 170 volts and as that occurs on both sides of the output, the output is around 340 volts of pulsing DC current which both charges and de-sulphates the batteries.

The current fed to the battery bank is controlled by the capacitors inserted in the mains 'live' line. These capacitors have to be very high quality and typically cost US $10 each. They look like this:

![Capacitor Image]

Each of them being 80 microfarads in capacity and rated for 400-volt use. Nader uses these in pairs, giving 160 microfarads for each pair and each pair passes 133 watts of charging power to the battery bank. These are non-polarised capacitors (meaning that they don’t have a Plus and a Minus side) and electrolytic capacitors will NOT do and are liable to explode if used in a circuit of this type.

The diodes are 40-amp 400-volt rated and they cost $3.50 each. Please understand that this circuit has DANGEROUS voltages EVERYWHERE and those voltages can cause injury or death if you are careless. So please be warned, this is not a circuit where carelessness can be tolerated at any time. The charger is connected to the batteries BEFORE the mains supply is connected, and the mains disconnected before the charger is disconnected from the battery bank.

This is not a circuit which I see as particularly safe to use. You will notice that one of the terminals which you handle and connect to the battery bank is actually one side of the mains. I am not inclined to recommend that anyone handles mains wires. It is vitally important that it is the “Neutral” mains wire, which in theory is connected to ground and so is perfectly safe. However, in practice, that is by no means always the case and it has been known for the ‘Neutral’ mains wire to float 180 volts away from the earth voltage (which you are standing on!). So, I suggest that the “Neutral” wire is connected to a real, physical, earth connection and that mains power is not switched on while that connection is being handled.

Having said that, the circuit works very well for Nader, and is silent in operation. The charging power depends on the number of capacitors used and so switching in the extra pairs of capacitors gives the choice of charging at 133 watts, 266 watts, 399 watts or 532 watts. Nader’s build looks like this:
The Weird Nature of Water and Advanced Electrolysis.

This chapter has been dealing with systems for enhancing vehicle operation with the use of water, so it seems appropriate to finish it with a brief note on water itself. To a casual glance, it appears that we know all about water. It’s composition is H$_2$O and when it breaks down, we get two hydrogen atoms and one oxygen atom - right? Well maybe, and maybe not.

The longer you spend looking at systems which use water, the more you get to realise that water is by no means as simple as you might initially think. There is a much maligned branch of alternative medicine called “Homeopathy” which is based on giving patients very dilute water-based solutions various chemicals. Sceptical investigators have run professional-quality tests intended to show that homeopathy is fraudulent and has no medical benefits whatsoever. Unfortunately, the tests did not work out the way that the investigators wanted. The tests showed that there actually was some benefit from the treatments being examined, and unfortunately, because a placebo control group was being used, the placebo effect was definitely not the cause of the effects recorded during the trials.

Determined not to just accept the results which went against their expectations, the testers started testing ever more dilute samples on the patients. They eventually got down to the level where there no longer remained a single atom of the chemical in the liquid being fed to the patients, but to their consternation, the medical effect remained. They tried water which had never had the chemical in it, and there was no medical effect. They returned to the apparently “pure” and definitely chemical-free water and the medical effect was seen again, in spite of the fact that there was not even one atom of the chemical remaining in the water.

This showed clearly that the water was different after having had the chemical in it, even when no chemical remained. They were forced into the opinion that water has “memory”. That, of course, is a conclusion based on the facts which are hard to explain. You may wish to deduce something else from those facts, and that is entirely up to you - just be aware of the facts.

Studies carried out by Mr Masaru Emoto here: http://www.vidaplena.net/Videos_VP/Videos_A-B/Agua.htm have shown that the thoughts of ordinary members of the public can alter the structure of water without there being any actual physical contact with the water, and many other very important effects. If the water receives positive thoughts and is then frozen, the resulting crystal structure will be like this:
While on the other hand, if negative thoughts are aimed at the water, whether just by looking at it and thinking, or by writing those thoughts down on paper, the resulting crystal shape is quite different when the water is frozen, as shown here:

It is not all that startling if you consider that the quantum mechanics researchers have been saying for a long time that experiments can be affected by the observer. People who build Joe Cells which operate through environmental energy focused by specially treated and structured pure water, record the fact that certain people can affect a Joe Cell in a negative way from a distance of fifty yards (or metres) away.

Personally, I am quite sure that we do not understand the fundamental nature of our environment and that we have very little idea of how we as individuals impact on our surroundings.

There is an extremely honest and reputable researcher called George Wiseman who operates through his company Eagle-Research (http://www.eagle-research.com). George is very experienced in producing “Brown’s Gas” and he publishes excellent instruction books on the subject. The really interesting thing is that Brown’s Gas is produced from water and that gas has the most remarkable properties which are not readily explained by our present day “conventional” science. When Brown’s Gas is used as the gas to power a cutting torch (like an oxy-acetylene torch) the resulting flame is nearly colourless and can be waved across a bare hand without any ill effects - the hand is not burnt. But when applied to a fire brick which is intended to resist high temperatures, it burns a neat hole through it. It will vaporise a tungsten rod which normally takes 6,000°C to do that, which indicates that the flame temperature depends on what it touches (!).

It can also weld aluminium to aluminium without the need for an inert gas. It will weld aluminium to brass and it can weld a steel rod to an ordinary building brick. It can fuse glass to a building brick. This is not “normal” for a chemical combustion reaction, showing that Brown’s Gas is not a “normal” chemical substance. As Brown’s Gas comes from water, does that perhaps suggest that water is not a “normal” chemical substance? I will leave you to make up your own mind about that, perhaps helped by the following, most enlightening presentation by Moray B. King.

A Presentation by Moray B. King

Moray King has produced a substantial document covering many aspects of free-energy with special emphasis on the more unusual systems and some of the difficult-to-explain things which people have discovered. As Moray's presentation has 166 pages containing many pointers to video clips and specialist web sites, this is just a brief summary of his pdf document which can be seen in full here: http://www.free-energy-info.com/MorayKing.pdf and which has the uncommon feature of an icon at the top left hand corner of each page, and if you click on that icon, then additional comments can be seen. He starts with:
Steve Ryan, a man living in Auckland, New Zealand, who was shown running a motorcycle on modified water, shown on a cynical TV video presentation at [http://www.youtube.com/watch?v=POJQKg9CRJc](http://www.youtube.com/watch?v=POJQKg9CRJc) where the complete ignorance of the presenters is demonstrated yet again. Steve has disappeared from public view for a very long time now. However, Moray raises the most relevant question: “How can water store enough energy to make it appear to be a fuel?” The first step in answering this question is to realise that causing cavitation (tiny stress bubbles) in the water inside an electrolyser, produces excess energy, and so, circulating the water inside an electrolyser while causing cavitation in the water is a major step forward, and one which seems to indicate that the majority of the energy in HHO gas does not actually come from the hydrogen. Instead, zero-point energy gets trapped in the water when the turbulence caused by the circulation, charges the water electrostatically, raising it’s energy content as it circulates repeatedly through the electrolyser.

Mark LeClair, the founder of the NanoSpire Corporation ([https://nanospireinc.com/](https://nanospireinc.com/)), discovered a microscopic crystalline form of water which has an extraordinary energy density. This crystalline form of water is similar to the microscopic plasmoids discovered by Ken Shoulders and the larger plasmoids discovered by Adamenko’s team at the proton-21 laboratory in the Ukraine. When a plasmoid strikes any element, the result is transmutation of that element. The excessive energy and most unusual properties of Brown’s Gas come from charged water gas clusters which are stored in a stable ring-form of the microscopic water crystals. This feature completely by-passes the standard electrolysis of water as examined by the great Michael Faraday where more energy is needed to split water than can be regained when the resulting gas mixture is burned. This is an entirely different process as explained at [http://peswiki.com/index.php/Video:Water_as_Fuel_%28via_ZPE%29](http://peswiki.com/index.php/Video:Water_as_Fuel_%28via_ZPE%29) in considerable detail on Sterling Allan’s PESWiki web site, and it shows why water can indeed act as a fuel. If you search for “water fuel” on YouTube, more than 41,000 videos can be found, most of which are demonstrating electrolyzers, which shows that there is a growing awareness of the potential of water as a fuel. There are many commercial electrolyzers available.

Brown’s Gas (HHO) has most unusual properties as demonstrated by Denny Klein’s use of it in a welding torch as seen here: [http://www.youtube.com/watch?v=6Rb_rDkwGnU](http://www.youtube.com/watch?v=6Rb_rDkwGnU) and Denny has also run his car with water appearing to be the only fuel – the power comes from the zero-point energy field but that energy is transported by the water. Surprisingly, nearly everyone who is working with, or experimenting on the gas produced by electrolysis, believes that the resulting energy comes from the hydrogen in the gas mix, while the reality is that this is not actually the case. Brown’s Gas has a cool flame of just 130 degrees Fahrenheit (water boils at 212 degrees Fahrenheit), and yet that same flame can vaporise tungsten which requires more than 10,000 degrees Fahrenheit and burning Hydrogen will never, ever, reach that temperature. Brown’s Gas can also dramatically reduce radioactivity in radioactive materials and burning hydrogen can’t do that. Also, when Brown’s Gas is analysed in a high-tech laboratory, very little hydrogen is found and instead there are gaseous water clusters with excess electrons.

These charged water gas clusters have the same strange energetic effects that the plasma-charged have and that appears to be a microscopic form of ball lightning, studied extensively by Ken Shoulders who named them “Exotic Vacuum Objects” or “EVO” when he became convinced that their excess energy was being drawn in from the zero-point energy field of ‘the vacuum’. These water gas clusters have a self-organised grouping of matter, plasma and zero-point energy. The typical grouping caused by this turbulent plasma is a vortex ring called a plasmoid (which has often been proposed as a model for ball lightning):

In a plasmoid, the electrons and ions spiral around the vortex ring and the force-free vortex creates a natural stability which sustains the plasmoid shape. These charge clusters can be produced quite easily as shown by Ken Shoulders in his US Patent 5,018,180 of 1991 where he shows that an abrupt electric discharge from a capacitor through a sharp pointed electrode on to a dielectric surface creates a charge cluster which travels on the surface of the dielectric to the anode. It appears to be a micron-sized form of ball lightning and it can punch a hole through the ‘witness’ plate, leaving a crater made by a high-energy event. The patent is well written and
describes many possible applications of his discovery.

The Exotic Vacuum Object formed by this process is believed to contain 100,000,000,000 electrons plus some 100,000 ions, giving it a charge-to-mass ratio similar to an electron and a really interesting fact is that it contains more energy than the energy which was stored in the capacitor which created it. These charge clusters adhere to dielectrics and they can remain for a long time. Many of them can clump together into a formation like a necklace. They can create holes through high melting-point ceramics such as aluminium oxide. Ken believes that the creation of these holes in ceramics is caused by the disruption of the electrons in the ceramic and so the hole ‘melted’ through the ceramic is not actually produced by heat. He has performed experiments which demonstrate the transmutation of one element into another and others which show radioactive materials being converted into benign elements.

Water gas clusters have the same characteristics as Ken’s Exotic Vacuum Objects and they cause the most unexpected effects of using Brown’s Gas where the cool flame (266 degrees F) does not boil water (which needs 212 degrees F to boil) http://www.watertorch.com/, and yet, that same flame can vaporise Tungsten which requires 10,031 degrees F, mind you, the Brown’s Gas flame does not vaporise Tungsten by heating it above 10,000 degrees Fahrenheit but instead, does it by disrupting the bonding of the molecules in the metal. Here are some comparisons:

This heating can’t possibly come from burning hydrogen. Some tests produce interesting results. For example, fill a balloon with the gas produced by electrolysis and leave the balloon sealed for some time. The tiny hydrogen atoms and molecules can, and do, escape through the material of the balloon, causing it to fall to the ground. But, the contents remaining in the balloon still produces a burning flame when pushed out through a small tube and lit. A similar experiment is to fill a paper bag with the gas. Seal the bag and leave it for twelve hours to allow the hydrogen to escape. What remains in the bag is a gas which is heavier than air and which can be ignited.

George Wiseman (http://www.eagle-research.com/) is a leading Brown’s Gas researcher who has found that browns Gas burns downwards in an imploding ring. In 2008, Chris Eckman measured the characteristics of Brown’s Gas at Idaho State University. The measurements showed that there was very little hydrogen (monatomic or diatomic) present. Instead, the gas was found to be a form of water with excess electrons, effectively, a gas which was neither water vapour nor steam. When ignited, the flame temperature was found to be 266 F. or 130 C. (Extraordinary Technology, vol 2(6), pp 15-25, 2008).

When using his acrylic electrolysers, George Wiseman has made an observation which he says is never mentioned in any textbook describing electrolysis:
Between the electrolysis electrode plates which have a wide spacing of more than 10 mm, three sets of bubbles are produced. Hydrogen is produced on the negative electrode plate. Oxygen is produced on the Positive electrode plate. But, in the middle of the gap between those electrode plates a third set of bubbles are generated. Many researchers believe that these additional bubbles form the most energetic component of the gas – the charged water gas clusters. Bob Boyce has made a similar observation, noting that when electrolysis first starts, there are two jets which start from the plates and collide in between the plates where the middle bubbles are formed.

Ted Suartt and Rob Gourley (http://www.wateriontechnologies.com/) have not only made the same observation, but have developed a process and applied for a patent where they intentionally produce and harvest just the middle set of bubbles:
Suartt and Gourley realised that the dominant electrolyser gas was not Hydrogen, and claiming that they are the first to discover this, named the gas after themselves as “SG Gas”. Their extraction process involves widely separated electrode plates and a method of extracting the gas bubbles produced in the middle region between those two plates and excluding the hydrogen and the oxygen produced. They have investigated the properties of water infused with the gas and claim that it has health benefits. They state that Rhodes Gas and Brown’s Gas are both “dirty cocktails” which include H₂ or O₂.

The anomalies of Brown’s Gas are similar to those of plasma charge clusters (Ken Shoulders’ EVOs). It adheres to matter and is electrically polarised. It gives an electric shock if it implodes to form water again. The isolated gas tends to implode instead of explode in piston experiments. However, if air is added to the mixture, the air is heated and that can cause overall expansion. In a welding torch it has a cool flame but it can vaporise tungsten. The flame cuts cleanly through solid, high melting-point materials including wood and ceramics, can weld dissimilar metals together and can even weld steel to clay brick. The claims of neutralising radioactive materials as well as the transmutation of elements are extraordinary. Todd Knudston comments on these properties at http://www.amasci.com/freenrg/HHO.html. At the 2011 Tesla Conference, Vernon Roth announced that he has observed element transmutation in his electrolysis cell. Details of this are given on Sterling Allan’s web page at http://peswiki.com/index.php/OS:Vernon_Roth%27s_Alchemical_Hydrogen.

Mark LeClair can explain how water cavitation creates microscopic craters in metallic surfaces, carves trenches in high melting-point ceramics, transmutes elements, and produces excess energy. Cavitation bubbles have been studied and they have been shown to produce unexpected excess energy. Sonoluminescence occurs when water mixed with an inert gas such as argon or xenon, is excited by ultrasonic waves. A blue light is emitted as each bubble collapses suddenly and symmetrically. If that blue light were produced by a heating effect, then the bluish spectrum would indicate temperatures of over 10,000 degrees Kelvin, which caused many scientists to suggest that it might be used for hot fusion. Nobel laureate, Julian Schwinger, suggested instead that the light is caused by the zero-point energy. Here, the abrupt scalar compression of the bubble walls activates a Zero-Point Energy coherence, emitting the blue light at a far lower temperature (http://en.wikipedia.org/wiki/Sonoluminescence). Mark LeClair has four patents on controlled cavitation (typically for the precision cutting of materials): US 6,932,914, US 6,960,307, US 7,297,288 and US 7,517,430.
Cavitation bubbles form in the low-pressure region behind any rapidly moving surface in water. Ship's screws are notorious for making cavitation bubbles and being damaged by them:

**Cavitation Erosion**

However, the most useful application of cavitation is inside an electrolyser. Archie Blue raised the effectiveness of his electrolyser by blowing air upwards through the electrolyte. The technique can be applied to many different electrolyser designs. The electrode plates should have a rough clean surface with a tiny inter-plate gap of less than one millimetre. A gap that small allows the electrolysis gas to cause cavitation. The electrical stimulation can use pulsed DC waveforms but with minimal current and electrolyte (remember that we are not trying to make hydrogen). Circulating the water rapidly can charge it electrostatically and possibly even enough to allow the removal of the external DC pulsing. There are many ways to produce cavitation in water: make electrolysis gas in narrow gaps, blow air through the electrolyser, create a Venturi vacuum, vibrate the water by mechanical, acoustical or ultrasonic means, oscillate an electric field via a toroidal coil or via pulsed waveforms. Here, charged or polarised clusters or bubbles will oscillate with the field causing turbulence and cavitation.

When a cavitation bubble collapses near a hole or irregularity, it forms a torus and all of the energy of the collapsing bubble gets concentrated into a re-entrant jet. The extreme pressure in the jet creates a new solid-state of water, a water crystal with a plasma bow shock wave which draws in Zero-Point Energy. If they collide, water crystals can form small rings, trapping the energy in a meta-stable torus form. This is the seed of the charge water gas cluster. When ignited, the ring breaks to re-launch the LeClair effect water crystal or alternatively, becomes a plasmoid Exotic Vacuum Object, either of which have excess energy.

Rapidly circulating water through an electrolyser causes numeric energetic effects. It charges the water by electrostatic rubbing, it causes turbulence and cavitation as it flows through the tight rough gaps, it can vibrate the plates producing reed cavitation and best of all, cycling the water repeatedly through the electrolyser integrates it's energy content, producing an ever increasing energy level. With water which is sufficiently charged, spraying it as a mist into the carburettor of an engine can give the illusion that water is a fuel.

This is just a brief summary of part of the contents of Moray King's presentation pdf document which you can read in full here: [http://www.free-energy-info.com/MorayKing.pdf](http://www.free-energy-info.com/MorayKing.pdf). An interesting, seemingly directly related video is: [http://www.youtube.com/watch?v=l-T7tCMUDXU&feature=youtu.be](http://www.youtube.com/watch?v=l-T7tCMUDXU&feature=youtu.be). Considering what Moray King has described, we need to consider more carefully the patented electrolyser designs of Charles Garrett and Archie Blue. First, however, having discovered and considered charged water clusters we need to consider the patent application of 2010 from Ted and Rob:

**Ted Suratt and Robinson Gourley**

Ted Suratt and Robinson Gourley have developed a new gas and have done very wide ranging and extensive testing with some of those tests extending over a period of two years. They describe a gas derived from water which they call SG gas (presumably from Suratt/Gourley) and that gas has remarkable properties, being capable of dissolving in liquids such as water and various fuels. It can also soak into and enhance solids such as wood chips. It can be used as a fuel but when burnt it only reaches a temperature less than 300 degrees Fahrenheit but has remarkable properties including the melting of metals with far higher melting points. That challenges present day concepts of what “melting” actually means. The gas can be compressed to 1000 pounds per square inch an it maintains its properties long term even when compressed. Very, very little power is needed to produce the gas, so their work looks like a step forwards towards a new technology. In my opinion, the infused water
produced by this process is likely to be what was used by Steve Ryan of New Zealand when he demonstrated running his motorcycle on “treated” water. Here is most of their patent:

**Method for Making a Gas from an Aqueous Fluid,**
**Product of the Method, and Apparatus Therefor**

**Abstract:**
A method for producing a purified, stable, compressible gas from an aqueous fluid. The gas is suitable for a variety of uses and may also be infused into water which itself is useful for a variety of purposes.

**Description:**

**TECHNICAL FIELD**
This invention relates to the generation of a purified, stable gas from an aqueous fluid, in which the gas may be stored under pressure and uses for the gas. Electrolysis of water is known to produce hydrogen gas (H₂) at the cathode and oxygen gas (O₂) at the anode. Due to the high heat of the chambers, water vapour also resulted from this process. If the hydrogen gas and oxygen gas were not effectively separated, such methods result in an impure gaseous mix which could not be effectively compressed or stored under pressure for industrial applications in a single container, and is deemed explosive and dangerous. Thus, it remained desirable to develop a method by which a useful, stable, purified, compressible single gas could be formed from water or an aqueous fluid.

**BRIEF DESCRIPTION OF THE DRAWINGS**

![Diagram](image)

**Fig. 1** illustrates a schematic of a preferred reaction chamber for the invention.
Fig. 2 illustrates the inventor's conception of the nature of the gas as formed from the process disclosed here.

Fig. 3 illustrates the inventor's conception of the nature of the gas as formed from the process disclosed here.
Fig. 4 illustrates graphs showing the absorption of Vitamin C by cells treated with SG Gas-infused Water and control. **Fig. 4A** shows the effect on basolateral cells and **Fig. 4B** on apical cells.
A method for generating a gas having desirable properties is herein disclosed. In addition, methods for purifying the gas is disclosed. The applicants refer to this gas as “SG Gas”.

As the first step of the method, an aqueous fluid is provided to a reaction zone. While various aqueous fluids, such as distilled water, tap water, or water taken from a river, stream, lake or the like may be used to generate electrical current at satisfactory levels, it is preferred to use an electrolyte solution for the aqueous fluid of standardised composition so that the conditions of the method can be better standardised for maximum yield of the gas.

The aqueous fluid is provided to a reaction zone which is preferably closed off so as to allow the reaction to occur under pressure. An alkali salt dissolved in distilled water is preferred as an electrolyte. Preferred alkali salts are potassium hydroxide, lithium hydroxide and sodium hydroxide. The specific gravity of the alkali salt in the solution is above 1.0. Most preferably, potassium hydroxide is employed at a specific gravity from at least above 1.0 up to about 1.2. If another electrolyte is chosen a mole ratio must be calculated for that substance so that the maximum mole ratio represented by the specific gravity of 1.2 provided for potassium hydroxide will not be exceeded.

These specific gravity values are as determined by a refractometer which provides readings that are temperature compensated. Most preferably, the electrolyte employed is potassium hydroxide (in powder form) dissolved in distilled water at a concentration sufficient to form a solution having up to 1.2 specific gravity. A suitable refractometer is the Westover Model RHA-100, portable refractometer.

Aqueous fluid is contained in a receptacle which can be made out of a variety of materials including sheet steel, stainless steel, CV-PVC and epoxy resin fibreglass. The apparatus and internal devices need to be heat resistant and waterproof. The reaction zone is comprised of the aqueous fluid.

The aqueous fluid is placed in a reaction zone in the method of the invention. Overall, the method employs creation of a magnetic field in the aqueous fluid and the periodic collapse of the magnetic field under conditions
which do not provoke electrolysis of the aqueous fluid. Under these conditions, a single gas is generated and collected. This gas has desirable properties and is useful for various applications. In a first step of the method, a magnetic field is applied to the reaction zone. Preferably, the magnetic field is applied by providing a source of electric power to the reaction zone. An electric current in the reaction zone provides a magnetic field.

In a preferred embodiment, two metallic end plates having an inside surface and an outside surface, and having the capacity to conduct an electrical current are used in the reaction zone in an opposing configuration. The inside of each end plate is partially submerged in the electrolyte solution. The metallic plates are preferably comprised of nickel alloy or stainless steel, but any metal can be used so long as such metal has the capacity to conduct an electric current and is preferably resistant to erosion by alkali solutions.

One of the metallic plates serves as a cathode and the other as an anode. The cathode and anode should be separated by a sufficient distance so that a magnetic field forms when current is applied to the reaction zone. The distance between the plates must be greater than one inch (25 mm) in the method of the invention and is preferably eight to sixteen inches (200 to 400 mm) apart. This distance is independent of the volume of the aqueous fluid employed or size of the reaction zone.

There is a relationship between the concentration of electrolyte solution and the amperage which will exist in the aqueous fluid upon application of current. The higher the specific gravity, the greater the amperage which will result. This will also affect the strength of the magnetic field, and increase the temperature of the solution.

Electrolysis (used industrially to produce hydrogen gas via the reaction \( 2\text{H}_2\text{O(l)} \rightarrow 2\text{H}_2(g) + \text{O}_2(g) \)) which is not desired in the method of the invention, could occur if the current is too high. The current may be too high if the specific gravity of the electrolyte exceeds the equivalent of 1.2 for potassium hydroxide.

In order for the magnetic field to be applied to the reaction zone, a power source (e.g., 110 volts DC) is applied respectively to the anode and to the cathode. An appropriate power source that may be used in the method of the invention is 110 volt alternating current which has been converted to direct current using a rectifying process (e.g., a diode bridge). Any standard power or voltage source may be used as long as it is direct current. When an electric current is applied to the reaction zone, a magnetic field is created in the reaction zone, which periodically collapses and causes the conversion of the water in the aqueous fluid into gas. Cyclic pulsation will be present in current even after alternating current is converted to direct current (for example a 120 Hz pulsation from household current) unless a smoothing circuit has been incorporated. This resulting cyclic pulsation is employable in the invention to periodically collapse the magnetic field, however using an auxiliary pulsing unit is preferable so that better regulation of pulsing may be employed. Any means for causing the electric current provided to the reaction zone to pulse at a frequency of 15 to 20 kilohertz decreases the wattage needed to create gas by approximately a factor of 10. The amount of energy needed to generate one litre of gas is 0.0028 kilowatt-hour and with a pulsing device associated with the reaction zone, the amount drops to 0.00028 kilowatt-hour or less to generate one litre of gas.

As the pulsing occurs, the stationary magnetic field alternatively collapses and is reinstated. It has been found that a reaction occurs in the electrolyte solution between the two end plates upon collapse of the magnetic field, which results in a release of a generated gas. Some of the same gas will be pulled toward the individual plates and released as part of the generated gas.

In a pilot plant apparatus for determining optimal conditions, a clear Plexiglas receptacle can be used for the reaction zone, so that one can visibly monitor the reaction with ultraviolet light and observe the generation of gas. This pilot plant preferably provides adjustment for the cathode and anode so that they can be moved to optimise the reaction for a given aqueous fluid composition and changes in pulsing duration and frequency.

Gas is generated not only at the electrodes but also appears as bubbles in the body of water between the electrodes. It has been found that use of minimal electric currents between two electrodes results from the electrodes being spread a sufficient distance apart of at least one inch (2.5 cm) and preferably eight to sixteen inches apart, thereby creating the aforesaid magnetic field enveloping the reaction chamber. A pure gas is produced in the body of aqueous fluid between the electrodes, without the production of a high levels of heat that would cause the water to vaporise (212° F). Rather, the reaction zone remains at a temperature not exceeding 120° F, dependent on ambient temperature. Normally, there is a 30° F temperature rise above ambient temperature assuming room temperature 90° F. The collection chambers contain no increase in oxygen gas, no increase in hydrogen gas, and no noticeable water vapour. Thus, costs are lowered, production speed increases, and the resulting gas is uniform in its properties. Also important, the resulting homogeneous gas can be pumped into a stainless steel cylinder and has been found to be stable and not explosive under pressures of over 1000 lbs per square inch.
The important functionalities in the process are the imposition of a magnetic field on the aqueous fluid and the ability to periodically collapse the magnetic field to generate the desired gas, under conditions short of those that will induce electrolysis. Other means which provide for these functionalities can be used. For example, in an alternative embodiment, wires could be inserted instead of plates in the reaction zone and when current passes from one wire through the aqueous fluid to the other wire, a magnetic field would be produced. In another exemplary alternative, a wire coil outside the reaction zone could be used to which a source of DC power can be supplied to create a primary magnetic field in the reaction zone. A wire coil placed in the middle of the solution can serve as a secondary magnetic field and when powered in the opposite direction of the current flow in pulses would collapse the primary field and create the necessary reaction to form the gas. Such a coil would be similar in concept to an car ignition coil.

When water is converted into gas, the natural conversion from liquid to gas creates an increase in volume and thus an increase in pressure within the reaction zone. While standard atmospheric pressure is about 14.7 psi at sea level, the pressure in the closed reaction zone is maintained between 30 and 100 psi by using a check valve at the outlet of the reaction chamber to control it, since maximum gas production occurs in this pressure range.

Now referring to Fig.1, a schematic of a reaction chamber is illustrated. Cathode (1) and anode (2) are in opposing configuration, preferably more than one inch apart and most preferably eight to sixteen inches apart. In the process of the invention, a current is passed through an aqueous fluid (3) and the current flow through the electrolyte creates a magnetic field. The electricity is pulsed, which collapses the magnetic field with each pulse of electricity. This produces the gas at a very efficient rate in the area of the solution between the electrodes, as denoted by 4 in Fig.1. The gas produced may be collected from the reaction zone through gas outlet (5) and subjected to further purification as described later.

The generated gas is then preferably exposed to a second magnetic field by providing a second reaction zone comprised of rare earth magnets. The strength of the rare earth magnets should be greater than fifty Gauss. Gas flows through a chamber exposed to rare earth magnets for purification. Rare earth magnets, dense metal magnets typically made from a composite of neodymium, iron and boron with or without a nickel coating or plating, are attached to the exterior of the chamber. Since SG Gas is paramagnetic and water vapour is diamagnetic the magnetic chamber strengthens the molecular bond of the gas and repels the water vapour back into the solution.

The purified SG Gas may be used immediately or compressed and stored in a gas storage tank. Purified SG Gas may be allowed to flow out of the second reaction zone directly to a torch attachment, to a compressor for storage in a pressurised vessel, or gas outflow valve for infusion into water or other substances.

In a method for making a compressible, stable gas with desirable properties, SG Gas is made according to the method of the invention. SG Gas can then be safely compressed and stored. SG Gas can be compressed above 1,000 psi. and can be stored in a pressurised vessel.

In an exemplary procedure for compression, SG Gas is discharged from the apparatus into a hose with a compressor attached. We use a Whirlwind Compressor, Model 2200-2 HPE, manufactured by High Pressure Eng. Co., Inc. A canister with pressure gauges is used to fill the chamber with SG Gas, using a hose to transport the SG Gas from the apparatus and compressor into the canister. We use an empty oxygen tank that has been vacuumed to remove any residual oxygen and water. The empty and vacuumed oxygen tank with pressure valve has a manufacturer name of White Martins, ABRE with dimensions of 23” (585 mm) diameter and 19” (480 mm) height. SG Gas is placed under pressure in the compression chamber up to and beyond 1,000 psi. for storage.

SG Gas remains stable and under pressure for one month and longer. To test its stability, wood chips were placed in a stainless steel tank and the tank filled with SG Gas. The wood chips absorbed SG Gas and additional SG Gas was used to refill the chamber and maintain a 30 psi pressure. Once the wood chips were saturated with
SG Gas, the tank was decompressed and pressure reduced to 0 psi. For a period of over 30 days, no pressure was generated assuming that no out gassing of SG Gas occurred. The wood chips displayed different burn properties after 60 days when compared to wood chips which had not been treated. The treated wood chips with absorbed SG Gas burned more efficiently when compared to that of ordinary wood chips thereby demonstrating the stability of the SG Gas bond with the treated wood chips.

**Analytical Testing and Observations of SG Gas:**

*Maximum Pressure:* SG Gas imploded when pressures exceeded 1,600 psi.

*Safe Pressurisation:* SG Gas remains safe and stable at pressures around 1,000 psi for over 30 days.

SG Gas should remain stable under pressure indefinitely, at least for a sufficient period of time to allow said gas to be utilised at any time from 30 to 60 days after generation.

The purified SG Gas was tested and exhibited properties of a pure, homogeneous gas that was found to be compressible as stated above, safe, also able to oxidise any non-oxidised substrate which its flame contacts and it is also able to reduce any completely oxidised substrate which its flame contacts. The following characteristics were observed:

*Ultra-violet Light Test:* Exhibits a blue grey colour appearance compared to untreated distilled water which exhibits no colour, when exposed to an ultra-violet light, manufactured by Zelco Industries Model 10015.

*Balloon:* The gas is lighter than air and so causes balloons filled with it to rise.

*Cooling:* The Balloon Filled with Purified Gas: A balloon remains inflated at or below $-10^\circ$ F.

*Ignition:* Purified SG Gas produced according to the above method was tested for ignition properties. When lit with an ignition source such as a spark, it implodes. The temperature of the flame produced upon ignition was estimated to be about 270$^\circ$ F using an infrared temperature device (Raynger ST2L infrared thermometer). However, when materials are exposed to the flame, it creates a chemical reaction with the material and base metals will rise rapidly to melting temperature, releasing heat and converting the gas back into water (H$_2$O).

Purified SG Gas was discharged from the reaction zone through a hose with a torch attached. A flash-back arrestor is recommended on the gas output of the apparatus. The gas may be exposed to an ignition source (e.g., spark or electrical arc) thus combustion of the gas occurs. The heat of the resulting flame on the subject torch has a temperature of approximately 270$^\circ$ F.

When an air/propane torch is burning, a small amount of SG Gas is introduced into the air mixing chamber of a lit propane torch, a single uniform flame cone becomes visible demonstrating a more efficient conversion of hydrocarbon and more heat from combustion of hydrocarbon, meaning it has a use as a fuel extender. One use is injection of SG Gas into an air intake of a combustion engine thereby reducing harmful exhaust emissions and increasing fuel efficiency. A by-product of this process is the creation of water during the combustion cycle that generates steam. The steam causes an increase in the torque generated by the engine resulting in greater power output. Depending upon the type of fuel, SG Gas extends fuel efficiency by a factor between 2 and 10.

When ignited purified gas contacts another substance, melting occurs within a short period of time, usually less than one minute. The results of some examples of substances exposed to ignited purified SG Gas are shown here:
Instead of melting a substrate, the ignited purified gas may be applied to a substrate with a view toward capturing the generated heat as a useful product. The heat generated can be transferred to a substance such as air or water, thereby producing hot air or steam that can then be used industrially, such as for example to drive a turbine or piston-type engine for production of mechanical energy. In a preferred method, the flame of the SG gas can be applied to a substrate in conduit form having an inside surface and an outside surface. A substance such as forced air or water can flow through the conduit adjacent to the inside surface of the conduit. The flame of the SG gas can be applied to the outside surface of the conduit which causes the heat-generating reaction to occur. The heat is then transferred to the substance flowing through the conduit, preventing melting of the surface but creating a useful heated fluid that can be used in further applications. An exemplary conduit is a metal tube or pipe, such as copper tubing. It has been further determined that SG Gas can be infused into other substances, rendering a useful product.

Candles: SG Gas infused into melted paraffin wax and poured into a mould with a wick will create candles that burn with lower carbon emission as observed using a Pace 400 Four Gas Analyser.

Fluids: The gas had an affinity for water and other liquids including fuels but bubbles from those liquids after they reach their saturation point. One novel use of the gas is infusing it back into water to create ionised or polarised water. The resulting gas-infused water creates smaller water clusters that are believed to permit faster cellular absorption and hydration.

In an exemplary method for infusing SG Gas into water, SG Gas is discharged from the reaction zone into a hose with a ceramic diffuser attached. For treating large volumes of water, a ceramic block diffuser may be used. The diffusers are used to reduce the size of the SG Gas bubbles to improve efficiency of water absorption. SG Gas may also be stored under pressure, and then infused into water.

It is preferred to infuse water that has gone through a distillation process prior to infusion of SG Gas into treated water with less than 1 ppm Total Dissolved Solids. One may use an absorption graph to determine the time required for achieving the desired absorption of SG Gas into water. The typical rate of 30% absorption is approximately one hour to treat 100 gallons of water. A higher saturation of SG Gas up to 100% of total absorption occurs with more infusion of SG Gas into water over time. The actual time and percentage of absorption of SG Gas are affected by the purity of water, volume of water, size of gas bubbles, temperature and other factors.

The resulting ionised or polarised water ("SG Gas-infused Water") clings longer to a magnet when compared to regular water. Absorption over time or saturation graphs to monitor changes in the water properties infused with SG Gas including capacitance levels may be prepared.
Fig. 5 shows a typical absorption over time graph for infusion of SG Gas into water. Subsequently, one may measure capacitance levels in the treated water over a time period exceeding 30 days to demonstrate that the gas is stable in water.

Other measurements: *Total Dissolved Solids* (TDS) dropped from a start of 0.33 ppm in untreated distilled water to a finish of 0.17 ppm after infusion of SG Gas into distilled water for a period of approximately 11 minutes. A Fluke 189 True RMS Multimeter was used to measure drop in capacitance.

**Storage of SG Gas in Water**: The resulting polarised water with SG Gas treatment remains stable and can be stored for 2 years or more. The actual maximum storage time has yet to be observed but in theory, SG Gas should remain permanently stable in the water.

**Absorption**: During infusion of SG Gas into purified water, we used a Fluke 189 True RMS Multimeter to measure drop in capacitance. The absorption over time graph is plotted to monitor the drop in capacitance. The first capacitance drop during initial infusion of SG Gas into a gallon of purified water occurs within the first three minutes of infusion. After that time, the capacitance gradually drops until the point of maximum saturation of SG Gas is typically reached between 8 and 20 minutes depending on variables including initial purity of water, size of gas bubbles, and volume of water to be treated. The resulting treated or infused water is referred to "SG Gas-infused Water".

**Other Parameters Monitored**: During infusion of SG Gas into purified water, a drop in the Total Dissolved Solids concentration, conductivity and resistively can be measured. An appropriate measuring device is a Control Company Traceable™ #4063CC meter.

**pH Test**: Lab tests show that distilled water had a pH of 6.8 and when infused with SG Gas had a pH change to 7.6.

**Ice Cubes**: SG Gas remains in SG Gas-infused Water or polarised water until freezing occurs when the SG Gas forms a gas bubble within the ice cube itself, sometimes producing capillary tubes on the surface of the ice cubes, where the SG Gas escapes.

**Ultraviolet Light Exposure**: SG Gas-infused Water was tested for the effects of ultraviolet light exposure. A clear spray bottle containing SG Gas-infused Water or polarised water placed in the Florida sun for over two years remained clear in appearance and without algae growth which had been observed in water not infused with SG Gas under similar conditions.

**Magnets**: A drop of SG Gas-infused Water clings to the surface of a magnet longer when compared to that of untreated water.

Many uses have been found for SG Gas-infused Water and some of these uses are listed here:
### Table 2: Uses for SG Gas Infused water

<table>
<thead>
<tr>
<th>Use</th>
<th>Advantages of SG Gas Infused water</th>
</tr>
</thead>
<tbody>
<tr>
<td>Drinking water for human and animal consumption</td>
<td>Efficient cellular absorption and removal of toxins</td>
</tr>
<tr>
<td>Water for food and manufacture of supplements</td>
<td>Pure form of water that improves product quality, shelf life, nutrient benefits, absorption and taste</td>
</tr>
<tr>
<td>Water for cleaning and enhancing the effectiveness of cleansers</td>
<td>Reduced need for emulsifiers and surfactants</td>
</tr>
<tr>
<td>Water for plants and crops, including hydroponics, floral arrangements and golf course turf</td>
<td>Greater size of plants, improved plant quality, longer viability and reduced scale build up in hydroponic water containers</td>
</tr>
<tr>
<td>Fertiliser solution for application on plants and crops</td>
<td>Higher yield and more vigorous growth</td>
</tr>
<tr>
<td>Water for aquariums and fish farming</td>
<td>Greater size of fish</td>

**Use in Process of Tar Sands Extraction:** Conventional water with petroleum solvents used in the separation of tar from sand was replaced with SG Gas-infused Water. SG Gas-infused Water was heated (no petroleum solvent added) with a sample of tar sands in a pan to approximately 160° F. Tar was observed separating from the sand, providing a cleaner and more efficient process with reduced by-products and emissions released from the tar extraction.

**Use for Improved Cleaning:** For laundry, one may add a quantity (half a US gallon in a standard washing machine tub of 12 US gallons for medium load and 16 US gallons for large load) of SG Gas-infused Water to the soap cycle of a top-loading washing machine and the remaining water (approximately 0.7 of a US gallon) is added to the rinse cycle. The polarised characteristic and smaller molecular size of SG Gas-infused Water enable the detergent and water solution to penetrate the cloth fabric more thoroughly and remove the dirt and grime. The addition of SG Gas-infused Water to the rinse assists in the complete removal of the soap residue which may contain residual dirt from the fabric. This process results in cleaner and stain-free laundry with less body oil and bacteria build-up. Laundry without these SG Gas-infused Water additives display less brilliant whites and retain a pungent odour caused by residual bacteria living in the fabric of the washed clothes.

**Reduced Use of Emulsifiers and Surfactants:** One may dilute cleaning solutions with SG Gas-infused Water for effective cleaning of surfaces to remove grime, oil and grease and the removal of bacteria. SG Gas-infused Water is a natural disinfectant without harsh chemical additives. Typically, one uses at least 1 part of cleaning solution with 20 parts of SG Gas-infused Water to maintain cleaning properties.
Biological Properties

Transport, Delivery and Absorption of Nutrients: In a controlled experiment, a standard drug metabolism test in vitro was conducted over a period of 21 days. This comparative test was performed on cell membrane permeability for Vitamin C solution (L-ascorbic acid) using (1) Hank's Buffered Saline Solution (HBSS) and (2) SG Gas-infused Water.

Caco-2 cells were used and permeability of the apical side (similar to intestine surface) and basolateral side (similar to underneath intestinal surface) for the separate solutions were determined. Vitamin C quantitation was conducted on HPLC (HP1100 equipped with PDA detector) and Zorbax C18 reverse phase column (4.6 × 250 mm, 5 micro) at 30 °C. Test results demonstrated Vitamin C permeability of SG Gas-infused Water was about 4 times higher than the control counterpart. (Hu, 2008).

Plant Growth: In a controlled greenhouse setting, four groups of ivy plants were watered using (1) 100% well water, (2) mix of 1 part of SG Gas-infused Water to 2 parts of well water, (3) mix of 2 parts of SG Gas-infused Water to 1 part of well water, and (4) 100% SG Gas-infused Water.

The ivy plants were harvested and dehydrated to allow measurement of dry plant mass. The fourth group of 100% SG Gas-infused Water had over 16 percent increase in mass when compared to that the first group of well water. (Reiser, 2006).

Fish Growth: Two home aquariums were used to hold two respective groups of goldfish. For a period of 30 days, SG Gas was bubbled into one aquarium and air into the second. It was observed that the goldfish in the former aquarium aerated by SG Gas grew at least 15 percent more and the aquarium tank remained cleaner with less algae growth.

Wound Treatment and Healing: The polarization of the SG Gas-infused Water provides natural anti-bacterial and non-toxic anti-infective properties that promote healing of superficial and multi-layer wounds and a reduction in pain perception. A fifty-year old woman burned herself by accidentally spilling scalding-hot coffee on to her hand. Upon seeking medical attention, a physician advised the patient that she might have to undergo abridement or dead skin removal and possible skin graft surgery. The patient washed the affected area with SG Gas-infused, purified water and applied a medicinal ointment. The wound was wrapped with a sterile gauze and the gauze was moistened with SG Gas-infused water to keep the wound hydrated. The patient reported an immediate and continuous lessening of pain with the application of the SG Gas-infused Water. Over a period of ten days with repeating the treatment steps of changing the moistened sterile gauze on at least a daily basis, the site of the wound developed new skin with minimal evidence of scarring. After the treatment regime the upper skin layer appeared to be healed, blisters appeared on the surface of the skin. The treatment with SG Gas-infused Water was started again and the blisters and the remaining layers of skin healed. The patient experienced healing and avoided debridement of dead skin, and skin grafts.

Skin Treatment: Topical applications twice a day on each side of a male volunteer's face in vicinity of his eyes were made. Two types of topical solutions were prepared with 1% magnesium ascorbyl phosphate (MAP), one using SG Gas-infused Water and the other using tap water. After 21 days, the volunteer observed on the side where SG Gas-infused Water solution was applied, a slight reduction in the depth of fine lines around the eye and a lighting of darker skin pigment when compared to that of the other area where the tap water solution was applied. (Puleo of Otima Specialty Chemical, 2008).

Eye Relief: SG Gas-infused Water may be sprayed into the eyes for immediate relief and lessening of redness that is comparable to use of commercial eye drops. This natural treatment without any chemical additives, assists in hydrating eyes and removing irritants such as dust and pollen.

Dental Care: A 50:50 solution of commercial mouth wash was mixed with SG Gas-infused Water and a capful of this solution was used twice a day after brushing teeth. Less plaque build-up and stains were noted by professional dental hygienists as compared to previous observations six months earlier when this solution had not been used.

Molecular Structure Based on Gas Properties

From observing the properties of SG Gas, the inventors believe that the process disclosed here results in a product not achieved by previously reported processes for the electrolysis of water into gas.

Given the low energy reaction that created the gas and the use of no catalysts, it is believed unlikely that any O-H bonds of water could possibly be broken in the process used. It is known that breaking O-H bonds requires two faradays per mole and the process of the invention only employs 2.8 watt hours per litre, which is about a maximum of 1.6 faradays per mole. Further, the SG Gas resulting from the process disclosed herein is flammable.
but the flame temperature of the gas is only about 270° F (132.2° C), as compared to diatomic hydrogen gas which is highly combustible and autoignites at 560° C. A hydrogen/oxygen torch flame is reportedly 3200° C (5792° F) However, the SG Gas flame melts metals easily, which indicates that it is likely that an oxygen is active. The gas flame also reduces ceramics, which indicates that the hydrogen is in an ionised state.

SG Gas has an affinity for water and other liquids including fuels but it bubbles from the liquids after they reach a saturation point. One use of SG gas is infusing it back into water to create ionised or polarised water.

SG Gas is always a gas at room temperature while normal water vapour requires energy to evaporate in great quantities. When combusted, the gas always returns to liquid water. When placed in a balloon, the gas initially floats the balloon but it seeps from the balloon rather quickly indicating that the gas has a small molecular structure.

One theory consistent with the properties observed is that no bonds of H₂O are broken when the process of the invention is used, but that the combination of the electric and magnetic forces restructure the water molecule. Gauss' Law that states there are no monopoles in magnetism, only dipoles. It is well known that liquid water forms hydrogen bonds with other water molecules in order to remain in a liquid solution.

Applying Gauss' Law to hydrogen, it has polar properties which open up a new configuration, one in which a hydrogen can be bound to another hydrogen and an oxygen. Upon exposure to an electric current, the electronegative strength of the oxygen atom is weakened, allowing a hydrogen atom to dislodge and magnetically bond to the other hydrogen atom that is strengthened by the magnetic field. Hence, the electric and magnetic forces made possible a shift of a hydrogen molecule from H-O-H to O-H-H creating a diatomic hydrogen molecule that is single bonded to atomic oxygen. As the exposed oxygen is a reactive site on the gas molecule an appropriate name is “HHOHydrogen”. This structure predicts that the oxygen is now active and can oxidise metals. It predicts that in the unburned gaseous state, the increased negative charge causes greater spacing among the gas molecules causing stability, a lower boiling point, a lower freezing point, and a higher vapour pressure.

The inventors have conceived of a new isomer of water - it contains the same atoms, only in a different configuration and thus exhibits different properties from normal water vapour. The gas does not cluster to create liquid water at regular atmospheric temperatures and pressures as does the molecules of normal water vapour. The gas exists in a higher energy state, burns by itself at a low temperature, and melts any substrates when exposed to the gas flame. The gas flame has a uniform blue colour appearance without yellow sparks indicative of water (H₂O) vapour or red sparks indicative of either H₂ or O₂ gas contamination. Hence, we call the resulting gas (SG Gas) an ionised gas or a plasma gas.

Now referring to Fig.2 and Fig.3, atoms shown are shown in their polar orientation for better understanding N meaning North Pole and S meaning South Pole. This dictates the orbital spin or magnetic flux. Fig.2 illustrates water prior to undergoing the process of the invention while Fig.3 illustrates the process and the believed effect on the aqueous fluid used.

While the magnetic field orients the atoms within the water molecule, the collapsing field induces a charge in the opposite direction and that dislodges the opposing hydrogen bond and allows it to bond to the other hydrogen atom in the ortho position as depicted in Fig.3. Ortho-hydrogen is more reactive than para-hydrogen and produces much more energy.
This reaction changes water from a liquid cluster to an ionised gas or plasma gas that will, when ignited, and the flame applied to a solid substrate, melt nearly any substance. Further, when the gas is infused into a water cluster it will bond to the water molecules and create a much smaller cluster of a different shape and properties allowing it to penetrate cells and hydrate animals and plants at a substantially faster rate.

It must be clear that due to the process used herein, electrolysis does not take place. “Electrolysis” is defined as a “method of separating chemically bonded elements and compounds by passing an electric current through them”. Electrolysis does not take place and no splitting of the water molecular bonds occurs, as is demonstrated by the fact that no increase in hydrogen or oxygen gas can be measured in the reaction zone. This is a key differentiator from the processes that have resulted in a gas being produced by electrolysis of water. The gases produced by electrolysis exhibit far different properties from SG Gas. Gases produced by electrolysis are explosive, cannot be pressurised and on ignition are heat-producing gases.

SG Gas is an ionised gas with the ability to oxidise or reduce any substance. On a non-oxidised substrate, such as steel, the active oxygen within the molecule will chemically bond to the steel bringing it immediately to its melting temperature and releasing hydrogen, which bonds with atmospheric oxygen to produce heat. On an oxidised substrate, such as ceramic, the hydrogen reduces the substrate by chemically bonding with the oxygen present within the substrate, melting the material and releasing atomic oxygen, which then bonds with the material. This double reaction is responsible for producing much more heat than an ordinary oxidation reduction reaction.

These reactions are proven on rusty steel and concrete. When ordinary gas, such as: methane, ethane, propane, butane, or acetylene are applied to rusty steel popping and spitting of material occurs due to the explosive reaction of the ferrous oxide being separated from the non-oxidized metal due to their different expansion rates. With SG Gas, this does not occur, since oxidation and reduction are occurring at the same time and the expansion rates are equal. On concrete when heat from an ordinary gas is applied, the portion the flame touches will expand and break loose from the rest of the concrete with an explosive force and spit pieces of hot concrete outward and leave holes in the concrete surface. Again, this does not occur with SG Gas because it is being reduced to a liquid form before the pressure of uneven expansion occurs.

Simply stated SG Gas is an ionised gas capable of oxidising or reducing almost any material without the adverse reactions created by heat-producing flames. Heat is the by-product of friction, in chemistry two atoms colliding together in a reaction known as oxidation and reduction cause this friction. A gas, referred to as a fuel, is usually a hydrocarbon that is easily oxidised, however, the carbon is what is being oxidised and the oxygen is being reduced meaning this is where friction occurs and these are the items being heated. Heat given off by these substances is refractive heat and the substances being heated are absorbing heat or, better stated, are being bombarded by fast moving hot gases. SG Gas may change the definition of melting point due to the lack of heat producing flames.

The Charles Garrett Electrolyser.
Charles Garrett was granted US Patent 2,006,676 on 2nd July 1935 in which he shows some impressive details. Firstly, he generated an extra electrical input by fitting a second (6 volt) alternator to his car. While the drawing shows the applied voltage swapping over in polarity, this was not done rapidly, just occasionally to even up any deterioration of the electrodes.

He maintained the water level in the electrolysis chamber with a neat carburettor-style float and pin valve arrangement. He improved the electrolysis by introducing a perforated tube below the electrode plates which allows the engine to suck air up past the plates. This cools the electrolyte (water with a few drops of hydrochloric acid) introduces water vapour to the gas mix and dislodges any bubbles on the plates, without the need for any extra mechanical device. Considering that he did this seventy-five years ago, it is an impressive piece of work. Please note that while only five electrode plates are shown in the diagram, in reality it is probable that many such plates were used since the gas volume is directly proportional to the plate area.
One point which should be noted is that the cars of that time had very much smaller capacity engines and so they will have needed far less HHO gas mixture in order to run adequately.

The Archie Blue Electrolyser.
More than fifty years after Charles Garrett was granted his patent, another one was granted to Archie Blue. The equipment described in the two patents operates in more or less the same way. Archie’s equipment is very simple to construct and uses straight electrolysis with no attempt at pulsing the electrical supply. Like Charles Garrett, Archie Blue claimed to have run a car on water alone, using his electrolyser design, which is shown here:
With this unit, air is sucked out of the exit pipe by the vehicle engine, while being pumped into the electrolyser by an air pump. The air flows down through the central pipe and is forced up through the non-aligned holes in the electrode plates, causing turbulence and probably, the formation of water-gas crystals. The air bubbles also stir the electrolyte into vigorous motion, dislodging the hydrogen and oxygen bubbles which form on the plates as a result of the electrolysis current flow through the electrolyte.

It is said that six of these electrolysis units are sufficient to run a car using just water as the fuel. It has been stated that electrolysis of water is optimum at 1.5 Volts, so it might be more efficient to connect the units in series where each unit receives 2 Volts rather than in parallel where each unit receives 12 Volts (unless, of course, the heating caused by connecting them in parallel is a factor in the very high efficiency of Archie Blue's system):

The air connection is the same for either method of wiring the cells. If wired in series, the voltage drop across each cell may not be the same although they were constructed in an identical fashion.
Please bear in mind that should you modify a vehicle to run on hydrogen, either as an additive or as a replacement for petrol, you need to clear it with your insurance company before using it on a public road, otherwise, you will be driving without insurance since any alteration to the vehicle automatically invalidates the insurance if the insurer is not notified and agrees the change. You may, of course, modify any stationary engine or any vehicle which you only run on private property. In the USA, the oil companies have influenced the local courts to such a degree that in some States, it is an offence to "run a vehicle on a non-approved fuel".

In passing, you may be interested to hear that I have been told that the Prohibition era in America had nothing at all to do with people drinking alcohol. The reality was that in the early days, Henry Ford was going to have his Model-T car running fuel-less by using a Nikola Tesla designed magneto system and an electric engine, but he was pressured into using an internal combustion engine to burn the gasoline which was an unwanted component of the local oil industry. This caused a problem for people on long journeys as there were very few gasoline filling stations at that time. To overcome the problem, the early cars were set up so that they could run on either gasoline or on alcohol produced by some 50,000 farmers scattered around the country. When the oil industry discovered how profitable it was selling gasoline, they opened many gasoline filling stations. They then wanted to exclude the farmers and have all of the profits for themselves and so Prohibition was introduced, not to stop people drinking alcohol (although that was the pretext), but in reality, to shut down the 50,000 alcohol stills which were their competition. When the stills were gone, then Prohibition was dropped as it had achieved it’s goal of a vehicle fuel monopoly.

The Electrolyser System of Paul Zigouras

In his document, Moray King draws attention to the HHO cell design of the American, Paul Zigouras who became very well known in the year 2011 due to his cell design which is perfectly capable of running a 320 horsepower marine engine. Paul, at age thirty, had a history of rebuilding marine engines and then selling them. He then was involved in helping a friend who had entered a competition for the car with the highest mpg performance. Paul found that by adding HHO to the air entering the car engine, that they could get 70 mpg on the flat when driving carefully. Their target was 100 mpg, and so they were disappointed by being 30 mpg short of their target.

Paul decided to work on the HHO angle to see what could be achieved and enlisted the help of a friend and sometime freelance employee who was expert in electronics as Paul was not familiar with electronics. Probably without understanding the underlying causes, they managed to utilise several operating principles – cavitation, charged water gas clusters, resonance, mechanical vibration and a 'splitting the positive' style power supply. The overall result was spectacular, culminating in a small cell, into which water could literally be hosed and only gas came out of the other end.

Paul never revealed the exact circuit design and it is reported that he sold the rights to the design for US $6,000,000. The purchasers then contacted the eBay buyer of the latest version of Paul’s circuit board and paid $20,000 to buy it back. The eBay buyer was happy with the deal as he had paid just $1,100 for it and so made a profit of $18,900 on the deal. At this time of writing (2013) some eighteen months have gone by and it seems quite clear that the present owners of Paul’s circuit design have no intention whatsoever, of sharing or manufacturing the design and so it has been effectively shelved, never to be seen again. They were not interested in the cell, but just the electronics board.

However, a number of things are known about the design, probably sufficient to allow a similar design to be produced. These items are as follows:

Paul made units in two sizes. The smaller version had between 20 and 30 plates each being 2-inches (50 mm) wide and 8-inches (200 mm) long, material 316L-grade or 318L-grade stainless steel one sixteenth of an inch thick (1.6 mm), stacked with a gap of just 0.635 mm between them. This small version could blast 2.5 (US) gallons of water per minute into gas, which is about 17,500 litres of gas per minute. The water was hosed in at one end, and no water reached the far end, which is quite spectacular performance.

The larger cell had 36 plates 3-inches (75 mm) wide and 10-inches (254 mm) long, also 316L or 318L-grade stainless steel 1.6 mm thick and with a gap of 0.635 mm between the plates. That size of cell could convert water to gas at the rate of 5 (US) gallons per minute (35,000 litres of gas per minute)

The techniques used with these cells is nothing at all like any of the various other electrolyser designs discussed in this chapter. This is because the cell operation is nothing like conventional electrolysis or even like DC pulse driven water splitting as used in the Stan Meyer “Water Fuel Cell”

Firstly the plates are grit-blasted with 60-grade silicon carbide at an angle of 45 degrees to the face of the plate, making sharp-edged craters in the surface of the plate. When water is forced through the very narrow gap
between these plates, these craters on both sides of that very narrow water flow causes turbulence and cavitation. Cavitation produces tiny bubbles in the water and in the book “Ultrasonics Methods and Applications” by Jack Blitz, it is stated that each cavitation bubble has a positive charge on one side and a corresponding negative charge on the opposite side. As the bubbles are very small, those charges are not far apart and it would not seem to be unrealistic to suggest that those charges cause electrolysis of the water on a very tiny scale. But, as there is a very large number of these bubbles, the overall effect might not be insignificant. The violent cavitation almost certainly produces charged water gas clusters, so what comes out of the end of the cell will be HHO gas, charged water gas clusters, plus whatever gases which were dissolved in the water and possibly water vapour.

The plates were shaped like this:

```
+---------------------------------------------+
| This edge sharpened                         |
|                                           |
| 200 mm or 254 mm                           |
|                                           |
| 50 mm or 75 mm                              |
|                                           |
| This edge slightly sharpened                |
+---------------------------------------------+
```

The edge facing the incoming water is sharpened to a knife edge, and the projection to take a push-on electrical spade connector has its outer edge slightly sharpened to make it easier to push the connector on to the plate and make a good electrical connection to the plate. Due to the very small gap between the plates, every second plate is turned over to give some clearance between the connectors. This places all of the positive connections on one side and all of the negative connections on the opposite side.

When being used to run a car, the HHO cell is placed inside the standard, rectangular, plastic air box which connects the air filter to the manifold air intake. This causes the incoming air to mix well with the HHO and other gases produced by the cell, before the mixture enters the engine.

The electronic circuit (valued at $6,000,000) has an ordinary automotive power supply of around 14 volts. This is supplied by a standard MSD 200-amp high performance alternator driven by the engine. The initial current draw for the larger (35,000 lpm) cell is 190 amps, but when the cell gets going, that current draw drops to a constant 10 amps, and the gas production rate is not related to the current draw. This process is not any kind of conventional electrolysis and has nothing at all to do with Faraday’s excellent lab work. The Coefficient of Performance is said to be between 5 and 10 although how that figure could be derived is by no means at all clear.

The circuit is said to produce a very clean square wave with very sharply rising and falling edges to the waveform. The frequency of the wave is in the 40 kHz to 44 kHz region and 30 separate transistors are used to drive the plates – presumably, one transistor per plate for the 30-plate version of the smaller cell. The waveform does not drop to zero volts, but instead, has a voltage offset of +1 volt. That is, the voltage oscillates between +1 volt and +14 volts and so there is always a voltage applied to the plates. As the circuit has never been disclosed, it is quite possible that the voltage is boosted well above the +14 volt level, however, that seems unlikely if 190 amps is the starting current. It is stated that at 44 kHz, the current needed is only one eighth of what would be expected for the HHO flow rate.

In a vehicle, the gas flow rate is controlled by improvising a linkage between the throttle and the valve which controls the rate of water flow into the cell. Not surprisingly, if the water inflow rate is cut down, the gas production rate has to fall also as there just isn’t any water remaining to be converted into gas. Each litre of water produces around 1,860 litres of HHO gas, and so if the cell output is 17,500 lpm, then the water inflow rate would be about 9.4 litres per minute or 157 ccs per second. However, it seems unlikely that when mixed with air, as much as 17,500 litres of HHO would be needed per minute. It is remarked that using hot water just under boiling point, is an advantage, although why that should be is not specified.

The cell buzzes quite loudly when operating. This is definitely not caused by a 40 kHz frequency signal as human hearing only goes up to 20 kHz at most. It might be a lower harmonic (20 kHz, 10 kHz, 5 kHz,…) or it might be caused by mechanical forces generated by the water flow. If tap water is being used, then dissolved solids will be left behind when the water becomes gas. This residue can be washed out of the cell by turning the water on and keeping the electrical power off as that washes the plates.
With this amount of information on the cell and electronics design, it could well be possible to replicate the cell and run vehicle engines from it. However, please be aware that Bob Boyce in America was handed a 3.5 year jail term for “running a vehicle on an unapproved fuel”. He beat that charge, but it should be clearly understood that an action like that is wholly unlawful and is part of the scam which attempts to force all vehicle users to burn oil.

Also in America, Bill Williams was running his Ford pick-up truck with a Joe Cell connected as a booster in “shandy” mode. He found that his truck used no fuel at all even though it was perfectly capable of drawing fuel in from the fuel tank. Bill destroyed his cell and does not talk about it due to intimidation from armed thugs. Details of his design along with more advanced Joe Cell designs are in chapter 9.

The Petro Dollar
However, things did not stop there by any means. To discover more, perhaps you should consider the following video at http://www.safeshare.tv/w/gQnBDHTCDs which states:

Why did the United States attack Libya, Iraq, Afghanistan and Yemen? Why are US operatives helping to de-stabilise Syria? And why is the United States government so intent in taking down Iran, in spite of the fact that Iran has not attacked any country since 1798?

And, what’s next? What are we headed for? When you look at the current trajectory that we are on, it doesn’t make any sense at all if you evaluate it on what we are taught in school. And it doesn’t make any sense if you base your world view on the propaganda that the mainstream media tries to pass off as news. But it makes perfect sense once you know the real motives of the powers that be. In order to understand those motives, we first have to take a look at history:

In 1945, Britain, with agreement, established the dollar as the world’s Reserve Currency, which meant that international commodities were priced in dollars. The agreement, which gave the United States a distinct financial advantage was made under the condition that those dollars would remain redeemable for gold at a consistent rate of $35 per ounce.

The United States promised not to print very much money but this was on the honour system because the Federal reserve refused to allow any audit or supervision of it’s printing presses.
In the years leading up to 1970, expenditures in the Vietnam War made it clear to many countries that the US was printing far more money than it had in gold, and in response, they began to ask for their gold back. This, of course, set off a rapid decline in the value of the dollar. The situation climaxed in 1971, when France attempted to withdraw its gold and Nixon refused. On 15th August, he made the following announcement:

“I have directed the Secretary of the Treasury to take the action necessary to defend the dollar against the speculators. I directed Secretary Connolly to suspend temporarily, the convertibility of the dollar into gold or other reserve assets except in amounts and in conditions determined to be in the interests of monetary stability and in the best interests of the United States”.

This was obviously not a temporary suspension as he claimed, but rather a permanent default, and for the rest of the world who had entrusted the United States with their gold, it was outright theft. In 1973, President Nixon asked King Faisal of Saudi Arabia to accept only US dollars in payment for oil, and to invest any excess profits in
US Treasury Bonds, Notes and Bills. In return, Nixon offered military protection for Saudi oil fields. The same offer was extended to each of the key oil-producing countries, and by 1975, every member of OPEC had agreed to only sell their oil in US dollars.

![Image of dollar and oil with soldier]

The act of moving the dollar off gold and tying it to foreign oil, instantly forced every oil-importing country in the world to maintain a constant supply of Federal Reserve paper, and in order to get that paper, they would have to send real physical goods to America. This, was the birth of the Petro Dollar. Paper went out, everything America needed came in, and the United States got very, very rich as a result. It was the largest financial con in recorded history.

The Arms Race of the Cold War was a game of poker. Military Expenditures were the chips, and the US had an endless supply of chips. With the Petro Dollar under it’s belt, it was able to raise the stakes higher and higher, outspending every other country on the planet, until eventually, US military expenditure surpassed that of all of the other nations in the world combined – the Soviet Union never had a chance.

The collapse of the communist bloc in 1991, removed the last counterbalance to American military might. The United States was now an undisputed Super-power with no rival. Many hoped that this would mark the start of a new era of peace and stability. Unfortunately, there were those in high places who had other ideas. Within that same year, the US invaded Iraq in the first Gulf War, and after crushing the Iraqi military, and destroying their infrastructure, including water-purification plants and hospitals, crippling sanctions were imposed which prevented that infrastructure from being rebuilt.
These sanctions which were initiated by Bush Senior, and sustained throughout the entire Clinton administration, lasted for over a decade and were estimated to have killed over five hundred thousand children. The Clinton administration was fully aware of these figures.

A TV interviewer speaking to Madeleine Albright, Secretary of State for Clinton, asked: “We have heard that half a million children have died, I mean, that’s more children that died than in Hiroshima, and, and is the price worth it?”. To which Madeleine Albright replied: “I think that this is a very hard choice. We think that the price is worth it”.

Miss Albright, what exactly was worth killing 500,000 kids for? In November of 2000, Iraq began selling it’s oil exclusively in Euros. This was a direct attack on the dollar and on US financial dominance, and it wasn't going to be tolerated. In response, the US government with the assistance of the mainstream media, began to build up a mass propaganda campaign claiming that Iraq had weapons of mass destruction and was planning to use them. In 2003, the US invaded and once they had control of the country, oil sales were immediately switched back to dollars. This is particularly noticeable as switching back to the dollar meant a 15% to 20% loss in revenue due to the Euro’s higher value. It doesn't make any sense at all unless you take the Petro Dollar into account.
On 2nd March 2007, US General Wesley Clark said: “So I came back to see him a few weeks later and by that time we were bombing in Afghanistan. I said: ‘Are we still going to war with Iraq?’ and he said ‘Oh it’s worse than that’. He said as he reached over on his desk and picked up a piece of paper and he said ‘I just got this down from upstairs (meaning from the Secretary of Defence’s Office) today, this is a memo which describes how we are going to take out seven countries in five years, starting off with Iraq and Syria, Lebanon, Libya, Somalia, Sudan and finishing off Iran’.

Let’s take a look at the events of the past decade and see if you see a pattern. In Libya, Gadaffi was in a process of organising a block of African countries to create a gold-based currency called the “Dinar” which they intended to use to replace the dollar in that region. US and NATO forces helped to destabilise and topple the government in 2011 and after taking control of the region, US armed rebels executed Gadaffi in cold blood and immediately set up the Libyan Central Bank. Iran has been actively campaigning to pull oil sales off the dollar for some time now, and it has recently secured agreements to trade it’s oil in exchange for gold. In response, the US government with mainstream media assistance has been attempting to build international support for military strikes on the pretext of preventing Iran from building a nuclear weapon. In the mean time they established sanctions which they openly admit are aimed at causing a collapse of the Iranian economy.

Syria is Iran’s closest ally and they are bound by mutual defence agreements. The country is currently in the process of being destabilised with covert assistance from NATO and although Russia and China have warned the United States not to get involved, the White House has made statements in the past month indicating that they are considering military intervention. It should be clear that military intervention in Syria and Iran isn’t being considered – it is a foregone conclusion. Just as it was in Iraq and Libya, the US is actively working to create the context which gives them the diplomatic cover to do what they have already planned. The motive for these invasions and covert actions becomes clear when we look at them in their full context and ‘connect the dots’. Those who control the United States understand that if even a few countries begin to sell their oil in another currency, it will set off a chain reaction and the dollar will collapse. They understand that there is absolutely nothing else holding up the value of the dollar at this point and so does the rest of the world. But instead of accepting the fact that the dollar is nearing the end of it’s lifespan, the powers that be have made a calculated gambit. They have decided to use the brute force of the US military to crush each and every resistant State in the Middle East and Africa.

That in itself would be bad enough, but what you need to understand is that this is not going to end with Iran. China and Russia stated publicly and in no uncertain terms that they will not tolerate an attack on Iran or Syria. Iran is one of their key allies, one of the last independent oil-producers in the region, and they understand that if Iran falls, then they will have no way to escape the dollar without going to war. And yet, the United States is pushing forward in spite of the warnings. What we are witnessing here is a trajectory which leads straight to the unthinkable. It is a trajectory which was mapped out years ago in full awareness of the human consequences. But who was it that put us on this course? What kind of psychopath is willing to intentionally set off a global conflict which will lead to millions of deaths, just to protect the value of a paper currency? It obviously isn’t the President. The decision to invade Syria, Libya and Iran was made long before Obama had risen to the national
spotlight, and yet, he is carrying out his duties just like the puppets who preceded him. So who is it that pulls the strings?

Often, the best answers to questions like this are found by asking another question “Cui Bono?” - “Who Benefits?” Obviously, those who have the power to print the dollar out of thin air have the most to lose if the dollar were to fall, and since 1913, that power has been held by the Federal Reserve. The Federal reserve is a private entity owned by a conglomerate of the most powerful banks in the world and the men who control those banks are the ones who pull those strings. To them, this is just a game. Your life, and the lives of those you love are just pawns on their chessboard. And like a spoiled four-year-old who tips the board on to the floor when he starts to lose, the powers that be are willing to start World War Three to keep control of the global financial system.

Remember that when these wars extend and accelerate. Remember that when your son, or your neighbour’s son comes back in a flag-draped coffin. Remember that when they point the finger at the new ‘bogeymen’ because the madmen who are running this show, will take this as far as you allow them to.

So, how much time do we have left? It’s a question which I hear constantly. But it is the wrong question. Asking how much time we have left is a passive posture. It is the attitude of a prisoner who is waiting to be taken out to a ditch and shot in the back of the head.

What are our chances? Can we change course? Also, the wrong question. The odds don’t matter any more. If you understand what we are facing, then you have a moral responsibility to do everything in your power to alter the course we are on, regardless of the odds. It is only when you stop basing your involvement on the chances of your success, that success actually becomes possible. To strip the ill-begotten power from the financial elites and bring these criminal cartels to justice, will require nothing less than a revolution. The government is not going to save us. The government is completely infiltrated and corrupt to the core. Looking to them for a solution at this point is utterly naive.

There are three stages of revolution and they are sequential. Stage One is already underway Stage One is the ideological resistance. In this stage we have to actively work to wake up as many people as possible about what is happening and the direction we are headed. All revolutions originate from a shift in the mind-set of the population and no other meaningful resistance is possible without it. Success in this stage of the game can be measured by the contagion of ideas. When idea reaches critical mass, it begins to spread on its own and seeps into all levels of society. In order to achieve that contagion, we need more people in this fight. We need more people speaking up, making videos, writing articles, getting this information on to the national and international stage, and we especially need to reach the police and the military.

Stage Two is civil disobedience, also known as Non-violent Resistance. In this Stage, you put your money where your mouth is, or more accurately, you withhold your money and your obedience from the government and you do
everything in your power to bring the gears of the State to a halt. Practiced in mass, this method alone is often enough to bring a regime to it’s knees. However, if it fails at this stage, Stage Three is inevitable.

Stage Three is direct physical resistance. Direct physical resistance is the last resort and it should be avoided and delayed as long as possible and only invoked when all other options have been thoroughly exhausted. There are those who ‘talk tough’ and claim that they will resist when the time comes, but what they fail to realise is that if you are inactive during the first two Stages and save your efforts for the last resistance, then you will fail.

When the Nazis were moving from door to door, dragging people out of their homes in Germany, that was the time to fight back physically, but due to the lack of ideological resistance and civil disobedience leading up to that moment, even an armed uprising would have likely failed at that point. An armed uprising can only succeed if the people have established an attitude of active resistance. And active resistance is only possible after their minds have broken free from the mainstream propaganda. If you want to fight back, then it’s now or never – you’re not going to get another chance, and the stakes are far higher than they were in Nazi Germany.

If you want to know more about the present situation, then watch the very informative web video at http://www.youtube.com/user/ThriveMovement, which also shows what you can do to improve things.

Chapter 11: Other Devices and Theories

Nikola Tesla's Ionised-Air Electrical Generator.
Tesla also designed a device for picking up energy from the air. As far as I am aware, it was never patented and I have never seen a specification of its output. Perhaps it was one of Tesla's failures but personally, I doubt that. It might make a very interesting experiment so see what level of output can be achieved using it. The construction is shown here:

It is essentially, a rectangular cylinder which contains two spherical electrodes like a Wimshurst machine. The cylinder is positioned vertically, so that when the electrodes are powered up with high voltage to create spark discharges, the air inside the cylinder is heated which causes it to rise up the cylinder. The heated air is ionised, so a magnetic field generated by a surrounding electromagnet, causes the charged ions to move to opposite sides of the cylinder. Electrode plates positioned inside the cylinder, provide an electrical path for the excess positive and negative charges to flow together through the load - lighting, heating or motor circuits typically.

On the surface, this system would appear to be less than 100% efficient, in that the amount of power applied to the device to make it operate should be less that the amount of power drawn from it to drive useful loads. I am not sure that this is necessarily so. Firstly, the air already contains charged ions before this device starts to generate more. These naturally occurring ions gain in number when a thunderstorm is likely, even to the extent of giving many people a headache by their presence. These naturally occurring ions will be picked up by this device and without any input power needed to create them, they are capable of providing output power.

Also, the whole earth is immersed in the zero-point energy field. This is seething energy at the quantum level whose effects can be seen even at 'absolute zero'. This field is made of small random effects which
makes it hard to obtain useful energy directly from it. The field needs to be structured before energy can be
drawn from it. One way to do this is to align the field with an event which causes coherent waves of energy
to radiate outwards as a 'radiant energy' wave - something like the ripples caused on the surface of a pond
when a large stone is dropped vertically into the water. The ripple 'waves' move outwards from the 'event' until they reach the bank of the pond. If there was a generator attached to a float in the pond, it
would be possible to pick up some energy from the ripples. The same can be done with 'radiant energy'
waves if you can create them and know how to pick up energy from them.

Radiant energy waves can be formed by very short sharp uni-directional electrical pulses. Pulses less than
one hundredth of a second are suitable for this. One way of creating pulses of that type is using a spark
gap. In Tesla's device shown above, sparks are generated continuously. These sparks will generate radiant
energy waves radiating out at right angles to the spark. Without a doubt, the vertical cylinder will have a
mass of radiant energy shooting up it when it is being operated. This is in addition to the air ions which are
being picked up. The only question is whether or not the electrode plate arrangement shown is capable of
picking up any of this excess energy. Considering the metallic pickup device used by Edwin Gray to capture
radiant energy as described below, it seems highly likely that some of that additional energy is, in fact,
picked up and used to power the loads.

It should be noted that Tesla’s device shown above, will generate UV radiation in the same way as any MIG
or stick welder does, so care should be exercised to avoid looking at the arc or allowing the UV to shine on
your skin, even if the skin is covered by clothing. You can get serious sunburn through thin clothing if it is
subjected to strong UV radiation. Also, radio interference is likely to be generated by the arc, so screening
should be provided during any tests. WARNING: Tesla accidentally discovered that electric spark
discharges in air, ignite and burn atmospheric oxygen and nitrogen, producing 12,000,000 volt waves. The
oxygen and nitrogen, both below atomic number 19 are thereby transmuted into alpha and beta charges
(stripped helium nuclei with +2 charge each, and electrons with -1 charges each) by the powerful radiation
produced, having a voltage potential of 12 Mev. This is almost three times the Mev level of gamma radiation
emitted by radium, it may well be the reason why Tesla did not publicise the device shown above, and
should you decide to experiment with it, please be aware of the potential hazard of this radiation.

A variation on the above device of Tesla’s is given in the book “Physical Chemistry” by E. A. Moelwyn-
Hughes, Pergamon Press, Oxford 1965, page 224. Rutherford and Geiger determined the fact that radium
puts out alpha particles at the rate of 34,000,000,000 per second, each having two units of positive charge at
4.5 million electron-volts. This is a staggering amount of energy which ionises the air inside the housing and
produces enough power to be capable of replacing the entire Four Corners power complex indefinitely.

The variation of Tesla’s device shown above, supports the lead container with its gram of radium on a strap
across the bottom of the housing. The radiation ionises the air and the magnetic field separates the charges
and directs them to opposite sides of the housing, to be collected and used via the electrode plates. There
does not appear to be any reason why strong permanent magnets should not be used instead of the DC electromagnet shown.

Dr Harold Aspden's Electrical Power Generator Patent.
Scientists freely acknowledge that more than 80% of the matter and energy in the universe is “dark matter” and “dark energy” where “dark” only means that we cannot readily see that form of matter and energy. The highly respected British scientist Dr Harold Aspden, has been awarded a patent for a system to collect this energy directly. The patent, which is one of several similar patents included in this eBook, is reproduced here:

**Patent GB2390941 21st January 2004 Inventor: Dr. Harold Aspden**

**ELECTRICAL POWER GENERATING APPARATUS**

**Abstract**
An electric generating device includes two capacitors 1 and 2, each having a pair of concentric electrodes and in-series connection to inductors 3 and 4. Each capacitor has an electrode connected to a high voltage DC source 5 and another connected to a low-voltage or earth terminal 6. An AC Power output may be produced from terminals between each capacitor and inductor or from a transformer where the inductor is the primary winding. Electricity production may be sustained by drawing energy from the vacuum medium surrounding the electrodes.

**Field of the Invention**
This invention relates to a new and non-conventional means for the generation of electrical power. The energy source is the quantum underworld of space, the aether medium of the vacuum state, long recognised for its ability to allow the storage of electric field energy by reacting as its intrinsic charge is displaced, a process understood by physicists by reference to the research findings of Clerk Maxwell.

**Background of the Invention**
The current state of the art of electrical power generation does not recognise the possibility of ultimately tapping energy from the aether. Physics is taught on the basis that energy cannot be created or destroyed, inasmuch as it is conserved in all physical processes, though it can be degraded in its usefulness, as by burning of hydrocarbons and conversion into heat which dissipates as by radiation into outer space. The aether as a source or as an absorber of energy is not deemed to serve any specific role in the physics of energy deployment, it having been dismissed from consideration by invoking the notion of 'field energy' without admitting the specific physical reality of something in space that accounts for the properties involved.

Theoretical physicists have, however come to suspect that space devoid of matter is nevertheless a seething sea of activity subject to sporadic energy fluctuations which can create electron-positron pairs that exist momentarily before decaying back into their quantum underworld. Yet those same physicists deny all possibility that this energy resource of space itself can be exploited to provide useful power on a scale large enough to rival the role played by atomic power plants and fossil fuel generating installations.

Curiously, they do subscribe to the belief that one day they may be able to generate power on a viable commercial scale from fusion reactors by processes replicating what they believe sustains the Sun's heat output as hydrogen is transmuted into different atomic forms. In contrast with this rather elusive objective, it having proved beyond reach even after half a century of effort, this invention is based on success in generating power by replicating, not the Sun's onward energy decay, but rather a process akin to that by which the Sun itself was created from energy drawn from the enveloping aether medium.

The invention to be described below has emerged from an in depth theoretical investigation into the properties of the aether and quite independently of any of the well known claims of published record which feature at the fringe of mainstream scientific literature. A recent and very well-presented account of what amounts to a century of relevant energy history is the book 'The Search for Free Energy' by Keith Tutt, published in 2001 by Simon Schuster (ISBN 0-684-86660-9). Here in this book is a comprehensive background of information concerning the energy devices of several researchers but the references to Nikola Tesla and T. Henry Moray are particularly pertinent to the subject of this invention and, though imposing a
limitation on what can be legitimately claimed by this patent application, they serve also as a basis for a very important lesson to those engaging in this field of invention.

The lesson is that it is not sufficient to build and demonstrate something that works, if you do not fully understand why what you have devised actually does work. This is especially the case here where one is claiming a source of energy hitherto unknown. The invention to be described below will, in its broadest sense, appear to be quite similar to what T. Henry Moray is said to have demonstrated in showing that substantial electrical power could seemingly be drawn from the aether using a simple wire antenna strung between two poles.

However, as will be seen, the antenna is not needed and the reason is that the energy source is not the radiant emission by some process involving radio wave propagation through the aether, but rather what can best be described as a phase-lock that couples the apparatus with the quantised motion of electric aether charge. There is a technique, to be described below, by which it is possible to exploit this phase-lock condition by setting up an energy oscillation involving an apparatus component and its enveloping aether, the result being that energy in an immediately useful electrical form is imported into the apparatus from that aether.

**Brief Description of the Invention**

According to one aspect of the invention, an electric power delivery circuit comprises two capacitors, each having a pair of electrodes formed by a pair of metal cylinders having concentric axes, each capacitor having an associated inductor series-connected to it to form a capacitor-inductor unit, DC voltage excitation means connected to a parallel combination of the two capacitor-inductor units, whereby to apply between corresponding electrodes of the capacitors a DC bias voltage which primes them with electric charge, and power output terminals, one at each point of connection between a capacitor and its associated inductor, whereby to provide for an AC power output owing to oscillations of electric charge between the two capacitors at the resonant frequency of the capacitor-inductor units.

According to another aspect of the invention, an electric power-delivery circuit comprises two capacitors, each having a pair of electrodes formed by a pair of metal cylinders having concentric axes, each capacitor having an associated inductor series-connected to it to form a capacitor-inductor unit, DC voltage excitation means connected to a parallel combination of the two capacitor-inductor units, whereby to apply between corresponding electrodes of the capacitors a DC bias voltage which primes them with electric charge, and power output terminals, one at each point of connection between a capacitor and its associated inductor, whereby to provide for an AC power output owing to oscillations of electric charge between the two capacitors at the resonant frequency of the capacitor-inductor units.

According to a feature of the invention the capacitors have no intervening solid or liquid dielectric medium separating their concentric electrodes.

According to another feature of the invention, two inductors are coupled electromagnetically by having a common ferrite core and their primary windings are connected to their associated capacitors in the polarity configuration which assures that, in their mutually resonant state, electric charge is exchanged between the two capacitors.

According to yet another feature of the invention, the central axes of both cylindrical electrode capacitors are mutually parallel.

According to a further feature of the invention, an electrical power delivery system comprises a plurality of these electric power delivery circuits, where the central axes have different angular orientations as between the different circuits.

According to a still further feature of the invention, in such a power delivery system, the difference in angular orientation of the central axes is at least 60°.
Brief Description of the Drawings

Fig. 1 shows an electrical power generating circuit incorporating two concentric cylindrical capacitors having central axes which are parallel.

Fig. 2 shows a modified version of the circuit of Fig. 1 with a transformer system providing the inductors and an output winding.

Fig. 3
Fig.3 illustrates a mutually inclined capacitor system comprising two pairs of concentric cylindrical capacitors.

**Detailed Description of the Invention**

The invention draws energy from the aether. To understand why the invention works, one needs to understand the process by which the aether stores energy when an electric field is set up across the dielectric separating two capacitor plates. Moreover, one needs to understand the means by which the aether determines the quantum of action, specifically in the form of the Bohr magnetron and the unit of angular momentum linked to Planck's constant.

It is not sufficient to imagine that electric charge in the aether is displaced from a rest position in a background continuum of opposite charge polarity to which it is attracted by a restoring force. Indeed, one must consider such action to be superimposed on a system of charge which has an underlying jitter motion, a quantum theory theme associated with the German physicist Heisenberg (Zitter-bewegung, which has the dictionary meaning 'Circular fluctuation movement, of spin'). When these two factors are combined, and the constraint added of there being a phase-lock which keeps that jitter motion in synchronism as between the charges, one finds that the physical theory involved has some very interesting consequences.

One of these consequences is that a spherical or cylindrical volume of aether, if spinning bodily about a central axis, will acquire a magnetic moment and set up an electric field inside that sphere or cylinder that is directed radially with respect to the spin axis. A summary analysis is presented in the Appendix to this specification, being, in part a quotation from pages 31-33 of a booklet entitled 'The Theory of Gravitation' which the Applicant of this invention, Dr. Harold Aspden, authored in 1959 and duly published early in 1960.

The induction of electric charge by 'aether spin' was there shown to give a physical basis, both qualitative and quantitative, for the geomagnetic moment, the property of body Earth of setting up a magnetic field which created magnetic North and South poles at latitudes offset from the geographic poles, with the geomagnetic polar axis precessing slowly around the Earth's spin axis at a rate of several hundred years per revolution. By identifying its source as a rotation of a sphere of aether coextensive with body Earth, a volume of aether relative to which the Earth could have a component of motion even though the aether spin frequency is equal to that of the Earth, this axial tilt of some 17 degrees has a physical explanation. However, that aspect of the aether's role was not seen at the time as offering anything of promise technologically. The physics involved is nevertheless very relevant and directly pertinent to the experiments on which this invention is based, the findings of which would otherwise be quite baffling scientifically.

The applicant has, over the 40 or so years since the theory was first published, given a great deal of consideration to the theoretical implication that, just as aether spin can set up electric charge displacement inside coextensive matter, so the setting up of an electric field directed radially with respect to an s axis can induce aether spin about that axis and with it develop angular momentum. Indeed, in the author's onward publications on this subject, as, for example, 'Physics Unified' published in 1980 by Sabbeton Publications, P.O. Box 35, Southampton, England (ISBN 0 85056 0098), it is shown how the onset of the force of gravitation when a disordered aether consolidated into an orderly structured form caused protons to accrete more rapidly than electrons, owing to their higher mutual rate of gravitational acceleration. This created stars with all initial positive charge and the associated aether spin resulted in the stars acquiring their spin states and shedding matter which consolidated into planets which share the angular momentum so generated. The aether with its property of spin as related by its electric charge density according to the formula presented in the Appendix is therefore the key factor if we attempt to account for the creation of the stars which populate our universe.

That same formula, however, is equally valid if applied to the circumstance where a radial electric field is set up between the concentric cylindrical electrodes of a capacitor formed around a hollow dielectric cylinder. It tells us how fast the aether within that dielectric will spin. The related theoretical analysis shows that the quantum phase-lock feature of the aether imports from the external aether world an amount of energy equal to that supplied in setting up aether charge displacement, this imported energy being the dynamic energy corresponding; to the acquired aether angular momentum. Guided by the argument concerning stellar creation one can see that this aether angular momentum can be transferred to matter and this process also has its energy transfer implications.

However, one can wonder what happens if, after setting up a radial electric field in that capacitor having concentric electrodes, the applied voltage is reduced, thereby withdrawing electric field energy from the capacitor. The imported energy present in kinetic energy form as a cylindrical shell of aether spins about the central axis of the capacitor will tend to sustain electric charge displacement. To conserve energy, since the
electric energy output that is, for the lowest dielectric constant (the permittivity of the vacuum), double the step, this energy can only be shed by augmenting that released electrostatically. In other words, the net input in each cycle of change. One can then envisage an oscillation escalating in energy content powered almost wholly by aether input before one taps into that source of power to draw off energy at a rate consistent with stable operation.

This is, of course, a bewildering prediction that no physicist could imagine as being at all possible and yet, given the relevance of the theoretical argument involved, as applied to the phenomenon of geomagnetism and stellar creation, which are supported by strong evidence in that book 'Physics Unified', once such a notion is conceived it surely has to be put to the test by experiment. This then, after decades of effort before this realisation has dawned, is the basis on which the Applicant has only now come to appreciate the amazing technological possibilities that lie before us and is asserting by this patent specification that energy can in fact be tapped from the aether on a commercially viable scale.

Given that aether theory indicates that the special form of capacitor described above will, if subject to an oscillatory charge condition, generate an excess of energy, a question to consider is why such a phenomenon has not manifested itself in bench-type experiments performed in numerous electrical laboratories over the past one hundred years. Ostensibly the implication is that the capacitor will exhibit a negative resistance if used with an inductor as a component in what would become a self-resonating circuit. The answer to this may be that if such a phenomenon has occurred it has passed unnoticed or been regarded as spurious or noise-related, being something connected with radio interference etc. Alternatively, and as a function of the size and scale of the apparatus, the effect may have lacked an exciting trigger needed to overcome an energy threshold set by such factors as circuit contact resistance or contact potentials as well as the basic resistance of the inductors which, with the capacitors, form the resonant circuit.

Note that, even for a capacitor of quite large physical dimensions, having regard to its accommodation on top of a laboratory bench, the actual capacitance is necessarily quite small. being of the order of a billionth of a farad. This means that a capacitor charge fluctuation of the order of a volt would only imply energy fluctuations that are of the order of a billionth of a joule per cycle. The situation is quite different if perchance a DC bias voltage of, say, 5,000 volts is applied to the capacitor. Then a small superimposed voltage fluctuation makes the related energy fluctuations very much larger with much greater prospect of an escalating self-resonance being triggered.

With this in mind the applicant perceived a possible prior art link with the experimental claims reported by Dr. Moray who, in 1929 is said (see pages 46-50 of the above-referenced recently-published book by Keith Tutt) to have powered six 100 watt light bulbs plus a standard 575 watt electric flat iron, merely by providing an earth connection and coupling an input lead to an overhead wire antenna. The apparatus involved had no other source of input power but included a special arrangement of capacitors and presumably some kind of high frequency inductor/transformer unit.

In spite of the attention given to the Moray demonstrations, it seems that the secrets involved in the design and construction of the apparatus remain unknown and so cannot feature in the prior art of published record. Nor, indeed, can the anecdotal evidence of Moray's efforts serve to show that the subject invention has been put to prior use. The technology as to how to replicate the Moray device, always assuming it did perform as claimed, has therefore to be rediscovered and, indeed, given that there is reference to his detectors incorporating some special substance which was referred to as 'Swedish stone', possibly the dielectric he used in his capacitor construction, there is a considerable mystery to unravel. More to the point, however, one is led to believe that Moray was implying that the energy he was tapping was radiant energy drawn from the aether, with that antenna featuring prominently because, without it being connected, the energy output fell to zero. However, as he surely may well himself have known, one just cannot draw power on such a scale from a simple overhead wire strung between two poles and so, without know how, he would have suspected that the energy inflow was coming into his capacitors via the action of that mystery substance he called 'Swedish Stone'.

The applicant here suggests that, based on an insight into the quantum workings of the aether medium as outlined above, the curious discovery demonstrated decades ago by Dr. Moray may have been attributable to setting up an oscillation in a resonant circuit including, a concentric cylindrical electrode capacitor which had a voltage bias of the order of a thousand and more volts fed from a connection to that overhead antenna but drawing no significant current from that antenna other than enough to prime his capacitor with charge.
and stimulate a high frequency fluctuation which could initiate an escalating circuit oscillation tapping aether energy from the aether spin induced in the capacitor dielectric.

This is speculation, but it is sufficient to justify the Applicant's interest in constructing a capacitor and seeking to verify the assumptions just made. Notwithstanding, the reference alcove to Dr. Moray and the note below concerning Nikola Tesla, what it leads to is new invention by virtue of full disclosure of details of operation and manufacture of something hitherto unknown, the actual means by which to harness a source of energy latent in the aether medium and deemed by those familiar with state of the art knowledge to be beyond man's reach. Furthermore, there are supplementary inventive features of a special nature because of the way the subject invention exchanges energy between two capacitors and also because the optimisation of aether power output from the capacitors is found to be a function of the orientation of the capacitor axes relative to the cosmic background owing to the Earth's rotation.

It seems here appropriate to mention something described by Nikola Tesla in his U.S. Patent No. 685,958. This was filed on 21 March 1901 and granted on 5 November 1901. It was entitled: 'Apparatus for the Utilisation of Radiant Energy'. By installing two metal plates, one high above the ground and the other at ground level, with wires connecting the plates to separate electrodes of a capacitor, it was stated that the capacitor became charged to a very high potential, the energy input being that radiated to Earth from outer space. This may well have motivated the efforts of T. Henry Moray but, so far as this Applicant's invention is concerned, no such input from overhead components is necessary as a quite different energy source is at work, namely the zero-point vacuum energy activity of our quantum underworld.

Referring now to Fig. 1, two capacitors 1, 2 formed by concentric cylindrical metal electrodes and having their central axes parallel, form part of a resonant circuit combination by each being series-connected to an inductor 3, 4 having a ferrite core. Their inner electrodes are connected to a high-voltage DC source 5 and their outer electrodes are separately connected through their corresponding inductors to a low-voltage or earth terminal 6. A resistive load device 7 is connected via switch 8 between the junction points of the capacitors and inductors.

In operation, owing to spurious electrical signals induced in the inductors, or to an imposed electrical stimulus provided by means not shown, the priming electric charge of the two capacitors will develop oscillations as charge is exchanged between the two capacitors. There is energy inflow owing to the quantum coupling of electric charge displaced between the concentric electrodes of each capacitor and the quantum activity of the underworld of the enveloping aether. This affords an electrical energy output which is supplied upon closure of switch 8.
Referring to Fig.2, the inductors 3, 4 are shown to have a common ferrite core 9 and to have secondary windings 10,11, which, by transformer action, can supply electrical power output between terminals 12 and 13.

The apparatus of Fig.1 and Fig.2 will, when viewed in side elevation, appear as having a capacitor form with an outer cylindrical electrode within which there is a slightly elongated inner cylindrical electrode, to facilitate the high-voltage connection to that inner electrode. Fig.3 shows, in very simple diagrammatic form, two such arrangements 14, 15, with the central axes of the two pairs of capacitors mutually inclined. There may, however, be three or more such pairs of capacitors, each pair constituting a circuit such as is depicted in Fig.1 or Fig.2.

The reason for configuring multiple capacitor systems, each with its own power output, in a combined manner with the outputs merged to supply an overall energy producing system is that the aether energy output of each capacitor unit is a function of axis orientation. This is because the quantum activity of the aether has its own preferred axis and, as the Earth rotates there is variation of the relative axial orientation in a daily cycle. Also, one needs to cater for systems applying, this invention in a mobile application, which also implies change of orientation and by having; the mutually inclined capacitor axis configurations one can be assured that the potential power output avoids the null situation that can occur if the capacitor axes of a stand-alone unit of Fig.1 or Fig.2 were to be at right angles to the aether quantum spin axis.

The capacitor electrodes can be of thin metal sheet foam and so of light weight and preferably are not spaced apart by any dielectric medium, whether liquid or solid. They need to be held apart by a simple insulating frame structure. The reason is, that the only dielectric medium that is operative in the functioning of the invention is the vacuum medium and to have a normal dielectric present implies more capacitance and so extra current oscillation without extra energy gain per cycle of oscillation. The key factor assuring operation is the need for circuit resistance to be low compared with capacitance that is solely attributable to the vacuum medium combined with the high voltage priming which greatly enhances the power output to weight factor.
The two capacitors of a pair are preferably of identical capacitance and structure, as are the inductors, so that the oscillation period of the two resonant sectors of the circuit is the same. The common ferrite core feature of the Fig.2 configuration assists in this role.

The apparatus will normally be designed to operate at a capacitor frequency of the order of 100 KHz or more, and a voltage of 10,000 V or higher, and so the transformer output of Fig.2 will be preferable with voltage duly adjusted to suit the application. The high frequency AC so produced can then be converted as needed by using the appropriate technology of known form.

Appendix

Extract from pp. 30-31 of 'The Theory of Gravitation', 1960 printed publication by the Applicant. Note that the earlier pages explained that the aether comprises a system of electric particles in a cubic crystal-like distribution set in a uniform background continuum of opposite charge polarity, the particle system and the continuum both sharing a common circular orbital motion of radius \( r \) and the relative velocity between the particles and continuum being the speed of light.

The Effect of Aether Rotation

Consider what happens when a large volume of the aether is rotating bodily. The continuum and particle system rotate together. There will be no resultant magnetic moment unless the particle distribution is disturbed. An evident disturbance is the centrifugal effect arising from aether rotation, but for the angular velocities of magnitude found in the solar system this effect is of negligible consequence. A much more important effect arises from the synchronising interaction between particles in the rotating volume. This requires that the particles shall move about their neutral points at the same angular velocity. Thus if a particle is to have a velocity component \( V \) directed in the plane of its orbit, whilst retaining a mean velocity \( C/2 \), its speed along its orbit must be of the form \( C/2 + V \cos(P) \), where \( P \) is the angle subtended by a line joining the particle and the centre of its orbit relative to a fixed reference datum in the inertial frame. To satisfy the above requirement the centre of the orbit cannot be the neutral point. Evidently the particle is distant from this neutral point by \( r + (2 V r / C) \cos(P) \). As \( V \) is much less than \( C \) the effect of this is that the particle is moving around a circular orbit whose centre has been displaced a distance \( 2 V r / C \) perpendicular to \( V \) in the plane of the orbit. If \( V \) is much less than \( w x \cos(A) \), where \( x \) is the angular velocity at which the aether rotates, \( x \) is the distance of the aether particle from the axis of rotation, and \( A \) is the angle of tilt of the axis to the common axial direction of the aether particle system, this displacement distance is \( 2 (w x r / C) \cos(A) \). Consider a disc-like section of the rotating aether of radius \( x \) and unit thickness. Then, the effective charge displacement arising from the effective physical displacement of the particles is \( 2 \pi x s (2 w x r / C) \cos(A) \). The disc has acquired a uniform charge density of \( 4(w r s / C) \cos(A) \) esu/cc. The polarity of this charge depends upon the direction of rotation of the aether.

When evaluated from the aether data already presented, the charge density is found to be: \( 4.781 w \cos(A) \) esu/cc. This charge density represents a charge component which rotates with the aether.

Calculation of the Geomagnetic Moment

For Earth, \( w \) is 7.26 \( \times \) \( 10^{-5} \) rad/sec and \( A \) is 23.5°. Thus the Earth’s charge density is, from the above expression, 0.000319 esu/cc. The rotation of this charge gives rise to a magnetic moment of:

\[
(0.000319)(4 \pi / 15)w R^5 / C \quad \text{where } R \text{ is here the radius of the Earth's aether.}
\]

If \( R \) is greater than the Earth’s radius (6.378\( \times \)\( 10^8 \) cm) by a small factor \( k \), the Earth’s theoretical magnetic moment becomes \( (1 + 5k)6.8 \times 10^{25} \) emu. This may be compared with the measured value of the Earth’s magnetic moment of 8.06 \( \times \) \( 10^{25} \) emu.

An upper limit of 0.035 is imposed on \( k \) suggesting the Earth’s aether terminates at a mean height of about 140 miles above the Earth’s surface. This suggests that the ionosphere may be a phenomenon arising at the aether boundary.

Claims

1. An electric power delivery circuit comprising two capacitors each having a pair of electrodes formed by a pair of metal cylinders having concentric axes, each capacitor having an associated inductor series-connected to it to form a capacitor-inductor unit, DC voltage excitation means connected to a parallel
combination of the two capacitor-inductor units, whereby to apply between corresponding electrodes of the capacitors, a DC bias voltage which primes them with electric charge, and power output terminals, one at each point of connection between a capacitor and its associated inductor, whereby to provide for an AC power output owing to oscillations of electric charge between the two capacitors at the resonant frequency of the capacitor-inductor units.

2 An electric power delivery circuit comprising two capacitors, each having a pair of electrodes formed by a pair of metal cylinders having concentric axes, each capacitor having an associated inductor series-connected to it to form a capacitor-inductor unit, DC voltage excitation means connected to a parallel combination of the two capacitor-inductor units, whereby to apply between corresponding electrodes of the capacitors a DC bias voltage which primes them with electric charge, each inductor being the primary winding of an electrical transformer, the secondary winding of which, serves to provide an AC power output owing to oscillations of electric charge between the two capacitors at the resonant frequency of the capacitor-inductor units.

3 An electric power delivery circuit according to Claim 1 or 2, wherein the capacitors have no intervening solid dielectric medium separating their concentric electrodes.

4 An electric power delivery circuit according to Claim 1 or 2, wherein the capacitors have no intervening liquid dielectric medium separating their concentric electrodes.

5 An electric power delivery circuit according to Claim 1 or 2, wherein the two inductors are coupled electromagnetically by having a common ferrite core and their primary windings are connected to their associated capacitors in the polarity configuration which assures that, in their mutually resonant state, electric charge is exchanged between the two capacitors.

6 An electric power delivery circuit according to Claim 1 or 2, wherein the central axes of both cylindrical electrode capacitors are mutually parallel.

7 An electric power delivery system comprising a plurality of electric power delivery circuits according to Claim 6, wherein the central axes have different angular orientations as between the different circuits.

8 An electric power delivery system according to Claim 7, wherein the difference in angular orientation of the central axes is at least $60^\circ$.

Comments by Dr Aspden on 19th March 2006:

**OUR ENERGY FUTURE**

A Message of Vital Importance

The world needs a new source of energy, one that is not an exhaustible commodity subject to power-play as between nations. Yes, one can dream and then awake to say this is impossible, but I urge those with the necessary skills to heed what I have to say in my three messages below.

First, however, let me introduce myself. My name is Dr. Harold Aspden. I am retired and elderly but have had a lifelong scientific interest in fundamental physics relevant to the energy theme. My 6-year university education in U.K. was at Manchester University and Cambridge University (Trinity College). My 33-year working career in U.K. comprised 9 years with English Electric and 24 years with IBM. Though having high technical qualifications (see below), being interested in the specialised field of protecting inventions pertaining to electrical engineering, I became a Chartered Patent Agent and later a European Patent Attorney. My last 19 years with IBM were spent as Director of IBM's European Patent Operations. This was followed, in my early retirement, by 9 years as a Visiting Senior Research Fellow at Southampton University and thereafter my scientific interest has been a private pursuit evidenced by my writings as on this and my related websites. My formal qualifications are: B.Sc., Ph.D., C.Eng., F.I.E.E., F.I.Mech.E., C.Phys., M.Inst.P., C.Sci., Wh.Sc.

Message No. 1: Physicists have come to recognise that there exists a quantum underworld alive with energy and permeating all space. However, their related research aims merely at probing experimentally the spectrum of elementary particles that have a transient existence as a product of that energy activity. The reward they seek is recognition should new particles be discovered and, by their properties, reveal
connections with other particles that help in formulating a new theory or verifying an existing theory. Sadly, they do not see that quantum underworld as a potential source of energy that we can harness. Nor have they understood how most of the energy shed in creating matter formed the elementary particle which bears the name proton and which, together with the electron, constitutes the hydrogen atom.

There is also a secret they have yet to fathom. It is the effect of creating a radial electric field centred on electrical charge around which that quantum underworld can develop a state of spin that causes it to shed energy. In the presence of a radial electric field set up by an electrically charge body, whatever constitutes that quantum underworld that permeates all space shares a motion like that of sequence dancers who keep in step with one another as they move around the dance floor, a synchronous motion, which, in the presence of that radial electric field can only be held if a secondary motion develops around an axis centred in that radial field.

How else could the Sun spinning about its own axis have come into existence? Here we have gravity attracting hydrogen atoms and pulling them so closely together that ionisation occurs, meaning freeing some electrons from their proton bonding, and so, because the mass of a proton is very much greater than that of the electron, creating a Sun having a body that is positively charged sitting within an outer shell of negative electron charge. Two free protons experience a mutual rate of gravitational acceleration that is 1836 times that experienced by the interaction of two electrons. The body of the Sun, therefore, has a uniform mass density and a uniform positive charge density enclosed within a compensating negative charge at its surface. This is because gravitational compaction forces balance the expansion forces attributable to electrostatic repulsion. It further means the presence of a radial electric field within the body of the Sun and, in turn, owing to the effect of this field on the space medium of the quantum underworld, this induces a state of spin accompanied by release of energy from that medium to feed the kinetic energy of that spin.

In depth analysis of the physics involved, meaning the effect of the resulting radial electric field on that quantum underworld, then allows one to calculate the resulting rate of spin and thereby understand how the solar system was created.

So, if the reader is a physicist, here is the way forward and full guidance on this is to be found on my parallel website www.aspden.org or in a new book of mine entitled Creation - The Physical Truth, that will be published in the near future. However, if the reader is not a physicist but has the technological aptitudes of the university-trained electrical engineer then it is Message No. 2 below that warrants attention.

**Message No. 2:** If it were possible to generate electrical energy by tapping an omnipresent medium it is surely to be expected that the occasional natural phenomenon might already have hinted at this possibility. Consider, therefore, the thunderball, a glowing spherical object sometimes seen, especially following a lightning storm. It appears aethereal in the sense that it can move unimpeded through matter, yet remains an enigma, an unsolved mystery of record in the annals of science. Lightning strokes are high current discharges which, as electrical engineers well know, can develop a 'pinch effect' squeezing the electron-carried current into a filamentary flow within a cylindrical channel of positively charged air. That implies a radial electric field, a pulsating radial electrical field if the discharge surges, a sure recipe for something to happen that could form a miniature Sun, the thunderball. So when we look at a thunderball we are looking at a natural phenomenon that has drawn energy from that quantum underworld of space, energy which is then dissipated, but energy shed by a process we can surely harness, once we understand the physics involved.

Scientists lacking the necessary imagination do not seek to understand how the thunderball is created and so they seldom write about it. So here we have something to think about. It is Nature's message telling us: "Produce a radial electric field, one that pulsates, and you can develop a spin that taps energy from the quantum underworld of space." As engineers, however, we need to be practical and, if possible, we should avoid trying to replicate a phenomenon that involves powerful electric discharges, if there are better ways in which to proceed.

So now I come to my primary theme in this Message No. 2. It is a brief survey of a few of the claims of record that have declared a mysterious energy gain and have features which I see as relevant to what has been said above. In particular I draw attention to the research findings of four different pioneers in what has come to be termed 'The Search for Free Energy', this being the title of a really excellent book by Keith Tutt, published by Simon & Schuster in 2001. Three of these are described in considerable detail in that work. I now ask you to keep in mind my reference to a radial electric field as I mention each of them below and do realise that electrical structures of cylindrical form are a key feature.

Nikola Tesla is famous for his research concerning electromagnetic induction and high voltage solenoidal transformer apparatus (Tesla coils) and he is said to have demonstrated an automobile which derived its
power by tapping energy from space. He did not disclose its design details and died leaving us with a mystery. Tesla coils comprise large solenoidal windings concentrically mounted and operate with high voltage pulsations between their cylindrical forms which must produce a pulsating radial electric field between those windings. So, although electromagnetic induction effects are the primary focus of attention, there is here scope for the electrical action described in Message No. 1 above. Tesla may well have stumbled experimentally upon a way of tapping energy from space, but without understanding the true underlying physical process.

Dr. Henry Moray, a pioneer of the 1920-1930 era, demonstrated something which merely needed a kind of antenna, a wire connected from tree tops to earth via electrical apparatus in the boot (trunk) of his automobile. It is said that the latter included several capacitors and that a kilowatt level of power was generated. In this case the automobile merely carried the test apparatus for demonstration at a location remote from a built-up area and any electrical power line interference. No doubt Moray was seeking to follow in Tesla's footsteps by drawing energy from the Earth's electric field, known to be measured in hundreds of volts per metre. It is likely that those capacitors were of Leyden jar type configuration, that is cylindrical in structural form, and that the wire linked to tree tops tapped charge at a kilovolt voltage level. However, the output power claimed could surely not have come from that source. Therefore one must assume that Moray used that treetop voltage input merely to prime the voltage across his capacitor electrodes, whilst incorporating some special feature in the operation of his electrical circuit that gave access to the energy of the quantum underworld. Capacitors having concentric electrodes of cylindrical form will, when charged electrically, have a radial electric field in the space between the electrodes. Several capacitors coupled together could give rise to oscillations of charge as between the capacitors and so lead to a pulsating radial electric field. Yet though demonstrating as possible something that should not be possible, a mysterious inflow of energy able to illuminate several light bulbs, Moray could surely not have understood the true physical process that was feeding energy into his apparatus. Again I see this as relevant to what is stated in Message No. 1.

Stan Meyer demonstrated apparatus that included sets of concentric tubular electrodes enclosed in a cylindrical container filled with water, the electrodes being fed by high voltage (5 KV) pulses. Combustible gas was generated, a mixture of hydrogen and oxygen, the burning of which generated far more heat than could be accounted for by the electrical energy input. Energy was being tapped as if from nowhere unless the source was the ambient medium of space itself. Here there was a pulsating radial electric field and electric charge oscillating between different components in Meyer's apparatus. Meyer did not offer any useful explanation as to the physical process underlying what he could demonstrate but persisted in conveying the message that the invention was wonderful and talking about a multiplicity of applications such as powering automobiles, ships etc. This is the project not mentioned in Keith Tutt's book. As for the Tesla and Moray projects Meyer's research was a U.S. based activity. It did, however, attract the interest of a British Admiral, Admiral Tony Griffin who was concerned with the impact of new technology upon the marine industries. Griffin witnessed Meyer's demonstrations and was interested in its development. Indeed an article on the subject mentioning Admiral Griffin and entitled 'Free Energy for Ever' was published in the January 1991 issue of the U.K. magazine Wireless World. The importance of the article was evident from the fact that the Editor of that magazine was the author.

Paul Baumann, a member of a Christian community in a isolated valley high in the Swiss Alps has constructed working free energy devices which have been demonstrated to visitors. The first working prototype was relatively small and included a pair of glass Leyden jars, concentric capacitors. Keith Tutt in his book devotes 30 pages to this subject. The high voltage needed to prime the capacitor operation was generated by a Wimshurst machine driven by the electric power generated. The community has, however, kept design details secret. In spite of such information as is available the underlying physical process governing its operation remains a mystery. Yet I can but feel confident that what I say in my Message No. 1 provides the answer.

Message No. 3: My Message No. 1 has drawn attention to the physical process by which the vast amount of energy needed to create the Sun was extracted from the quantum underworld that permeates all space. My Message No. 2 has drawn attention to the reported efforts of just some of the several energy research pioneers who actually demonstrated apparatus that, contrary to accepted scientific principles, drew energy from a mystery source. My Message No. 3, based on recognising the common physical feature can but be the suggestion that technology for generating our power needs from the hidden underworld of space has to be possible. Accordingly, I will now outline what I see as the basis on which to build the ultimate power generating device that harnesses the physical principles presented in Message No. 1.

Being 78 years of age and no longer having access to university research laboratory facilities, I can but leave it to others to take note and, hopefully, prove me right. If proved right then the world will benefit and the
impending energy crisis will be avoided. Hopefully also, the scientific community might then be willing to accept my claim as to how the quantum underworld deploys its energy into proton creation and is active in producing the phenomenon of gravitation. I know of no other theory that has been able to derive theoretically the value 1836.152 of the proton/electron mass ratio. I would like to see that recognised as my contribution to man's knowledge.

Consider a capacitor formed by a pair of concentric cylindrical electrodes, something many of us remember from the school physics laboratory, the Leyden jar. However, the capacitor structure I have in mind is very much larger and has to be operated at a quite high voltage. When that voltage is applied between the electrodes electric charge is displaced in the underlying vacuum medium located between those electrodes. A commensurate amount of electric charge is thereby held in place on those electrodes, a negative polarity charge on one and a positive polarity charge on the other. Given my claim that this is accompanied by 'vacuum spin', aether rotation, which has imported an equal amount of energy owing to a quantum phase-lock as between the charge of the vacuum medium, we have the energy gain we seek to exploit.

The problem, however, is that, with this simple capacitor configuration, the only control parameter available is the reduction of the voltage between the electrodes. This will shed energy within the circuit of the apparatus used, the outflow of electric charge at the voltage difference merely delivering energy equal to that originally supplied by our voltage source. The added energy imported from space is merely dispersed by the 'vacuum spin' slowing down but expanding beyond the bounds of the capacitor electrodes as it conserves its angular momentum. The energy imported from the quantum underworld of space has no way of enhancing the energy output of the capacitor circuit and so is left to dissipate itself and eventually be reabsorbed by that quantum underworld that pervades all space.

However, now consider a concentric electrode capacitor having a third cylindrical electrode intermediate the inner and outer electrodes. Here we have a control parameter other than the voltage between the outermost and innermost electrodes, because we can wonder about the voltage of the central electrode whilst retaining the other voltage difference at a constant high level. In fact, by keeping the latter voltage difference constant but varying the voltage of the intermediate electrode we can decrease the capacitor energy of one half of the overall capacitor as that of the other half decreases. The imported energy shed by one half of the overall capacitor can then contribute to the action that energises the other half and thereby induce oscillations from which energy can be extracted and deployed as a power source.

One needs two such capacitors having their central electrodes coupled through a load circuit in order to capture the 'free energy' inflow and get it to do useful work rather than being dissipated. An inductance in the coupling circuit can determine the oscillation frequency and, since the energy inflow increases with frequency, this should no doubt be well into the kilocycle region. The figure below is a simple schematic diagram of the electrical apparatus that I have in mind.

So my Message No. 3 is what I may describe as a 'thought experiment', one that I cannot verify myself, owing to my age and lack of facilities. I therefore can but record my thoughts and hope that others will prove me right and not wrong.

The capacitors depicted in the figure should have their electrodes spaced so that the capacitance C as between their central and outermost electrodes is the same as the capacitance C between their central and innermost electrodes. Suppose that the outermost electrodes are maintained at a voltage of 20,000V relative
to the innermost electrodes. This means that the two central electrodes will be at an intermediate voltage which we expect to be 10,000V in the absence of oscillations. However, as with any ever-active electrical system, there will be minor voltage fluctuations affecting the central electrodes. So we may ask what happens if the voltage of the central electrode of capacitor A decreases owing to electric charge being shed by the inner capacitance C but gained by the outer capacitance C. Think about that for a moment. You will see that it implies reciprocal action in the opposite sense by capacitor B, as current flows from A to B via the central inductor coupling. Yet no net current flows from the 20,000V power source.

Now, of course, common sense backed by our scientific training assures us that this system can but keep its equilibrium without those minor voltage fluctuations building up in some way. Yet, if we heed Message No. 1 and keep in mind Message No. 2, there is a question we must ask. If current does flow through that central link between A and B, one half of A and one half of B both shed energy and so release the imported 'vacuum spin' energy, if such is present. This occurs as other halves of A and B have to gain energy and as angular momentum of the imported 'spin energy' spreads into the other sections of the capacitors. The question then is: "Does that imported energy escape, as it does for the two-electrode capacitor configuration, or might it be retained and so augment the action?"

I submit the answer can only be provided by actual experiment. If the energy does escape then there is nothing further to discuss. However, if some of that energy is captured then we can expect an escalation of oscillations in that inductive link and so can then say that a new source of energy has been discovered. Those oscillations will be a function of the capacitance C and the inductance of the load circuit. Given a high frequency and a high voltage a significant level of power per unit volume of capacitor structure will be produced. If power output at a level commensurate with the claims of Tesla, Moray, Meyer and Baumann results the world's energy future is then assured. A pollution-free energy resource powered by the quantum underworld of space will be at hand wherever we are on body Earth.

The Design of Paulo and Alexandra Correa.
Paulo & Alexandra Correa have discovered a way of converting Tesla's longitudinal waves into ordinary electrical power. They have made US Patent Application 2006/0,082,334 entitled “Energy Conversion Systems” in which they show various ways of achieving this energy-type conversion.

Their techniques range from applying the longitudinal wave energy coming from a Tesla Coil directly to two capacitors via diode rectification and the voltages generated are related directly to actual ground earth potential:

The patent application forms part of this set of documents so the full details can be examined. A theory of operation is presented based on their many experiments and observations, and the practical form of one of their conversion devices is:
Professor Konstantin Meyl.

Another key person in the advancement of current theory and analysis is Professor Konstantin Meyl who has described how field vortices form scalar waves. He has described how electromagnetic waves (transverse waves) and scalar waves (longitudinal waves) both should be represented in wave equations. For comparison, transverse EM waves are best used for broadcast transmissions like television, while longitudinal scalar waves are better for one-to-one communication systems like cell phones.

He also presented the theory that neutrinos are scalar waves moving faster than the speed of light. When moving at the speed of light, they are photons. When a neutrino is slowed to below the speed of light, it becomes an electron. Neutrinos can oscillate between e- and e+. Fusion involves e-, and a lightning flash involves e+. Energy in a vortex acts as a frequency converter. The measurable mixture of frequencies is called noise.

Dr. Meyl has pointed out that Tesla measured the resonance of the Earth at 12 Hz. The Schumann resonance of the Earth is 7.8 Hz. Meyl shows how one can calculate the scalar wave of the Earth to be 1.54 times the speed of light. He has developed a model which ties the expansion of the earth to be the result of the earth’s absorption of neutrino energy. The ramifications of this model are that neutrino energy can be tapped. He took this to the next step and postulated that Zero Point Energy is neutrino power – energy from the field; available at any time, and present everywhere. To show the place of neutrinos in conventional science, Meyl noted that the 2002 Nobel Physics prize was in regards to work on neutrinos. The English-language version of Dr. Meyl’s web site is at http://www.meyl.eu.

Nikola Tesla’s Magnetohydrodynamic Propulsion Drive.

Tesla performed an experiment in which he applied high-voltage high-frequency alternating current to a pair of parallel metal plates. He found that the ‘space’ between the plates became what he described as “solid-
state” exhibiting the attributes of mass, inertia and momentum. That is, the area transformed into a state against which a mechanical push could be exerted. This implied that, using this technique, it should be possible to produce a spaceship drive anywhere in space, if the mechanism for thrusting against the ‘solid-state’ space could be determined. Further experiments convinced Tesla that powerful electromagnetic waves could be used to push against (and pull against) what appears to be ‘empty space’. The drive principle is based on the Hall-effect used in semiconductor magnetic sensors, and is called the magnetohydrodynamic (“MHD”) effect. This might be illustrated like this:

Here, a box is constructed with two metal plates forming opposite sides and two insulating plates holding them in position and surrounding an area of ‘space’. High-frequency, high-voltage alternating current is applied to the metal plates and this creates an electric field “E” acting between the plates as shown in black. A magnetic field “B” is generated by the electrical field. The magnetic field acts at right-angles to the electric field, as shown in blue. These two fields produce a propulsion thrust “F” shown in red in the diagram. This propulsion force is not produced by ejecting any matter out of the box, instead, it is produced by a reaction against the ‘solid-state’ condition of space-time caused by the high-frequency electromagnetic pulsing of that area of space. This is enormously more effective than a jet engine. The thrust increases with the fourth power of the frequency, so if you double the frequency, the effect is sixteen times greater.

To put this into perspective, consider the force being applied against gravity to lift an object into the air. The force pulling the object downwards is gravity and its strength is given by:

Gravitational force:

\[ F = g \times M \times m / r^2 \]

where
- \( g \) is the gravitational constant \((6.672 \times 10^{-8} \text{ cm}^3 \text{ g}^{-1} \text{ s}^{-2})\)
- \( M \) is the mass of the first body
- \( m \) is the mass of the second body and
- \( r \) is distance between the two centres of mass
The lifting force is given by:

Lorentz Force:  Force on an object = Electric force + Magnetic force

\[ F = q \times E + q \times v \times B \]

where
- \( q \) is the charge on the object,
- \( B \) is the magnetic field,
- \( v \) is the velocity of the object and
- \( E \) is the electric field

How do these forces compare? Well, the electromagnetic force is stronger than the gravitational force by a factor of about \( 2,200,000,000,000,000,000,000 \) times. That number (2.2 x \( 10^{39} \)) is too big for anybody to really visualise, so let me put it another way.

If the amount of energy used to mechanically lift an object a distance of one hundredth of an inch (one quarter of a millimetre) off the ground, were used as an electromagnetic lifting force, then that amount of energy would lift the object more than \( 3,472,222,000,000,000,000,000,000,000,000,000,000,000 \) miles off the ground, or in metric units, more than \( 5,588,001,700,000,000,000,000,000,000,000,000,000,000 \) kilometres off the ground. This kind of drive is an entirely different kind of animal. This Hall-effect type of drive if used in a spaceship would require only a very small amount of input power to drive the ship at great speeds and over great distances.

As the device shown above operates directly on the space-time field which penetrates all matter, there would appear to be no reason why it should not be used to drive a conventional vehicle by positioning it in a horizontal position rather than the vertical position shown in the diagram. Throttle operation could be by very slight adjustment to the frequency of the AC pulses applied to the metal plates. However, Bill Lyne indicates that horizontal movement is better achieved by producing Tesla’s very short, high-voltage high-frequency DC pulses at the front of the vehicle while at the same time generating very high-voltage high-frequency AC waves at the back of the vehicle. This style of drive is said to pull the vehicle along rather than push it along.

The Unified Field Theory is being searched for by scientists who want to come up with a theory which encompasses the force of gravity with the electromagnetic force. In my opinion, they would have more chance of success in trying to find a needle in a haystack which does not contain a needle since when the entire haystack has been disassembled, it becomes clear that there never was a needle in it. In my opinion, there is no such thing as a “force of gravity”, in fact, there is no such thing as gravity. Find that hard to believe? Well, let me explain.

If when standing, you hold an object a waist level and let it go, it “falls” and lands near your feet. Yes agreed, and yet I suggest that there is no such thing as gravity. If you suspend a pendulum close to a mountain, the pendulum does not hang down vertically but moves slightly towards the mountain. This is said to be because the mountain attracts the pendulum. Sorry Chief, but I suggest that it just ain’t true and the mountain does not attract the pendulum. The Moon orbits around the Earth which requires a continuous acceleration inwards towards the Earth and this is said to be caused by the attraction of gravity pulling the two bodies of matter together. Well, yes the Moon does orbit the Earth but not because of “the force of gravity”.

The reason why “the force of gravity” is so tiny compared to electromagnetism is because there is no such force at all. Yes, indeed, all of the observed phenomena which are supposed to be gravitational, do exist exactly as seen, but I suggest that there is no such thing as “the force of gravity” and the Unified Field Theory is not needed. Let me explain:

The Zero-Point Energy field exists everywhere in the universe and it flows in every direction equally. It acts like a flow of particles thousands of times more tiny than electrons, and so, it flows through matter. No matter can shield completely from the flow of this energy field. But, a tiny percentage of the flow does happen to collide with the electrons, atoms and molecules of matter as the energy flow moves through matter. The bigger the chunk of matter, the more of the energy flow collides with it. The collisions convert the energy into additional mass, which is why our Sun is not losing mass as rapidly as theory would predict. The situation is like this:
The force of the Zero-Point Energy field is slightly reduced having passed through (and interacted with) the large mass of the Earth. This reduced strength is indicated in the diagram by the light-blue arrows. The incoming Zero-Point Energy field is not reduced in strength in any significant way as the molecules in the atmosphere are not nearly as tightly packed as those in the matter which makes up the Earth itself. The imbalance of these two thrusts causes a net push towards the surface of the Earth.

For clarity, the diagram only shows the field acting in one direction, while in reality, the same situation applies in every possible direction around the planet. When you let an object go and it moves towards the surface of the planet, it is not being pulled down by "the force of gravity", but instead, the downward push of the Zero-Point Energy field is greater than the upward push of the Zero-Point Energy field which has just passed through the planet. The object moves "downwards" because the push from above is greater than the push from below.

Exactly the same thing applies to cause the effect that a mountain appears to have on a pendulum. In reality, the mountain has no effect on the pendulum, apart perhaps from a minor electrostatic influence. The main effect is caused by the flow of the Zero-Point Energy field:

Here, the (very roughly drawn) mountain, reduces the push of the Zero-Point Energy field which passes through it, due to its interaction with the matter with which it collides on its trip through the mountain. The push of the Zero-Point Energy field on the side of the pendulum is not diminished, so there is a net push towards the mountain and that makes the pendulum move in the direction of the mountain. The effect is not very large, so the pendulum does not move much out of the vertical as the downward push towards the surface of the planet is quite marked, so the pendulum needs to be very near the mountain for this effect to be observed.
This can also be seen in the Casimir Effect where two non-magnetic metal plates, which are not carrying an electrostatic charge, are suspended very close to each other. The plates do not hang straight down but move towards each other. This is the same effect as is caused by a mountain near a stationary pendulum, or plumb-line. Each plate screens out a little of the Zero-Point Energy field which passes directly through both plates, so the second plate gets slightly less of a push:

The result is that between the plates, the horizontal force pushing them is unbalanced. Hang just one plate up and the horizontal Zero-Point Energy ("ZPE") forces coming from the right exactly balance the ZPE forces coming from the left, and the plate hangs vertically below its point of suspension with the supporting cord (shown in red in the diagram above) hangs vertically. But with two plates as shown, the push from the left is reduced very slightly as it passes through the left hand metal plate. This means that there is a lesser push from left to right on the right hand plate. This causes the plate to move very slightly to the left, until the horizontal pull caused by the red cord not being vertical, just balances the difference in the ZPE thrusts on that plate. So, the right hand plate moves slightly to the left.

The same thing happens with the left hand plate. The ZPE thrust coming from the right is slightly reduced as it passes through the right hand plate, and the left hand plate moves slightly to the right until the angled pull of its supporting cord balances the net thrust on that plate. The overall effect is that the gap at point "A" in the diagram is very slightly larger than the gap at point "B", though the amount is not nearly as great as suggested by the diagram, which has been deliberately exaggerated to show the effect clearly. There is nothing complicated about this, it is just simple common sense. Remember that the pull of the supporting cord "C" is the exact equivalent of a vertical force "D" along with a horizontal force "E". Here, the vertical force D exactly matches the weight of the plate, and the horizontal force E exactly matches the unbalanced ZPE force (if they did not match exactly, then the plate would move until they did). The further away from the vertical that the plate moves, the greater the resulting horizontal force caused by the pull of the supporting cord.

Tesla expressed this in a very slightly different way in his Dynamic Theory of Gravity (1897) which states that all bodies emit microwaves whose voltage and frequency are determined by their electrical contents and relative motion. He measured the microwave radiation of the earth as being only a few centimetres in wavelength. He said that the frequency and voltage were influenced by the velocity and mass of the earth, and that its "gravitational" interaction with other bodies, such as the sun, was determined by the interaction of the microwaves between the two bodies.
If you find the concept of producing a driving force through pushing against the space-time continuum to be difficult to accept, then perhaps you should consider the US Patent granted to Boris Volfsen on 1st November 2005. The important thing about this patent (which is crammed full of long words) is not whether or not it presents a realistic mechanism for a practical space drive, but the fact that the US Patent Office in the year 2005, granted the patent after what presumably was careful consideration. With that in view, it is hardly possible to consider Tesla to have been totally confused when he designed (and built) his “electric flying machine” which operated by pulling on the space-time field.

Tesla used high voltage at gigahertz frequencies for his electropulsion system. The propulsion of a vehicle powered by a Tesla drive is by the use of an additional AC generator at the back (which stiffens the space-time continuum behind the vehicle) and a DC ‘brush’ generator at the front (which weakens the space-time continuum in front, causing the vehicle to be pulled forwards).

Tesla was very astute. He deduced that ‘empty space’ actually contained:

1. Independent carriers which permeate all space and all matter and from which all matter is made. These carry momentum, magnetism, electricity or electromagnetic force, and can be manipulated artificially or by nature.

2. ‘Primary Solar Rays’ (starlight) which travel at the speed of light, having frequencies far above X-rays, gamma and UV radiation.

3. ‘Cosmic Rays’, particles in space propelled by the Primary Solar Rays.

4. X-rays, Gamma rays and UV electromagnetic waves, all of which travel at the speed of light.

5. Ordinary visible and Infra-Red electromagnetic waves which travel at the speed of light.

6. Rapidly varying electrostatic force of enormous potential, emanating from the earth and other gravitational bodies in space.

When we grasp the actual nature of the universe, it becomes clear that we have a much larger range of opportunities for producing usable energy in large quantities and at minimal cost.

Additional information can be found in Boris Volfsen’s US Patent 6,960,975 of November 2005 “Space Vehicle Propelled by the Pressure of Inflationary Vacuum State” which is reproduced in the Appendix.

If you find the thought of generating a gravitational field, difficult to come to terms with, then consider the work of Henry Wallace who was an engineer at General Electric about 25 years ago, and who developed some incredible inventions relating to the underlying physics of the gravitational field. Few people have heard of him or his work. Wallace discovered that a force field, similar or related to the gravitational field, results from the interaction of relatively moving masses. He built machines which demonstrated that this field could be generated by spinning masses of elemental material having an odd number of nucleons -- i.e. a nucleus having a multiple half-integral value of h-bar, the quantum of angular momentum. Wallace used bismuth or copper material for his rotating bodies and “kinemassic” field concentrators.

Aside from the immense benefits to humanity which could result from a better understanding of the physical nature of gravity, and other fundamental forces, Wallace’s inventions could have enormous practical value in countering gravity or converting gravitational force fields into energy for doing useful work. So, why has no one heard of him? One might think that the discoverer of important knowledge such as this would be heralded as a great scientist and nominated for dynamite prizes. Could it be that his invention does not work? Anyone can get the patents. Study them -- Wallace -- General Electric -- detailed descriptions of operations -- measurements of effects -- drawings and models -- it is authentic. If you are handy with tools, then you can even build it yourself. It does work.

Dr Peter Lindemann gave a lecture at the TeslaTech conference which is very informative and which I would highly recommend. It is available on DVD from http://www.free-energy.ws/products.html under the title of "Tesla's Radiant Energy". He makes a number of important points, some of which are repeated here.
We tend to think of the battle for industrial electricity to have been between Thomas Edison's DC system and Tesla's AC system, with Tesla winning. Unfortunately, while true, that is not the full story as Tesla moved on from AC to more powerful systems, and Tesla lost out on those systems, leaving us today, with a workable, but much inferior system. We need to see the overall picture clearly. James Clerk Maxwell produced his famous equations, relating electricity and magnetism (which are actually two faces of a single entity called “electromagnetism”). Subsequently, H.A. Lorentz damaged those equations, throwing away the parts which showed that free-energy was available for use if we knew how to access it.

Out present day position has grown up where, while we realise that "gravity" is $10^{-39}$ times less powerful than electromagnetism, we see "static electricity" as a weak and useless thing which needs to be avoided. The reality is quite different as Tesla points out and demonstrates. Tesla describes "static" and "radiant" energy as being a force which appears to have no ultimate limits at all. That is, it is capable of providing unlimited power. Our knowledge of this power is so inadequate that we believe that power can only flow in a circuit which is a closed-loop and the power flow has to be a stream of electrons. This is most definitely not the case.

The more powerful radiant energy flows like an electrically charged sound wave passing through incompressible air and which can be fed down a single wire without the slightest difficulty. In fact, you can even skip that one wire and use the earth instead, transmitting power with what appears to be no wires at all. The actual, final and most important contest was between closed-loop electricity and single-wire power transmission, and that contest was one which Tesla lost.

The nature of this radiant energy is so different to what we think of as conventional electricity that it is perfectly possible to light a filament light bulb held in one hand, while grasping a single wire in the other hand. When doing this, there is no sensation whatsoever and nothing at all is felt. Videos on this subject are at https://www.youtube.com/watch?v=3uXL4_Yas2k and https://www.youtube.com/watch?v=6BnCUBKgmnnc at this time. An excellent set of teaching videos are at http://journal.borderlandsciences.org/videos/.

In his lecture, Dr. Lindemann remarks that his understanding of the subject has been helped considerably by the book (http://www.free-energy-info.tuks.nl/TeslaBook.pdf) "The Inventions, Researches and Writings of Nikola Tesla" and the book (http://www.datafilehost.com/download-c74378fc.html) "The Secrets of Cold War Technology - HAARP and Beyond" which describes some of the early work done by Tesla. He also praises the book "Tesla's Vocabulary for Dummies" which is a joke on his part as there is no such book in spite of his appearing to show some quotations from it in his DVD lecture.

One feature of radiant energy which becomes clear from Tesla's description of it, is that the most useful effects which can be gained from it, start at a DC pulse frequency of 1 MHz which is far higher than experimenters use today. He stresses that we do not actually know the exact nature of electricity and that all of our present day measuring instruments are based on electron theory and so just do not measure radiant energy. In a way, it is a bit like the difference between AM radio and FM radio. Both are perfectly valid and work well, but an AM radio will not receive an FM radio signal and an FM radio will not receive an AM radio signal. Unfortunately, radiant energy is much more powerful than conventional electricity and it is not dangerous like electricity is. It should be noted that Hermann Plauston's very detailed patent - US 1,540,998 (http://www.free-energy-info.tuks.nl/PatD6.pdf) is on methods of capturing and using this radiant energy, and he describes any multi-aerial systems which produce a net output of 100 kilowatts as being a "small" system. I don't know about you, but I would settle for a system which produced less than 10% of that fuel-less output.

The best information on radiant energy comes from the writing of Tesla and Dr. Lindemann draws attention to one of Tesla's patents, US 685,957 (http://www.free-energy-info.tuks.nl/PatD37.pdf) which explain how this radiant energy can be captured and used. Tesla also used a motor design which is effective with this type of energy. The motor has two windings, the first being fed directly and the second one receiving a 90 degree delayed pulse through a capacitor.

One thing that Tesla points out is that there is an incompressible gaseous medium filling the universe and which is composed of particles which are much smaller than hydrogen atoms. Mendeleev who constructed the table of elements indicates quite clearly that there should be two gaseous elements which are lighter than hydrogen, but he did not put them in his table because he did not know what they are.

**The Nature of Gravity by Maurice Cotterell.**

The comments by Joseph H. Cater later in this chapter include the statement that gravity is electromagnetic radiation of a frequency just below that of infra red. The extract from Karl Schappeller's work, also later in this chapter, states exactly the same thing and the same frequency. The extracts from Joseph Newman's
book, also later in this chapter, point out the effect of electron spin on attraction and repulsion. The document [http://www.free-energy-info.tuks.nl/Cotterell.pdf](http://www.free-energy-info.tuks.nl/Cotterell.pdf) is a paper on gravity by the very able Maurice Cotterell, part of which is quoted here:

**How Gravity Works**

“How Gravity Works” explains how Electricity and Magnetism work together to produce the force of Gravity and in doing so, they reveal the underlying science behind Newton’s equation which he tried in vain to uncover, namely, the reason why Gravity is proportional to the masses of two attracting objects, why it grows weaker in proportion to the square of the distance between them, and the nature of the “Gravitational Constant” which continues to perplex researchers to this day. It explains why all objects accelerate to Earth at 32 feet per second every second. It explains why the atom is comprised of eight orbital shells and why those shells fill with electrons in the way that they do. It explains how permanent magnetism works at atomic level, the nature of so-called ‘Dark Matter’, the reason why spiral galaxies are spiral, why the centre of the Earth is boiling hot and how the Earth’s magnetic field is generated.

Scientists cannot understand why the positive protons on the centre of atoms simply do not spring apart – their positive charges repelling each other. In 1935, a researcher named Yukawa suggested that another substance or particle must exist to ‘glue’ the protons in the nucleus together - a kind of atomic ‘velcro’. But an objector to Yukawa pointed out that if indeed that were the case, then there would have to be two kinds of velcro - a velvet side and a hook side (so to speak). But another researcher pointed out that protons covered in the velvet-side would not stick to other protons covered in the velvet-side, and that protons covered in the hook-side would not stick to other protons covered with the hook-side. So, another researcher pointed out that for such a scheme to work, there would have to be three types of each of the three types. Thus, the crazy field of Particle Physics was born. In the decades that followed, Particle Physicists were granted billions of dollars to find out what makes the atom stable. Since then, they have been searching for more than 300 imaginary sub-atomic particles. The Concise (Oxford) Science Dictionary comments: “… the whole elaborate theory is circumstantial… none of the smaller particles have ever been identified in experiments… the theory does not claim to have been verified”.

Cotterell shows that none of the particles actually exist, and more importantly, that none are necessary. To explain why the atom does not spring apart, he returns to firm ground and to the 1930s pioneering work of Ernest Rutherford and James Chadwick and shows that by simply changing the perceived shape of the electron and neutron, the gravitational mechanism is exposed, explaining away the mysteries of the atom and many of the mysteries of the cosmos.

**Summary Part 1:**

![Diagram](image)
(A) A coil-shaped electron (shown in black) makes the hydrogen atom dynamic [come alive]. The amount of helically polarised electric field forced from the poles of the proton is maximum when the electron is horizontal, that is, after 180 or 360 degrees of orbital travel. Shown at the top left is the plan view of a hydrogen atom. The horizontal electron slices through the electric field (shaded pink). A magnetic field is induced into the coil which pushes against the electric field, causing it to topple on its own axis (like the opposing blades of a windmill) as it orbits the positive proton.

The orbiting coil-like electron sucks energy from the proton causing the proton to compress, release heat and cool rapidly.

Once the spinning electron-magnet passes the vertical position, the super cold proton sucks in ambient heat and expands rapidly; compression and expansion of the proton results in cyclical changes of capacitance [electric field] proportional to the surface area between the particles.

(iii and vii) The ends of the electron-magnet radiate maximum amounts of helically polarised magnetic energy after 90 degrees and 270 degrees of orbital travel [when vertical]. Hence the magnetic and magnetic radiation is displaced by 90 degrees and the electromagnetic (EM) radiation from the northern sector is displaced in phase by 180 degrees from that of the southern sector.
(B) (i) The orthodox view of a helium atom (containing two neutrons) precludes an understanding of gravity - each electron is passive [dead] and the spherically shaped neutrons render the atom unstable. Moreover, the electron is shown as a purely 'electric' particle when in fact it is electric for only half the time, and magnetic for half of the time. **The electron is an 'electromagnetic' particle.**

(ii) This new view of the helium atom accommodates a gravitational mechanism - the coil-shaped electrons bring the atom to life and the spike-shaped neutrons make the atom (the contents of the old neutron and the spiked neutron being identical). **Supporting evidence: 31/3/08 researchers of the Hohn-Meitner Institute in Berlin announced that 'neutrons behave like compass needles' – Science Daily.**

(C) hydrogen spins axially and autonomously and so it radiates helically polarised ElectroMagnetic energy into space. **[Supporting evidence: 'hydrogen radiates helically polarised EM energy' www.sciencenews.org]**
Helium [the only electrically geometrically symmetrical atom to contain spiked neutrons] also spins axially and autonomously and hence, likewise radiates helically polarised electromagnetic energy. In free space, hydrogen and helium are prime movers in the gravitational mechanism. Other atoms cannot autonomously radiate helically polarised electromagnetic energy because they do not spin axially or autonomously. However, when helically polarised electromagnetic radiation from hydrogen or helium bombards neighbouring atoms, it causes the nucleus of those atoms to spin in the same direction and, at the same time, causes the orbiting electrons in a cascade of atoms to synchronize their spin. As a result, the magnetic moments of orbiting electron-magnets in a cascade of atoms attract each other. This is the force of Gravity.

**Summary Part 2:**

(2A and 2B) The ‘Motor Effect’; helically polarised electromagnetic radiation from the hydrogen atom acts upon the negative charges of the neighbouring atom, causing the nucleus and the electron cage to spin axially and at the same time, synchronizes the spin of the electrons in both atoms [Supporting evidence: Nature 2009;458 (7238):610 DOI:10.1038.nature07871 (persistent spin helix)]. The mass of the electron is twice that of the neutron-negative charge, hence the torque on the electron-cage is twice that on the neutron-negative charges in the nucleus. Thus, the electron-cage spins faster than the nucleus.

(2B) The ‘Generator Effect; orbiting electrons in the neighbouring atom now ‘generate’ helically polarised electromagnetic radiation. The power of the atomic ‘generator’ is proportional to the differential speed between the nucleus and the electron cage and to the number of orbiting electrons (atomic mass).
Electromagnetic output is a function of the number of electrons [atomic mass] (‘g’) AND of the difference in rotational speed between the nucleus and the electron cage (‘f’).

(2C) Gravity radiation from the hydrogen atom bombards neighbouring atoms sucking them towards the source of the radiation. [Here, to facilitate explanation, the magnetic wave (shown in blue) is shown radiating from the nucleus whereas in actuality, it radiates from the orbiting electron].

(2D) The corkscrew-style electromagnetic radiation from the neighbouring atom now, likewise, sucks nearby atoms towards itself. Both atoms suck in the same direction, thus gravity from the Sun and the Moon pull in the same direction. [To facilitate explanation, the electric waves (shown in red) are shown radiating from orbiting electrons].
(2E) As gravity radiation propagates and moves away from the atom, it decreases in field strength [per metre squared]. For every unit of distance travelled, the radiated energy diverges geometrically. This causes the radiated energy to reduce by the square of the distance travelled (‘d²’). The numbers inside the square in the diagram above show the field strength of the radiating electromagnetic energy in volts per square metre. [Squares are used here just for illustration purposes as the diverging wave is actually conically-helical as seen in Figure 2F].

(2F) The frequency of the helically polarised electromagnetic radiation from the Earth remains constant. However, as m approaches M, the spiralling electromagnetic radiation accelerates the differential rotation between each atomic nucleus and electron-cage of which m is made. As a result, the ‘relative’ atomic frequency increases and hence the output of the ‘atomic generator’ increases, uniformly increasing the attracting electromagnetic force between m and M in accordance with a square-law scale as m proceeds along the electromagnetic spiral. M thus attracts m with square-law [d²] uniform acceleration. In the diagram on the right, m is shown spiralling towards M with the electromagnetic wave stationary, but in reality, m approaches M in a straight line as the wave spirals across m.

(2G) Hence Isaac Newton’s equation for the force of gravity; where the force is proportional to the masses (m and M) of the two attracting bodies and the strength of the force decreases inversely with the square of the distance between them (d²).

\[ F = \frac{GmM}{d^2} \]

G is Newton’s gravitational constant \(6.67428 \times 10^{-11}\) N m² kg⁻² - the instantaneous alternating magnetic force between any two electron-magnets in neighbouring atoms.

Maurice Cotterell gives a more advanced and in-depth explanation of this process in his latest book “FutureScience” in which the introduction says:

**The 12 great mysteries of Physics**

You can be forgiven for believing that Isaac Newton discovered the force which makes apples fall to the ground, but he did not. He simply gave the force (F) a name (“Gravity”) and noted that the strength of the force, whatever it might be, depends on the size of the Earth (Mass M2). He also figured out that the strength of force on the apple depends on how far away the apple is from the Earth to begin with and he noted, like Galileo before him, that as an apple falls it speeds up and travels faster and faster until it hits the ground. At first, Newton set down the relationship between the force and the masses in a shorthand way (a formula) saying that F (the strength of the force) could be found by multiplying m1 by M2 and then by dividing the result by the square of the distance between them (d²). There was just one problem: every time he did the calculation he finished up with the wrong answer. He eventually discovered that the only way to get the right answer was to multiply the wrong answer by ‘667 billionths’. He did not know where this tiny amount of force came from, but just like he had done with Gravity, he gave the mysterious number a name – “the Gravitational Constant” G. This made his formula \(F = \frac{GmM}{d^2}\). It is hard to believe that since then, that is, for more than 350 years, still no-one understands what gravity is or what causes it or why we have to multiply the wrong answer by G to get the right one. To this day, no-one understands what G is or even where it comes from. That’s how sophisticated we are. No-one understands why objects fall to the ground.

The second most embarrassing problem for modern Science is that no-one understands why positive charges in the middle of atoms simply do not just spring apart which is what you would expect, given that positive repels positive. To overcome the contradiction, physicists decided that the positive charges must be glued-together in some way and so, for the past 75 years they have been searching for the ‘glue’ or more precisely, more than 300 types of glue – but as yet have not found any.

Also, no-one understands (given that positive attracts negative), why the orbiting negative electrons of atoms do not simply get sucked into the positive bits in the middle of the atom. They just ‘cannot understand it’.
When you place a magnet on the door of a refrigerator, you probably imagine that scientists understand how a magnet actually works, but they do not. As far as they are concerned, it seems to work by magic so they gave it the name magnet.

Switch on the light and you no doubt take it for granted that the people who supply the electricity understand how it works, but they do not. Physicists are pretty sure that an electrical current is simply the movement of atomic negative charges along a wire. The problem is that no-one understands why, whenever a current flows, a magnetic field appears around the wire.

When they look skywards at night, astro-physicists cannot understand what makes the stars cluster together into galaxies, because their calculations contradict what their eyes can see. To overcome this, they say that there must be other sources of gravity out there, like planets and dust which cannot be seen because it is dark. So they named their fantasy planets ‘dark matter’, at least for the time being, until they can figure out why their calculations do not make sense. Neither can they understand why stars spiral into galaxies, but they cling to the hope that when (or if) they understand how gravity actually works, that the reason for the double-spiral of galaxy formation will become clear.

“FutureScience” explains in a simple way, how Electricity and Magnetism work at atomic level, and how they work together to produce the force of Gravity and in so doing, reveal the underlying science behind Newton’s equation – the underlying science which he tried in vain to uncover – the reason why Gravity is proportional to the masses of the two attracting objects, why it grows weaker in proportion to the square of the distance between them, and the nature of the mysterious ‘Gravitational Constant’ which continues to perplex researchers to this day. It explains why all objects accelerate to Earth at 32 feet per second every second. It explains why the atom is comprised of 8 orbital shells and why the shells fill with electrons the way that they do. It explains the nature of so-called ‘dark matter’, the reason why spiral galaxies are spiral, why the centre of the Earth is boiling hot, how the Earth’s magnetic field is generated, how to generate gravity waves, how gravity waves can be used to produce unlimited quantities of free energy, how to generate antigravity waves, how antigravity waves can be used to de-couple hydrogen bonds in water, separating hydrogen from oxygen and providing unlimited supplies of free hydrogen to fuel hydrogen-powered cars, and how antigravity radiation can be used to cause the disintegration of matter in water and living tissue (phasor weapons technology).

The book goes on to explain the cause of the Sunspot cycle and how the Sun affects life on Earth: the cause of global warming and global cooling, how the 289-day spinning Sun regulates fertility in females, how the Sun’s radiation causes 12 types of genetic mutations which result in 12 types of personality (sun-sign astrology), how sunspots cause schizophrenia, how the Sun controls bio-rhythms and our day-to-day behaviour, how the Sun causes catastrophe cycles and the rise and fall of civilizations, and how mobile phones and power lines cause cancer.

**How the discoveries were made**

In 1935, in an attempt to explain why protons in the centre of atoms do not simply spring apart, a researcher named Yukawa suggested that another substance or particle must exist to ‘glue’ the protons in the nucleus together - a kind of atomic ‘velcro’. But an objector to Yukawa pointed out that if indeed that were the case, then there would have to be two kinds of velcro - a velvet side and a hook side (so to speak). But another researcher pointed out that protons covered in the velvet-side would not stick to other protons covered in the velvet-side, and that protons covered in the hook-side would not stick to other protons covered with the hook-side. So, another researcher pointed out that for such a scheme to work, there would have to be three types of each of the three types. Thus, the crazy field of Particle Physics was born. In the decades that followed, Particle Physicists were granted billions of dollars to find out what makes the atom stable. Since then, they have been searching for more than 300 imaginary sub-atomic particles. The Concise (Oxford) Science Dictionary comments:

“... the whole elaborate theory is circumstantial... none of the smaller particles have ever been identified in experiments... the theory does not claim to have been verified”.

FutureScience shows that none of the particles actually exist and, more importantly, that none are necessary. To explain why the atom does not spring apart, the Author returns to firm ground and to the 1930s pioneering work of Ernest Rutherford and James Chadwick and shows that by simply changing the perceived shape of the electron and the neutron, the gravitational mechanism is exposed, explaining away the mysteries of the atom and many of the mysteries of the cosmos. The book is aimed at the general reader with no prior knowledge of Science and it uses many illustrations to convey the concepts simply and concisely.

Maurice Cotterell’s web site is [http://www.mauricecotterell.com/](http://www.mauricecotterell.com/)
Maurice also comments on the recent Cold fusion generator development of Rossi as follows:

**E-Cat generator not ‘cold fusion’**

The Energy Catalyzer (also called E-Cat) is a purported cold fusion or Low-Energy Nuclear Reaction (LENR) heat source built by inventor Andrea Rossi with support from physicist Sergio Focardi. An Italian Patent, which received a formal but not a technical examination, describes the apparatus as a ‘process and equipment to obtain exothermal reactions, in particular from nickel and hydrogen’. Rossi and Focardi say the device works by infusing heated hydrogen into nickel, transmuting it into copper and producing heat. An international Patent Application has received an unfavorable International preliminary report on patentability because it seemed to ‘offend against the generally accepted laws of physics and established theories’ and to overcome this problem the Application should have contained either experimental evidence or a firm theoretical basis in current scientific theory. (http://www.peswiki.com)

**FREE ENERGY?**

**YES but it's not 'Cold Fusion'**

**How they think it Works:** The Energy Catalyzer works—they believe—by placing nano to micro sized particles of nickel powder in a reactor along with pressurized hydrogen gas and special undisclosed (for proprietary reasons) catalysts. When the contents of the reactor is heated (using a series of resistors in the reactor) to approximately 400 to 500° C, nuclear reactions start taking place. The strength of the reaction can be changed by varying the pressure of the hydrogen in the reactor. The output energy can be up to 400 times the input energy. No precious metals or radioactive substances are placed in the reactor. After the reactor is turned-off the reactor can be opened and no radiation can be detected. The process appears to transmute nickel into copper and trace amounts of other elements such as zinc. It will not work with deuterium (heavy hydrogen)—but they don’t know why.

If it’s not ‘Cold Fusion’, how does it really work?

...it works by ‘Periodic Scaling’
How to generate gravity waves, and free energy, using 'Periodic Sealing'

ambient heat and light

Hydrogen is the prime mover in the gravitational mechanism because it spins axially and autonomously.

Fill each of 120 containers with one each of the elements and align the containers in a straight line in rising atomic number order. How does it work? Gravity waves from the hydrogen atoms in the hydrogen container will bombard the container next in line containing helium. The helically polarized electromagnetic gravity waves from the hydrogen container will act upon the spiked-neutrons in the helium atoms causing the helium atoms to spin axially in the same direction. The helium atoms will now generate and radiate helically polarized gravity waves, sucking-in ambient heat to fuel the process. In this way ambient heat is converted to gravity waves and more heat. Helically polarized gravity waves from the helium atoms will act upon the spiked-neutrons in the lithium atoms causing those atoms to spin axially in the same direction. The lithium atoms will now generate and radiate helically polarized gravity waves, again, sucking-in ambient heat to fuel the process. This sets up a chain reaction along the line of containers; hydrogen, the prime-mover, activates every atom in the chain. Containers along the chain will become increasingly hotter and massive amounts of gravitational energy and heat will radiate from the end of the chain following atom 119, ununennium. [from FUTURESCIENCE = FORBIDDEN SCIENCE of the 21st-century by Maurice Cotterell]

Note: the line of containers will be influenced by gravity waves from the Earth and so should be stacked vertically, silo-like, with hydrogen uppermost. Water may be used in place of hydrogen, and dangerous elements may be omitted, at a cost to efficiency.
John Searle's Permanent Magnet Drive/Generator.
Professor John R.R. Searle of Britain developed an electrical generation system based on two rings of magnets being spun relative to one another. The magnet orientations oppose each other to produce a magnetic splatter field.

The E-Cat generator uses 'Periodic Scaling' to generate heat in the same way; the hydrogen fuel, used in the process, sucks in ambient heat and converts the heat to gravity waves—that's why liquid hydrogen is the most effective super-coolant. The corkscrew-style electromagnetic gravity waves from the hydrogen atoms then excite the nickel atoms causing the nickel to get hotter. The hydrogen fuel then sucks in more heat from the nickel and radiates more gravity waves that again bombard the nickel. Some of the fuel is consumed in the process. This cumulative excitation continues until the availability of heat in the ambient air, and nickel, is constrained by energy transfer considerations.
The outer magnets in the diagram above are referred to as “rollers”. When three rings of rollers are placed one inside the other, then the outer ring rotates of its own accord, without any external power being applied. If pick-up coils are placed around the outside, then electrical current is generated with a COP of infinity. The method of imprinting the necessary magnetic pattern on both the rollers and the stators is a difficult and expensive process.

Dr. Terry Moore has recently built a replication model of this Searle technology and his model video is available at http://www.youtube.com/watch?v=bb3N1epMG7A. The Searle device also demonstrates a gravitic effect and John has built what would loosely be described as a “flying disc” using this technology. If high voltage is applied to the device when it is rotating, then a surrounding corona develops and strong upward electrogravitic forces are generated.

Dave Lawton’s Gravity-Wave Detector.
It has been reported that Nikola Tesla made a device which allowed him to hear sounds at great distances. I have never seen any details of the circuitry used by Tesla. However, Dave Lawton has produced such a device, and he reports that he could hear conversations taking place four and a half miles away from him. Interestingly, the sounds from that distance were also travelling through a solid stone wall some three feet thick. The circuit for this device is described in this document.

In my opinion, the device is not picking up audio signals in the manner of a conventional microphone where air pressure waves vibrate a transducer, creating an electrical signal which is then amplified. The interesting thing is that it is distinctly possible that some other mechanism is coming into play here. This opinion is supported by the fact that Dave’s circuit is an upgraded version of a monopole gravity-wave detector. Dave used this device to record the “sound” of the Shumaker-Levy comet colliding with Jupiter.

The circuit shown here is quite conventional electronically speaking, comprising of two 741 operational amplifiers connected as a two-stage amplifier. The unusual feature is where a small amount of white noise is being fed into the microphone input:
The white noise is generated by the 5-volt zener diode. The level of this white noise component is controlled by the 1.5 megohm variable resistor plus the 10K fixed limiting resistor. While the range of these two components is 10K to 1.501 Meg, the working setting is normally very high and so only a very small amount of white noise is fed into the input of the first 741 op. amp. to modify the microphone input.

The adjustment of this injection of white noise is the main control of this most unusual circuit, and it has been found that when the setting is just right, the circuit has the feel of a public address system just about to go unstable from positive feedback. The unit build looks like this:

The theory of operation was put forward by Gregory Hodowanec in the April 1986 issue of the Radio-Electronics Magazine, where he puts forward the theory that the source of noise in electronic devices is caused by gravitational waves and he suggests that there are monopole gravity waves. This does not oppose the gravity waves predicted by Einstein. Gregory views these monopole gravity waves as being much stronger than those suggested by Einstein, and consequently, much easier to detect.
He also suggests that monopole gravity waves have been seen for many years and have been described as “low frequency noise” signals or “flicker noise”. These signals have also been called Microwave Background Radiation, supposedly caused by the “Big-Bang” though this cause is disputed by some.

Gregory views our universe as a finite, spherical, closed system, i.e. a black body. Monopole gravity waves propagate in Planck time so their effects appear everywhere almost simultaneously. Gravity wave energy can be imparted to ordinary objects. So it is suggested that the fact that a fully discharged electrolytic capacitor can develop a charge when disconnected from all circuitry, is down to the interaction of the capacitor with monopole gravity waves.

Gregory suggests the following circuit for examining monopole gravity waves:

![Gravity Wave Detector](image)

Details of this and the theory can be found at [www.rexresearch.com/hodorhys/remag86/remag86.htm](http://www.rexresearch.com/hodorhys/remag86/remag86.htm). Dave has taken that circuit and extended it substantially to give added gain plus a controlled feed of white noise, without relying on the characteristics of a capacitor, capacitors being notoriously variable in precise characteristics.

The unit is operated by turning the gain up until the circuit just reaches self-oscillation, and then backing the gain off very slightly. The white noise source is then adjusted until the unit is producing a somewhat echoing quality to the sound. The result is a device which has unusual characteristics. The circuitry is so simple and cheap, that you can easily try it out for yourself.

**Butch Lafonte’s Motor/Generator.**

Butch has designed an intriguing Motor / Generator system based on the balancing of magnetic and electrical forces. This clever design operates according to the following statements made by Butch:

1. If a magnet is moved away from an iron-cored coil, it generates a voltage:
The voltage generated for any given magnet and speed of movement, is directly proportional to the number of turns of wire which make up the coil.

2. If a magnet is moved away from an air-cored coil, it also generates a voltage. However, the big difference is that the voltage is of the opposite polarity. In other words, the plus and minus connections are swapped over:

Again, the voltage generated for any given magnet and speed of movement, is directly proportional to the number of turns of wire which make up the coil.

So, if these two arrangements are joined together, they produce a system where the voltages cancel each other exactly, provided that the number of turns in each coil are adjusted to produce exactly the same voltages. The mechanical attraction and repulsion forces also balance, so the circuit can be arranged to have no net effect when the rotor is rotated:

It follows then, that this motor arrangement could be introduced into an existing circuit without affecting the operation of that circuit. The arrangement would look like this:
Here, there is no net electrical or magnetic drag on the rotor as the magnets move away from the coils. The battery supplies current to the load in the normal way and rotor arrangement has no effect on the operation of the circuit.

However, when the rotor reaches 100° or so, past the coils, the On/Off switch can be opened. This leaves the rotor in an unbalanced condition, with there being an attraction between one magnet and the iron core of one coil. There is no matching repulsion between the other magnet and the air core of the other coil. This produces a rotational force on the rotor shaft, keeping it spinning and providing useful mechanical power which can be used to generate additional power. This extra mechanical power is effectively free, as the original circuit is not affected by the inclusion of the rotor system.

From a practical point of view, to give high rotational speed and long reliable life, the On/Off switch would need to be an FET transistor with electronic timing related to the rotor position.

There is no need for the rotor to have only two magnets. It would be more efficient if it had four: or better still, eight:

Or better still, eight:
And if you are going to have eight, there is no need to have the V-shaped cut-outs which just create turbulence when spinning, so make the rotor circular:

And the stator supporting the coils matches the rotor:
Ferrite is a better material for the cores of the coils. The stators go each side of the rotors and the hole in the middle of the stators is to give clearance for the shaft on which the rotors are mounted:

A system of this type needs accurate timing which is solely related to the rate of rotation. This is best arranged by the use of a bistable multivibrator as described in the Electronics Tutorial of Chapter 12. You will notice the two Timing Coils shown at the right hand side of the diagram above. These are used to toggle the bistable On and Off and they are adjustable in position so that both the On and the Off can be set very precisely. The output of the bistable is set to switch an FET transistor On and Off to give circuit switching which is not affected by either the switching rate or the number of times the switch is operated.

The Rotor / Stator combination can be wired to act as either a driving Motor or an electrical Generator. The difference is the addition of one diode:
With this arrangement, for each rotor, all four pairs of Cored coils are wired in parallel across each other, and all four Air-cored coils are wired in parallel across each other. To improve the clarity, the above diagram shows only one of the four pairs, but in reality, there will be four wires coming into the left hand side of each of the screw terminals.

In the case of the Generator arrangement, you have the option to connect each of the four pairs in parallel as in the Motor arrangement or to connect them in series. Connected in parallel, the coils can sustain a greater current draw, while if connected in series, they provide a higher voltage. The voltage could be further increased by increasing the number of turns on each coil.

**Joseph Newman's Motor.**

Joseph Newman is a man who impresses me. He performs experiments, reports the results and then bases theoretical conclusions on the results of his own experiments. This is the true scientific method.
Joseph has been granted a patent and he has written a book. I would recommend that you buy a copy of his book and help support his work by doing that, but unfortunately, as I understand it, the printing plates for the book were destroyed in a fire and printed copies of his book are effectively unobtainable. You can download a .pdf version from the [http://www.free-energy-info.tuks.nl/](http://www.free-energy-info.tuks.nl/) web site but please be aware that the overall file size is 100 Mb and so the download will take quite some time. A background download can be had from [http://www.mediafire.com/view/?oe5obw6offqfs3](http://www.mediafire.com/view/?oe5obw6offqfs3) or the alternative [http://www.filefactory.com/file/b4q6b3d/Newman.pdf](http://www.filefactory.com/file/b4q6b3d/Newman.pdf) link while the link to Joseph's own web site is [http://www.josephnewman.com/](http://www.josephnewman.com/).

In very brief outline, Joseph has built a motor which can access free energy. He has a theory about where the excess energy is coming from and how it is acquired by his designs. He has also built a large stationary motor to demonstrate his theory and he has built a motor into a car. The car engine runs on very minor battery power. Joseph’s patent is included in the Appendix.

With the kind permission of the Joseph Newman organisation, I am going to attempt to introduce you to the important scientific conclusions reached by Joseph and the Energy Machine which he designed and which is based on those conclusions. Joseph has a keen enquiring mind and thinks things through for himself rather than blindly accepting everything he is told. This description contains illustrations and wording taken from parts of Joseph’s book published in 1984, and I should like to express my thanks for being given permission to use this material.

Joseph Newman’s motors all consist of a very powerful permanent magnet which rotates or oscillates in or near a coil with a very large number of turns of copper wire. The coil is energised by a battery pack, and the magnetic field produced by the coil provides the force needed to move the permanent magnet. A mechanical switching device or “commutator” reverses the direction of current flow through the coil every half cycle, and in some models, it also cuts off the current input between the current reversals.

The main difference between Joseph’s designs and previous motors is one of scale as Joseph uses very large coils and very large ceramic magnets weighing up to 700 pounds. His smaller motors use powerful rare earth magnets and the coils are wound with 100,000 turns of copper wire. This creates a very high coil resistance and the battery pack voltages are correspondingly high, being in the hundreds to thousands of volts range.

The torque or turning power applied to the magnet in these motors is proportional to the magnet strength, the number of turns in the coil and the current flowing in the coil. In Joseph’s motors, very large torques can be developed by very small currents. In one demonstration, a motor running on 3,000 volts at 0.8 milliamps has such power that it is not possible to stop the motor by holding its two-inch (50 mm) diameter shaft, though the current can be raised by trying to stop it, to 3 milliamps, or nine watts of power.

Joseph’s motors are different in other ways. If fluorescent tubes are connected across the motor coil, they light up due to the coil’s collapsing magnetic field each time the current direction is switched. These fluorescent tubes are used to protect the mechanical switch from arcing damage. The additional power produced in these tubes is at a very high frequency of 10 to 20 MHz. This radio-frequency current has been accurately measured and it exceeds the battery input current by a factor of five to ten times in the different motors. The measured current and voltage were in phase, indicating a real power output.

To understand the thinking behind these motors, we need to follow Joseph’s experiments and the deductions which he made from those experimental results. Joseph considered, and thought carefully about statements made by the two scientific giants James Clerk Maxwell and Michael Faraday, and this led him to valuable
insights:

It appears that Maxwell and Faraday were the only people who considered that “lines” of magnetic force are actual physical entities and not just a method of representing notional forces and those “lines of force” are actually streams of **matter in motion**.

Maxwell says: “**In speaking of the Energy of the field, however, I wish to be understood literally.** All energy is the same as mechanical energy, whether it exists in the form of motion or in that of elasticity, or in any other form. **The energy in electromagnetic phenomena is mechanical energy**”.

Joseph then considered Michael Faraday’s Electrical Generator and the implications of the way in which it operated:

![FIGURE 1](image1)

Here, a loop of wire is moved downwards from level “A” to level “B”. This movement causes an electrical current to flow leftwards along the wire as shown by the red arrows. Joseph’s question was “why does it go in that direction every time the wire is moved in that way?”

![FIGURE 2](image2)

If the wire is moved upwards through the same magnetic field, then the current flowing in the wire moves in the opposite direction. Why? How does the current “know” which way to go?

![FIGURE 3](image3)

If you turn the magnetic field round by reversing the position of the magnetic fields and then move the wire loop in the same way as before, the current flows in the opposite direction. How does the current “know” which way to flow, or which way round the magnets are turned as it does not touch them?
The next interesting point is that if the wire loop is moved up and down between the magnets, but turned to be parallel to the flux flowing between the poles, then no current flows in the wire, no matter how quickly the wire is moved up and down.

Another point is that if the wire loop is moved slowly up through the magnetic flux, the electric current which flows as a result of that slow movement, moves at the speed of light, flowing from “A” towards “B”.

Now, if the wire loop is disconnected and turned over, the part which was at “A” now moved to “B”, and the same movement of the wire carried out - the current flow is in exactly the same direction although its path along the wire is reversed (because the wire has been reversed). This shows that the direction of current flow is not affected by the wire itself.

According to conventional teachings, this electric current flow was not a result of the magnetic field as the magnetic lines of force were supposed to be imaginary, consisting of Potential Energy and no Kinetic Energy. It became clear to Joseph that this conventional teaching was wrong. Instead, it seemed clear that the magnetic field consists of particles which have mechanical characteristics, and those particles must be moving at the speed of light within the magnetic field.

A key question seemed to be: “how does the current ‘know’ which direction to flow?” as the direction was always consistent. After careful consideration, it occurred to Joseph that the answer was provided by the
actions of a gyroscope:

Here, if the axle of the spinning flywheel, or gyroscope, is pressed downwards it moves off in the direction shown by the red arrows. However, if the axle is pressed upwards:

then the axle moves in the opposite direction as shown by the red arrows. This effect is, of course, reversed if the direction of rotation of the gyroscope is reversed (as it will be if viewed from the other side, in the same way as the current flow direction in the wire is reversed if the magnetic poles are swapped over).

Now, if the gyroscope axle is moved up and down equally on both sides, there is no resulting sideways force:

The action of the gyroscope axle matched the current flow in the wire in every respect, so it became clear to Joseph that the particles flowing between the poles of the magnet were spinning as well as moving at the speed of light. This gyroscopic mechanical motion of the particles accounts for all of the characteristics of the current flow in a wire which is being moved through a magnetic field. This is a major insight on the part of Joseph.

May I remark that these particles are not coming from the magnet itself, but are flowing in from the zero-point energy field, that flow being caused by the broken symmetry of the zero-point energy field generated by the dipole effect of the poles of the magnet. That is why energy can (appear to) be drawn from magnets for years on end.
Joseph then went on to consider the physical aspects of permanent magnets. There were two very significant facts which had to be considered. The first of these is that different materials have markedly different magnetic characteristics:

A bar of soft iron does become a permanent magnet when pulsed briefly with a strong magnetic field, but if exactly the same level of magnetic pulsing is applied to a similar bar of an alloy of iron, nickel and cobalt, a permanent magnet is also produced, but the magnetic field of the alloy is very much stronger than that of the soft iron bar. This shows that the molecular structure of the bar has a major effect on the resulting magnet.

In passing, please be aware that the more powerful magnets available nowadays are so strong that they can easily injure you. If you pick up a magnet and inadvertently get close to a second one, the loose magnet will jump some inches and try to connect to the one in your hand, crushing your fingers in the process and proving very hard indeed to shift in order to deal with the injury. I have also seen it alleged that US ‘AlNiCo’ (Aluminium / Nickel / Cobalt alloy) magnets are deliberately doped with K40 isotope which renders them useless fairly quickly. The source of this information is highly dubious, but the extra sales advantages to the magnet manufacturers would be significant. Also, the advantages for the people wanting to suppress the creation of free-energy magnet motors would be major as many talented US inventors are likely to think that their successful magnet motors were failures because the magnets appeared to be “drained of power” by being used in their design, when in fact, the design is perfectly good. So I will leave you to make up your own mind about the matter and remark that Bill Muller found that his powerful Chinese-manufactured magnets were in perfect condition after eleven years of use.

Another point which Joseph considered was the fact that when successive magnetic pulses are applied to a ferromagnetic metal bar, the resulting magnetic field strength reaches a definite maximum value, and further pulsing has no further beneficial effect:
This is considered to be the magnetic pulse aligning atoms in the metal. Eventually, all of the atoms are aligned and so not further effect can be produced by further pulsing. This alignment can be destroyed if the metal bar is heated to a sufficiently high temperature, forcing the atoms into such an energetic state that the alignment is lost.

It should perhaps, be stressed here, that the magnet itself does not have any power, in spite of seeming to have. Tom Bearden explains this clearly by pointing out that what happens is that the opposite poles of the magnet created a “dipole” which unbalances the random ‘quantum foam’ nature of the local environment (the zero-point energy field) and that causes continuous energy flows from the environment. The “magnet” power is coming from the environment and not from the magnet itself.

If you find this hard to believe and think that you are just getting back the electromagnetic energy which you pumped into the metal when creating the magnet in the first place, then apply simple arithmetic. Assume that you get back exactly 100% of the original power and calculate how long that amount of power would allow the magnet support its own weight against gravity, when attached to a vertical metal surface. Then ask yourself how come the magnet can do it for years and years on end. Point proved conclusively?

Joseph concluded that the attraction of “unlike” magnetic poles and the repulsion of “like” poles is caused by the gyroscopic spin direction of the actual physical streams of the “lines of force”, which he has shown that both of the scientific giants, Maxwell and Faraday were convinced were actual physical entities. The intuitive genius Nikola Tesla described the zero-point energy field as having the physical characteristics of a gas, capable of having motion, exerting pressure, and yet having particle size so small that it can flow through any physical material. Joseph has concluded that this field flow has a specific spin direction as it flows, certainly for flows caused by the magnetic dipole of a magnet. It should be remembered that the scientific teaching of present day educational institutions is at least fifty years out of date. We have the most unusual situation where the scientific literature of a hundred years ago is actually of better quality than that of today which does not describe the actual world at all well. Currently, misconception is alive and very well.

For example, Maxwell produced equations describing how the world works. Admittedly, these equations are very difficult for people to understand. H. A. Lorentz simplified these equations and his results are mistakenly described as Maxwell’s which they most certainly are not. Tom Bearden illustrates it this way; consider a sailing boat being driven along by the force of the wind against the sails:
Maxwell says that there is a vast swathe of wind blowing across the ocean, capable of powering a long row of a thousand sailing boats side by side. This is the actual physical case. Lorentz has 'simplified' things by saying “we will consider one boat and only one boat. As the rest of the wind does not touch any part of the boat we can ignore it”. While that is true for that one boat, what science teaching now says is that the wind can only power a single boat. This is not the actual case, as the environmental wind is not limited to powering just one boat (sailing regattas would not be much fun if that were the case!). This, of course, is just an illustration. Maxwell's equations cover energy and power for the whole universe, and deal with all cases. Lorentz has taken a sub-set of the conditions described by Maxwell's equations, just the group which apply to “closed systems” – just one boat on the ocean. Science has latched on to this and now confidently states that everything is a “closed” system, when in fact, as the zero-point energy field flows through everything, everywhere at all times, and is capable of supplying unlimited additional energy anywhere at any time, there is probably not a single instance of a “closed” system anywhere in the universe.

Joseph Newman, and all other serious inventors, have to fight against this “conventional” science teaching, which is now so entrenched that it has become the equivalent of religious dogma, and ‘scientists’ are unwilling to consider valid observations which do not fit in with the very limited Lorentz concept of the environment. They say “perpetual motion is impossible” which means that Newton was wrong when he said that a moving body will keep on moving indefinitely unless some force acts on it to stop it. Presumably, then, the Earth can’t keep on orbiting the Sun (gosh, I hope it doesn’t stop today as that would be very awkward). Come on – get real!!

You can see then, that when Joseph performs tests and then bases his conclusions on the results of those tests, that he is applying the true scientific method, and people who say that his verified results are impossible because Lorentz says so, are not being scientifically honest. No honest person can ignore genuine scientific observations.

Joseph’s deduction that magnetic lines of force are formed of actual physical particles spinning in gyroscopic motion as they move along their magnetic path at the speed of light, was not something which was obvious to scientists, in spite of the fact that both Maxwell and Faraday had both explicitly described these lines of force as being ‘kinetic magnetic energy’:

As a wire passes in front of and across the end of a bar magnet, the current flows in one direction, pauses, and then flows in the opposite direction. This occurs due to the gyroscopic flow direction of the particles. For instance, on one side of the South end of the magnet, the lines of force spin “up” while on the other side
of that same South end, they spin “down”. A spinning gyroscope will move at right angles to the force acting on it, so as the gyroscopically spinning particles encounter the particles of the wire, they move “up” or “down” the wire at right angles to the direction in which they first encounter the wire. Please note that it is the gyroscopic spin direction of the particles which determines magnetic ‘attraction’ or ‘repulsion’ and not the direction of flow of those particles along their line of force:

It should also be realised that although we draw ‘lines’ of force around a magnetic device, the reality is that these are really shells of force and the magnetic flow is really like water flowing in a river. While we may draw arrows to indicate direction and strength of currents in a diagram of the river, the reality is, of course, that there is water flowing at all points in the river and not just along the lines which we decide to draw. The same applies to the magnetic flow around a magnet, it exists like a solid mass flowing through and around the magnet. You don’t see it or feel it because the particles are so small.

Now to the details of how to construct a device to take advantage of this magnetic movement and output more power than is required to make it operate. Let me remind you again that we are talking here of a Coefficient of Performance (COP) which is greater than 1 in a system which has an overall power efficiency of less than 100%. This is, of course, due to the additional energy flowing in from the zero-point energy field. Joseph visualises the apparent energy gain as being conversion of a small amount of matter into its energy form \( (E = mc^2) \), and while this is probably correct, it will be particles of the zero-point energy field which are being converted into their energy form and not particles from the metal of the magnet. It must be remembered that the particles of the zero-point energy field keep swapping over from energy to physical form all the time anyway. Energy is never “used up” but merely converted from one form to another and the zero-point energy field contains such a staggering amount of energy that all of the visible matter in the whole of the universe could be created from the energy in a single cc of the zero-point energy field. So, if a few sub-sub-sub-microscopic particles of the zero-point energy field switch into their energy form to produce what looks like excess power to us, that is an item so trivial to the field that it is not even worth mentioning – less than the effect of taking one grain of sand off a beach one hundred miles long. The conventional conception of the way things are is so far away from reality that it is ridiculous, (and that is even without saying anything about the effect that the time axis dimension has on the energy balance and flow of energy).

But back to Joseph’s design. Firstly, he points out that it is generally agreed (courtesy of Gustav Kirchhoff) that in the situation shown here:
In any given instant of time, the amount of current flowing into the system ("X") is exactly matched by the amount of current flowing out of the system ("X"). But, if measuring equipment is attached across the coil at the moment of switch-off, an additional amount of current ("X") flows out of the coil. This is generally agreed, and it suggests that a quantity of current "X" flows into the coil and yet a quantity of “2X” flows out of it (COP=2).

Joseph examines this situation in practical detail as follows:

Consider an air-cored coil with an interior diameter of 10 feet, a height of 8.32 feet and would with 1,000 feet of 40-gauge copper wire. That length of wire has a resistance of 1,049 ohms and weighs 0.02993 pounds. If 100 volts DC is connected across it, then a current of about 95 milliamps will flow, which is a power input of 9.5 watts. With just 31.8 turns, it will produce a weak magnetic field of 0.012 Gauss, with a mere 0.000014 Joules of energy stored in it. With a tiny inductance of just 0.003 Henries, if the current is stopped and the ends of the coil shorted together, only an insignificant current would flow.

Now, repeat the experiment, but this time, use 5-gauge copper wire. As it has a resistance of 0.3133 ohms per 1,000 foot length. To equal the same resistance and match the previous current flow, a massive length of 3,348,000 feet needs to be used. This length of wire will weigh 335,469.6 pounds which is 16.77 tons. The 10-foot interior diameter coil, 8.32 feet tall, wound with this wire will have about 90,000 turns. If 100 volts DC is now connected across the coil, the same 95 milliamp current will flow with an input power of 9.5 watts, the same as before. But due to the massively larger coil, it has a magnetic field of 23.7 Gauss, which is 1,905 times larger than the previous coil, and with 116 Joules of energy stored in the magnetic field. This is a phenomenal 8,000,000 times more energy than in the 40-gauge coil of the previous example. A phenomenally larger current flow would now occur if the current input was stopped and the coil shorted out, as that would generate an inductance of 25,700 Henries which is more than eight million times the inductance of the previous coil:
Joseph then built a smaller version of his design, as shown here: this prototype used 5-gauge insulated copper wire weighing 4,200 pounds and 300 pounds of 30-gauge copper wire wound over the 5-gauge winding, and a massive 4-foot long, 20-inch diameter permanent
magnet of some 600 pounds in weight. The coil was wound with an inner diameter of 4-feet and a height of about 3-feet, wound on a fibreglass tube. The overall weight was about 5,000 pounds.

Everybody who was it was asked: “Based on your expertise, how much power would be necessary to simply operate this device mechanically?”. Answers ranged from 200 watts to 1,000 watts. On learning that it had an air-cored coil, other skilled individuals stated that in their expert opinion, the unit would be highly inefficient since it contained no iron core. However, from the design information already presented here, it can be shown that the actual necessary power input is less than 1.5 watts providing a power output far in excess of 100%.

Dr. Roger Hastings, Principle Physicist at Sperry Univac Corporation and former Associate Professor of Physics at North Dakota State University, tested this prototype and showed that it had an 800% efficiency – that is a Coefficient of Performance of 8.0 which is impressive. In addition, Dr Hastings estimated that with a 1.5 watt power input, the back emf exceeded 80,000 watts. In operation, the 600-pound, hand-made magnet rotates at just 200 rpm.

Joseph’s patent which is in the Appendix, indicates four different ways of implementing his design principles. It is very clear that Joseph has proved his point by producing and constructing a device which Oliver Lorentz considered to be impossible, thanks to his throwing out the free-energy sections of Maxwell’s equations. Joseph Newman has clearly earned our respect.

You can see J L Naudin’s builds and tests of small models at [http://jnaudin.free.fr/html/qm11bp.htm](http://jnaudin.free.fr/html/qm11bp.htm).

**Daniel Cook’s Motionless Generator.**

In 1871, Daniel Cook obtained US Patent 119,825 for “An Improvement In Induction Coils”. The highly-respected Dr Harold Aspden considered this to be a very serious piece of equipment, operating as paired cross-linked capacitors, and his opinion carries very considerable weight. It is a very simple device which could be interesting to test, especially as it does not involve any electronics or complicated construction.

Howard Halay who is an experienced free-energy developer, says “what Cook is saying is this: 'Electricity will always flow from a high voltage to a low voltage'. Cook uses the principle of a spike collapsing back-EMF in such a way that the current constantly flows in the same direction. In this process it constantly overcomes the initial current which is of opposite polarity. It constantly increases in voltage until the limit of the components is reached. In order to start it, you can use another coil superimposed on top which induces the "start" current, or alternatively, you can use a magnet to generate this starting current. The device then goes into "runaway" mode so you have to use sufficient insulation and sufficient diameter wire to prevent fire. He then uses an ingenious device to prevent runaway in the form of a powerful rheostat. The rheostat is then shorted to draw power out of the system. The rheostat prevents the device from shutting down. Cook states that you need sufficient length of wire for the device to work. He recommends using 2000 feet of wire. He also uses a long and thick iron core. This will have the effect of limiting the frequency to manageable levels and it will also limit the high voltage to a realistic value. I believe that this is Thomas Henry Moray's secret and that the long wires which Moray used, were deliberate misdirection. (Moray used an electromagnet to induce his starting current). I also believe that this is also Steven Mark's secret. A further point which I have discovered in conjunction with experiments made by 'Grumage' is that all of these devices need static electricity to operate. This explains why Moray's device sometimes would not start (i.e. damp weather). These OU devices are in fact static electricity vortex or suction devices. Also Bedini's devices work less well at night (when static electricity intensity is reduced by lack of sunlight - hence creating morning dew). Examining the Daniel Cook patent, draws attention to the use of obsolete terms which can be found in the 1842 book “Manual of Magnetism” by Daniel Davis Junior ([http://www.free-energy-info.com/Davis.pdf](http://www.free-energy-info.com/Davis.pdf)).

The Cook patent does use some terms which may not be familiar to many people as they are terms which were common 170 years ago but are not commonly used today. Daniel Davis uses these terms, which makes them easier to understand. For example, he envisages that each coil will have a screw connector called a “cup” at each end of the wire and so, instead of referring to the “ends” of a coil, he refers to the “cups” of that coil. Davis also performs some experiments which may help us to understand how Daniel Cook’s motionless generator works. Some of the experiments performed are familiar and some are not. He starts by constructing wet-cell batteries using copper and zinc electrodes with a copper sulphate solution between them. He observes that with two or more connected in series, that the electrical effect is greater:
This is normal and what we would expect when connecting batteries together in series. He also determines that the power which such a battery can provide, increases as the wetted surface area increases:

![Battery Diagram]

This is not surprising, but this effect can produce an unexpected effect. The methods of detection of electrical effects used by Davis include a galvanometer (which is effectively, a voltmeter) and the intensity of an electrical shock felt by a human being holding the ends of an induction coil. For this, Davis winds a pancake coil from flat, insulated metallic ribbon, and places it in various positions near a large helically wound coil which has a large number of turns:

![Induction Coil Diagram]

When the switch “S” is closed, the coils act as an air-core transformer and the rapidly changing current flow in coil “A” induces a voltage in coil “B”. That induced voltage is high as coil “B” has many turns and a substantial shock can be felt when the ends of that coil are held as shown above.

Davis then found that placing several thin metal sheet between the coils had little effect but if a 2.5 mm thick iron plate is used, then there is little or no induced voltage in coil “B”. Interestingly, if a radial slot is cut in that plate, then it has little or no effect on the induced voltage and strong shocks are again felt. The induced voltage is very short in duration when the switch is closed as the current flowing through coil “A” reaches a steady state very rapidly and so there is no longer a varying magnetic field. An interesting effect is seen if the switch is left closed and one of the battery plates is raised, reducing it’s wetted surface area. An induced voltage is produced in coil “B” for the entire duration of the plate movement, producing a much longer overall effect. The galvanometer shows that the voltage across coil “A” is effectively unchanged and yet the induced voltage continues. Presumably, this is from the resistance of coil “A” being so low that the current flow through it is limited by the battery’s ability to supply current, and so, raising one plate reduces the current through the coil without changing the supply voltage, and the reducing current flow in the coil produces a reducing magnetic field and a long period of output from coil “B”.

Davis then experiments with cascading coils to see if the much higher induced voltage can produce an even greater effect in an additional coil, and finds that it does:
Davis makes the following observations about the direction of current flow for induced voltages in a chain of coils which are widely spread apart to avoid magnetic interaction. That is to say, the direction of current flow is not caused by magnetic induction, but instead, solely by back-EMF. For this, he uses a plus sign “+” to indicate current flow in one direction, and a minus sign “-“ to indicate current flow in the opposite direction. He cascades seven coils like this:

The patent drawings give an impression of a small, compact device. That is not the case as the smallest size indicated by Daniel Cook is a bundle of iron wires 600 mm (2 feet) in length and 50 mm (2 inches) in diameter, wound with coils which have at least 150 metres (500 feet) of wire in each coil, and ideally, twice that length of wire. When completed, this is a large and heavy device and it is likely that miniature versions will not work. Cook says:

My invention relates to the combination of two or more, simple or compound, helical coils with iron cores or magnets, in such a manner as to produce a constant electric current without the aid of a battery.

Fig.1 represents the different parts of a compound helical coil and iron core.
In carrying out my invention, I do not confine myself to any particular mode of coil construction or to any particular size of wire, observing only that the quantity of wire in the various coils must be sufficient to produce the required result; also, the material used to insulate the wires must be suitable for producing the required result. However, I generally prefer to use the same size of wire in the construction of both simple and compound coils.

When constructing simple coils, to produce the required voltage and current, it is desirable to use a long iron core as shown as **A** in Fig. 1. This iron core may be two, three or even six feet in length, and two, three or more inches in diameter. The coil should be wound from good quality copper wire, insulated with silk or shellac. The iron core **A** may be a solid bar or a bundle of separate iron wires, the latter giving better results and providing more current for any given wire diameter. While the wire may be fine or coarse, I prefer to use No. 16 (1.23 mm diameter) or even thicker wire, as the power output is in proportion to the length and diameter of the wire.

When using compound coils, it is preferable in some cases to use a small wire, say, No. 30 (0.255 mm diameter) or even less, for the primary coil, and No. 16 or even larger for the secondary coil. With this combination, the initial secondary current of the primary coil being very small in comparison to the terminal secondary current of the secondary coil, offers little resistance to the terminal secondary, hence a quicker action is obtained. Alternatively, the primary coil may be of uninsulated wire coiled into a solid helix, being insulated only between the coils, in which case there is little or no opposing initial secondary current.

Helically wound coils alone with large quantities of wire will produce similar results. A ribbon spiral may be substituted for the secondary coil **C**, say, of three, six, twelve or twenty-four inches in width and of any convenient length, but always of sufficient length to raise its output current to the level necessary to sustain itself through its action on the primary coil **B**. In the use of compound coils, it is important that the secondary
coil should be wound in the same direction as the primary coil, and the primary and secondary coils be cross-connected as shown in Fig.2. The action will then be as follows:

The secondary current of the secondary coil C, will circulate through the opposite primary coil B, while at the same instant, a secondary current from the primary coil B will be generated and circulate through the opposite secondary coil C, both currents flowing in the same direction in the opposite coils B and C, producing a combined magnetic action on the iron core A in the centre. The opposing initial secondary currents of the two coils B and C being overpowered, do not show in the main circuit D of the device, there being eight distinct currents developed in the action of one entire circuit of the two pairs of coils, two terminal and two initial secondary currents to each pair of coils, the four initial secondaries constantly opposing the circulation of the four terminal secondary currents, but the initial secondaries being of much lower voltage and current than those of the terminal secondary, are overcome, leaving a sufficient surplus terminal power to overcome the resistance of the primary wire and charge the bar A to the degree needed to reproduce itself in the opposite secondary coil. By this means, a constant current is kept flowing in all of the coils.

These coils may be constructed using 500 feet to 1,000 feet or more for each of the primary and secondary coils. The longer, and better insulated the wire, the greater is the power obtained from the device. The larger the wire diameter, the greater the current obtained.

If only single coils are to be used, it is preferable to have a wire length of 1,000 feet or more in each coil. The action is the same as with the compound coils, but only four currents are produced: two initial and two terminal currents, the latter flowing constantly in the same direction - in effect, there being only one current in the same direction.

The action in the coils may be started by using a permanent magnet, an electromagnet or by pulsing an extra coil wound around the outside of one of the coils of the device. If the load circuit is broken for any reason, the current stops immediately. It is then necessary to perform the start-up procedure again to get the device restarted. This can be overcome by permanently connecting a resistor across the terminal of the load so that if the load circuit is broken, the device can continue under very much reduced current until the load is restored. By this means, the device becomes the direct equivalent of a battery.

A rheostat D may be introduced into the main circuit to limit the current and prevent the overheating of the coils through the drawing of excessive amounts of current. The iron cores may also be used for producing electromagnetic motion when the device is operating.

******

In 1870 there was nothing much in the way of electronic components available to Daniel who did exceptionally well to produce his self-powered design. With its size of 0.6 to 1.8 metres in length and the substantial weight of the iron cores, it does not lend itself to mobile applications. With present day components, Daniel's system can be reproduced in a much more compact and lighter form. I don't know who originated it, but I recently came across the "Rene-Rator" circuit which shows the Daniel Cook design using toroids (presumably ferrite) instead of the long iron cores wound with coils, and diodes used to control the feedback.

It is clear that the power output of such an arrangement will be limited by the capacity of the toroids to carry magnetic flows and so I might suggest that the 'Nanoperm' nanotechnology high performance toroids such as the http://www.magnetec.us/shop/details.php?id=73&kategorie=5&main_kat=&start=50&nr toroid from Magnetec GmbH might improve performance. However, please understand clearly that I have not built this circuit and while I believe that it would work well, experimentation will be needed in order to find the best working arrangements. The circuit is shown like this:
You will notice that the direction of the coil windings is not specified and so it is left up to you to arrange the magnets and input windings so that they oppose each other.

It seems certain that the circuit will oscillate at its resonant frequency and that frequency will be high. As Daniel found it necessary to control the current with a rheostat, it might be advisable to place controls on the circuit to prevent runaway from the positive feedback used in the circuit. A circuit breaker placed between the two toroids could impose a safety limit on current and protect the insulation of the wiring. A Metal Oxide Varistor placed across one of the input coils could be used to limit the voltage generated if that is found to be necessary.

I would expect a good deal of experimentation to be needed to find a good working circuit, and so I asked my friend Edmund Cook who is experienced in the use of simulation software, to assess the circuit and its operation so that there could be some assessment of what factors have the greatest effect. The magnet strength relative to the quality and size of the toroid has to be important because if the magnet puts the toroid into saturation, that would probably not be helpful in power production, but that, of course, is merely my uninformed opinion and test results are the only way to optimise the circuit.

Having examined the circuit, Edmund states that the arrangement should be different and he has produced the following diagram:

Every second wave, marked red, coming from the output coils is the actuator pulse for the "input" coils to block the magnetic field of the permanent magnets. The permanent field retracts from the core inducing a current flow in the output coils. After the input "pulse" is gone, the permanent magnet will restore the magnetic field in the core, causing a "back-EMF" in the output coils.
Edmund says: Each output coil’s half wave (shown in red), is the opposing input coil’s actuating pulse, which opposes the permanent magnet’s magnetic field influence on the toroid core. Note how this cyclic blocking and augmentation creates a natural resonance between the coils as the ebb and flow of current is regenerated and sustained by the permanent magnets. Particularly noteworthy are the self-enhancing characteristics developed by unifying the directions of the windings and the polarity placements of the magnets and both the Outputs’ and Inputs’ subsequent collapsing fields’ counter-EMF. I find the structure of this circuit to be fascinating, especially when considering how the directions of the windings and the subsequent collapsing fields can be used directly to influence, and therefore, accentuate the overall field strength of each coil. The directions of all the windings are of critical importance for not only the fields on each toroid and the intended function of the diode, BUT also for the proper interactions between the two, intensely interlaced Output Coils. The original drawing was dysfunctional on numerous details.

This circuit has two outputs and no external inputs and so it needs to be started by applying an AC signal to one of the two magnet coil pairs.

As already mentioned, I personally, would prefer there to be protection in the circuit against over voltage or the current rising to an unacceptably high level which would cause overheating of the wire and possible damage to the insulation of the wire. While a fuse is shown in the following diagram, I would prefer a circuit breaker. The Metal Oxide Varistor is chosen for whatever voltage you intend to run the circuit at, and the diodes need to be able to handle more current than the wire can manage. I would suggest that fast acting diodes are used. These measures should not affect the operation of the circuit and it is likely that many people would consider them to be unnecessary. However, if you wish to include them, then I would suggest the following circuit arrangement:
If you build this circuit and get it going, then please let me know about it with details of the coils, toroids and magnets used so that your success can help other replicators.

Michael Eskeli’s “No Work” Generator.

One of the greatest expenses for many families is the cost of heating or cooling a home. Any device which can help with this task is definitely welcome. Michael Eskeli has produced several most interesting designs which may have been overlooked due to lack of emphasis of what they do.

Normally, a central heating system uses an expensive method of heating a liquid, typically oil, which is then pumped through radiators around the building by a low energy pump. The vast majority of the cost is in heating, typically, a furnace and very little is spent on moving the heated liquid through the radiators. In this design from Michael, the cost of the heating is zero, and all that is left is a low-power (quarter to half horsepower) input, needed for spinning a rotor against the friction of its bearings and stuffing box.

As this seems impossible, a little very technical explanation is given here. This information has come from the web site of Scott Robertson at [http://www.aircaraccess.com/](http://www.aircaraccess.com/) with his kind permission. In broad outline, the device comprises of a disc-shaped housing with a closely-fitting rotor spinning inside it. A gas under pressure and a liquid under pressure are both fed into the device and they intermingle in a pulsating sequence which alternately compresses and releases the pressure on both fluids. This heats both fluids very effectively, and most interestingly, without the use of any user-supplied heating power and without the
use of any heating fuel. This next paragraph is for Engineers, so if you don't understand it, then just ignore it, as the important thing is to understand what the device does, rather than exactly how it does it.

The Heat-Pump Work Cycle: The example diagram above shows the sequence of events caused by the rotation of the disc inside the device housing. This “Pressure / Enthalpy” or “Pressure / Internal-Energy” diagram shows the pressures and temperatures during a single pressure cycle of the device. Using nitrogen as the gas, the cycle starts at point “1” which has a pressure of 150 psi and a temperature of sixty degrees F. A pressure wave now hits the mix of nitrogen and the liquid. This pressure wave moves us to point “2” where the pressure has been boosted to 540 psi which raises the temperature to 280 degrees F.

Moving to point “3” is where the wanted heat is passed throughout the gas a the liquid (performing the heating task which is the whole object of the exercise), even though the pressure is maintained, so at point “3” there is a pressure of 540 psi and a temperature of 138 degrees F. Next, comes a major drop in pressure, taking us to point “4” pulling the temperature down to below freezing: 250 psi at just 4 degrees F. At point “5” the pressure is dropped further to 150 psi, still at 4 degrees F. Point “6” takes us to 250 psi at 60 degrees F from where the cycle takes us back to point “1”, and the sequence starts all over again.

The compression takes place on leg 1 to 2 and leg 5 to 6. The actual amounts are 53.2 and 13.5 respectively, giving a Compression Total of 66.7 B/lb.

The expansion takes place on leg 3 to 4, leg 4 to 5, and leg 6 to 1. The actual amounts are 31.6, 16.6 and 18.7 respectively, giving an Expansion Total of 67.0 B/lb.

As these two are virtually identical, the overall result of a complete cycle is effectively work-free.

This work cycle can be readily performed by the Centrifuge-Type Heat Pump. This is a unit which has only one moving part, the rotor, the working fluid, such as nitrogen, is sealed in with the rotor and circulates in passages in the rotor. The circulation of the working fluid inside the rotor is accomplished by density control alone, in accordance with the work-cycle shown above, and there is no work input to the working fluid from the rotor shaft. Thus the work input for the heat transfer is nil, and a work-free heat pump results.

In the diagram shown below, an axial cross-section and an end view with sections removed, shows a typical heat pump rotor suitable for use with the work-cycle discussed above.

In the diagram, 10 is the heated-fluid heat exchanger, 11 is the heat-supply heat exchanger in two parts, and 12 are the vanes in passages which return the working fluid from the periphery to the centre of the disc. The work cycle process is of the non-flow type for the working fluid in this rotor, and this provides higher performance that that in the example shown above.
The fluid to be heated is usually a liquid, such as water, which enters and leaves the rotor via the rotor shaft. Similarly, the heat-supply fluid circulating through heat exchanger 11, is a liquid which enters and leaves via rotor shaft passages.

The work-free heat pump obviously has many uses. One such use is in heating all types of buildings and homes, resulting in cost-free heating, since no fuel is needed, and the power usage is nearly nil. In the heat pump shown above, power is needed to drive the rotor against friction which may require a quarter to half horsepower motor.

Another use is in power generation, resulting in cost-free power since the unit uses no fuel, the energy source being either ambient air, or water from some natural source. (Attached turbine generates the power; part of this is used to overcome the heat pump friction loss and the remainder is available for generation of electricity). Further uses are in portable power and transportation vehicles, etc.

The apparatus and methods and work cycles are patented. For basic heat pump, see US Patent 3,926,010 and Canadian Patent 984,827.

Michael Eskeli.

Here is one of Michael’s many patents:

**US Patent 3,650,636**
**21st March 1972**
**Inventor: Michael Eskeli**

**ROTARY GAS COMPRESSOR**

**ABSTRACT**

Method and apparatus for a compressor for compressing air, gases and vapours isothermally using a liquid stream to compress the gas; the liquid issuing from an impeller intermittently, with the gas being entrained between these liquid pulses and compressed by the liquid; the liquid having high kinetic energy when leaving the impeller and in slowing the kinetic energy is converted to pressure for both the liquid and entrained gas. Also, this compressor may be used advantageously to compress vapours, wherein the liquid is the same fluid as the gas, in which case condensation of the gas to the liquid occurs, and work of compression is reduced.

**BACKGROUND OF THE INVENTION**

This invention relates generally to devices for compressing gases, air and vapours, in which a liquid is in intimate contact with the gas or vapour to be compressed.

**DESCRIPTION OF PRIOR ART**

There are numerous devices and machines available for compressing a gas or a vapour. In some of these machines a liquid is rotated inside an eccentric casing, so that the machine rotor will cause the liquid to pulsate and the space between the rotor blades is increased or decreased, and this variation compresses the gas. These machines are called liquid piston type machines. Another device is the jet ejector compressor, where a stream of liquid or gas is used to entrain the gas or vapour to be compressed, and the kinetic energy of the stream is converted in a diverging nozzle to a pressure.

The main disadvantage of the liquid piston type machine is its poor efficiency, since the liquid is rotated in the machine and requires relatively large power input for compressing the gas. In the ejector compressor, the velocity of the liquid stream is limited and it entrains poorly of any gas; therefore the efficiency of the device is very poor. The available kinetic energy in the liquid stream is high, but due to poor entrainment of the gas by the liquid, results for the device are poor.

**BRIEF DESCRIPTION OF THE DRAWINGS**

![Diagram](image)

**Fig.1** is an end view of the compressor casing, showing the exterior.
**DESCRIPTION OF PREFERRED EMBODIMENTS**

It is an object of this invention to provide a method and a device for compressing gases or vapours essentially isothermally in which the kinetic energy contained by a liquid stream is used to compress said gas to a higher pressure where the liquid in slowing in speed will increase its pressure and increase the
pressure of the gas being entrained in it. Also, it is an object of this invention to provide a method and a device in which the gas may be partially or fully be condensed in the liquid stream thereby lowering the work of compression; this occurring when the gas or vapour being compressed is the same fluid as the liquid; that is, the gas being compressed is the vapour phase of the fluid, and the liquid being used for as the motive fluid is the liquid phase of the fluid.

Referring to Fig. 1, there is shown an end view of the compressor, where 10 is the compressor casing, 11 is the liquid inlet, 12 is the gas or vapour inlet, and 13 is the outlet.

In Fig. 2, a side view of the compressor is shown. The impeller 22 is rotated by shaft 28, supported by bearings and sealed by packing 23 and stuffing box 24. Alternately a mechanical seal could be used. The liquid that is used as the motive fluid enters through opening 11, passes through the impeller 22 and leaves the impeller at a high velocity and entering the throat section 21 and from there the diffuser section 29 in the casing 10. After leaving the diffuser at a higher pressure, and at a lower velocity, the gas and liquid mixture is collected in annular space 30, and from there passes out through opening 13. The liquid entrains gas from annular space 31, and the gas enters the annular space from outside through opening 12.
In Fig. 3, the impeller 22 is shown in more detail, where 38 is the fluid passage, and 36 is the opening for the drive shaft.

In Fig. 4, the impeller is shown, with 22 being the impeller and 38 being the fluid passage.

In operation, the compressor functions in a manner similar to a jet ejector compressor. A motive fluid is accelerated in a passage in the impeller to a high velocity; this corresponds to the motive fluid nozzle in a jet ejector. However, the fluid stream issuing from the impeller, when it rotates, is not continuous as seen by the compressor casing, since in this particular instance, the impeller has four fluid passages, with solid material between them. Therefore, the flow from impeller, as seen by the compressor casing, is pulsating, with empty spaces between the high speed liquid; these empty spaces being filled by the gas from the annular spaces, item 31, Fig. 2, and the gas being rapidly moved with the liquid to the outer annular space 30, and from there to discharge. This pulsating action improves the entrainment of the gas by the liquid, and more fully utilises the kinetic energy available in the liquid stream.

The sizing of the fluid passages and the calculations related to them, are fully described in thermodynamics literature for jet ejectors and for steam injectors. The space of the passage 38 in Fig. 3, would be either converging for liquids that do not vaporise when leaving the passage; or the passage could be diverging at its outlet for fluids which will vaporise either partially or fully when leaving the passage. Of the non-vaporising liquids, water would be an example, and of the partially vaporising types, butane would be an example, both at atmospheric temperatures, and at low pressures. As illustrated in Figs. 2-4, passageways 38 comprise a converging section nearest the centre of the impeller but are at least non-converging at the discharge section. Preferably, the at least non-converging section is a diverging section for better taking advantage of the energy available in the motive fluid to achieve higher exit velocities.

The fluid passages shown in Fig. 4, item 38, can be radial as illustrated, or be forward or backward curved, depending on the fluid used. Also, the throat section 21, of Fig. 2, may have vanes of proper shape to prevent circular motion of the fluid after it leaves the impeller. Vanes of this type are commonly used in
turbines and pumps and so are not described here. There are four fluid passages shown in Fig. 4, but this number will be determined when calculations are made for the size of the passages, and the frequency of pulses of liquid required to maintain suitable pressure and volume relationships inside the compressor; also, the rotational speed of the impeller would enter into these calculations.

Normally, the amount of liquid is large when compared to the amount of gas or vapour. Therefore, when compressing a gas, the heat of compression from the gas is transferred to the liquid, resulting in a temperature increase of the liquid, as well as of the gas. This temperature increase is much less than it would be for the gas alone, resulting in nearly isothermal compression, and therefore reduced work of compression, as compared to isentropic compression which is often used in rotary compressors. Also, if a liquid that will expand in the impeller is used, with an expanding fluid passage, the temperature of the motive fluid is lowered, and the fluid velocity greatly increased, resulting in much better efficiency for the compressor; this is similar to the function of converging-diverging nozzles in jet ejectors.

The operation of the compressor may be inferred from the above descriptive matter. A liquid source is connected to the impeller inlet Fig. 1, 11 and a gas or vapour source is connected to the gas inlet Fig. 1, 12. Discharge from the compressor is from Fig. 1, 13. A suitable power source, such as an electric motor, is connected to shaft Fig. 2, 28, causing the shaft to rotate. The liquid is accelerated by the action of the impeller, and as it passes through the annular space Fig. 2, 31 in a pulsating flow, it entrains the gas and carries it to annular space 30, from where it discharges.

Materials of construction for the compressor would be similar to those used to make pumps for pumping liquids. Cast iron, steel, bronze, brass, stainless steel and various plastics could be used.

CLAIMS
What is claimed new is as follows
1. A machine for compressing gaseous fluid and having the major components of:
2. The machine of claim 1 wherein said at least non-converging section is diverging.

Cold Fusion.
Cold fusion was initially accepted with great excitement. It then appeared to be discredited, primarily as a matter of fear of losing the funding for the decades old "hot" fusion research. At the present time, there are some two hundred labs. which have confirmed the findings and so there is no doubt as to the reality of the system. In essence, it is said that nuclear fusion can take place at room temperature, under certain conditions. However, a commercial working device is now reaching the market with details at Sterling Allan's website: http://peswiki.com/index.php/Directory:Andrea_A._Rossi_Cold_Fusion_Generator.

If you want the background details of cold fusion history, then there are several web sites which follow the progress in this field, including "Cold Fusion Times" at http://world.std.com/~mica/cft.html where considerable detail is available. However, although a cold fusion generator is unlikely to be something which you can knock together in your back yard, the process is edging steadily towards general use. In 2012, the Rossi "Ecat" cold fusion generator is expected to launch. The web site http://ecat.com/ is already taking orders and the home unit producing 10 kilowatts, is expected to sell for US $500 and have an annual running cost of just $20.

In August 2015 Rossi gained a full patent for his commercial design. At that point in time Rossi had a one megawatt generator operating perfectly and continuously for a whole year. Here is his patent:

FLUID HEATER

ABSTRACT
An apparatus for heating fluid including a tank for holding fluid to be heated, and a fuel wafer in contact with the fluid. The fuel wafer includes a fuel mixture, reagents and a catalyst, and an electrical resistor or other heat source in thermal communication with the fuel mixture and the catalyst.

Description:
BACKGROUND

Many heat transfer systems use hot fluids as a heat transfer medium. Such systems include a heat generator, a heat transfer medium in thermal communication with the energy source, and a pump to move the heated medium to wherever the heat is needed. Because of its high heat capacity and its abundance, a common heat transfer fluid is water, both in its liquid and gas phase.

A variety of heat generators are in common use. For instance, in nuclear power plants, nuclear fission provides energy for heating water. There also exist solar water heaters that use solar energy. However, most heat transfer sources rely on an exothermal chemical reaction, and in particular, on combustion of some fuel.

SUMMARY

In one aspect, the invention features an apparatus for heating fluid, the apparatus including a tank for holding fluid to be heated, and a fuel wafer in fluid communication with the fluid, the fuel wafer including a fuel mixture including reagents and a catalyst, and a heat source, for example an electrical resistor, in thermal communication with the fuel mixture and the catalyst.

Among the embodiments are those in which the fuel mixture includes lithium and lithium aluminium hydride, those in which the catalyst includes a group 10 element, such as nickel in powdered form, or in any combination thereof.

In other embodiments, the catalyst in powdered form, has been treated to enhance its porosity. For example, the catalyst can be nickel powder that has been treated to enhance its porosity.

In those embodiments that include an electrical resistor, the apparatus can also include an electrical energy source, such as a voltage source or current source in electrical communication with the resistor.

Among the other embodiments are those in which the fuel wafer includes a multi-layer structure having a layer of the fuel mixture in thermal communication with a layer containing the electrical resistor.

In yet other embodiments, the fuel wafer includes a central heating insert and a pair of fuel inserts positioned on both sides of the heating insert.

A variety of tanks can be used. For example, in some embodiments, the tank includes a recess for receiving the fuel wafer. Among these are embodiments in which the tank also includes a door for sealing the recess. In yet other embodiments the tank includes a radiation shield.

Also included among the embodiments are those that further include a controller in communication with the voltage source. Among these are controllers which vary the voltage in response to the temperature of the fluid which is being heated.

In another embodiment, the invention features an apparatus for containing and heating a fluid, the apparatus also has means for holding a fuel mixture containing a catalyst and a reagent, and means for initiating a reaction sequence mediated by the catalyst to cause an exothermic reaction.

Another aspect of the invention is a composition of matter for generating heat, the composition including a mixture of porosity-enhanced nickel powder, lithium powder, and lithium aluminium powder, and a heat source in thermal communication with the mixture for initiating a nickel catalysed exothermic reaction.

Another implementation of the invention has a method of heating a fluid, the method including placing a mixture of nickel powder, lithium powder, and lithium aluminium hydride in thermal communication with the fluid; and heating the mixture, thereby initiating an exothermic reaction in the mixture.

These and other features of the invention will be apparent from the following detailed description and the accompanying figures, in which:

BRIEF DESCRIPTION OF THE FIGURES
Fig. 1 shows a heat transfer system having a heat source;

Fig. 2 is a cut-away view of the heat source in Fig. 1;

Fig. 3 is a cross-section of the wafer for use in the heat source of Fig. 2;
Fig. 4 shows an exemplary resistor in the central layer of the wafer shown in Fig. 3.

Fig. 5 shows the heat source of Fig. 1 operating with a conventional furnace.

Fig. 6 shows plural heat sources connected in series, like those in Fig. 2.

Fig. 7 shows plural heat sources connected in parallel, like those in Fig. 2.
Referring to Fig. 1, a heat transfer system 10 includes a pipe 12 for transporting a heated fluid in a closed loop between a heat source 14 and a thermal load 16. In most cases, for example where there is hydraulic resistance to be overcome, a pump 18 propels the heated fluid. However, in some cases, such as where the heated fluid is steam, the fluid’s own pressure is sufficient to propel the fluid. A typical thermal load 16 includes radiators such as those commonly used for heating interior spaces.

As shown in Fig. 2, the heat source 14 is a tank 20 having a composite shield made of lead, an inlet 22 and an outlet 24, both of which are connected to pipe 12. The interior of the tank 20 contains fluid to be heated. In many cases, the fluid is water. However, other fluids can be used. In addition, the fluid need not be a liquid fluid but can also be a gas, such as air.

Tank 20 has a door 26 which leads to a receptacle 28 protruding into the tank. Radiating fins 30 protrude from walls of the receptacle 28 into tank 20. To maximise heat transfer, the receptacle 28 and the fins 30...
are typically made of a material having high thermal conductivity, such as metal. A suitable metal is one not subject to corrosion, such as stainless steel.

Receptacle 28 holds a multi-layer wafer 32 for generating heat. A voltage source 33 is connected to the wafer 32, and a controller 35 for controlling the voltage source 33 in response to the temperature of the fluid in tank 12 as determined by a sensor 37.

![FIG. 3](image)

As shown in Fig.3, the multilayer fuel wafer 32 has a heating section 34 sandwiched between two fuel sections 36 and 38. The heating section 34 has a central layer 40 which is made of an insulating material, such as mica, and that supports a resistor 42.

![FIG. 4](image)

Fig.4 shows a typical central layer 40 having holes 44 through which a resistive wire 42 has been wound. This resistive wire 42 is connected to the voltage source 33. First and second insulating layers 46 and 48, made of a material such as mica layers, encase the central layer 40 to provide electrical insulation from the adjacent fuel sections 36 and 38.

Each of the fuel sections 36 and 38 feature a pair of thermally conductive layers 50 and 52, such as steel layers. Sandwiched between each pair of conductive layers 50, 52 is a fuel layer 54 which contains a fuel mixture having nickel, lithium, and lithium aluminium hydride LiAlH₄ ("LAH"), all in powdered form. Preferably, the nickel has been treated to increase its porosity, for example by heating the nickel powder to times and temperatures selected to superheat any water present in micro-cavities that are inherently in each particle of nickel powder. The resulting steam pressure causes explosions that create larger cavities, as well as additional smaller nickel particles.

The entire set of layers is welded together on all sides to form a sealed unit. The size of the wafer 32 is not important to its function. However, the wafer 32 is easier to handle if it is of the order of half an inch thick and 12 inches on each side (12 x 300 x 300 mm). The steel layers 50 and 52 are typically 1 mm thick, and the mica layers 40 and 48, which are covered by a protective polymer coating, are of the order of 0.1 mm thick. However, other thicknesses can also be used.
When operating, a voltage is applied by the voltage source 33 to heat resistor 42. Heat from resistor 42 is then transferred by conduction to the fuel layers 54, where it initiates a sequence of reactions, the last of which is reversible. These reactions, which are catalysed by the presence of the nickel powder, are:

\[
\begin{align*}
3\text{LiAlH}_4 & \rightarrow \text{Li}_3\text{AlH}_6 + 2\text{Al} + 3\text{H}_2 \\
2\text{Li}_3\text{AlH}_6 & \rightarrow 6\text{LiH} + 2\text{Al} + 3\text{H}_2 \\
2\text{LiH} + 2\text{Al} & \rightarrow 2\text{LiAl} + \text{H}_2
\end{align*}
\]

Once the reaction sequence is initiated, the voltage source 33 can be turned off, as the reaction sequence is self-sustaining. However, the reaction rate may not be constant. Hence, it may be desirable to turn on the voltage source 33 at certain times to reinvigorate the reaction. To determine whether or not the voltage source 33 should be turned on, the temperature sensor 37 provides a signal to the controller 35, which then determines whether or not to apply a voltage in response to the temperature signal. It has been found that after the reaction has generated approximately 6 kilowatt hours of energy, it is desirable to apply approximately 1 kilowatt hour of electrical energy to reinvigorate the reaction sequence.

Eventually, the efficiency of the wafer 32 will decrease to the point where it is uneconomical to continually reinvigorate the reaction sequence. At this point, the wafer 32 can simply be replaced. Typically, wafer 32 will sustain approximately 180 days of continuous operation before replacement becomes desirable.

The powder in the fuel mixture consists largely of spherical particles having diameters in the nanometre to micrometer range, for example between 1 nanometre and 100 micrometers. Variations in the ratio of reactants and catalyst tend to govern reaction rate and are not critical. However, it has been found that a suitable mixture would include a starting mixture of 50% nickel, 20% lithium, and 30% LAH. Within this mixture, nickel acts as a catalyst for the reaction, and is not itself a reagent. While nickel is particularly useful because of its relative abundance, its function can also be carried out by other elements in column 10 of the periodic table, such as platinum or palladium.

Fig.5 to Fig.7 show a variety of ways to connect the heat source 14 in Fig.1. In Fig.5, the heat source 14 is placed downstream of a conventional furnace 56. In this case, the controller 35 is optionally connected to control the conventional furnace. As a result, the conventional furnace 56 will remain off unless the output temperature of the heat source 14 falls below some threshold, at which point the furnace 56 will start. In this configuration, the conventional furnace 56 functions as a back-up unit.

In Fig.6, first and second heat sources 58 and 60 like those described in Fig.1 to Fig.4 are connected in series. This configuration provides a higher output temperature than can be provided with only a single heat source 58 by itself. Additional heat sources can be added in series to further increase the temperature.

In Fig.7, first and second heat sources 62 and 64 like those described in Fig.1 to Fig.4 are connected in parallel. In this configuration, the output volume can be made greater than that which could be provided by a single heat transfer unit by itself. Additional heat transfer units can be added in parallel to further increase output volume.

The Work of Karl Schappeller.

There have been a number of quite outstanding men who have had great insight as to how the universe is and how it operates. One of these is Karl Schappeller who is virtually unknown. One of the reasons for this is the fact that publicising his work has been strongly opposed by people who do not want his understanding to become widely known. One device produced by Karl in order to prove that his understanding of things was correct, produced substantial amounts of excess energy, and while I do not know of anybody who has replicated his device, I am including here, a short presentation on the subject, written by Henry Stevens and the book by Cyril Davson can be downloaded from http://www.free-energy-info.tuks.nl/Davson.pdf and read in full.

In the presentation by Henry Stevens, he mentions UFOs or flying discs. There has been a propaganda campaign waged against the general public for more than fifty years now, with the objective of persuading people that “UFOs” are not real, and if they were, then they would be the vehicles of “little green men”. This campaign has been remarkably effective and members of the public in general will immediately dismiss flying discs as being “impossible” and not something which any sane person would consider for a moment. This attitude is based on an almost total lack of knowledge of the facts. There are at this time, large numbers of
flying discs, built by humans and capable of spectacular flight abilities. There are two varieties: those which need the atmosphere to operate and those which don’t.

If you feel that this is a “load of rubbish” then take a look at the following US patents:

This small selection of forty-six patents is restricted to just those which have the well-known circular “flying saucer” shape. Do you seriously think that not a single one of these patents had a test prototype which flew or that they were all piloted by “little green men”?

I have no interest in flying machines which need an atmosphere as they are just advanced versions of conventional aircraft. In the early 1900s, Nikola Tesla designed and built what he described as his “flying machine”. This was a small device without wings and which ‘flew’ without the use of a fuel. This design of Tesla’s was taken by the Germans and during World War II, developed and experimented with. After the war, it was taken to the USA and developed further at Groome Lake, and at this time, the US, UK, Canadian and Russian governments have got large working copies which they keep as secret as they possibly can. One major cover story is that these craft belong to “extraterrestrials” who have such an advanced level of technology that we will never be able to understand it. It is a good story, as it is not possible to disprove it. If you want a good deal of specific information on this, then read “The Hunt for Zero Point” by Janes researcher and writer Nick Cook.

While I have no particular interest in electrogravitic propulsion (or "anti-gravity" as it is popularly known and incorrectly termed) if the subject interests you then take a look at the YouTube video sequence of Stan Deyo who was one of the people who developed electrogravitic propulsion for an international group, several decades ago. Stan explains "gravity" as being the product of spin affecting the space-time continuum.

**The Karl Schappeller Device**

Was the Schappeller device an engine used in German field propulsion saucers? This is a possibility. Because so little has been reported about this device in the English language, the following is a report describing Karl Schappeller and his device in some detail.

Karl Schappeller (1875-1947) literally went from being born in poor-house to owning a castle during his lifetime. His economic success was mirrored in his experiments in energy as a lay-scientist, culminating in the invention of a free-energy device which attracted considerable attention around 1930. Schappeller made no secret of his invention and actively sought private financing to manufacture and distribute the results of his research. He was in touch with financial concerns and he even spoke with a representative of the British Admiralty concerning the utilisation of his device to power Royal Navy’s ships (1).

At this time, 1930, the device was somehow appropriated and further worked upon by a governmental organisation of the German Weimar Republic, the Reichsarbeitsgemeinschaft or Reich Works Association (RAG). At least one aim of the RAG was to make Germany self-sufficient in energy production. Specifically, they published their intentions to utilise many Schappeller devices in a system of broadcast energy distribution throughout Germany which would result in the entire elimination of the electrical grid (2). As we know, Adolf Hitler assumed power three years later and for strategic reasons, he was also very interested in making Germany independent of foreign sources of energy. It is known that political and scientific structures were set up to work on the energy problem as evidenced later by the synthesising of gasoline and oil products from coal by the 3rd Reich. One of these political and scientific structures was contained within the SS and it is known that Karl Schappeller actually met with SS Reichsfueher Heinrich Himmler in Vienna in 1933 (3).
Left: Inventor Karl Schappeller Right: Karl Schappeller's Device. A. Steel outer casing. B. Special ceramic lining in which tubes are embedded. C. Hollow centre, filled by glowing magnetism when in operation. D. Tubes, circuit and earthing.

Fortunately, there are good descriptions of the Schappeller device upon which to draw in both German and English. Per Vril-Mythos is a complete discussion of Schappeller, his device, the history and the controversy surrounding it. "Vril, Die Kosmische Urkraft Wiedergeburt von Atlantis" and "Welt dynamismus Streifzüge durch technisches Neuland an Hand von biologischen Symbolen" represent an attempt by the RAG to popularise their ideas in booklet form. Finally, British electrical and mechanical engineer, Cyril W. Davson, visited Karl Schappeller in Austria and spent three years learning of his device and his theory before the Second World War. Davson's descriptive book, "The Physics of the Primary State of Matter", was written in 1955, after the war and the death of Schappeller.

Before describing the device itself it should be understood that Schappeller and all writing about his device believe that the energy-source being tapped is aether energy, sometimes called "Raumkraft" or "Raumenergie", that is space-energy (4)(5)(6). This device was also said to be capable of, perhaps with some tuning, emitting aether as a radiant energy (7). The physics of aether energy is described by Davson as "primary physics" as opposed to "conventional physics" which he believed could only be considered to be a secondary, derivative understanding.

**Aether Theory**

For readers who have never heard of "aether", perhaps the simplest explanation for aether physics is that of the late Dr. Hans A. Nieper (7) entitled “Revolution in Technology, Medicine and Society”. Aether could be thought of as an energy source emanating from everywhere equally at once. The universe could be considered, as is often said, to be "a sea of energy". It forms a background of energy everywhere, and since it is everywhere all the time, it is difficult make independent measurement of it. This aether energy is in constant motion. All energy is radiant energy, according to this theory. This can easily be appreciated as to electromagnetic radiation but it is also true of that very elusive thing called gravity. Newton described the effects of gravity but he never told us exactly what it was. Dr. Nieper tells us that gravity is really a push, and not a pull. Gravity is acceleration and is caused by the aether field. Again, all energy is radiant-energy whose fundamental basis is aether radiation.

*From the aforementioned book by Dr. Nieper:*
In addition, Nieper established the axiom that, "all natural accelerations can be attributed to a single unified basic principle, namely, the interception (or braking) of a field energy penetrating from the outside (gravity acceleration, magnetic, electromagnetic, electrostatic and radiesthesic acceleration)".

In trying to explain aether, it might be thought of as an all-pervasive liquid, occupying all of space. This liquid concept is useful because a liquid can not be compressed but can only transfer the energy attempting to compress it from one location to another. This is how the brakes of a vehicle work. The driver presses the brake pedal when he wants to slow down or stop. The plunger of the brake pedal attempts to compress the liquid in the master cylinder. The master cylinder is connected to each wheel by metal tubes full of liquid. When pressure is put on the master cylinder by the driver it is transmitted to each of the four wheel cylinders full of the same fluid which transmits the force, moving the brake mechanism, slowing the wheels of the vehicle.

In a similar way, the aether serves to transmit energy through this "non-compressible" quality. In a primary electric coil and secondary electric coil, for instance, induction in the secondary does not take place directly from the primary as is now said by current physics, but instead, the induction between the two windings is due to the aether field. This concept of the energy transfer function of the aether field is also expressed by Davson.

Using this perspective, that all energy is radiation, the braking of aether radiation, that is the slowing down or stopping of this radiation, can cause a transfer to other forms of energy. The word "energy" means the entire electromagnetic spectrum. That includes, electric, magnetic and electrostatic fields. This means heat. This also means gravity. Again, gravity is the primary radiation of the aether field. It radiates from every point in the universe equally.

This concept seems ridiculous until it is given some thought. One might ask: "How can gravity be a push when we know better?" After all, things fall to earth, don't they? The answer is that the effects which we feel and call "gravity" are due to aether shielding. Aether radiation can be braked, that is slowed down and absorbed by mass. It is then re-radiated or converted into mass. It is re-emitted as slower aether radiation or even as heat. Some of it can, and is, converted into mass inside a planet. If there is a loss of aether radiation, then there is shielding. Thus, a planet would shield from this radiation in one direction. That direction is always toward its centre which is the direction of greatest mass and that is what we describe as "down". This is simply the area which contains the maximum amount of shielding. In all other directions the aether radiation continues to exert its push on us. The area of minimum shielding is directly opposite the area of maximum shielding, so things fall (or more correctly are accelerated or "pushed") towards the earth.

Think about this for a minute. Being in deep space is rather like being underwater. Underwater, the pressure at all points is so similar that we feel weightless. We are weightless in deep space because the aether field exerts a push on us from all directions equally. In space, the nearer one gets to a large body the stronger the push is from the opposite direction since the body shields or converts the aether radiation. The result of this thinking is a mechanism totally different from "gravity" as we know it but appearing as exactly the same observed phenomena.

The beauty of this aether theory of gravity is that gravity functions like every other form of radiation. Its underlying cause, aether radiation, can be converted to mass or, in certain circumstances, re-radiated or converted to other forms of energy. No Unified Field Theory is necessary. The aether field is the unified field. Further, there is no need to look for something separate called "anti-gravity". If gravity is a push then it is all anti-gravity. All we have to do to make a UFO, is to find this particular gravity frequency and find out how to generate it.

Aether physics was a lost physics. Physics was hijacked early in the 20th Century by the alleged results of the Michelson-Morley experiment. This experiment assumed that "aether" was matter. There is some confusion here. We know now that particles moving near the speed of light are measured as waves, that is energy, rather than as matter. Nevertheless, aether theory has been discredited among physicists who, in turn, discredit others who raise the subject. It is only through the efforts of "free-energy devices" and free-energy researchers, that this knowledge is being returned to us. Without this aether theory, the reason these devices work cannot be explained at all. Rejection of aether theory allows these devices to be dismissed as "theoretically impossible" and so "fraudulent" by implication. They are marginalised and dismissed as "perpetual-motion devices". According to established physics, perpetual-motion devices violate the physical laws of conservation of energy. Without an aether theory as an explanation, they do violate the laws of conservation of energy and so their detractors are able to simply dismiss them out of hand. The simple fact that some of these free-energy devices actually work, does not seem to bother these scientists in the least. Rather than change the theory to accommodate the observed facts, the facts are ignored and
substituted by dogma. Whether we like it or not, we are living in an energy Dark Age.

Instead of aether theory, we have all been led to focus upon Einstein and his Theories of Relativity. Two or three generations of scientists have wasted themselves on "trying to prove Einstein right". This misguided thinking has resulted in stagnation. One need go no further than the many "free-energy" devices which have arisen to the level of notice in spite of accepted scientific theory to see that this statement is true.

Needless to say, German scientists of the Nazi period laboured under no such illusions. They never abandoned aether physics. This was the fundamental reason why field propulsion UFOs were first developed in Germany. After the Second World War two different sciences developed, both called "Physics". One was the relativity-based concept taught in schools, while the second, more esoteric type, was used secretly, by the secret government, for deep "black projects".

**Structure of the Schappeller Device**

According to Davson's description, upon which we will rely, the Schappeller device is really composed of two separate units, the rotor and the stator. The stator is constructed as follows: Its surface is round or ball-shaped, being composed of two half-shells of steel. These half-shells contain the internal structure and are airtight. Attached at the "pole" of each half-shell is an iron bar-magnet, most of which is positioned inside the sphere. This means that the bulk of each magnet is inside the steel ball, one opposite the other. There is a space between the two bar magnets at the very centre of the sphere.

An insulating ceramic material, is placed on the inside of the steel ball, leaving a hollow central area. Within this hollow area, and around the space between the magnets, are two coils mounted. These start at the pole of the bar magnet and finish at the centre of the sphere, with a connection leading out of the sphere to the rotor. These coils are wound using a hollow copper tube filled with a special, secret substance called the "electret". Upon leaving the sphere, the electret-filled copper tubes are replaced by conventional copper wire. An electrical connection is made from the outside surface of one pole to one pole of a special type of battery which is grounded at the other pole or, alternatively, to a special device called an "Ur-machine" which will be discussed later.

This electret is a permanent magnet within the sphere. This type of magnetism is not identical with ferromagnetism or electromagnetism, it is much stronger. The actual composition of Schappeller's electret remains a secret, but another electret has been made by Professor Mototaro Eguchi. It consists of carnauba wax and resin, perhaps also containing some beewax. It was kept in a strong electric field while baking slowly until it solidified. For purposes of the production of Schappeller spheres, a complete electret manufacturing plant would have to be set up, which has no parallel in present science.

Before being set into operation, all the air is pumped out of the hollow core of the sphere. This whole ball is mounted on a swivel mechanism so that the poles can be moved from the vertical to the horizontal. The stator is not attached to the rotor. The stator can function without the rotor and the stator is capable of producing electrical energy without the rotor. The rotor could also be used to generate additional electrical energy.

The rotor consists of a steel wheel of special design fixed on the shaft to be driven, and surrounded on its outer surface by magnets which are attracted and repelled by the force of the stator. The copper wire attached to the internal electret-filled copper tubing, runs through this wheel and supplies electric power to the magnets. The magnets are hollow and filled with the same electret. There is always an odd number of magnets.

A variant of this rotor comes to us from Taeufer, who refers to this further development as the "Ur-Machine". This machine is composed of six sphere units as described above, five revolving around a sixth one which is positioned either above or below the plane of the other revolving spheres. A seventh unit would be employed to rotate the five rotating spheres and so would be offset, and not attached to the others. The five rotating spheres would charge the sixth stationary sphere. The sixth and seventh spheres would function as an anode and cathode and so ground the unit. The Ur-machine could be used to activate other spheres instead of a battery-earthing procedure.

As a prime mover, an engine, the rotor would be used to turn a drive shaft. The stator would be offset, that is, moved off centre in relation to the rotor. Schappeller worked out various angles of efficiency. The drive shaft could be used to power any number of machine applications such as, for instance, the propellers of a ship.
Means of Operation

The device is started through a connection to a totally unique battery and a connection to the earth (12). A specific excitation impulse must be given to the device (13). This electric impulse is conducted through the iron magnet and jumps the gap in the centre of the sphere to the other iron magnet.

What occurred then sets this device apart from all others. In the vacuum of the sphere, in the centre space between the two bar magnets a field of "glowing magnetism" is set up. This glowing magnetism is something entirely unique. It is recognised as a magnetic field, but much more powerful and unlike any magnetic field produced by an iron bar or an electric coil. Once the initial input had been made to start the device, the battery and ground can be disconnected. The device then continues to operate on its own (14).

For an understanding of what is really happening here we have to consider the bar magnet. We think of a bar of iron with two poles, one positive and one negative or perhaps one north pole and one south pole. But there are really three components to the bar magnet. There are the two poles and the neutral zone between the poles. If we cut the magnet in half we get two new poles. For the Schappeller device, this neutral zone is very important. Imagine a bar magnet running through the vertical axis of the ball. Then imagine the centre section cut out. We now have a north pole at the top of the ball, a south pole at the bottom of the ball just as we do with the planet Earth. In the centre we have a missing section with a south pole, opposing the north pole at the top of the ball and, likewise, a north pole opposite the south pole at the bottom of the ball. We have now four poles and a split bar magnet with a gap in its centre section.

It is this gap in the centre where Schappeller's "glowing magnetism" is generated by grounding, that is, charging the device via a special battery and an earth connection. This glowing magnetism is the mystery. Davson cites Schappeller's calculations and gives this form of magnetism as being a thousand times more powerful than that produced by present magnetism (15). He also states that in this form of magnetism the electricity is stationary while the magnetism is radiated (16).

To state this again, Davson contends throughout his book that this glowing magnetism is not found in secondary physics, that is, in modern physics, and that this glowing magnetism is a manifestation of primary physics. As a phenomenon of primary physics, it is responsible for, and can generate, heat, electricity and magnetism.

After initial stimulation and in a state of glowing magnetism, no further input of energy is needed from the battery. The device is able to draw in energy to it directly from the surrounding aether, bind this energy though its magnetic electret material, that is the filling in the hollow copper coils of the internal coil, and then re-radiate energy producing heat, electricity, magnetism or mechanical work depending upon the application.

Stated another way, this is an implosion device and it is described as such (17) (18). Unlike the Schaubberger device which is associated with the word implosion, the Schappeller device operates purely at the energetic level. Energy is drawn towards the centre, through the magnets, into the field of glowing magnetism, and then radiated outward.

My first explanation for this output of radiant energy involves the concept of the Bloch Wall. A Bloch Wall is defined by Van Norstrand's Scientific Encyclopedia, 1958 edition, pages 201 and 202, as: "This is a transition layer between adjacent ferromagnetic domains magnetised in different directions. The wall has a finite thickness of a few hundred lattice constants, as it is energetically preferable for the spin directions to change slowly from one orientation to another, going through the wall rather than to have an abrupt discontinuity" (18).

In electromagnetics the Bloch Wall is external to the hardware itself. It is the point of division of the circling vortex, or spin, of the electronic magnetic energies of the north and south poles. The negative north pole magnetism spins to the left while the positive south pole spins to the right. Energy is being conducted into the Schappeller device through the un-insulated poles and being conducted and spun on its way to the centre of the unit. The point of zero magnetism, no spin and magnetic reversal, where the two spin fields join, is the Bloch Wall (19).
Oscillating circuit. Charged capacitor (electric field) discharges, current carried through insulated wire to charge coil (magnetic field) which discharges, charging capacitor. Oscillating electric and magnetic fields yield electromagnetic waves.

The Bloch Wall radiates energy. Remember, if energy is coming in then it must be going out. The Bloch Wall may generate radio, radar and other electromagnet frequencies but what is most interesting is that it is actually able to radiate gravity as according to Dr. Richard Le Fors Clark. According to this interpretation, the conjunction of two dipolar generated force-field vectors, a quadropole force field or gravity is generated according to Dr. Clark. Gravity being a quadropole source, it radiates in a circular, 360° pattern of two cycles. Dr. Clark has fixed the point of emission as below that of radar and above infrared at $10^{12}$ Hz (20). Dr. Richard Le Fors Clark believes that gravity is a radiation (20) and so it is a "push".

Another Opinion
In late 2001, I wrote a magazine article on the Schappeller device (20) which contained most of the material described above. In that article, I requested alternative explanations for the Schappeller device. I received a letter from Mr. Michael Watson, BSc, Charted Physicist and Member of the Institute of Physics in the United Kingdom. But there was something in Mr. Watson's background even more impressive than his professional credentials. Cyril W. Davson was a family friend whom Mr. Watson knew well in his youth and with whom he had discussed Schappeller and his ideas at some length on many occasions. In Mr. Watson's letter was a brief summary of Schappeller's theory in which he cut through most of the confusing terminology.

This summary is important for a couple of reasons. Mr. Watson's summary of Schappeller's aether theory as described by Davson dovetails nicely into the ideas of Schauburger yet seems to allow for Tesla's experimental results on aether as explained by Bill Lyne. The following is what I learned from Mr. Watson's letter:

Most of us have heard of the two Laws of Thermodynamics. These are laws of heat. The First Law of Thermodynamics states that energy is conserved, meaning that the total amount of energy in the universe always remains the same. This is no surprise for most of us and it is not the real concern here.

What is of concern is the Second Law of Thermodynamics which discusses heat and entropy. The word "entropy" might be thought of as a state of randomness or chaos. Negative entropy would then mean movement toward a less random or more ordered state of any particular thing. If we apply this to a system, then entropy tends to increase until the system breaks down in utter chaos. This will occur unless the system is re-charged with additional outside energy. A concrete example of this might be helpful:

Imagine a new car just coming off an assembly line. It has taken a great deal of energy to find, refine, forge, weld, and paint the metal parts of this car. This same concept also applies to all the other components of the car. This energy and organisation constitute a highly organised state, or, in other words, a state of negative entropy.

What happens next illustrates entropy. The car is purchased. Whether it is driven hard or just sits in the garage does not matter in the long run because what happens to the car is that it starts to fall apart. This change may be small at first and may only occur at the molecular level, but it occurs nevertheless. The engine, transmission, paint, rubber, electronics, etc. all will fail with time. Even if the car just sits in the garage, in a thousand years the metal will eventually oxidise. Finally, the car rusts away forming a reddish brown heap. This is exactly the opposite of the organisation and energy used to put the car together. This disorganisation is entropy. The only thing which will reverse this, as we all know, are additional inputs of energy by the owner in the form of maintenance and repairs.

All things in a relative state of order move toward a state of disorder. In terms of heat, heat will always flow into a colder place from a warmer place. When something is heated there is a rise in its entropy. With increasing heat its molecules move faster and faster in random chaos, just as a bomb does when it explodes. Increasing heat means increasing randomness and chaos which is entropy. Cold, then, can be seen in terms of negative entropy. Any cold object is simply more organised and less random than the same object once it is heated.

Schappeller had something to say about the Second Law of Thermodynamics. He said there was another and unknown thermodynamic cycle which runs opposite the Second Law. To name this idea we will call it "Reverse Thermodynamics". It is the reverse of the Second Law of Thermodynamics in that it leads to an increase in entropy. Not only is there an increase in order but there is an increase in cold! Schappeller, according to Mr. Watson's letter, built his spherical device primarily to demonstrate the principles behind this Reverse Thermodynamics. It was not designed as a practical machine.

To demonstrate the difference between the Second Law of Thermodynamics and Reverse Thermodynamics two theoretical machines shall be examined. Actually, a machine running according to the Second Law of Thermodynamics is not theoretical at all. Combustion machines are of this type. For simplicity sake we will use a wood burning stove such as the type invented by Benjamin Franklin for the heating of a house.

Wood is put in a hollow iron vessel with an adjustable hole at one end. The adjustable hole admits atmospheric oxygen. An initial small input of heat is added to the wood and oxygen until burning occurs. A great deal of heat is produced once the wood begins to burn. We know heat expands. Carbon, carbon dioxide and water vapour are also produced as by-products of the combustion. Entropy is increased. Since entropy is increased, so is pollution so perhaps we all can agree that this is a good example of the destructive technology so characteristic of the world in which we live.
In our example of a theoretical Reverse Thermodynamic machine the by-products of the previous example can be used as fuel. But Schappeller's machine has the additional property of being creative, that is, negatively entropic. Schappeller believed the creative process to be individualistic, so we need a specific template to use as a pattern for this creation. Heat, water, and carbon dioxide are fed into this machine. Quite amazingly, oxygen is yielded as a by-product of this reaction! The heat is also absorbed in Schappeller's Reverse Thermodynamic machine! This absorption of heat is another way of saying that the machine is implosive in nature rather than expansive or explosive as was the heat producing machine. What is most amazing, however, is that entropy is actually reduced yielding, something which has been created - wood!

Actually, this machine is not theoretical either. It exists and works as we speak. These machines are all around us. We call these machine "life". In this case our machine is a tree. In the tree, energy, sunlight, is absorbed and combined in a cold process with water and carbon dioxide to form wood. The template used as a pattern for this seemingly intelligent, creative, process is simply a seed. In this type of reaction the "cold" force is something other than the absence of heat. This cold is an active cold. It is a "densifying", implosive cold. It is a life-giving cold. This is a cold, life giving force. To quote Watson: "This process is life force and the reverse of the second law of thermodynamics; it is the vital force; Vril."

This is one huge difference between the physics of Schappeller and Schaubberger and the physics of the Nineteenth Century. The physics of the Nineteenth Century explain everything in terms of the inanimate. Laws of physics are written using inanimate examples. Chemical reactions are described which stem from inanimate models. Animate models are simply made to conform with the inanimate assuming that life is just a special case which eventually will be shown to be nothing but chemistry and so subject to the same Second Thermodynamic Law as the inanimate. Schappeller and Schaubberger both say in their own ways that this is not so. They say, each in their own ways, that a new and different law of thermodynamics applies to living forces. They say that this more akin to a life process than previous theories allow. They say this force is creative. Those who subscribed to these new ideas claimed that it was not only a new physical law but a new science and that Germany would lead the way in this new science. Let us take a closer look at what is claimed to be the physics behind this new science.

The first concept to be considered is cold. Cold in this sense does not mean the mere absence of heat. This is interstellar cold, the cold found in the vacuum of space. In this relative vacuum, matter is not found in sufficient quantity to be used to measure this cold. Think about how we measure cold. We measure matter which is cold. We measure the heat in air or water for instance. In the absence of matter how would cold be measured? There is no doubt that if we could, for instance, place a thermometer in a glass of water in deep space, the temperature recorded would be at or very near absolute zero, 0° Kelvin or -273° Centigrade or -460° Fahrenheit.

The presence or absence of matter in deep space may be the subject of conjecture. The presence or absence of energy in deep space is something universally accepted. For instance, we all know that light passes through interstellar space. We see the proof when we look up at the stars, planets or the moon. Besides visible light, other electromagnetic radiations freely pass through space. These include x-ray, gamma and cosmic rays. Yet besides electromagnetic radiation many people now believe that in the depths of space there resides another form of energy with is found there as well as everywhere else all around us. This energy sometime goes by the name of "zero-point energy" but for our purposes we can simply call it "aether energy". It is sometimes argued that this energy is really the result of aether rather than the aether itself and that aether really is matter. For a moment, let us postpone this discussion and focus on the vast, stretches of interstellar space which are filled with aether energy, near or at absolute zero.

Mr. Watson points out Dawson's words on page 83 of "The Physics Of The Primary State Of Matter" where he says: "Cold is not therefore the absence of heat, primary heat and cold having nothing to do with molecular action (in the cosmos) there are no molecules available".

The reader may recall that something strange happens to electrical energy at absolute zero. For instance, if a disc of conducting material is held at absolute zero and the disc is given an electric charge, the electric current will circulate around and around the disc forever, never losing its energy as it would if the disc were sitting on an office desk at room temperature. This property of cold is instrumental in the storage of at least one form of energy. The vast stretches of cold interstellar vacuum must be seen as a vast energy storage sea in a state of heightened negative entropy. Schappeller called this undirected matter-energy reserve potential "latent magnetism". Out of this latent magnetism, both energy and matter could be produced with the corresponding stimulation. The non-excited electromagnetic field was viewed by Schappeller simply latent magnetism. Matter is a condensation out of bipolar aether. Therefore, electromagnetism is a product
of matter and is nothing more than bipolar aether in a different condition. Latent magnetism could be, then, excited into matter. Latent magnetism could be influenced by either of the thermodynamic principles discussed, the Second Law of Thermodynamics or by Reverse Thermodynamics. This vast aether field, whose most notable characteristic is the property of cold, latent and awaiting stimulus, is the predecessor of both energy and matter as we know them.

Since primary cold, this vast reserve of negative entropy potential, is responsible for both matter and energy and since all energy eventually degenerates into heat, it follows that, as Davson puts it, again on page 83: "Primary heat, as may now be understood, is composed of cold energy". This is seems like a surprising play on words, especially from a man of science, nevertheless, this statement follows perfectly from Schappeller's reasoning.

We turn now to Schappeller's concept of "stress". Both heat stress and cold stress can be applied to an electromagnetic field. Heat stress is the usual type of stress applied to electromagnetic fields in secondary physics. Secondary physics is the physics of our everyday world according to Schappeller. Primary physics is the physics dealing with the cold force and aether yielding matter and energy, which constitute the secondary reactions and so Schappeller uses the term "secondary physics" to describe our world as we know it.

An example of heat stressing of the electromagnetic field is the capacitor and the coil. A charged capacitor produces an electric field and a charged coil produces a magnetic field. A charged capacitor and coil, connected by a wire circuit alternately charge and discharge each other, producing electromagnetic radiation until the heat caused by the resistance of the wire degrades the whole process into heat. Heat stress on the electromagnetism is +/-.

Cold stress on the electromagnetic field is something totally new to our science and technology. It is also seen in terms of +/- but the machines used to produce it are not known in our world. Mr. Watson did not say this but if we return to our examples of heat stressed machines, the capacitor and the coil, the corresponding cold stressed machines might be the Schappeller sphere and the Schappeller coil electret. The sphere collects the charge through the magnets, holds and condenses it in its glowing centre corresponding to the electric field of the capacitor. The internal coils filled with electret produce a magnetic field in the presence of the intense and pulsing electric field. According to my interpretation, the whole Schappeller sphere is a combined capacitor/coil combined into one machine made possible through an initial input of cold stress.

As in our example of the capacitor/coil interaction producing an electromagnetic wave, so an attraction exists between a machine obeying the Second Law of Thermodynamics and one obeying the law of Reverse Thermodynamics. This attraction can lead to interaction. For example, an imploding or centripetal vortex can couple with an exploding or centrifugal vortex. The centripetal vortex is an example of a system following the law of Reverse Thermodynamics while the centrifugal vortex represents system following the Second Law of Thermodynamics. We have all seen these two systems working together in everyday life. The common toilet is such a machine although the centrifugal side forms inside the drain pipe which is out of sight.

Perhaps there is another example which is more germane to our discussion. It is the diagram of the Vril power plant. (This engine diagram is used here as an example for discussion and is not a blind endorsement of the diagram's existence or accuracy.)
In this interpretation of this diagram, we are really dealing with two separate devices. First, is the central spherical device which may be a refined version of the Schappeller sphere. An initial charge would be imputed into the sphere to start it after which the unit would continue to gather up the surrounding energy. This is a Reverse Thermodynamic machine. The sphere generates a magnetic field which could be offset by rotating the Schappeller device. The offset field would feed and so rotate the arms of the electric generator surrounding the sphere. The electric generator would gather electric energy, feeding the four large broadcasting fixtures on the walls of the saucer. These fixtures might be, for instance, Tesla pancake coils. The electric generator is an example of a machine complying with the Second Thermodynamic Law.

Both components of the power plant are bonded together in a single system since the output energy of the broadcasting fixtures on the walls of the saucer constitute additional input energy for the sphere. The two components attract one another and use and depend upon one another as they circulate and recirculate energy. As the energy level of one component increases so does the energy level of the other. Indeed, the biggest problem facing the use of such an engine may be getting some means of stopping it.

The actual levitation might be the particular electromagnetic radiation coming out of the sphere. In this interpretation, the broadcast fixtures are used to steer the saucer. Davson gives output frequencies for the sphere as $10^6$ Hz.

Mr. Watson points out in his letter that one reason machines utilising the Reverse Thermodynamic principle have not been recognised is that a cold stressed magnetic field is a cold machine. Even a centripetal vortex cools rather than heats. All our devices of measurement ultimately measure heat in some form. Measurement of cold is more difficult. The example already given, the problem of measuring temperature in interstellar space in the absence of matter is an example of this problem.

Finally, the reader will recall that Mr. Watson points out that electromagnetism itself manifests bipolarity, yielding four components in all. These are +/- hot electromagnetism and +/- cold electromagnetism. The reader will recall that two hot electromagnetic components can be joined (the capacitor and the coil) and set into a cycle producing an electromagnetic wave. Is it possible that two complementary hot electromagnetic and cold electromagnetic machines could be set into cycle producing not a bi-polar but a quadropolar, $360^\circ$ radiation to produce gravity, such as the one described by Dr. Richard Le Fores Clark?

**Planned Uses for the Schappeller Device**

If the above discussion has any meaning at all in the quest for an answer to the UFO question, one use for which the Schappeller device must have been destined was that of a power plant for a flying machine. Was this so? The Schappeller device had many planned uses. In 1930 this device was planned as a source of broadcast energy, reminiscent of Tesla, for both German homes and industry. The device could also be used as a generator, battery, transformer, or antenna (21). It is reported that toward the end of the war the SS researched the possibility of using this device in the form of a death ray (22). But additionally, and in answer to our question, the Schappeller device was envisioned as a levitation device for a flying machine. Here is some of that discussion from our sources:

*The new dynamic technology will, in the future, be able to drive electric locomotives and cars without the manufacture of costly armatures and everywhere through connection to the atmospheric voltage network.*
Hypothetically, is certainly the installation of a sufficient number of central amplification facilities which transports from the Ur-Machine the specific magnetic impulse from the dynamic spherical element. New types of aircraft with magneto-static power devices and steering, which are completely crash and collision proof, could be built for a fraction of the cost of today’s aircraft and without the lengthy training of everyone who will be servicing these aircraft. (From “Vril Die Kosmische Urkraft Wiedergeburt von Atlantis” by Johannes Taeufer, page 48).

“Our goal must be to drive forward the space ship problem to new understanding and realisation! Here a definite postulate can be established: "A spherical space ship with its own atmosphere” also technical creation of small planets with world dynamic propulsion and buoyancy! Will this be possible? -- Major powers in the world prepare themselves in any case presently, especially in Germany.”

The above from “Weltdynamismus Streifzüge durch technisches Neuland an Hand von biologischen Symbolen” pages 11 and 12. Please note the use of the words “spherical space ship”(Kugelraumschiff).

From Davson’s “The Physics Of The Primary State Of Matter”, page 240: “The Rotor is laminated to prevent eddying and the magnets do not project; the Rotor periphery is thus entirely equi-radial. The Rotor is fixed to the shaft to be driven and the Stator is fixed about a metre above the earth’s surface. The latter is, of course, flexible because the earth can include the sea or even the floor of an aether-ship.”

From Davson, page 199: "As has already been explained, the new Technique will not concern itself with the air as a supporting medium, but directly with the aether. Therefore, the body may be a vertical sealed cylinder with conic ends or any other suitable form. Such a body is obviously rigid and inelastic, and it must contain an aether stress of sufficient intensity to support its mass against thiser stress of the earth’s stress field, which means that the glowing magnetism core in the Stator, provided in the body to be lifted, must be able to vary its intensity according to the height at which the aether-ship is to be raised and supported whilst in transit, as the aether stress or field, itself, varies inversely as the square of the distance from the earth’s surface. The actual design and solution of all the various problems in the production of such ships, the choice of methods of propulsion, whatever independent or directional, belong to the new Technique, whereas here we are only interested in the principle as applied to the problem of Gravitation.”

Finally, from Davson, page 177: “Now the reason that an unsupported body falls to the ground is primarily because it has “no hold” on the medium. It was previously explained that any inert mass or body has only a latent stress field which functions merely as the force of cohesion and has no mobility and thus only a latent internal stress field and no external stress field. This means that it has no “hold” on any elastic medium such as the aether or the air, therefore it must fall, and it falls towards the greater inductive energy.

If the inductive energy, through some exterior cause, could be made suddenly to increase enormously, there would come a point when the body would be supported, or rather suspended, before it reached the earth’s surface. The new Technique could accomplish this by placing a Schappeller Stator in the body in question, where the body is suitably constructed, thus setting up a glowing magnetic stress field which would hold or keep the weight or mass of the unit body suspended, not in the air "the stress field would have no reaction on the air" but only on the earth’s magnetic stress field. This is the basis of the new principle for ‘aether ships’.”

Employing the Schappeller mechanism is only half the total explanation. In a field propulsion saucer there are possible two types of "drive" needed. The first is the “Auftrieb” or levitation. Employment of levitation makes the craft buoyant. It weighs nothing. If it weighs nothing it can be moved very easily. "Antrieb”, impulse or motive power is the second drive involved. It moves the craft directionally. Levitation only would be supplied by the Schappeller system. Directional movement is so far best explained, in my mind, using the Tesla pancake coils as explained by Bill Lyne.

**Concluding Thoughts on the Schappeller Device**

In the end, what can be said of the Schappeller device? Certainly, it did exist. It drew attention and funding from people within the German government of the time. It was studied by a qualified outsider, a British engineer, for a period of three years and was judged to be genuine.

However, there are some obvious problems. Exotic energies have been evoked which have not been explained satisfactorily. Therefore, the facts are not yet proven. Certainly more proof is required before the claims made for this device or the energies involved can be wholly accepted. For the time being we must put this discussion aside, awaiting further correlations.
There are some solutions connected with this device also. If we accept the idea that both the Schuberger and the Schappeller devices worked on the theory of implosion, then one explanation will serve to explain them both. It also allows for an aether-as-matter explanation. This may fit into the evidence gathered by Nikola Tesla. The commonality of these devices could then be sought and perhaps a more efficient device built as a result. We will pick up this theme again in the discussion section of this book.

It should be pointed out that the quest for this "new science" is not specific to Schappeller or Schuberger. Mr. Watson passed on these words from Ehrenfried Pfeiffer, a scientist who collaborated with Dr. Rudolf Steiner around 1920. Although he is not happy with the translation, he sent it as he found it which is as it is presented here:

"...the method of science, in a materialistic sense, is based on analysis splitting apart, disintegration, separation, dissecting and all the procedures which have to destroy and take apart, to work on the corpse rather than to grow, to develop, to synthesise. That the human mind was captured by these methods of braking apart: in that I saw the source of our present situation. My question (to Rudolf Steiner) was therefore: is it possible to find another force or energy in nature, which does not have in itself the objective of atomising and analysis but instead builds up, and synthesises? Would we discover that constructive force, which makes things alive and grow, develop adequate building up of methods investigation, eventually use this force for another type of technique, applied to drive machines, than because of the inner nature of this force or energy we might be able to create another technology, social structure, constructive thinking of man rather than destructive thinking? This force must have the impulse of life, of organisation within itself as the so-called physical energies have the splitting, separating trend within themselves."

My question to Rudolf Steiner in October 1920 and spring 1921 therefore was: “Does such a force or source of energy exist? Can it be demonstrated? Could an altruistic technology be build upon it?”

My questions were answered as follows: “Yes, such a force exists, but is not yet discovered. It is what is generally known the aether (not the physical aether) but the force which makes things grow, lives for instance in the seed as Samenkraft. Before you can work with this force you must demonstrate its presence. As we have reagents in chemistry, so you must find a reagent for the aetheric force. It is also called formative aetheric force because it is the force which relates the form, shape, pattern of a living thing - growth. You might try crystallisation processes to which organic substrata are added. It is possible then to develop machines, which react upon, and are driven by, this force. Rudolf Steiner then outlined the principles of the application of this force as source of a new energy...”

Since this quest for a new science with the accompanying new machines had a relatively long history in Germany, certainly pre-dating the 3rd Reich, it is almost certain that the Schappeller device or others built along a similar understanding were further developed during the Nazi period. What became of it after the war is not known. It can be assumed that this device did not escape the scrutiny of the numerous Allied intelligence units tasked with combing Germany for examples of German science. Perhaps someday a government report will be de-classified explaining all this as it was in the case of another free-energy machine, that being the Hans Coler device, which was declassified by the British in 1978 (23) and which worked, according to Mr. Watson, using the same principles of cold magnetism. Until that final reckoning comes, aspects of the Schappeller device will still remain a mystery. And until a more final reckoning comes, the question of whether or not the Schappeller device was used as a source of field propulsion in German flying saucers, must be deferred.

Condensation-Induced Water-Hammer.

There is another little-known effect which has a high potential for being a useful technique, and this is the water hammer effect produced by the sudden condensation of steam. Under suitable conditions, the effect can be harnessed to provide motive power.

One of the techniques which has been used is shown above. Here, steam under 55 psi pressure is forced into a tubular structure through a ring orifice. That steam then passes through a doughnut-shaped nozzle where it hits a stream of heavily aerated water. The bubbles in the stream of water are drawn in by the

venturi effect of the water flow past small apertures in the tube. The result is a rapid series of water hammer shock waves which, because of the shape of the shock wave chamber, boost the water as it exits from the tube. This produces a thrust in the opposite direction, effectively forming a jet engine which is particularly suited to water-borne vessels. In the diagram shown above, the device shown is designated as an Underwater Jet Engine. The diagram is from the web display at: http://www.newscientist.com/data/images/ns/cms/dn3321/dn3321-1_843.jpg and is copyright of the New Scientist.

William Hyde's 10 Kilowatt, COP=10, Electrostatic Power Generator.
This is best described by his patent, a slightly re-worded version being shown here:

This patent describes a device which can be a little difficult to visualise and so some colour shading of parts has been used to help matters. Essentially, it is two circular rotors spinning inside a section of plastic pipe. These rotors generate electrostatic energy which people have mistakenly been led to believe is not a source of significant power. This design by William Hyde has an electrical output which is some ten times greater than the mechanical input power required. A Coefficient Of Performance = 10 result like this, has to be significant, especially since the device is of fairly simple construction.

Electrostatic energy field power generating system

Abstract:
Externally charged electrodes of an electrostatic generator induce charges of opposite polarity on segments of a pair of confronting stators by means of electric fields within which a pair of rotors are confined during rotation to vary the charge binding field linkages between confronting rotors and stators by a shielding action of the rotors in a plane perpendicular to the field flux. A high electric potential difference induced between the stators resulting from such rotation of the rotors, is transformed by an output circuit into a reduced DC voltage applied to a load with a correspondingly increase current conducted through it.

Description:
This invention relates to the generation of electrical power by conversion of energy from an electrostatic field. The conversion of energy from a static electric field into useful electrical energy by means of an electrostatic generator is already well known in the art as exemplified by the disclosures in U.S. Pat. Nos. 2,522,106, 3,013,201, 4,127,804, 4,151,409 and 4,595,852. Generally, the energy conversion process associated with such prior art electrostatic generators involves the input of mechanical energy to separate charges so that a considerable portion of the output is derived from the conversion of mechanical energy.

It is therefore an important object of the present invention to provide an electrostatic generator in which electrical power is derived from the energy of static electric fields with a minimised input of mechanical power.
Summary:
In accordance with the present invention, static electric fields are established between electrodes externally maintained at charge levels of opposite polarity and a pair of internal stator discs having segmental surfaces that are dielectrically spaced to confine thereon charges induced by the electric fields. A pair of rotor discs are rotated within continuous electric fields in planes perpendicular to the field flux to locationally vary the charge linkage established by the electric fields between the electrodes and stator discs. Such changes in charge linkage are effected by rotation of electrically conductive segments of the rotor angularly spaced from each other to partially shield the stator discs from the electric fields. The segments of each rotor disc have charged faces confronting the electrodes in its field to shield the stator disc over a total face area that is one-half the total area of the confronting segment surfaces on the stator disc to which the induced charges are confined. Charges on the rotors and stators are equalised by electrical interconnections established through the rotor shafts. The stator discs are electrically interconnected with an electrical load through an output circuit transforming a high potential between the stator discs into a reduced dc voltage to conduct a correspondingly multiplied current through the load.

Brief Description of the Drawings:
These and other objects and features of the present invention will become apparent from the following description taken in conjunction with the preferred embodiments thereof with reference to the accompanying drawings in which like parts or elements are denoted by the same reference numbers throughout all of the different views shown in the drawings and where:

Fig.1 is a simplified electrical circuit diagram corresponding to the energy conversion system of the present invention.
**Fig. 2** is a side section view of an electrostatic generator embodying the system of Fig. 1 in accordance with one embodiment of the invention.

**Fig. 3** and **Fig. 4** are partial section views taken substantially through planes indicated by section lines 3--3 and 4--4 in Fig. 2.
Fig. 5A and Fig. 5B are schematic partial laid out top views of the electrostatic generator of Figs. 2-4, under static and dynamic charge distribution conditions, respectively.

Fig. 6 is an electrical circuit diagram of the output circuit of the generator shown in Fig. 2, in accordance with one embodiment.
Detailed Description of the Preferred Embodiment:

Referring now to the drawings in detail, Fig. 1 diagrammatically depicts the energy conversion system of the present invention generally referred to by reference numeral 10. As shown in Fig. 1, the system includes a pair of electrostatic fields 12 and 14 established by electrostatic charges of opposite polarity applied to electrode plates 16 and 18 from some external energy source. Thus, the electrostatic field 12 is established between electrode 16 and a stator disc 20 while the electrostatic field 14 is established between electrode 18 and a stator disc 22. In accordance with the present invention, electrostatic charge linkages established by the flux of the fields between the electrodes and stators are periodically varied by displacement within the continuous energy fields 12 and 14 in response to rotation of rotors 24 and 26 aligned with planes perpendicular to their common rotational axis and the field flux, as will be described.

The rotors are mechanically interconnected with an electric motor 28, as diagrammatically illustrated in Fig. 1, which rotates them around their common axis. Electrical energy may be extracted from the electric fields 12 and 14 during rotation of the rotors 24 and 26 (by motor 28) through an output circuit generally referred to by the reference number 30. The output circuit 30 as shown in a simplified fashion in Fig. 1, includes two pairs of current-conducting diodes 32A, 32B and 34A, 34B. The diodes of each pair are connected with opposite polarity and each pair is connected in parallel to one of the stators 20 and 22. The diodes of each pair are also electrically connected across an electrical load represented by resistors 36A and 36B with capacitor networks 38A and 38B interconnected between each pair of diodes by means of which the voltage potential between the stators 20 and 22 is reduced in favour of an increased current through the electrical load.
Referring now to Figs 2, 3 and 4 in particular, a physical embodiment of the energy conversion system shown in Fig.1 is shown. The electrodes 16 and 18 are in the form of circular plates or discs made of an electrically conductive metal having external surfaces 40 and 42 adapted to be charged from the external source as already mentioned. The internal surface 44 of electrode 18 is thereby adapted to maintain a positive charge opposite in polarity to the negative charge of the electrode 16 which is maintained in a stable ion form within a dielectric surface portion 46 of the electrode 16. The energy conversion system may be enclosed within an outer housing 48 to which the electrodes 16 and 18 are secured.

With continued reference to Fig.2, the stators 20 and 22 mounted by housing 48 in axially fixed spaced relation to the electrodes 16 and 18 are provided with bearings 50 and 52 supporting the powered rotor shaft driving the shaft assembly which has electrically conductive shaft sections 54 and 56 to which the rotors 24 and 26 are respectively connected. In the embodiment illustrated in Fig.2, the drive motor 28 is mechanically interconnected with the shaft sections 54 and 56 through an electrically nonconductive shaft section 58 of the power shaft assembly for the simultaneous rotation of both rotors 24 and 26 at the same speed and in the same direction about their common rotational axis perpendicular to the parallel spaced planes with which the electrode and stator discs are aligned. The electrically conductive shaft sections 54 and 56 are respectively keyed or secured in any suitable fashion to hub portions 60 and 62 of the rotors and are provided with flange portions 64 and 66 forming electrical wipers in contact with confronting surfaces of the stators 20 and 22, which are inductively charged by the static electric fields 12 and 14 to equal levels of opposite polarity.
As more clearly seen in Fig.2 and Fig.3, the rotor 24 has several angularly spaced, field linkage controlling segments 68 projecting radially outwards from the hub portion 60. Each rotor segment 68 is made of an electrically conductive metal having a face 70 on one axial side confronting the adjacent electrode 16. The faces 70 confronting the electrode 16 are charged positively by the electric field 12 extending between the dielectric surface portion 46 of electrode 16 and the stator disc 20. While the electric field 12 projects through the spaces 72 between the rotor segments 68, the rotor segments 68 themselves shield portions of the stator disc 20 from the electric field.

The rotor 26 is similarly formed with rotor segments 74 angularly spaced from each other by spaces 76 through which the electric field 14 extends between the positively charged surface 44 of electrode 18 and the stator 22. The rotor segments 74 of rotor 26 as shown in Fig.2, are provided with dielectric surface portions 78 confronting the internally charged surface 44 of electrode 18. While the rotor segments 74 are negatively charged by the electric field 14 within the surface portions 78, they also shield portions of the stator disc 22 from the electric field as in the case of the rotor segments 68 already described. The internal dielectric surface portion 46 of electrode 16 and dielectric surface portions 78 of rotor 26 act as a stabiliser to prevent eddy currents and leakage of negative charge. Further, in view of the electrical connections established between the rotors and the stator discs, the charge on each stator is equalised with that of the charge on its associated rotor.

As shown in Fig.2 and Fig.4, the stator disc 20 includes several segments 82 to which charges are confined, closely spaced from each other by dielectric spacers 80. The segments 82 are electrically interconnected with the rotor segments 68 through rotor shaft section 54. Similarly, the segments 84 of the stator 22 are electrically interconnected through the rotor segments 74 and rotor shaft section 56. The segments 82 and 84 are therefore also made of electrically conductive metal. Each of the segments 82 of stator 20 is electrically interconnected through the output circuit 30 with each of the segments 84 of the stator. The stator discs being fixedly mounted within the housing 48, centrally mount the bearings 50 and 52 through which the electrically nonconductive motor shaft section 58 is journaled as shown in the embodiment of the invention illustrated in Fig.2. Further, the total area of the charged segment surfaces on each of the stator discs is greater than the total area of the faces 70 or 78 on the segments of each associated rotor disc 24 or 26. According to one embodiment, the total charged stator surface area is twice that of the rotor face area.
According to the embodiment of the invention illustrated in Fig. 6, the output circuit 30 includes the two oppositely poled capacitive circuit networks 38A and 38B connected across each aligned pair of stator segments 82 and 84 on the stators 20 and 22 by means of the oppositely poled diodes 32A and 34A. Each of these capacitive circuit networks includes a capacitor 86, the opposite sides of which are connected by oppositely poled diodes 88 and 90 to positive and negative load terminals 92 and 94 across which a suitable electrical voltage is established for operating an electrical load. The diode 88 is connected to the junction 102 between diode 104 and one side of capacitor 106. The diode 88 is also connected to the junction between one side of capacitor 100 and the diode 32A. The diode 90, on the other hand, is interconnected with the junction 96 between diode 108 and capacitor 100. Also, diode 90 is connected to the junction between the other side of capacitor 106 and the diode 34A. The foregoing circuit arrangement of capacitive network 38A is the same as that of network 38B by means of which aligned pairs of the stator segments 82 and 84 have the electrical potentials between them transformed into a lower voltage across the load terminals 92 and 94 to conduct a higher load current.
Fig. 5A illustrates the distribution of charges established in the electric fields 12 and 14 between the electrodes and stators under static conditions in which each of the rotor segments 68 and 74 are positioned in alignment with one of the stator segments 82 and 84 to thereby shield alternate stator segments from the electric fields. The charges established by the electric fields are therefore confined to the faces of alternate stator segments confronting the electrodes and are equalised with the charges established on and confined to the shielding faces of the rotor segments confronting the electrodes by virtue of the electrical interconnection between the rotors and stators as already mentioned. As depicted in Fig. 5B, when the rotors are rotated, the charge linkages established by the electric fields between the electrodes and alternate stator segments 82 or 84 are interrupted by the moving rotor segments 68 or 74 so that previously shielded stator segments become exposed to the fields to re-establish field energy linkages with the associated electrodes. Such action causes electrical potentials to be established between the stator segments 82 and 84.

It will be apparent from the foregoing description that the electrostatic energy fields 12 and 14 of opposite polarity are established maintained between the externally charged electrodes 16 and 18 and the internally charged stators 20 and 22 under static conditions as depicted in Fig. 5A. During rotation, the rotors 24 and 26 continuously positioned within the energy fields 12 and 14, exert forces in directions perpendicular to the field flux representing the energy linkages between electrodes and stators to cause interruptions and reestablishment of energy linkages with portions of different stator segments as depicted in Fig. 5B. Such energy linkage locational changes and the charge binding and unbinding actions between electrodes and stators creates an electrical potential and current to flow between stators through the output circuit 30. Thus, the output circuit when loaded extracts energy from the electric fields 12 and 14 as a result of the field linkage charge binding and unbinding actions induced by rotation of the rotors. The stator segments 82 and 84 shielded from the electric fields by the moving rotor segments 68 and 74 as depicted in Fig. 5B, have electric potentials of polarity opposite to those of the external electrodes 16 and 18 because of the field linkage charge unbinding action. Previously shielded stator segments being exposed to the electric fields by the moving rotor segments, have the same electric potential polarity as those of the external electrodes because of field linkage binding action. Since the forces exerted on the respective rotors by the electric fields 12 and 14 of opposite polarity act on the common rotor shaft assembly perpendicular to these fields, such forces cancel each other. The energy input to the system may therefore be substantially limited to mechanical bearing losses and windage during conversion of electrostatic field energy to electrical energy as well as electrical resistance losses and other electrical losses encountered in the output circuit 30.

Based upon the foregoing operational characteristics, rotation of the rotors in accordance with the present
invention does not perform any substantial work against the external electric fields 12 and 14 since there is no net change in capacitance thereby enabling the system to convert energy with a reduced input of mechanical energy and high efficiency, as evidenced by minimal loss of charge on the electrodes. It was therefore found that working embodiments of the present invention require less than ten percent of the electrical output energy for the mechanical input. Further, according to one prototype model of the invention, a relatively high output voltage of 300,000 volts was obtained across the stators. By reason of such high voltage, an output circuit 30 having a voltage reducing and current multiplying attribute as already described, was selected so as to render the system suitable for many practical applications.

The Suppression of Knowledge.
Early in October 2011, Sir Christopher Woodhead, former Chief Inspector of Schools in England, stated that children should leave school at age 14 and become apprentices. While I personally have a high opinion of apprenticeships for certain professions, this appears to me to be a direct attempt to lower the education levels of the UK population even further than it already is now, where many sales staff are unable to perform even the most basic arithmetic as part of their jobs.

The basis for how we live our lives and understand the things around us, society, personal relationships, family values and the like, is rooted in what we are told by “the authorities”. Unfortunately, much of what you have been told is just not true. You have been lied to about science, astronomy, the environment, global warming, government, taxation, war, energy, inventions, education, terrorism, health, finance and the media, to name just a few topics which spring to mind.

Science: There has been, and still is, systematic, deliberate, and frequently brutal suppression of scientific fact. We are being told that you have to “burn a fuel” in order to produce power which is then “consumed” when we use it to power our lives. This is a deliberate lie. We are told “scientific” things which are sheer fantasy and designed to keep the truth from us. The objective is to keep the people of this planet ignorant, weak, and subject to the people who know the real facts, and to remove all possible wealth from the ordinary person.

Astronomy: We are told that the only way we can get into space is to use rockets. The people who say this not only know it is a lie, but they themselves have had electrogravitic drive vehicles for at least fifty years now. This sort of rubbish is roughly the equivalent of telling people that they can only get around by hopping on one foot. We are told that the speed of light is a constant and that is a lie. We are told that nothing can go faster than the speed of light, and that is a lie. We are told that gravity depends on mass, and that is a lie. We are told that the Earth is the only planet in our solar system which has an atmosphere, and that is a lie. In fact, almost all of what we are told is incorrect.

The Environment: We are told that we need to run our lives by burning “fossil fuels” which are limited in quantity and so there is “an energy crisis”. While some oil is produced by the decay of organisms and vegetation laid down in earlier eras, oil wells which were pumped supposedly dry are actually filling up again with oil created in the crust of the Earth and which does not come from decaying vegetation and organisms. Nor is there the slightest need to burn oil for power, or have central power stations and fragile wires running all over the countryside. Those things are wanted by the powerful elite in order to control ordinary people and to part them from their money.

Global Warming: We are told that man’s burning of fossil fuels is causing global warming through the production of Carbon Dioxide. This is the most ridiculous rubbish possible. Carbon dioxide is a natural gas, essential for plant growth, which in turn is essential for our survival. Carbon dioxide levels have long since reached the level where any increase has almost no further effect on warming. The percentage produced by man is trivial, as the vast majority comes out of volcanoes, the next largest amount is produced by animals and insects, and man’s contribution is minor. Global warming and global cooling are natural events which were taking place long before man was around in any significant numbers and certainly, centuries before the burning of fossil fuels started. The contribution from all of the cars in all of the would is only about 1.7% of man’s minor contribution and the fussing about “carbon footprint” is only a con which is being used to extract more money from the ordinary person.

David Archibald in this document http://www.davidarchibald.info/papers/Climate_Outlook_to_2030.pdf, published the graph shown here in 2006:
This graph clearly shows that even a big increase in the present carbon dioxide level has almost no impact on atmospheric temperature. It has also been calculated that an increase to 620 ppm would give a temperature increase of only 0.16°C. The graph shown above, together with its calculations should have ended any further discussion about reducing carbon dioxide emissions. However, this has most definitely not been the case.

For financial reasons, a decision has apparently been taken to keep up the pressure on carbon dioxide reductions, resulting in senseless investments on new technology for capture and storing carbon dioxide, “beautiful” windmills absolutely everywhere and the mandatory use of bio fuel (which has a negative impact on food production). Don’t forget about all the revenue which ‘governments’ are getting from “climate taxes”.

All these taxes and the massive spending of taxpayers money, really threatens the economic foundations of the whole of the western world, but worse still are the consequences of the commitment to bio fuel. This mad strategy has caused a near doubling of the cost of cooking oil and essential foods such as rice, because farmland is now being used for the production of bio fuel. These increases are hitting poor countries the worst as the people can no longer afford to pay for basic necessities.

If the intention of the IPPC and the world’s politicians is to starve people to death, then they are definitely on the right track through their continued insistence on the supposedly harmful effects of carbon dioxide. In reality, the greenhouse gas which has the most effect is actually water vapour which accounts for about 98% of all warming. I wonder how the politicians are going to prevent water vapour from getting into our atmosphere!

In his video “An Inconvenient Truth” Al Gore points out the close correlation between the fluctuations of global temperatures and the levels of carbon dioxide in the atmosphere. He point out strong rises and falls in the average global temperature (nearly all of which are before mankind started burning oil) and the related strong rises and falls of carbon dioxide concentration in the air. What he is very careful to avoid mentioning is that the changes in carbon dioxide concentration, lag behind the global temperature changes by some 600 years. The carbon dioxide concentrations are a result of the global warming and not the cause of it.

This is further emphasised by the speech given by Prof. Ian Plimer to the British parliament. That speech can be seen at https://www.youtube.com/watch?v=iEPW_P7GVB8&feature=youtu.be and is reproduced here:
I’m a geologist. And the one thing that we miss out on in looking at climate change is the past. Climates have always changed. Climate changes in the past have been greater and faster than anything we experience in our lifetime, and sea levels have always changed, not by the modest couple of millimetres that people are having connections about. We have had in the past, sea level changes of ‘only’ 1500 metres – that’s a sea level change!! And if we look back in the history of time, the atmosphere once had a very large amount of carbon dioxide in it. It has now got less than 0.04%. Where did that carbon dioxide go to? It went into chalk, limestone, shells and life, and we’ve been sequestering carbon dioxide out of the atmosphere for only 10,500,000,000 years. This planet has been de-gassing carbon dioxide since it first formed on that Thursday 4,567,000,000 years ago.

Carbon dioxide is a natural gas. It has dominated the atmosphere for an extraordinarily long period of time, and we now are at a dangerously low level. If we halved the amount of carbon dioxide in the atmosphere, we would have no terrestrial plants. Carbon dioxide is plant food. It is not a pollutant. To use words like pollution with carbon dioxide is misleading and deceptive. But the past gives us a wonderful story. In the past we have had six major ice ages. We are currently in an ice age. It started 34,000,000 years ago, when South America had the good sense to pull away from Antarctica and there is a circum-polar current set up which isolated Antarctica and we start to get the Antarctic ice sheet. We have had periods of glaciation and Interglacials. We are currently in Interglacial, and during that 34,000,000 years we have refrigerated the Earth. But for less than 20% of time we have had ice on planet Earth. The rest of the time it has been warmer and wetter and there has been more carbon dioxide in the atmosphere. And what did life do? It thrived.

Six of the six great ice ages were initiated when the carbon dioxide content of the atmosphere was higher than now – in fact, up to a thousand times higher than now. So we have from the geological evidence, absolutely no evidence that carbon dioxide has driven climate. For some odd reason, the major driver of climate is that great ball of heat in the sky which we call “the Sun”. You heard it here first – it is really quite unusual!! And we change our distance from the Sun. Every 100,000 years our orbit changes from elliptical to circular, and we have a cycle of 90,000 years of cold and 10,000 years of warm. We are in one of those warm cycles now. Every 43,000 years the axis changes a little bit, and every 21,000 years we get a bit of a wobble. Each of those orbital events puts us further from the Sun. Every now and then, we get bombarded by cosmic rays coming from a supernova eruption coming from somewhere out there, and if the Sun’s magnetic field cannot drive these away, we start to form low-level clouds. We've got extremely good evidence that this process has been going on for a very long period of time.

Every now and again, continents start to move, and they move with very rapid rates. They move about ten inches every year. And at one time a continent can be over a pole and at another time it can be at the Equator. Those moving continents change the major heat balance on the Earth and that’s the ocean currents. The oceans carry far more heat than the atmosphere does. Every now and then, because of major geological processes we get a great bulge on the ocean floor, of new volcanic rock. That changes ocean currents. Every year we have 10,000 cubic kilometres of seawater which goes through new volcanic rock on the ocean floor. That exchanges heat. The reaction between seawater and the rocks stops the oceans becoming acid. When we run out of rocks, the oceans will become acid – but don’t wait up, it will be a long time.

We see 1500 volcanoes on planet Earth. We only measure twenty of them, and very few of those measurements are really accurate, but they tell us that a little carbon dioxide leaks out of those volcanoes. But what we don’t hear is that there are at least 3,470,000 volcanoes on the sea floor which leak out huge amounts of carbon dioxide. We have pools of liquid carbon dioxide on the sea floor. So, early first carbon dioxide – where did it go and where did it erupt? Where did it come from? It came from rocks. What did it
do to the planet? We did not fry and die. We didn’t have runaway greenhouse.

Now that’s just geology – that’s not important (!) Let’s look at more modern times. In more modern times we have drill cores which have gone through the ice sheets. Snow, when it falls, catches and traps some air. That air is trapped in the ice. We can later extract it from the drill core and measure the amount of carbon dioxide in the air, and we can see with our cycles of glaciation and Interglacials, that when we finish an interglacial event, that we release carbon dioxide some 800 years later. So, what is that telling us? It is telling us that temperature is driving carbon dioxide and not that carbon dioxide is driving temperature. Oh yes – but that is only hundreds of thousands of years ago – forget that.

Well, let’s go to more modern times. We have been measuring temperatures accurately since 1850 and the accuracy is plus or minus 1-degree Celsius for those ancient measurements. We’re being told that this 0.7-degree Celsius rise is going to create a disaster!! I’ve only got to move a single step away and I’ve had a 0.7-degree Celsius rise. Where do you people go for your summer holidays? You go to a warm climate. We are creatures from the rift valley – we like warm climates. If someone from Helsinki moves to Singapore, there is an average temperature rise of 22-degrees Celsius. Singaporeans don’t drop dead in the streets from the temperature. So, we are creatures of warm climate. We have been measuring temperatures and we have seen a slight warming from 1860 to 1890. Then a slight cooling to 1910 and then a warming until 1940, so that is to say that the North West Passage was open. Then a cooling until 1977, and now warming until the end of the century, and now we are in a period of cooling. So, we have had these cycles of warming and cooling. Strangely, these cycles are actually related to changes in heat balance in the oceans.

So, we have these 60-year cycles over a long warming event. We are in a period of global warming. It has been warming since the minimum 330 years ago. Those were the times when you had the ice layers on the Thames. These are the times when the Dutch masters painted hoar frosts and bitterly cold conditions. That was the time when the Sun was a bit inactive and we had no sunspot activity. So, we are in a long period of warming and one of the questions that I ask in this book (“Heaven and Earth: Global Warming: the Missing Science” by Prof. Plimer ) is ‘which part of the last 330 years of warming is due to human activity and which part is natural?’ These are questions which kids should ask their school teachers and they are deliberately unanswerable questions, because I am of the view that many children are being fed environmental propaganda in the schools and are not being given the critical and analytical facilities to be able to dissect an argument.

So, we are in a period of warming – what’s the worry? It’s quite normal. And let’s just look at history. The one thing which the climate industry (which it is) ignores, is history. In Roman times it was warm. It was considerably warmer than now. We know that, they kept good records. They grew olives up the Rhine river as far as Borne. They had wine grapes in Yorkshire. We know from their clothing that it was warm (possibly they were going to an orgy but I think that more likely it was warm) and that warming suddenly stopped in 535 AD, and we entered the Dark Ages. In 535 AD we had Krakatoa which filled the atmosphere with aerosols. And it wasn’t a big volcano – only 30 cubic kilometres of aerosols go into the atmosphere. We had bigger ones in Yellowstone and they had even bigger ones in New Zealand where 10,000 cubic kilometres of aerosols have gone into the atmosphere (and we pray for another one as that’s the only way that we’ll beat them at rugby – wipe them out). We had two volcanoes, one in Rahall and one in Krakatoa in Indonesia in 535-536 AD leading to the Dark Ages. It was cool. What happened? Crops failed. We starved. We had civil unrest. We had cannibalism. We broke out of that into the Mediaeval Warming. The first to feel it were the Vikings as the seas became calmer. They could get further fishing. They actually got to Newfoundland which they called ‘Vinland’. In Greenland, grapes and barley were growing. The grapes were deep as there was no permafrost. It was a wonderful benign climate, five degrees warmer than now. Eric the Red was saying ‘Come to Greenland, it’s a wonderful climate’ and it was. And then we went through 23 years of low solar activity and in 23 years we went from the Mediaeval Warming into the Little Ice Age, and that, as I said, ended 330 years ago.

So, what do you think would happen after a Little Ice Age – do you think that it would get colder or that it would get warmer? The only reason that the arguments of Science have got any traction in society is that they have been related to the last 30-years or 40-years of temperature measurements. I see with great interest that the Met Office is telling us that this is the hottest year on record. They might be on a different calendar to me, but I didn’t think that this year is finished yet. And this time last year I was in London as I was the year before, and it was miserable – it was cold, it was very cold. So, those sort of predictions made just before a big climate conference, one has to be very sceptical of. In Science, scepticism is not a pejorative word. In Science there is no consensus. In Science there are constant battles. A good example: we all ‘knew’ that we got ulcers from an acid stomach and stress, and we took pills and rubbed our bellies and hoped the ulcers would go away. But two scientists who were not following the mainstream, who were not following the consensus, were arguing that this was due to a bacteria. And no one listened. Ultimately,
one of them took the bacteria, developed ulcers, took the antidote, and for that they got a Nobel Prize. You do not get a Nobel Prize for following a consensus or saying that the science is settled. I believe that we have had an enormous corruption of Science and the Scientific Method. I believe that the monies which are floating around for Climate Research (which is a current fad and fashion), are quite perverse. I believe that we are putting Science backwards, and come the next inevitable pandemic, we may not have the weapons to handle it – we might go waving herbs and chanting, rather than creating an antidote. So, this, for me, this Climate Industry has made a huge attack on the Scientific Method. It has been an attack on my Science and history, and things are fortunately are changing.

I finish with one last point: You’ve got your Climate Change Act, we’ve just got a Carbon Tax in Australia. Nineteen bills went through Parliament, and our Carbon Tax is to lower carbon dioxide emissions from our employment-generating industries in Australia. And it’s wonderful – we’ve led the world in suicide (!) and our Carbon Tax is to knock down our emissions by 5%. Now you can do the sums and the sums are very simple. The IPCC says that 3% of annual emissions are from humans. Why is it that that 3% drives climate change and not the other 97% is beyond me, but that’s another matter. Australia put out 1.5% of the world’s CO₂ emissions. You can do the calculations and by Australia knocking back their emissions by 5%, we will by the year 2050, have lowered global temperatures by 0.00007 degrees Celsius. So I do hope that you enjoy our sacrifice in giving you a warmer climate here in England!!

**Government and Taxation:** It appears that the sole purpose of government is to enrich the people in power at the expense of the ordinary person. People in a democracy are supposed to be “free” but this is a gross illusion. If you were working all week in a company and at the end of the week you were paid £1,000 cash. When you start going home, an armed gang of thugs threatens you and steals £800 of your £1,000 and that happens every week without fail. So, what do you think of that arrangement? Good or bad? That is what government does for you at this time. But, you say, “we live in a democracy, so we can fire the politicians”. That is the equivalent of having three exits from your workplace and each exit has a different gang of thugs ready to rob you. Yes, indeed, you have choice. You can choose which exit to use and therefore, which particular gang of thugs robs you.

You think that is overstating the case? I have seen it calculated that 80% of everything you earn is taken away from you in “taxes” and there is justification for that figure when you consider what contributes to the cost of everything you do. You pay taxes. Can you remember being asked if you would be willing to pay tax?

Oh, but you say, we need taxes in order to pay for public services, health, education, transport, etc. Yes we do, but how much of your money actually goes on that. In the UK there is a large annual “car tax” which was introduced with the excuse that it was needed to finance the building and repair of roads. I understand that at least 85% of that money is not spent on the roads. There is a massive tax on vehicle fuel and I have seen the figure of 85% mentioned. If that is the case, fuel should only be one sixth of the price charged and that extra cost finds it's way into almost everything else, food, clothes, electrical goods, all manufactured items, heating, electricity supply, gas supply, etc. etc. In addition, there are major taxes on alcohol, tobacco, service industries, travel, and everything else that ‘politicians’ can think up. So you're a free person living in a free democracy? Who are you kidding? Do you actually have “sucker” stamped on your forehead? For further information, visit [http://www.yourstrawman.com](http://www.yourstrawman.com) where the facts are laid out clearly.

Take the case of America. The objective of the Civil War was to make money for the unscrupulous. A really major fraud was perpetrated on the American people at that time. They believed (and most still do) that the United States is the government of the American nation. That is not the case. “The United States of America” is actually a commercial conglomerate of private corporations, corporations with names like “The State of Arizona”, or, “The State of Texas”. Federal taxes are imposed on the American people, but that goes directly into the private finances of these companies and not a single dollar of it goes to benefit any ordinary American citizen. There is much more detail on this in Chapter 15.

**War:** The general public is held subject to what passes for ‘government’ through fear and ignorance. The government announces that some country needs to be attacked and invaded in order to “free” the people and establish democracy. So, generally without any realistic reason, that country is attacked and invaded, much of the civilian population killed, massive property damage inflicted, and great distress and hardship caused for many people. This is organised by the politicians. Do they themselves take part in the fighting? No. Who benefits from the war? Answer: the arms manufacturers, and companies such as Halliburton which are paid taxation money to rebuild what the local army has just spent time destroying. The country attacked is likely to have its assets stolen and then be saddled with a massive fake debt so that it can be forced to pay incredible amounts of “interest” for decades afterwards. The lucky country has been attacked, damaged, citizens killed, infrastructure destroyed, assets stolen and then robbed for years afterwards by the
people who caused that devastation. You did say that you live in "a free democracy", didn’t you?

**Energy:** The energy companies are very keen to sell you fuel for you to burn to “get” energy to run your vehicles, home appliances, heating, etc. They are also very keen that you should not discover that you are surrounded by energy which can be used for all those things without paying the local energy company anything. Most people imagine that the electrical power which flows out of the wall socket in your home (and for which you have to pay a good deal), comes along the wires from the generator station which burns fossil fuel to drive the generators. That is not the case, as not a single electron of the current you use actually comes from the power station but instead is collected locally from free environmental energy. If you knew how to do it, then you would have no need for the power company, power lines across the country, power stations or oil drilling and shipment around the world. Cars don’t need fuel to run but that information is heavily suppressed and you are lied to when you are told that you need to burn a fuel to power your life.

**Inventions:** When they discover that there is such a thing as free-energy, most people think that what is needed is a scientific breakthrough in order to develop the technology needed to let everyone have free energy. The reality is quite the reverse as the technology has been discovered and implemented literally thousands of times. You are being lied to when you are told that free-energy is “impossible”. I am reliably informed that in America alone, more than 40,000 free-energy patents have been confiscated by the (private company called the) Patent Office. Inventors are then silenced by a gag order under the absurd excuse that the invention is “of National Security importance”. Inventors who don’t try to patent their inventions are intimidated, some are murdered, some are attacked and their reputation smeared, some are illegally put in mental institutions, some are framed and all suffer massive financial opposition if they try to start manufacturing a product for sale – not even Cal-Tech managed to get past that financial block. I personally know several researchers who have been unlawfully intimidated.

**Education:** There is a massive program of “dumbing-down” education combined with the deliberate teaching of things which are known to be completely wrong. After only a few decades of this, many adults can’t perform basic arithmetic or construct simple sentences in their native tongue. Science and Engineering are neglected and most people don’t understand how things work. Most schools no longer allow schoolchildren to perform experiments in chemistry or physics, usually with the excuse that it is ‘too dangerous’. University students are told that there is no such thing as perpetual motion, which is as laughable as saying that water isn’t wet. Newton actually said that gravity is a push and not a pulling force as indicated by the mis-translation of his Latin original text. This incorrect notion of gravity is still taught in spite of the fact that many governments have had electrogravitic drive vehicles since the early 1960s, driven by electromagnetic waves just below the frequency of infrared, disproving what is supposed to be Newton’s theory, in a most resounding fashion. Any academic who steps out of line and admits that students are being taught rubbish, is immediately attacked with every possible means to discredit, ridicule and isolate him. The objective in all of this is to manoeuvre the general public into a weak position where they are ignorant, uneducated, fed false information and distracted with things of no importance. The ultimate aim is the slavery of the masses without them even realising that they are being enslaved.

**Terrorism:** The main way to make people give up their rights and do whatever you want is through fear. The book “1984” (dated that way because it was written in 1948) explains how this is done. Fictitious enemies are invented in order to frighten people and stop them complaining when vast amounts of their money is given to vested interests under the guise of being steps to protect them from this imagined danger. The “cold war” was completely fake with both sides using it as an excuse. The invasion of smaller countries is never, ever, for the reason given publicly, but is always for financial gain by the people in power and their commercial colleagues. The reasons given for these invasions are so ridiculous that it never ceases to amaze me that the public actually accept and believe these wild stories. One of the strands of this continuous deception waged against the public is fake “terrorism”, frequently bolstered up by “false flag” attacks to discredit the perfectly innocent people who are supposed to have made those attacks. Any real terrorist attacks are normally a response to atrocities committed against the supposed “terrorists”. The commercial companies which pass for governments, are the biggest terrorists around.

**Health:** The pharmaceuticals industry is one of the biggest money-making operations on the planet. It may come as a shock to you, but they don’t want to cure people. Instead, they want people to go on buying expensive medication at heavily inflated prices. Long term health treatments are their ideal situation as that provides them with a continuous revenue stream. Several people have come up with very effective cures for cancer and other serious illnesses, and those people have received the same unjustifiable, outrageous treatment as do the inventors of free-energy devices. The pharmaceuticals industry is well aware of the highly beneficial effects of colloidal silver, but they will never produce any as they can’t patent it and charge highly inflated prices for it. Consequently, they are not interested as their only objective is to make money, and it is definitely not to cure people.
Bob Beck’s Electronic Pulser.
The late Bob Beck emphasised this in his video lecture which may still be available at:
http://video.google.com/videoplay?docid=3383948315844379358&ei=XdqBSruaK5_sgAPr28iBq&g=Suppressed+Medical+Discovery%3A+Dr.+Robert+C.+Beck+%28Cancer%2CAIDS%2C+anything+viral%29#

Here is an excerpt from that lecture:

For the last five years I have spent my own money (no government or university funding) in investigating a thing which has proven to be the most remarkable thing for all diseases that I have ever heard of personally, and I have been in this field for about forty years.

I have a stack of IRB Studies – PCR laboratory reports from major hospitals around the United States, and until these are peer-reviewed published, I am not supposed to show them to anyone who is not a medical doctor because of patient confidentiality.

Now, how many of you have read that there is no cure for AIDS? That is an absolute lie. There has been a perfectly workable, 95% accurate cure for HIV and cancer and herpes and hepatitis and Epstein-Barr and about a dozen other incurable diseases, which was invented on March 11th 1990 at the Albert Einstein College of Medicine in New York City by Drs Kelly and Wymans.

And what happened to this breakthrough which is far more important than penicillin, antibiotics, anything you can name? - it has been suppressed. And why has this information been withheld from you – information which you can easily prove for yourself (don’t take my word here for anything: check it out)? I found recently that the Mafia owns about 51% of major pharmaceutical houses as well as working the other side of the track with the illegal drugs from South and Central America and China.

The medical cartels in this country (USA) will charge you from $50,000 to $200,000 if you have terminal cancer and this is for surgery and chemotherapy and radiation and hospital care.

Consider a packet of Wrigley’s Spearmint chewing gum. That packet of chewing gum cost me a nickel (5 cents or $0.05) when I was a young man and I paid $1.32 for that packet at the Chicago Airport recently - $1.00 for the gum plus $0.32 for taxes and handling. The price of that package of chewing gum is every penny (cent) that it takes to cure [and I’m not supposed to use this word as only a doctor may use the word ‘cure’] most of the known diseases in America today. And why haven’t you heard about this? – because General Electric, Westinghouse, and the other companies have billions of dollars tied up in X-rays, CAT scanners and MRIs which are leased to health organisations, and for $1.32 you can cure yourself without doctors, without pharmaceuticals, without medicines, certainly without surgery, certainly without chemotherapy, without any drugs, without any herbs, any homeopathy remedies – you can do it for yourself and it has been done.

People keep asking “why haven’t I heard about this, why are there no hospital studies?”. There are hundreds of them. Here is one test result: At this date, the eleventh of August 1998 this patient had only about 3,063 particles of HIV in his blood. But now, as this test develops, the PCR on the third of November 1998, (several months later), the count was less than 1 in a hundred, which means that the test result was zero as far as this test was concerned. We have a stack of these reports a foot and a half (45 cm) deep, where every one of these full-blown AIDS patients, every one even though some of them were on life-support systems or needed attendants to lift them from the bed, these people are symptom-free now. Every single one of them is back at work. Not one of them has the symptoms of AIDS. So, if you read in your newspaper ‘the proceeds of the baseball game this Saturday will be donated to a search for a cure for AIDS’ that is an absolute lie.

There is, and has been, a cure for AIDS – all AIDS – a cure for about 95% of cancer, a 100% cure for Epstein-Barr, hepatitis, lupus, about a 50% cure for herpes, and I’ve been funding these out of my own pocket. I have absolutely nothing whatsoever for sale. God has been exceedingly good to me – I think that I am going about my Father’s business here, and I am paying for it myself and I am giving to the world.

There is a free paper available entitled “Take Back Your Power” (a web download link for this is http://www.free-energy-info.tuks.nl/Beck.pdf) you do not need doctors, nurses, chiropractors, herbs, pharmaceuticals, surgery. Only if you are going along with the politically-correct solutions do you need these things that your neighbours have been depending on for all these many generations. There was paper entitled “Blood Electrification and Immune System Restoration with Microcurrents – A Proven, Startling,
Rapid, Inexpensive and Safe Discovery for Positive, Controllable Remissions”. Now we found that this information has been suppressed. The doctors who discovered this, and let me tell you about the discovery: In 1990, they put a couple of small platinum wires into a Petrie dish that contained highly infected human blood, and the infection there was a very, very strong dose of HIV which was supposedly the cause of AIDS. They found that when they had electrified this blood, the HIV could no longer attach to any receptor sites in the blood. That means that the healthy cells could not be infected by the HIV. The only mention of this incredible discovery was in Science News March 30th 1991, page 207, ‘Shocking Treatment Proposed for AIDS’ and it tells about how these two doctors had given a paper on this process saying, ‘the experiments described on March 14th at Washington DC at the first International Symposium on Combination Therapies, showed that the shocked viruses lost the ability to make an enzyme crucial for their reproduction and could no longer cause the white cells to clump together – the true key signs of viral infection.

The only papers which I was able to find that got into the American press were Science News article in Longevity News ‘Electrocuting the AIDS Virus’. But what happened in the Longevity article (which was December 1992, page 14), was that Dr Colley said ‘it will be 15 years before this process is ready for human experimentation’.

We have been doing it, sub-rosa, with patient consent, for over five years here, and we have the test results to prove it. When I was lecturing to a room of about 800 people, an 80-year old man came up and said ‘Bob, I was sent home today, my cancer had metastasised all through my system. I was told to go home and make my will, as I had at the most, about two or three weeks to live. I went home and I made my will and I saw your article in some magazine and I did it. I am now free of all cancer. My biopsies are clean, my CAT scans are clean. I went back to work, and being an attorney, I had to work sixteen hours per day to catch up on all the work I had missed while I was in intensive care. Now I’m jogging three miles per day’ (and there were tears running down his face).

We have had women who have had lupus for about ten years, barely able to make it from the couch in front of the television to the bedroom. They are back at the malls now, spending their money, walking around and able to hold jobs full-time. Do any of you know Linda Wright? She brought in a clean blood test one day and said ‘my doctor had to send this to two different labs – he’s never seen a person with clean blood after that person has had lupus’.

We have dozens of these people, and not one of these people went to the doctor for the cure, except for the people who are on this Institutional Review Board study at a hospital in Huntington Beach and Newport Beach, California. Now, the point is, in my humble opinion, and we can put anything against this because we know that it is true at this time, when I first started this I thought ‘this is kind of interesting’. I have looked into five hundred things that never worked, the Rife Machine never worked, Holderclarke’s Machine does not work, many, many, many of these devices work only marginally, and I felt ‘I’m about to be taken in again’. I have built Mucalsky multiple-wave oscillators as you know. I have built almost every electro-medical device since I’ve been in California (since World War Two began), and these things worked at best, marginally. But the thing which you can build for yourself, there is nothing that you have to buy. The circuit diagram and all of the instructions for building this, are in the paper. This is the one which I designed in 1991 to make an experimental study with, and you can get a kit from an electronics store. I get not one nickel from the tens of thousands of dollars worth of these kits which they have sold.
There is a parts list on page 4 that tells you what is needed. Even if you don't know what a resistor is, or a capacitor is, put the list on the counter at Radio Shack and tell them to give you what is on the list. The retail price ready-made is around $150. If you build it yourself it will cost $15 to $20 and this machine will not only make colloids, which is the most powerful medicine known to man, (which is why the FDA has stamped it out recently).

SOTA Instruments Inc. Canada (1-800-224-0242) builds these devices because the owner read the article in PACE magazine and his wife had chronic fatigue syndrome and Epstein-Barr so badly that she was non-functional. She is now up and around and is totally well today because my husband built this little box for about $15. The box straps on the arm with the electrodes positioned on the radial and ulna arteries and puts a very small electrification into the body which removes all parasites, viruses, fungus, microbes, pathogens – everything in the blood which does not belong there and was not there the day that you were born, eventually (after two or three weeks) being neutralised and discarded by your body, dead or alive by the spleen, the kidneys and the liver. This is darned exciting but when the hospitals tried to patent this, US Patent 5,188,738 presented to Dr Colley on February 23rd 1993, describes the process, as do fourteen other patents from Harvard MIT, page 1 column 1 says ‘because of this problem (the fact that there is no known antibiotic or vaccine for any of these incurable diseases) the present invention has been devised to attenuate any bacteria, virus (including the AIDS HIV virus), parasites and fungus contained in blood contributed by a donor, these being rendered ineffective for infecting a normally healthy human cell’. Before these claims were accepted by the patent examiners, they had to provide the examiners with massive proof.
Now there has been a cure, a known cure and it costs $1.32 per patient so there is no money in this if they are trying to sell you combination therapies for $20,000 to $60,000 per year.

I strongly recommend that you get the paper as it contains the exact electrode locations which have been found to work the best and get the maximum current into the blood. It is almost as if God the Creator had locked the back door approach to the problems and with an adversary like the Holy Spirit which is within – the Bible says 'look within, not without'. And this time, the adversary is within. The 'aliens' in your blood are the things which are holding down your lifespan to seventy or eighty years. Many, many generations ago, according to the sacred texts, they lived to be several hundred years old, Solomon, David, Methuselah, etc.

So, we have raided about a dozen different medical textbooks including Grey's Anatomy, and we've published the exact spots where you can access the lymph tissue where these germs are going to be hibernating. After you clear yourself and get a clean bill of health, after three to five years you will re-infect yourself when many of these viruses which are latent, start germinating. And with this information, and these circuit diagrams and these instructions, we have literally given you back to yourself.

We are going to show you all of this before I leave here. This is not my opinion any more, we have enough proof that it is a statement of fact and we can bank on it. If you are too lazy, too stupid, too electronically impaired or too frightened to build your own, there are forty known companies (and probably a hundred that I know nothing about) that are building these things full-time and they are getting the most remarkable reports back. I do meet these people, and NO, I do not get a nickel from any single one of these companies, and all of this information is in your paper.

Now what else do we have to watch for here. Nobody has ever to this day died of AIDS. Did you know that? They have died of the opportunistic infections, pneumonia, Parkinson's sarcoma, etc. etc. that can attack when you have these germs in your body. Now what else do we have to watch for here. Nobody has ever to this day died of AIDS. Did you know that? They have died of the opportunistic infections, pneumonia, Parkinson's sarcoma, et c. etc. that can attack when you have these germs in your body.

So, once you start on this cocktail therapy, you are stuck with it for life, as long as you live, and as you know from the International AIDS Conference in Japan last year, they found that none of these AZTs etc. prolonged the life of one single AIDS patient by even one day. Their's is simply a promise, they are engineered to get your money while they give you hope. I was beaten up and bloodied; I was hit over the head and had blood running down my face, by 'AIDS Act Up' David Buller it was that was running this crusade in New York city in February. He called the New Yorker Hotel and said that they would burn down the hotel, so they gave me a bodyguard (who wasn't around there all the time) and said 'Bob, do not use the front door but go around the back and use the service entrance – never go out the front door of this hotel. The last day when I was there and I had to run out to get a shuttle to take me to the New Jersey airport to bring me home, there was a guy standing across the street with a video camera and a guy who hit me over the head and bloodied me, and I didn't chase him down the street because my knees aren't very good as I don't have any cartilage in them.

But when's the last time that you saw me Ivan – about three years, four years ago? Do you notice anything that's different? I lost 130 pounds – I weighed 290 and I have pictures of me to prove it. My hair on top was thinner than some of my old good buddies here. As soon as I got rid of the adversaries – the aliens in my blood, my immune system took over and I got rid of the half a pound or so of parasites which every man, women and child in America (if he's more than four days old) is carrying. A new-born baby, after four hours has breathed enough air to become infected. If you live in America, there are 140 known indigenous parasites. If you live in Africa or the tropics, there are 500 identified and known parasites and probably half as many again that are unknown. When we got these parasites out of my body by wearing this device on my wrist, an amazing thing happened. I began losing weight like crazy. I thought 'my God, have I got stomach cancer or am I wasting away with something?'. No, I was in better shape than I was before I started.
This is a theory: about 30% of the parasites which live in human beings, and these can range from fourteen feet (4.27 m) long if they are a tape-worm down to microscopic size (which is why they have to use microscopes to do the stool analysis if you go in for a check), these parasites were setting my appetite. If you will think about this for a minute, it is not what you eat or how much you eat that has anything whatsoever to do with your weight. It is how much of what you eat you store as fat because the parasites have changed the P51, the leptin and about five or six known neuro-transmitters in the hypothalamus to feed them tomorrow. Many of these parasites have co-existed with mammals – apes, elephants …. for twenty million years and the anthropologists will tell you that they find them whenever they find a carcass frozen in the ice floes, these things have had parasites for as long as ever man has been on the planet. These parasites have learned to use you as a meal and not kill you because then they are going to die themselves, like ebola which runs its course in a couple of weeks. Many of these viruses do that, but these parasites almost kill you and use you for a meal in the same way that we send cattle to a feed loft before we take them to market. And when these parasites vanished from my body, and this is provable by dark-field microscopy, phase-contrast microscopy, any doctor who does this analysis can prove it, you don’t have to take my word for it, I lost all of that weight and before this time I had offered $10,000 cash currency ‘under the table’ to anyone who could get this weight off of me.

I had tried dozens of diet plans. I had tried these canned-meal Jenny Craig type adventures. I had been injected with pregnant mare’s urine. I know that some of you have been through the same things. I had taken legal amphetamines to control my appetite … I had tried everything until I had nearly killed myself. And until I found the true cause of what I believe is about 30% of the people who are overweight, and this was certainly me, I was terribly embarrassed to find the airline stewardess running down the aisle with a seat-belt extender because the seat-belt wouldn’t fit around me. I couldn’t sit in the booth in a restaurant because I’d have to sit on a chair, etc. etc.

The lady at the back of the room, Jane had inoperable cancer when I met her. She said “I’m going along with blood-cleansing here, and not the chemotherapy and radiation which the doctor had said that if I do not have I will surely die”. And her daughter Cathy was outraged because her mother didn’t do all of this chemotherapy and have her hair drop out … Now she is totally well. Her last several physicals – biopsies and CAT scans – have shown not one speck of cancer anywhere in her body. Neither have dozens and dozens of ‘terminal’ cancer patients.

Now, why does this work for cancer? We started out working with viral and microbe and parasitic diseases. When oncologists in the East began reporting many, many, many cancer cures, we had to have a telephone conference between about for or five of us. Now what’s really happening here? I don’t believe it until I see the medical proof. So I guess you know that about three months ago Explorer magazine published an article entitled ‘Total Cancer Remissions through Blood Electrification combined with Silver Colloid’. And this article of two pages is reprinted in it’s entirety in the paper which you should be taking home with you.

Social Security does not want you to live if you get to be 65. I’m now way past that. I don’t act like it, but I am way past that. The Director of Social Security – I will not mention his name because he picks me up at the airport when I’m in Washington and drives me where I’m going – I’ve stayed in his house – says ‘Bob, we want anyone who reaches 65 to be stored like cord-wood in an old-age home and given mind-control drugs like valium and let him die because Social Security is bankrupt now’, it won’t be bankrupt in five years time as it is bankrupt now. And if you restore perfect health to these people with a device that will fit in your shirt pocket, the job market will not absorb the people getting out of college today. Even if McDonalds has a smart cash register, they can’t add or subtract, they can hardly write a paragraph and you want to get these experienced people back in the jobs market?’. I said ‘hell yes!’ I was 65 nearly ten years ago.

Another problem: this steps on the toes of all the vested interests. They are expecting to make hundreds of thousands of dollars off of you: Health Management organisations, insurance companies, hospitals, …. If you own a boat that thing is written into the budget of the boat builder down there in San Pedro. These medical people expect to see you come in there some day and spend a lot of money, but if you do this for yourself, you will get well. There are seventeen of us who I know of, and I know sixteen of them personally, who this day have immortal blood. Now this is a rather dramatic claim, so let me tell you what it means. Toward the end of last year, there was a dark-field microscopist ‘Mike’, you know his name, he is world famous, he’s the fellow who trains doctors all over the world how to use this type of technology for diagnostic work. He invited a chap in who had been on one of these devices for about six months, and he said ‘Let’s look at your blood’, so he pricked his finger, put that drop of blood in a microscope slide and looked at it. And he said ‘you don’t have any background clutter in your blood’. Of course, they couldn’t see viruses as this was a light microscope with a magnification of about three thousand times, back-illuminated. He said
'just a minute – I must have done something wrong', so he stuck another finger, then he went to the earlobe and made a slide and said 'what have you been doing? anyone who has ever come to me, man, woman or child, in the last thirteen years, you can see the parasites, many of the germs, microbes and bacteria swimming around in the blood but you don’t have any at all. The patient said that he had been on the blood cleaner so Dr Mike said ‘give me some of those, I’ve got to test them on some of my patients – I don’t believe you’. He did, and they worked.

Now, in Colorado, blood is considered ‘toxic waste’ or hazardous waste. It must be picked up and disposed of by incineration by registered toxic waste disposal people. Dr Mike had thrown these three or four slides in a box underneath his laboratory table. He looked down at this box about twenty-seven days afterwards and checked the slides again under the microscope. That blood was still alive. The half-life of human blood on an unsealed microscope slide is between two and a half to four days maximum. Twenty-seven days had gone by and the red cells were swimming in the plasma exactly the same as the minute he had drawn that blood. It had not crenated (serrated around the edge) – a fibrin reaction had not set in although it had evaporated around the edges. Now let’s get to the point. One month after that, that is some fifty-one days later, those slides had not yet been picked up for disposal, so Mike checked them again. The blood had ‘circled the wagons’: there was about a half a millimetre spot in the middle where the cells had not evaporated and were still alive.

The people in his practice who had been tested upon with the blood cleansers have now got immortal blood. Now, what does this mean? If ‘the adversary is within’ he might not be a man with a red tail and horns out there somewhere with the number 666. Just as the Holy Spirit dwells within this temple, so might the adversary, at least the aliens which have been involved with us over many, many moons are in there and you can see them if you go to a dark-field microscopist, if you get rid of those, who knows what is going to happen? What happened to me. I was so fat that I was in a wheelchair and I had been given up for dead. The doctors who came to see me, friends of mine who were Medical Doctors who hadn’t made a house call in Beverley Hills in thirty years, were coming down to my apartment saying ‘Bob, you’d better dispose of whatever you’ve got – you’ll never walk again. I was given so many tests. I brought Dr. Alexander Everett from Washington, paid his way, put him up in the Red Lion hotel. He worked on me until he said ‘Bob, I’ll have to go back now, there is nothing that anyone can do for you’. And I was in a wheelchair, but I’m sure as hell not dead! Everything is working well again.

My blood pressure when I started this averaged 219 over 190 and was borderline diabetic with blood sugar 425 to 475. Today my blood pressure is 130 to 140 over 70 to 75 and after just three weeks my blood sugar had dropped to 150, which at that time was considered normal.

So I’m here to share this information with you. I have nothing for sale. There are people who are selling things, I’m not one of them. Part of that is because I believe that God’s work should be given freely. I expect to get my reward somewhere else if I don’t come back to this planet of painful endeavour. I have a lot of theories about this and also the Food and Drugs Administration has come to my door with drawn guns at three o’clock in the morning. I have been beaten up by the people supporting the pharmaceutical houses who don’t want a $1.32 cure for AIDS.

Bob also speaks of his use of colloidal silver, (a document on which can be downloaded using the download link [http://www.free-energy-info.tuks.nl/Silver.pdf](http://www.free-energy-info.tuks.nl/Silver.pdf)) although Bob’s method of production looks more simple. He says:

This is a glass of water which I got out of the kitchen. I’ve taken a single 9-volt battery and put a little “grain of wheat” bulb (6 to 12 volt 55 milliamp) in series with the battery and these two silver wires. There is no known germ, bacteria or microbe which can survive what I am about to do right now. I’m going to put these two silver wires into this glass of water, about half an inch (12 mm) apart, and leave them there for about three minutes. That is all it takes. This is tap water and you can make this silver colloid for about one tenth of a cent per gallon and that is the most powerful medicine known to man. After three minutes Bob stirs the colloid with a plastic knife and demonstrates how a laser beam reflects off the microscopic particles of silver suspended in the water and then drinks the water. Bob drinks two or three glasses of colloid each day. The colloid prevents you from contract secondary infections during the first three weeks while you are getting well with the blood electrification process.
Finance: Money only has value when backed by something of worth. The largest purchase that most people make is buying a property. This is often done by taking out a mortgage with a financial institution such as a bank or a Building Society. For this, most people sign a mortgage agreement with the bank, agreeing to pay back the mortgage amount plus a large amount of interest, generally over a period of many years. If you default on the repayments, typically after many years of payments, the bank takes your property and sells it in order to gain as much money as they can. What you are not told is that the mortgage agreement is a contract and no contract is valid unless something of worth is offered by both parties and full disclosure of all circumstances is made. The bank does not offer anything of value as it just invents the money, creating it out of thin air and without any backing of something of worth. The bank regulations actually forbids the bank from lending out money deposited by its members, so a bank cannot legally enter into any such mortgage agreement backed by the funds deposited with it. Further, no contract is valid unless there is a “wet ink” signature by both parties and a wet ink signature can only be made by a human. A bank cannot make a wet ink signature, nor can some other individual sign a contract on behalf of somebody else, so, no mortgage agreement is actually valid in law. Also, the bank being aware of this and not making it clear to you the mortgagee, is in breach of the “full disclosure” requirement of a contract, which is enough to invalidate the contract anyway. Therefore, if a bank tries to take your property for lack of payments, they are acting unlawfully and are not entitled to do so. They usually get away with it, because most people are not aware of the real facts involved.

The Media: You are expected to believe that the media is an honest and unbiased source of information. The reality is that all of the main media outlets are owned by just a few, very rich individuals, and their objective is not to provide unbiased reporting. It appears that they have three main objectives.

First, they want to make money and objective and truthful reporting does not necessarily help towards that goal. You will never, ever, find honest reporting of anything to do with free-energy or any other positive thing which individuals can do for themselves. For example, if a “report” is made on say, an HHO booster to improve mpg and reduce harmful emissions dramatically, it will be arranged that the supposed results show that these thing are not worthwhile. Contrast that with the reality that Dr Scott Cramton can use HHO gas from the electrolysis of water, to reduce the fuel requirement of any diesel engine by at least 60%. No matter how you try, no major news outlet will every report the honest facts as that could damage the excessive revenue stream of the oil companies.

Second, they want to generate as much fear and worry as possible because doing that over an extended period, causes the average person to be more amenable to having their freedoms taken away from them. It facilitates the introduction of surveillance on everybody, identity papers (birth certificate, driving licence, passport, social security number, voting register, National Census record, etc. – very much in the Nazi occupation style), going to war with countries which have never harmed you, considering people to be dishonourable just on the basis of their nationality, and the like. Try counting the items reported in the daily news which are negative – murders, attacks, dishonesty, deaths through accidents, deaths through natural disasters, kidnappings, piracy, violence, environmental damage, etc. and compare that number to the count of positive things reported on – happy events, acts of kindness, successful ventures, etc. and see what ration you get, day after day, after day. This is not just sales being boosted because people love to read about disaster. Instead, it is a deliberate, long-term policy of psychological warfare against ordinary people.

Third, they deliberately divert the attention of people away from anything of real importance by promoting and encouraging excessive interest in things of no importance. There is a deliberate dumbing-down of almost all TV programs in the UK, the promotion of excessively violent video games, the promotion of trivia such as celebrities and their activities, dieting, gossip, fashion, and other irrelevant topics. They want you to
give all of your attention to these things and not notice what is actually going on all around you.

**Joseph Cater’s Comments.**

Joseph H. Cater has produced a book entitled “Ultimate Reality” which I find impossible to buy at any reasonable price level. In it, he points out many things which he supports with strong evidence. These things seem startling because, and only because, the present educational system deliberately encourages us to believe things which are clearly not true. Google books have a partial copy of the “The Ultimate Reality” at:

[http://books.google.com/books?id=ySsNiCPUPeCc&printsec=frontcover&dq=the+ultimate+reality+cater&cd=1#v=onepage&q&f=false](http://books.google.com/books?id=ySsNiCPUPeCc&printsec=frontcover&dq=the+ultimate+reality+cater&cd=1#v=onepage&q&f=false)

The things which Joseph Cater states are so unusual that it would be easy to write him off as a crank. However, he backs up what he says, with a considerable body of realistic evidence which makes it very difficult to ignore what he says, in spite of the fact that most of his findings flatly contradict what we have been taught from an early age, and so accept as being reality. Whether or not you accept what he says is entirely up to you, but it is difficult for an honest person to reject his presentation out of hand.

He puts forward a strong case for there being a deliberate programme of scientific misinformation and suppression aimed at keeping the general public completely ignorant as to the actual physical realities of the solar system and the universe in general, and as a result, reality is very far from the popular conception. Mr Cater’s description of matter provides reasoned explanations for a whole range of anomalies which conventional science can’t adequately explain, and he quotes numerous experiments which provide firm evidence that what he is saying has a substantial basis in fact.

Here is a very brief summary of some of what he says in his book “The Ultimate Reality”:

The biggest single factor is in the erroneous theory of sub-atomic particles. Mr Cater states that reality is actually much more simple than conventional theory suggests. The universe is filled with a range of energetic particles which he describes as “higher order ethers” and “lower order ethers”. These ether particles are in continuous random movement at different frequencies and they produce a number of different kinds of composite particles including “Hard electrons” (with which we are already familiar) and “Soft electrons” which have very different properties. Soft electrons can draw hard electrons into themselves, masking the properties of those hard electrons. Combinations of ether particles form photons and all matter is composed of photons and these ether particles.

The operational forces which govern all matter in the universe are only electrostatic force and magnetic force, and the actions of both of these are modified by many different combinations of the two types of electron. As light is composed of photons and as they interact with the two types of electrons, many observed scientific facts have led to wholly incorrect deductions. Mr Cater indicates that the New World Order “elite” carefully foster and support these false conclusions, suppress information and physically alter observations before they reach the public. Mr Cater points out a number of instances where the alteration of data has not been sufficient to suppress the facts.

It is not possible to mention all of the points which Mr Cater makes, so please understand that the following is only a minor selection from a cohesive whole and much of the supporting evidence which he provides in his book is omitted here.

Mr Cater says:

1. The current theory of gravity is completely wrong, and gravity is caused by a component of the electromagnetic spectrum of about one trillion cycles per second (0.3 to 4.3 mm wavelength; located above radar and below the infra-red region). The theory of gravity put forward by Sir Isaac Newton does not account for the amount of deflection of a plumb bob near a mountain. An asteroid as small as 150 miles in diameter, can have a surface gravity about the same as Earth’s and some asteroids have moons of their own orbiting around them. This would be impossible if Newton was right.

As a result of the real cause of gravity, our Moon has a much higher surface gravity than was expected, (and consequently, a serious atmosphere). NASA had a major problem with the lunar landing of 1969 because if the real facts became known, then it would demonstrate that a major section of physics, as it is currently presented, is incorrect and they want to keep things exactly as they are at present. The Moon, in common with most planets, is not solid. When part of the lunar lander was dropped back on to the surface of the
Moon, a seismic detector left on the surface showed that the Moon vibrated like a bell for about an hour afterwards. That would not have happened if the Moon were solid.

There is very clear evidence that NASA has censored the Moon landing very heavily, but their attempts at suppression have been flawed and some obvious pointers exist. For example, NASA claimed that the space suits of the astronauts weighed 185 lbs when on Earth. Photographs exist, showing an astronaut leaning over backwards and then regaining his balance. That would be a physical impossibility even under reduced gravity, and this implies that the “life support” systems were actually empty and not needed because there is an atmosphere. The high surface gravity is also seen when the astronauts ran. Even the slowed-down version released by NASA can’t conceal the length of the steps and the height off the ground which are the same as they would be on Earth.

If the Moon had one sixth of the Earth’s gravity as is claimed by conventional science, then the point at which the gravitational pull of the Earth balances that of the Moon would be about 22,000 miles from the Moon. The Encyclopaedia Britannica states this distance as being about 40,000 miles, which agrees with various other sources. That could only be so if the Moon’s surface gravity were much higher than the supposed one sixth of Earth’s gravity.

On more than one occasion, an Apollo astronaut tripped and fell on his face. Under one sixth gravity, that just would not happen, especially with a fit and active astronaut. Also, the rover vehicle used in later landings was 10’ long, 7.5’ wide and 4’ high with 32-inch diameter wheels. The Earth weight was 460 pounds and under one sixth gravity, that would only be 75 pounds, but the astronauts had great difficulty unloading it from the lunar module. Engineers on Earth had already determined that to operate under one sixth gravity, the rover would have to be 20’ long and have a 20’ tread. With a loaded earth weight of 1,600 pounds, it would need a turning radius of well over 80 feet to avoid tipping over at 10 mph or more than 20 feet at 5 mph and descending steep hills would not be possible without major problems. But, the astronauts did descend steep hills and they made very sharp turns at maximum speed.

One of the photographs brought back by the Apollo 12 trip, showed an astronaut carrying instruments hanging from a bar. The instruments had an Earth-weight of 190 pounds, supposedly 31 pounds on the Moon, but the pronounced bowing of the bar would not have been caused by just 30 pounds.

During the early Moon trips, the astronauts stated that when they left the atmosphere, the stars were not visible. This is understandable as the atmosphere scatters starlight, making stars appear larger and so become visible to the naked eye. Outside the atmosphere, there is no scattering and the stars are too small to be seen without a telescope. On the Apollo 11 trip, shortly before reaching the Moon, Collins stated “Now we’re able to see starts again and recognise constellations for the first time on the trip. The sky’s full of stars ... it looks like it’s night side on Earth”. This demonstrates that the Moon has a significant atmosphere caused by much higher gravity than one sixth that of Earth, although the refraction of light through that atmosphere is less than the refraction caused by Earth’s atmosphere.

Mr Cater points out that NASA is well aware of the real nature of gravity and had electrogravitic drives long before the 1969 Moon shot. Not only that, but due to the fact that the Moon is bigger than currently believed, further away and possessing a higher surface gravity, that rocket power used during the flight was supplemented by an electrogravitic drive. Any honest person who has studied the evidence is well aware that there are many craft with electrogravitic drives and most of these seen in the last sixty years, are man-made. (All governments are very keen to suppress this information as national boundaries could not be maintained if electrogravitic drive vehicles were available to the public).

2. Relativity, proposed by Albert Einstein, is not correct and Mr Cater spends quite some time demonstrating that relativity is wrong. Prior to Einstein, the Transverse Wave Theory of light was universally accepted. Waves cannot exist without a medium which vibrates in some manner to transmit them. Therefore, the “ether” which permeates all of the universe was accepted. The Michelson-Morley experiment was set up to test this. A ray of light was split into two parts which were made to traverse different paths of equal length. The motion of the Earth through the ether should then cause the recombined rays to show diffraction patterns. They didn’t. It did not occur to anyone that if light were retarded by passing through the ether, then bodies such as planets would be seriously retarded by their passage through it and would slow down and stop. This experiment also gave rise to the ridiculous idea that the speed of light is a constant, in spite of the well-known fact that the speed of light through water is only 75% the speed of light through space. It was also proposed that the speed and direction of movement of an observer didn’t matter, That time slows down on a moving system, that a body will shorten in the direction of motion and that the mass of a body will increase the faster that body moves. These are ridiculous suggestions. The famous \( E = mc^2 \) equation was actually derived from the Lorentz equations in 1903, two years before Einstein got into the act.
Physicists argue that particle accelerators demonstrate the increase of mass with speed. This is not the case and the experiments actually demonstrate a very important principle which provides a better understanding of many physical phenomena. It is an established fact that a magnetic field develops around a charged body when it is given a velocity. Where did the magnetic field come from? In the particle accelerator, as the particles accelerated, magnetic fields developed around them. As the total energy of the system remains constant, the magnetic field must have developed at the expense of the electrostatic field - the transformation of one kind of energy into another kind. This conversion from repelling electrostatic charges to magnetic fields causes the particles to clump together, giving the false impression of an increase in mass. Further, as the electrostatic component drops to almost zero, the accelerating force diminishes to near zero also, giving the false impression that a material body can’t travel faster than the speed of light. The reality is that bodies can travel many times the speed of light.

According to General Relativity, a gravitational field will tend to slow the passage of time and the stronger the gravitational field, the more marked the effect. It was found that Caesium clocks run faster at high elevations than they do at ground level. This has been taken as a proof of the validity of Einstein's ideas. The concentration of soft particles is higher near the ground than at high elevations and that makes clocks run faster at high elevations. As to the speed of light not depending on the velocity of it's source, the Sagnac experiment of 1913 provides direct proof that the observed velocity of light is dependent on the velocity of it's source, disproving Relativity. Mr Cater provides extensive demonstrations (as do other people) that Einstein's deductions are not correct.

3. It is clear that gravity is responsible for the tides, but the standard explanation is wholly inadequate, being based on the assumption that gravitational effects have unlimited penetration. In other words, the only attenuation when passing through matter is due to the inverse square law, which actually would be a violation of the law of conservation of energy.

It is well known that a body cannot be given an acceleration relative to another body if both bodies experience the same acceleration. It follows then that since large bodies of water are accelerated relative to the Earth to cause tides, the water is being experiencing a different acceleration than the Earth as a whole, otherwise, there would be no tidal movement of water across the surface of the Earth. Assuming that gravity has unlimited penetration causes problems when accounting for tidal movements. Since the distances between the Sun and the Earth and the Moon and the Earth are large in comparison to the diameter of the Earth, all parts of the Earth will experience nearly the same gravitational attraction from these external bodies if gravity has unlimited penetration. High tides tend to occur when the Moon is at it's zenith, both directly underneath the Moon and simultaneously, on the opposite side of the Earth.

The Earth’s orbit is inclined to the Equator by 28 degrees and so the Moon is never further North or South than 28 degrees. According to Newton’s theory, the highest tides should occur near the Equator but the reality is that the highest tides are experienced much further away from the Equator, both North and South of it. Mr Cater provides an in-depth discussion of these effects, demonstrating that Newton’s concept of gravity is wrong.

4. It is generally accepted that energy, in any form, flows from a higher potential to a lower one. The law of redistribution of energy states that when radiant electromagnetic energy interacts with matter, the resulting radiation as a whole, is of a lower frequency than the original light. This is why temperatures at lower elevations are generally higher than those at higher elevations, as sunlight passing through air converts to lower frequencies including infrared which activates the thermal motion of atoms and molecules, thus producing heat. Any dynamic unit is less active as a whole, than the individual parts comprising it. The higher ethers consist of the smaller, more active particles while the lower ethers are composed of the large, more complex and consequently less active particles. Both ethers occupy the same 3-dimensional space (which is the only space that there is).

When light of a given frequency range is produced, only the ethers associated with this light are directly activated. Light photons are composed of combinations of ether particles. Photons combine to form the penetrating particles which accompany this light. Particles composed of light in the lower frequency ranges are referred to as “soft” particles while those associated with gamma rays and above are referred to as “hard” particles.

Soft particles are more penetrating than the photons from which they are made, because, unlike the larger soft particles, photons have a relatively great surface area in proportion to their mass. Soft particles, and particularly soft electrons, play a vital role in all life processes and in other chemical reactions. The energy of field intensity of and around the higher ether particles is greater than that of the lower ethers. The diameter
of a particle is inversely proportional to the average frequency of it’s constituent light.

5. The energies radiated from the Sun are continuously transformed into ever lower frequencies as they penetrate into the Earth. In this manner, nearly all of the original ultraviolet is transformed into lower frequency radiation by the time it penetrates the shell of the Earth. It is the transformation of some of the radiation from the Sun into gravity-inducing radiation which holds the Earth and the other planets in orbit around the Sun and give the illusion that the Sun has about thirty times Earth gravity. It should be mentioned that soft particles penetrate solid matter more readily than hard particles which are, of course, an integral part of matter.

All matter continuously radiates soft particles of many different kinds due to the interactions of the fundamental particles. These radiated particles undergo a transformation effect, according to the transformation law, when passing through large concentrations of matter. When this occurs, some of the radiation is transformed into gravity-inducing radiation. This is the source of some of the surface gravity of both the Earth and the Moon. The greatest contributing factor to Earth and Moon gravity is the transformation of radiation resulting from the thermal agitation of atoms and molecules. The particles resulting from this activity are comprised of lower-frequency photons. Such radiation is more readily transformed into gravity-inducing radiation because it is closer to this frequency band to begin with. A significant portion of this radiation, originating miles below the surface, is converted into gravity-producing energies by the time it reaches the surface. Most of the gravity radiation of the Earth and the Moon is created in the topmost fifty miles of their crusts. Below that level, much of the energy from the Sun has been transformed into softer particles, and that material of the Earth and Moon is permeated with them.

These soft particles screen out gravity radiation more effectively than solid matter does. This is because the others with which they are associated, are closer in frequency to the gravity radiation band. This explains why Moon gravity is nearly equal to Earth gravity. At the same time, it is clear why the Cavendish Experiment for determining the so-called “gravitational constant” was misleading – there wasn’t enough material in the bodies used in the experiment to produce any radiation transformation. The gravitational effects produced by the bodies were due entirely to the thermal agitation of the molecules, without any transformation of radiation. The thermal agitation of molecules produces infrared and only an infinitesimal portion of this radiation is in the gravity-producing frequency range. This “gravity constant” plus the idea of unlimited gravity penetration, requires scientists to assume that the Earth has a tremendous mass and an iron core four thousand miles in diameter.

It is significant that some of the Cavendish Experiments indicated that gravity effects varied with the temperature. When the large sphere used in the experiments was heated, the smaller sphere had a greater tendency to move towards the larger sphere. When the larger sphere was cooled, the smaller sphere receded. This was explained away as being caused by convection currents although they failed to explain how convection currents could produce such an effect. A detailed account of this can be found in the 11th edition of the Encyclopaedia Britannica in the section entitled “Gravity”. (If they felt that air currents were skewing the results, then the experiment should have been repeated inside a box which had the air removed).

As mentioned before, matter produces infrared radiations which are partially transformed into gravity radiations. In the case of mountain ranges, there is not enough matter to transform significant portions of such radiations into gravity radiations. Much of the radiation will escape from the tops and slopes of the mountains before they can be transformed, since their average heights are generally small compared to their horizontal dimensions. The gravity radiations produced deep in the interior of the mountains are partially dispersed by the overlying mass. This is the cause of the plumb bob enigma which is a source of annoyance to conventional physicists because the plumb bob is not pulled towards the mountains to the extent demanded by Newtonian laws.

Another problem is that, in comparison to the Sun, the Earth radiates only an infinitesimal amount of radiation per unit of surface area but it is able to keep the Moon in it’s orbit around the Earth. Even allowing for infrared radiation passing from the Earth to the Moon and converting to additional gravitational radiation there, it still wouldn’t be enough to keep the Moon in orbit unless the Moon were hollow and had a shell not more than a hundred miles thick.

In 1978, scientists were shocked to discover that some of the asteroids have moons which orbit around them at respectable velocities. According to Newton, this is impossible as the gravity of an asteroid would be far too feeble to allow this. When a body is a few miles across, it is large enough for gravitational radiation to be produced. This effect increases rapidly as the size of the body increases as far more infrared is transformed than is screened out by the outer layers of the mass. The effect continues until the body is about 150 miles
in diameter and beyond that point, the screening effect of the outer layers keeps pace with the rate of increase of the transformation of infrared into gravity radiation. This means that all planets have practically the same surface gravity.

Mr Cater explains how soft and hard particles and the limited penetration of gravity account for Earth upheavals, continental drift, earthquakes and volcanoes. He also remarks that if the Earth were a completely solid ball and the Newtonian version of gravity were correct, then the Earth would be completely rigid and no Earth changes would occur other than some minor erosion, and there would certainly be no mountains left by now.

One of the most fundamental physical laws involves the relationship between the electrostatic and magnetic fields. One transforms into the other and vice versa. Inertia is a third factor involved in the relationship between the electrostatic and magnetic fields. The kinetic energy of a moving charge is manifested in its magnetic field. The magnetic field increases at the expense of its electrostatic field (as dictated by the law of conservation of energy). The role of inertia and the conditions governing its magnitude are now apparent. The inertia of a body is dependent on its ability to generate a magnetic field when it is given a velocity. The greater the inertia, the greater this ability.

The magnitude of the inertia of a body is directly proportional to the energy of the magnetic field which the body develops for a given increase in velocity. It follows then that inertia is dependent on the total electrostatic charge of a body. This is also true for so-called "uncharged" matter. In the supposedly uncharged state, all atoms and molecules have a net positive charge. Therefore, even atoms and molecules develop a magnetic field when they are given a velocity.

In 1901, Max Planck found that he could only derive the correct distribution in frequency of the radiant energy in the cavity of a black body as a function of the temperature of that body, if he assumed that energy exists in discrete units. He came up with NHV where N is an integer, V is the frequency of the light involved and H is a universal constant (expressed in terms of energy multiplied by time, that is, erg-seconds). This is now known as Planck's Constant and is \(6.6 \times 10^{-27}\) erg-seconds.

The kinetic energy of a light photon is inversely proportional to the frequency. The lower frequency light, consists of larger and more massive photons travelling at the same velocity as the higher frequency photons. On average, the number of photons in any given ray, and the number of accompanying soft electrons will be a constant, regardless of the frequency. This is in accordance with the conclusion that the average distance, or mean free path between ether particles of the same kind, is a constant, regardless of the ethers involved. The average number of photons comprising a soft electron will also be independent of the frequency. This means that the diameter of the surface area of a soft electron, will also be inversely proportional to the frequency. Soft electrons accompanying light, travel at a velocity which is less than that of light. The soft electrons pick up speed, by bombardments of faster moving photons.

From a superficial glance, it seems that the average velocity of soft electrons should be independent of the frequency of the light associated with them. This is not so. The soft electrons associated with the higher frequency, travel at a higher velocity, and herein lies the key to the photo-electric effect. Although the lower mass of the higher frequency soft electrons is offset by the lower kinetic energy of the bombarding higher frequency photons, the surface area is greater in proportion to mass. This means that in proportion to mass, the electrons associated with the higher frequency light will receive a greater bombardment of photons and so, a greater accelerating force. The ratio between surface area and volume, or mass, is inversely proportional to the ratio between the diameter of two given spheres. Since the other factors balance out, it follows that the resultant average kinetic energy of soft electrons in proportion to mass, is directly proportional to the frequency of the light with which they are associated. As soft electrons collide with a surface, the hard electrons which they contain, are released and they bombard the surface, producing the photo-electric effect. They will be travelling at the same velocity as the soft electrons which housed them, so their average kinetic energy will be proportional the frequency of light.

Quantum mechanics is considered the most monumental achievement of twentieth century physics. In view of the principles presented above, it is not surprising that mathematical juggling with Planck’s constant would account for many experimental results (in a quantitative sense). Quantum mechanics experts have enjoyed considerable success in this respect, especially in the realm of atomic spectra, without knowing why. In reality, quantum mechanics does not even qualify as a theory or a concept. It is merely an attempt to give mathematical descriptions of certain phenomena with Planck's constant and his valid assumption as a starting point. Modern "theoretical" physicists have absolutely no conception of why their mathematics agrees with certain experimental results. Yet, they have led themselves to believe that by giving mathematical descriptions of such phenomena, they have actually explained them.
It now becomes evident, why a mass can travel through space at a constant velocity, and encounter no decelerating force. The ether particles are so active that the closing forces at the back of the moving body, tend to equal the resistive forces encountered at the front. The rear portion creates a temporary void which is rapidly filled in by the surrounding ether particles, producing an effect very much like the Coander Effect. During the filling in process, the fundamental particles comprising the rear of the body are bombarded with ether particles travelling at a higher velocity than is normal. Also, the ether particles of which the mass is comprised are so relatively sparsely distributed throughout space, the situation is equivalent to a great mass travelling through a highly rarefied atmosphere.

8. During the creation of a photon, the ethers in the vicinity are suddenly compressed. Some of the ether particles are forced close enough together to adhere to each other. This aggregate is then propelled outwards with great force in a manner similar to a compressed spring being released. The photon reaches the speed of light after this accelerating force has been expended, which happens in a distance equal to the so-called wavelength. This process is repeated in the same region and another photon is produced which follows the first one, just one wavelength behind. A wide range of ethers are periodically affected during the production of ordinary light. This results in a countless variety of such particles being propagated in all directions with many different wavelengths. Since many photons are projected in all directions, many collisions will result, causing a significant portion to adhere to each other in aggregates.

The great majority of soft electrons are created during fluctuations in light velocity when passing through media of varying density, and even in it’s passage through outer space. Any slowing down, produces a backing up of photons and a consequent combining into relatively huge aggregates. In the beginning, these aggregates move much more slowly than the free photons. Consequently, some of the photons which were created at a later time, catch up and adhere to the aggregate. Their collisions with the aggregate particles causes the particles to speed up. This is the origin of the particles which always accompany light. Particles formed in this manner will vary greatly in size, stability and penetrating ability. It has been shown that soft particles will penetrate ordinary matter more readily than the hard particles. So, ether particles combine to form photons which in turn, combine to form light particles. This, light particles will disintegrate into photons.

Atoms are comprised of hard particles which are uniform in size and structure and it follows that they were produced by an entirely different process. When light enters a medium, it encounters a conglomerate of soft particles created by the activities of the fundamental particles of the atoms which comprise the medium. This causes the light to slow down and the particles of light to crowd together inside the medium. If a beam of light enters a medium at an angle, the portion entering first will travel a shorter distance than the rest of the beam during the same interval of time. The portion of the beam entering the medium later is pulled by magnetic attraction of the particles, towards the side which reached the surface first. This causes the beam of light to be bent or change direction, accounting for the refraction of light which has never before been adequately explained.
Mr Cater then goes on to resolve the famous wave-particle paradox, and the also points out that the famous Michelson-Morley Experiments actually disprove the Transverse Wave Theory of light.

9. It must be realised that nature’s laws are basically simple. To gain a deeper understanding of the nature of electrons, protons and electrostatic forces, it is necessary to look for an uncomplicated picture of the fundamental particles and the cause of their behaviour patterns. The collision laws involving the molecules of a gas can be applied to the ethers. Also, it can be deducted that electrostatic forces are the result of an imbalance of ether particles bombarding fundamental particles of matter.

It seems logical to assume that electrons and protons have a spherical shape as a sphere is the most stable and efficient geometrical form. It also has the smallest surface area for any given volume. However, such an assumption leads to insurmountable difficulties. Electrons and protons have a preferred direction of spin in relation to their direction of motion. The electron follows the left hand rule, while the proton spins according to the right hand rule. With a perfect spherical shape they could not have any preferred direction of spin. However, the preferred directions of spin can be readily accounted for if the particles are pear-shaped or egg-shaped and they are hollow.

When ether particles have a preferred direction of motion away from the electrons due to reflections, a pulsating electric field results. The excessive flow away from the electron tends to reduce the bombardment of incoming ether particles. A temporary low ether pressure around the particle is a result of this and in turn, this reduced pressure reduces the reflections and that causes the ethers to move in again and a sudden increase in ether bombardment results. This is something akin to the Coander Effect. The cycle is then repeated. It is to be expected that an electrostatic field is no exception and in this respect, “electrostatic” is a misnomer. The fluctuations are at such a high frequency that experimental results will see the (average) force as being a constant.

The behaviour of beams of electrons and protons in strong magnetic and electric fields indicates that protons have about 1836 times the inertial mass of electrons. Inertia is directly proportional to charge, indicating that the total charge of a proton is 1836 times as great as that of an electron. The idea that the hydrogen atom consists of one electron and one proton has never been questioned. To quote from a science magazine: “When protons crash into each other, they release showers of electrons, which suggests that protons are made up of particles more basic than themselves”.

On the basis of relative charge effects alone, it follows that a hydrogen atom, instead of having only one electron orbiting a proton, that there are at least 1836 orbiting electrons. However, since the proton has relatively little movement in comparison to the electron, a far greater percentage of the electrostatic field of the electron has been transformed. This means that in order for the hydrogen atom to have close to a neutral charge, there must be thousands of electrons in one hydrogen atom. This seems to create a paradox as the amount of electricity required to liberate a given amount of hydrogen in electrolysis indicates that only one electron is necessary for every atom of hydrogen.

Scientists have never comprehended the source of the electricity that powers electrical equipment. There are unlimited quantities all around us, permeating all of known space. This hard electricity is camouflaged by softer particles which are also distributed throughout space. The flow of this limitless source of electrons can easily be set into motion. The electricity employed in electrolysis merely triggers the flow of far greater quantities. Also, when a hydrogen atom is ionised, it only needs to lose a very small percentage of it’s electrons instead of being reduced to only a proton.

Matter is rendered visible by the steady formation of soft particles generated by the activities of the fundamental particles. It is then apparent that frozen hydrogen would be completely invisible if electrostatic fields were not cyclic and the hydrogen atom had only one electron. Cyclic electrostatic fields are largely responsible for the complex spectral pattern of all of the elements. The cyclic pattern of hard-particle interactions is complex. This complexity increases rapidly as the number of fundamental particles in the atom increases.

Since electrons move at much higher velocities in the atom than protons do, they cover much more territory and so a higher percentage of their electrostatic charge is transformed into magnetic energy. This means that the positive charge in the atom will overbalance the negative charge and so, give the atom an overall positive charge. This explains why electricity tends to move towards ground and the Earth must posses a positive charge.

The electrostatic field effects near the atom in close proximity to the electrons, will be negative. Moving outwards, this negative effect diminishes quickly and a zone of positive field effect exists. The position and
intensity of these zones, determines in part, the chemical and physical properties of the atom. There are regions where the atoms will attract each other and regions where they will repel each other. Ether particles have a similar structure and follow the same pattern.

The velocity of orbiting electrons in atoms is not uniform. There are periodic fluctuations resulting from mutual interferences within the atom itself and from adjacent atoms, in addition to the pulsating electrostatic fields. It must be noted that the properties of the atom are not observed individually, but as a collective group. The region of activity for the protons is relatively small and a significant number of electrons are trapped here. This region is the origin of neutrons, which are actually collapsed hydrogen atoms. It is interesting to note that when hydrogen is subjected to ultra high pressures, it behaves like a high concentration of neutrons and passes through the container which is being pressurised as though it didn’t exist.

A more detailed discussion of the structure of the neutron is in order. The new concept of thousands of electrons comprising the hydrogen atom (to say nothing of the other atoms), provides, for the first time, a means of accounting for the properties of the neutron.

When a cloud of electrons orbiting the proton is forced into close proximity with the zone of repulsion, as described earlier, their motions become restricted. As a result, there is a lowering of the average velocity with a consequent increase in their negative electrostatic charge. This provides a stronger bond between the proton and the electrons. The orbital speed cannot be increased because of the zone of repulsion surrounding the proton, and the crowding of the electrons. The higher overall negative charge of the electrons almost completely cancels out the positive charge of the proton. The result is a particle which is electrically neutral, as far as most experiments can determine.

The electron cloud comprising the hydrogen atom is further removed from the proton and the individual electrons are not restricted in their orbital motions. The average velocity is much higher and consequently, the hydrogen atom has a high positive charge. The atoms of the gaseous elements, such as hydrogen and oxygen, are highly magnetic. Therefore, two atoms combine in much the same way as two bar magnets, to form a molecule consisting of two atoms. This is the reason why the molecules of nearly all the gaseous elements consist of two atoms. The combination has a still higher overall positive charge than a single atom has. As a result of this, the molecules have a strong mutual repulsion which keeps them widely separated at normal temperatures and pressures. Thus, they remain a gas even at extremely low temperatures.

The presence of electrons in the “nucleus”, nullifying repulsive forces, along with the magnetic fields resulting from the motions of neutrons, is the major source of the so-called “mysterious force holding the nucleus together”. In reality, the pinch effect of magnetic fields is the prime force which holds the atom together. Orthodox physicists have complicated the picture by claiming that many different forces exist: magnetic, electrostatic, gravitational, nuclear, and others to which they have ascribed odd names. In reality, only electrostatic and magnetic forces exist and there are two, and only two, basic particles – electrons and protons. Since the electrostatic field effects around the electron and proton are cyclic, the magnetic fields which they generate will also have a cyclic intensity.

10. Although neither spin when at rest, both the electron and the proton start to spin in a definite direction when they are given a velocity. This is contrary to the assertions of modern theorists who talk about particle spin with reckless abandon. The electron always follows the left-hand rule, while the proton follows the right-hand rule.

When placed in an electrostatic field, they move in such a manner that the large end is facing in the direction of their motion, regardless of their original orientation. The reason for this is not difficult to discern. If they are hollow and the shell is of a certain thickness in proportion to it’s diameter, then the larger end will have more surface area in proportion to it’s mass than the smaller end will have. The thickness of the shell at the smaller end will be much greater in proportion to it’s diameter. This means that ether bombardment at the larger end will tend to give it a greater acceleration than that imparted to the smaller end and as a result, the larger end will be forced ahead in the direction of motion.

The picture is still incomplete. In order for the particle to have a preferred direction of spin, the frontal surface must be grooved in the manner of a right-hand or left-hand screw. Such a shape is consistent with recent experiments at the Argonne National Laboratory, which studied the shattering of proton beams aimed at target protons. The results indicated that protons are not spherical. A detailed account of such experiments can be found in the article “The Argonne Experiments and The End of Quarkery” by Eric Lerner which appeared in the Oct-Nov 1997 issue of Fusion Magazine. In the article he showed that some of the basic assumptions of quantum mechanics are contradictory, and he dispensed with the popular theory in
particle physics which assumed an ever-growing family of hypothetical particles called “quarks”.

It has been noted that a magnetic field surrounds a moving charge. The magnetic lines are in the form of circles. An electron or proton tends to carry ether particles around with it in a circular motion as it moves through the ethers. This is due to the mutual repulsion between the ether particles and the ether particles comprising the particle. The reactive forces cause the particle to spin and they produce a vortex motion in the ether itself. The greater the velocity of the particle, the faster it spins and the more ether particles are caused to flow around it in the direction of the spin. It is this flow of ether particles around a moving charge which produces the magnetic field effects observed. A three-dimensional view of this magnetic field shows that it resembles a corkscrew spiral or vortex.

The ether particles which would normally cause repulsion between two adjacent particles at rest, spin when they both move and the electrostatic repulsion drops off and is replaced by a magnetic field which draws the two particles together. This effect is also seen in two adjacent wires carrying a heavy current flowing in the same direction. The wires are drawn towards each other.

If two unlike charges move along together, they spin in opposite directions, generating magnetic fields of opposing polarity which tends to push the particles apart.

An electron or proton moving in a magnetic field has two forces acting on it. One force tends to push it down the magnetic lines of force because of excessive ether particle bombardments in one direction of flow. The other force is perpendicular to the lines of force. If the velocity of the particle is high, then the latter force is by far the more significant. This force is a result of Bernoulli’s principle. Magnetic fields tend to capture large quantities of soft electrons.

11. The conventional theory of geomagnetism lacks merit. According to it, the major portion of geomagnetism is the result of electric currents flowing in a molten iron core 2,000 miles beneath the surface of the Earth. Even if such a core did exist, the conclusion would still be false. Scientists are somewhat vague as to how a magnetic field could extend 2,000 miles beyond an electric current considering that it takes a very powerful current to produce even weak magnetic effects a short distance from the current flow. The electrical resistance of iron at the alleged temperatures of the core would be staggering, which raises the question of how the necessary massive potential difference is produced to drive a large current in the core in the first place.

A great wealth of evidence supports the conclusion that geomagnetism is produced by the Earth’s rotation. The intensity of the field is dependent on the concentration of negative charges in the atmosphere and the crust and on the rotational velocity. Since the concentration of charges in the atmosphere fluctuates in a 24-hour cycle, the magnetic field can be expected to fluctuate accordingly. This is an established fact.

Supposedly uncharged atoms and molecules are not electrically neutral, but possess a positive charge. It has always been assumed since the days of Newton, that inertia is directly proportional to mass. This has been shown to be incorrect as inertia depends on total charge and is therefore independent of mass. It follows that an atom has less inertia than any of the fundamental particles of which it is composed. The small overall charge of an atom is the result of the equalising of positive and negative charges. It’s slight ability to generate a magnetic field for a unit increase of velocity is due to electrons following the left-hand rule while protons follow the right-hand rule. The inertia of an atom is limited because the magnetic fields of the electrons and protons from which it is constructed, cancel each other out to a major degree. Stripping electrons from an atom will give it a strong positive charge and much greater inertia even though it now has less mass. Adding electrons to it can also raise it’s inertia if the extra electrons cause it to end up with a greater overall charge than it had before. The Nobel Prize winner Gabriel Lippman confirmed this when he found that bodies in a charged state have greater resistance to acceleration than they have in their uncharged state.

Since matter behaves like a positive charge, it follows that gravity radiation will accelerate positive charges in a direction opposite to that of the direction of its propagation. A gravitational field repels negative charges. When the hair on a person’s head is given a strong negative charge, it stands straight up due to the negative charges on the hairs carrying the hairs with them as the charges are pushed upwards by gravity.

The bulk of the radiations and soft particles of matter cover only a relatively narrow part of the electromagnetic spectrum. They are produced by the interactions of the fundamental particles of the atom in addition to the interactions of the atoms themselves. Incidentally, it is the soft particles comprised of photons close to, and in, the visible range which permeate matter that make matter visible. If only the hard particles were present, solid matter would be invisible, although completely tangible.
The leading part of the gravity radiation front produces negative charge effects, while the trailing portion which has passed a given body must have substantially reduced negative charge effects. The spin of the particles in gravitational radiation have a gyroscopic effect which keeps the particles orientated in the same position and the particles have little tendency to scatter.

![Diagram showing photon behavior](image)

The faster moving photons overtake the soft particles and tend to adhere to them in irregular patterns, creating a perforated and extremely rough surface on this part of the particle, not unlike that of a positive charge. This has a tendency to cancel out much of the negative field effects on this part of the particle. The bombardments accelerate the particles to such an extent that no more photons can adhere to them. Therefore, the rear part maintains a positive charge, or at least, a much reduced negative charge.

Another important factor which contributes to a reduced negative charge at the rear is that there is a far greater photon concentration in this region than exists at the frontal portion. This is a result of a backup of photons caused by the lower velocity of the soft particles accompanying the radiation. This photon concentration tends to divert the normal ether bombardments (which produce the electrostatic effects) from their usual paths. Since gravity radiations produce forces, it follows that there are interactions which eventually disperse the radiation, accounting for the limited penetration of gravity radiation. Gravity is an electrostatic effect, not some space warp or mysterious force with imponderable properties. If matter is impregnated with sufficient quantities of negative charges, especially soft electrons, it will become weightless and even levitate.

Some individuals have the ability to do the reverse of levitation, possibly by expelling large quantities of negative charge from their bodies. A dwarf who had a normal body weight of 123 pounds demonstrated under strict anti-fraud conditions that he could increase his weight to 900 pounds.

The physics of levitation was demonstrated in part when missiles were found to have lost most of their original weight after travelling through the Van Allen Radiation Belt and returning to Earth. The weight loss continued for some time and containers in which pieces of the missile were placed, also lost weight. The radiation belt contains high concentrations of negative charges of all kinds, from hard electrons to the very soft ones. The missile became impregnated with negative charges as it passed through this region, absorbing an abnormal quantity. The more penetrating softer particles opened the door for the harder particles to enter. The loss of weight of the container would have been caused by the missile gradually losing some of it’s excess negative charges and those charges being absorbed into the container.

12. Faster than light travel is possible because the accelerating gravity beam travels with the mass being accelerated. At ultra-high velocities, or where most of the electrostatic potential of matter has been transformed, cohesive forces will tend to break down and the material will cease to be a cohesive solid. However, spaceships can travel many times the speed of light provided that the ship and the occupants are impregnated with the right combination of negative charges which would prevent any extensive transformation of the electrostatic mass into magnetic energy. At ultra-high velocities, the closing forces on the rear of the craft no longer compensate for the forward resistance, so it requires a steady application of accelerating forces to maintain velocities many times that of light.
The evidence concerning spaceship propulsion demonstrates that the famous Einsteinian equation \( E = mc^2 \) falls far short of representing the energy potential of matter. From the kinetic energy equation \( E = 0.5mv^2 \) it follows that a body travelling at only 1.5 times the speed of light (which isn’t even a cruising speed for most spaceships) has a kinetic energy which exceeds the value of Einstein’s celebrated equation. At this velocity, only a miniscule part of the energy potential of the mass has been released. The meaninglessness of the famous equation is also evident, because inertia is dependent only on net charge and not necessarily on mass or quantity of material.

13. Another item which demonstrates the validity of the information presented here is the fact that determinations of the gravity “constant” “g” is always significantly higher when measured in mines. This is to be expected as the soft electron concentration is much higher below the surface than it is above the surface. Another fact which disturbs physicists (and consequently given little publicity) is that objects at the bottom of mine shafts weight significantly less than they should according to Newton’s concept of gravity.

Another enigma which is damaging to the academic viewpoint is that experiments indicate that gravity doesn’t impart the same acceleration to all substances. To try to deal with this fact, they have to introduce a mysterious fifth force which is supposed to be an extremely feeble repulsive force with a limited range. It is supposed to be more prevalent in some substances than in others. The concepts already explained here show that this is to be expected. Different atoms and molecules have different total positive charge effects in proportion to the number of fundamental particles from which they are made. Consequently, they will not be given the same gravitational acceleration even if the mass is identical.

14. We now come to questions such as; How does the law of redistribution of energy work? What are the real principles behind colour perception? Why is the velocity of light independent of it’s frequency? Why is this velocity equal to the ratio between an electromagnetic and electrostatic unit of charge? The answers to these questions have never been given before.

When materials are subjected to high temperatures, great fluctuations occur in the velocity of electrons in their orbits. This in turn, creates interactions and interference effects between electrons moving in opposite directions inside atoms and between electrons in adjacent atoms. These interactions generate changes in the electrostatic field effects of the electrons, which will cause regular and distinct changes in their so-called orbits. This is because the charge on the electron varies with it’s velocity. Abrupt changes in the velocity of a particle disrupt the ethers which results in the formation of photons.

The larger the atoms, the more complex the interactions, and consequently, the more intricate the spectral pattern. The photons comprising the electrons, determine the range of the ethers which will be disrupted. These ethers are intimately connected with the electrostatic field intensity of the electrons. Thus it follows from this new definition of Planck’s constant, just why this definition must be taken into consideration in all of the calculations concerning the frequency of light produced in interactions.

The electrostatic field effects around an electron depend on the range and level of the ethers deflecting off the sides of the particles. This range is not necessarily the same as the range of ethers affected by sudden changes in the velocity of the electrons, but there is a direct correlation between the two. Planck’s constant has a role throughout the procedure as all ether particles have the same kinetic energy.

The law of redistribution of energy states that when light interacts with matter, new light with a lower average frequency than the original is produced. One of the most simple demonstrations of this is shining a blue or violet light through a large number of filters of any type. The emerging light is always red. All of the colours which we normally see are combinations of different frequencies of photons. A wide frequency range of soft particles and photons will tend to be grouped together. This means that bands of light in the blue, indigo and violet ranges will contain other colours down to the reds, although the reds will make up only a very small percentage. The human eye sees only the dominant colour, and prisms cannot separate them. The colour experiments of Edwin Land proved this to be the case.

In the May 1959 issue of Scientific American, Land showed that two black and white transparencies produced from black and white film, were exposed to filtered light from two different (reasonably spaced apart) parts of the spectrum, the resulting superimposed images were in full colour. This shows that it requires subtle combinations of frequencies for the eye to perceive colour if the light isn’t in a narrow frequency band. Otherwise, the eye will see things in various shades of black and white, which contain all the colours but in the wrong combinations to be seen as colours. This is what occurs for people who are subject to ‘colour blindness’.

Under certain conditions, light reflected from a mirror can have greater intensity than the incoming light. The
light has to be of high intensity. When the particles of the incoming light collide with the mirror, those that are reflected are instantly brought to a halt. This produces a tremendous disturbance of the ethers which results in the creation of new photons which are added to the photons which are reflected. In addition, many of the photons reflected and created, combine to form soft electrons, and so the reflected light has a higher percentage of soft electrons than the incoming light beam.

It follows that repeated reflections of a light source such as the Sun, would result in a highly lethal laser-like beam. This has been demonstrated on numerous occasions. Perhaps the most notable demonstration occurred near White Sands, New Mexico in the early 1950s. It was witnessed by an acquaintance of a personal friend of Mr Cater’s, and it was something which he wasn’t supposed to have seen. About thirty-five four foot diameter mirrors were arranged so that the resulting beam was directed at the rock wall of a mountain. It immediately created a neat hole through 200 feet of solid rock.

An associate of Mr Cater’s found that by putting a strong negative charge on the mirrors that their reflective power is considerably increased. He charged a series of metallic mirrors to 20,000 volts and found that after 10 repeated reflections from the Sun, the resulting beam was very lethal. This shows that it is the negative charges deposited on a mirror surface which enables it to reflect most of the light that falls on it. Incoming light immediately deposits negative charges on the surface and those charges repel the rest of the light. The more intense the incoming light, the higher the concentration of negative charges placed on the surface. This accounts for the fact that highly lethal beams reflecting from the surface do not destroy the mirror. The mirrors must be metallic and preferably concave. Glass mirrors do not work as much of the incoming light is lost before it reaches the reflecting surface and much of the shock effect of the light reflection is lost due to the glass slowing down the incoming beam. The incoming light must strike the mirror in as nearly a perpendicular direction as is possible. If soft electrons associated with colours known to be highly beneficial could be concentrated using this method to produce rapid healing.

15. The question arises: Why is the velocity of light independent of it’s frequency? This is implicit in Maxwell’s equations but it still isn’t explained. When the ethers are disturbed to produce a photon, a fraction of them are compressed and a great number are forced close enough together to adhere to one another. The higher the ethers affected, the more rapidly and suddenly this displacement has to occur in order for a photon to be produced, otherwise, the ether particles will escape this compression since they are very active. This momentary compression quickly returns to normal, rather like a compressed spring being released. This rebound hurls the aggregate photon forward at the speed of light. The distance of this rebound is equal to the so-called wavelength, or distance over which the photon is accelerated to the speed of light.

This is exactly what happens when lower ethers are disturbed to form lower frequency photons, except that the rebound takes place over a greater distance with a lower average acceleration of the photon. Since the warped pattern is identical in both cases, both photons reach the same velocity, which is independent of the actual wavelength produced. As both photons receive the same thrust, it can be seen that lower frequency photons must have a greater mass, that is, the frequency of light is inversely proportional to the mass of the protons which form that light.

The behaviour of electrons and protons in a particle accelerator shows that at the speed of light, all of their electrostatic potential has been transformed into magnetic energy. This shows that the velocity of light relative to it’s source is the ratio of it’s Electromagnetic Unit of charge (“EMU”) and it’s Electrostatic Unit of
charge ("ESU"). The ratio EMU / ESU is equal to the speed of light "C". Calculating from these details, shows that the total pressure exerted on a single electron by the surrounding ethers is 14.4 dynes which represents a pressure beyond normal comprehension when the minute size of an electron is considered.

16. We now need to consider the role of soft electrons in promoting chemical changes and maintaining life. It has been repeatedly confirmed that magnetic fields have considerable healing properties and will stimulate plant growth. What has not been realised is that it is not the magnetic fields themselves which are responsible for this effect, but it is the soft electrons which they capture and concentrate. One pole of a magnet has beneficial effects for certain ailments, while the opposite pole is not as effective.

One of the most significant properties of soft electrons is their ability to promote chemical changes. A change in a molecule is not likely to take place without lessening the chemical bond or attraction among its constituent atoms. Soft particles interpenetrating the molecule will bring about this condition by carrying harder electrons in with them, which in turn weakens this bonding by offsetting the positive charge effects of the nucleus. Soft particles tend to camouflage a variety of harder particles. This is a vitally important property because in this manner, other atoms which are going to take part in the chemical change, also have their zonal effects temporarily altered so that they can come into more intimate contact during the reaction. The soft particles tend to act as catalysts for the reacting particles and the soft particles tend to get disintegrated in the process, releasing additional energy which expedites the reaction and allows the normally powerful electrostatic field effects within the atom to return to their original state. The release of the hard electrons contained within the soft particles which disintegrate is the source of much of the heat produced during chemical reactions.

17. The properties of water: water is a universal catalyst because of its unique ability to collect and concentrate an enormous quantity of soft electrons of all kinds. This is the reason why water has the highest specific heat of any know substance. The large amount of energy contained in water in the form of soft particles, has been demonstrated by experimenters on many occasions. For example, a number of reports show internal combustion engines running with water as the fuel. No reasonable explanation for this has been given as it appears to be contrary to all the rules of chemistry. However, the disintegration of the more unstable soft particles contained in the water when subjected to compression and ignition inside the engine, accounts for this seeming impossibility.

Water is a unique substance being comprised of two of the most chemically active elements, both of which are gaseous elements. The fact that three oxygen atoms can combine to form ozone, indicates that the oxygen atom is extremely magnetic, indicating that a higher percentage of its orbital electrons are moving in approximately the same plane. This leaves fewer orbital electrons tending to offset the positive charge of the nucleus and other portions of the atom. Consequently, two side of the oxygen atom possess an inordinately strong overall positive charge. When hydrogen atoms combine with an oxygen atom, the electrons on the side of the hydrogen atoms adjacent to the oxygen atom are brushed aside. This is on the segment of the oxygen atom where most of the electrons of the oxygen atom are orbiting. The normal flow of electrons around the proton of the hydrogen atom is diverted to become a flow which encircles the oxygen atom and the outer periphery of the hydrogen atom. This results in a powerful magnetic and electrostatic bond between the hydrogen atoms and the oxygen atom. The electron flow around the hydrogen atoms is extremely rapid, resulting in a very high overall positive charge on the hydrogen atoms. As there is a very strong mutual repulsion between the hydrogen atoms, they will line up on opposite side of the oxygen atom, giving water the structure H-O-H. This molecule has strong and extensive positive zones, so the attraction zone is a considerable distance from the molecules. This is why the specific gravity of water is low, despite the strong positive charge of the molecules.

The great affinity of water for soft electrons is now apparent. The large positive zones between molecules are havens for soft electrons, drawn there by the attenuated, but significant, attraction of the hard electrons captured by the soft electrons. Although soft electrons are large compared to hard electrons, they are still very small compared to an atom. Therefore, the spaces between water molecules can harbour large quantities of soft electrons, without them being bound to the water molecules.

Perhaps the most baffling feature of water is that it expands when it freezes. The high concentration of soft electrons greatly weakens the forces of attraction and repulsion between the molecules. As a result, the average kinetic energy of the molecules at the freezing point are still sufficiently large to allow the molecules to move in and out of the zones of attraction and repulsion, without being confined in the attraction zone. The cooling must continue until the soft electron concentration reaches the stage where the attractive forces become strong enough to confine the molecules to the attractive zone. When this occurs, the water becomes a solid. Since the attractive zone is an inordinate distance from the molecules, the average distance between molecules becomes greater than it was when the water was in a liquid state. At the
freezing point, the molecular activity is low enough to permit soft electrons to enter or leave the substance without disintegrating. In order for the water to be transformed from a solid back into a liquid, the same quantity of soft electrons must be injected into it as were removed when it changed from a liquid to a solid.

The melting and freezing temperatures of water vary considerably due to the differing amounts of soft electrons contained in it. Another unusual feature is that in cold weather, hot water pipes have a greater tendency to freeze than cold water pipes do. This is because the heating of the water drove off many of the soft electrons normally contained in the water and due to the low temperature of the surroundings, these soft electrons were not replaced, and as a consequence, freezing to become a solid happens more easily.

One tends to think of colloids as ultra-small particles of solid matter. However, molecules of water can adhere to each other to form aggregates of water molecules, which are effectively, colloids as well. Colloids have strong electrical properties as indicated by the fact that they are not affected by gravity. The field zones around any such colloidal group will be much stronger than that around a single water molecule. Water with a high percentage of such colloidal groups can capture a very large number of soft electrons which are beneficial to health. Abnormal conditions in certain places can favour the formation of water colloids and that can account for the healing properties of water found in some places, such as Lourdes in France.

18. Hard particles can be captured by softer particles and this is deeply involved in a wide range of phenomena, from the transmission of heat and electricity, to the formation of clouds.

Ether particles have zones of attraction and repulsion. Since photons are composed of ether particles, they will in turn, possess zones of attraction and repulsion. In the case of ether particles, these zones will be correspondingly smaller in proportion to the diameter of photons. When protons combine to form electrons or protons, the same zones are present between these particles. However, the zones of attraction are minute when compared to the diameter of the electron or proton, and like particles, seldom if ever get close enough together at sufficiently low velocities for the attractive forces to become effective.

The situation is entirely different when two similar particles composed of photons but with widely differing frequencies, approach each other. Electrostatic attraction or repulsion is considerably lessened because each is associated with ethers which differ considerably from each other. When they are ion direct contact with each other, electrostatic repulsion tends to vanish, since there can be little or no bombardments on the sides facing each other. Since each particle associated with ethers is somewhat different, they will tend to interpenetrate. This means that they will be completely within the ether attraction zones of one another. As a result, the harder particle is captured by the softer one. In a similar manner, the captured harder particles will, in turn, capture still harder particles and this process continues until electrons normally associated with electricity are confined. This combination of particles tends to nullify the electrostatic forces which are normally produced by the confined particles, camouflaging the captured harder particles so that their presence is not readily apparent.
The ether particles normally bombarding the hard electrons and protons which produce electrostatic field effects, tend to be diverted from their normal paths by the presence of softer particles or media between the repelling like charges and/or the attracting unlike charges. These interpenetrating softer particles produce an ultra-high concentration of ether particles around the hard particles. The motion of these ether particles is greatly restricted. This offers a barrier to the higher ether particles which normally bombard the hard particles. This has a tendency to slow them down, and any which do collide with the hard particles, do so with considerably less impact than normal, therefore they tend to become electrically neutral and their motion slows to nearly a halt.

Soft particles permeate matter as well as the spaces between matter, yet they do not to any great extent, neutralise the electrostatic field effects of the fundamental particles, because they are more concentrated and their rapid motion tends to prevent capture. However, additional concentrations of soft particles of the right kind, injected into matter, can render the elementary particles within the atom, electrically neutral and the matter becomes what is known as “dematerialised”. This conglomeration of soft and hard particles renders the soft particles electrically neutral.

It should be noted that only hard particles or the fundamental particles of the atom, are hollow. All other particles, including photons, do not have this tendency because of the nature of their formation. If the softer particles were hollow, they would be unable to capture harder particles. Hard particles entering a hollow, soft particle, would maintain their charges and force a mutual repulsion. Therefore, they would escape immediately. Photons, if hollow, would tend to be less stable, and the probability of forming other particles would be lessened.

When a soft particle disintegrates, a chain reaction occurs. The disintegration releases the confined, harder particles. The energy released during the disintegration is generally sufficient to disintegrate the weaker hard particles which it originally captured. This, in turn, results in the disintegration of still harder particles, until the very hard and stable electrons of electricity are released. Highly interesting experiments performed in Poland by two scientists; Howsky and Groot, demonstrated the ability of soft electrons to house and camouflage harder electrons, and to release them under certain conditions. These experiments were also a great confirmation of other principles already mentioned here, especially those involved with levitation.

A small quartz crystal was attached to an oscillator which generated radio frequencies of several kilowatts. This caused the crystal to lose its transparency and increase its volume 800%. The crystal then levitated and carried the oscillator, as well as a 55 pound weight, to a height of two metres above the floor. An account of this was given in an issue of Science and Invention magazine and it included a photograph of the levitation.

19. The energies concentrated inside a pyramid have been shown to be extremely beneficial to humans. Soft particle bombardments from outer space and especially from the Sun, concentrate inside the pyramid. Some, passing through the surface of the pyramid are slowed down to such an extent that the Earth's gravitational field, repelling the negative charges, tends to keep them inside until collisions with other particles drives them out.

Most of the particles collected by the pyramid, concentrate along the edges as would be expected, since electricity on any charged body tends to do much the same thing, with concentrations at points and along edges. In fact, pyramid frames have been found to be nearly as effective as the closed pyramid, if, and only if, there is a continuity in the framework and no breaks in any of the joining parts.

The soft electrons collected on a pyramid frame or closed pyramid, soon reach saturation point and continued bombardment causes the excess to drop down inside the pyramid. This, coupled with the gravity-repelling forces, causes a high concentration inside the pyramid. The proportions of the pyramid are
apparently a factor in its performance. If the sides are too steep, many of the soft electrons will move along the edges into the ground outside instead of being forced inside the pyramid. If the sides are not steep enough, not many particles will be collected as they strike the material at nearly a right angle which causes only a small reduction in velocity. If they strike at a sharper angle, there is a greater tendency for them to be retained by the material.

If two sides of the base are aligned with magnetic North, it is allegedly more effective. Pyramids can be rendered more potent by lining the interiors of a non-metallic enclosed pyramid, with metal foil such as aluminium or copper. The foil allows a greater quantity of soft electrons to accumulate around the non-metallic outer portion because the soft particles do not pass through the metallic substance as easily, causing a back-up of soft particles. During the process, the foil absorbs large quantities of soft particles before many of them can enter the pyramid. Pyramids also radiate soft electrons upwards from the peak.

Many of the soft particles which are stopped briefly on the outside of the pyramid, are repelled upwards by the Earth's gravitational field, and as well, by soft electrons attached to the pyramid. This produces a funnelling effect which ejects soft electrons from the apex of the pyramid. The Earth's gravity accelerates soft particles at a far greater rate than it does ordinary matter as soft particles are associated with ethers which are much closer to those of the gravity-inducing particles than is the case for ordinary matter. After the pyramid becomes saturated, a greater quantity of soft particles than ever, will concentrate inside. The foil will continue to radiate a high concentration of soft particles during the night when the number of particles bombarding the pyramid is considerably reduced.

It is found that pyramids work better during the summer than at any other time of the year. They are also more effective in the lower latitudes because most of the energy concentrated by the pyramid comes from the Sun. There are conflicting opinions as to the effectiveness of pyramids because of this as there is little understanding of the principles involved. For example, those who experiment with pyramids in Canada may claim that they don't work while those in Southern California will contradict them. A pyramid does not increase the flow of soft particles through the area covered by the pyramid as the same concentration flows outside the area. What a pyramid does, is impede the general flow of soft particles and produce a back-up
of particles inside and below the pyramid, and consequently, a higher concentration of soft electrons in these regions. The material used in a pyramid is of great importance. This was demonstrated when a wealthy man in the Midwest built a pyramid-shaped house five stories high, which was then covered with gold-plated iron. The phenomena produced were completely unprecedented. For example, ground water was forced to the surface and flooded the first floor. This was because the soft particle concentration inside and below the pyramid was so great that ground water was impregnated with such an abnormal concentration of negative charges that it was repelled upwards by the Earth's gravity.

Gold atoms have extremely high positive electrostatic field effects, more so than any other atom. This is why gold is the most malleable of all substances. This means that soft electrons will have a greater affinity for gold than for any other metal. As a result, abnormally high concentrations of soft electrons will concentrate around gold. This effect is greatly enhanced when gold is in contact with iron. These dissimilar metals produce an EMF which is turn, causes a flow of electricity or eddy currents resulting in the iron being magnetised. The magnetic field produced, captures additional soft electrons. A higher concentration of soft electrons is created by this combination then could be produced by a similar thickness of gold foil alone. It follows that by far the most effective material that could be used for pyramids is gold-plated sheet iron (galvanised iron should not be used).

With everything else being the same, the greater the size of a pyramid, the better the performance. The reason for this is that the thicker the layer of concentrated soft electrons through which the incoming soft particles must pass, the more they are slowed down when passing. This results in a greater back-up of soft electrons and an increase in the concentration inside the pyramid. Another reason is that a large pyramid has a greater ratio of volume to surface area. Soft electrons are continuously leaking away from the surface of the pyramid, the larger the pyramid, the lower the percentage of soft electrons which is lost. Consequently, very small pyramids are ineffective.

20. Viktor Schauberger of Austria was puzzled by the fact that large mountain trout could remain motionless for as long as they liked in the fastest flowing water in streams. When disturbed, they escape upstream with fantastic speed. He also noticed that water gets charged up through swirling vortex action as it flows around obstructions. As the water is highly agitated, it gives up large quantities of hard and soft electrons to the fish, causing the entire outer surface of the fish to get a high negative charge. This charge repels the outer electrons of the water molecules, totally eliminating drag and as a result, the water exerts almost zero force on the fish. This effect is even more enhanced as the fish moves upstream, much more so than if the fish went downstream. The negative charge also helps the fish jump as the Earth's gravity boosts it upwards.

21. Brown's gas, produced by one form of the electrolysis of water has properties which seem bewildering to most scientists. Using it, allows steel to be welded to a clay brick and the flame is not harmful to human flesh. The flame temperature depends entirely on what it is applied to. It can also reduce nuclear radiation by 96%. The properties of Brown's gas confirm the information above. Water has a very large capacity to store soft electrons in addition to those already present in the structure of water. Brown did not separate water into hydrogen and oxygen. Instead, he added additional soft electrons to the water molecules. These additional charges greatly weakened the cohesive forces between the molecules, converting the water to an unstable gas. All of the properties of Brown's Gas follow naturally from this. Under welding conditions, the vast concentrations of soft electrons supply the release of sufficient quantities of hard electrons to produce the needed heat. In addition, the soft electron concentrations enable iron atoms to partially interpenetrate brick molecules to produce a bond between brick and iron. Also, with the ultra-high concentration of soft electrons, the gas can readily neutralise the positive charges of nuclear radiation.

22. We need to examine the source of the Sun's radiant energy. One thing that all suns seem to have in common is their great size. The astrophysicists speak of white dwarf suns of planetary size or less. It is clear that any claims made by astronomers or astrophysicists concerning celestial determinations, have about the same degree of merit as the other scientific claims which have already been mentioned. There is nothing to justify the existence of a white dwarf. For one thing, due to it's allegedly small size and limited gravitational influence, it could only hold very small bodies of asteroid size in orbit around it and those would have to be only a short distance away from it. According to the fallacious theories of orthodox science, a white dwarf consists of atoms with practically all of their electrons stripped away, giving it enormous gravity. It will be shown that astrophysicists have no way of accurately determining the distance or the size of any celestial body.

The larger the body, the greater it's mass or volume in proportion to it's surface area. This means that as the size increases, it is less probable that the energies produced by the normal activity of the atoms in the body's interior will escape from the surface without a resulting increase of temperature at the surface. The energy radiated from the surface will be in the form of photons and other particles of all types. Below a critical size,
the surface area is sufficient to allow all of the radiant energy created in its interior, to escape without an increase in temperature. In fact, such a body will lose heat unless it receives sufficient energy from its surroundings.

As a body increases in size, its surface area becomes increasingly inadequate to allow the radiated energy in its interior to escape without a buildup of heat at, and below, the surface. The surface will not radiate the heat or energy outwards as quickly as it is created in the interior. The rate at which energy is radiated from a surface increases rapidly with a resulting increase in surface temperature. This varies as the fourth power of its absolute temperature. For example, within a certain temperature range, if the temperature is doubled, the rate at which energy is radiated in the form of photons and soft particles, increases by a factor of 16.

The critical size of such a body will depend on its composition. For example, if it contains a high concentration of mildly radioactive substances, this critical size will be less. If the body is hollow, then the dimensions would have to be greater. The red giants, if they are even close to the dimensions claimed, would have to be hollow and have relatively thin shells, otherwise, they would not be red as their surface temperatures would be astronomical.

The actual source of the energy which is finally radiated out into space is the soft particles and photons which are normally radiated by the atoms of the material inside a sun. This is due to the activities of the fundamental particles. Because of the great mass of a sun, an abnormal concentration of these soft particles is always present in the interior. This concentration is greatest near the surface. There is a steady increase in intensity, from the centre toward the outside. This results in a continuous disintegration of a high percentage of those particles near the surface, accompanied by a great increase in temperature, which in turn, results in a greater rate of disintegration, with the release of harder particles which produce the higher temperatures. At the same time, there is an increase in the rate at which the soft particles are created. The temperature will decrease steadily as the centre is approached and any sun will have a relatively cool interior.

The principle that size is the major factor in a celestial body's ability to radiate is confirmed by the behaviour of very large planets such as Jupiter and Saturn. An application of this principle indicates that bodies of such size should start radiating more energy than they receive from outside sources. Recent determinations indicate that Jupiter and Saturn do, in fact, radiate more energy than they seem to receive from the Sun. A probe showed a surprisingly higher temperature in Jupiter's upper atmosphere than was formerly believed to exist.

It now becomes apparent that the conventional theory which states that the radiant energy of the Sun is produced by thermonuclear reactions is complete nonsense. One thing to consider is that if this were the case, the Sun's radiation would be so lethal that no life could exist on any of the planets in the solar system.

Occasionally, throughout the universe, the gradual build up of heat in the interior of suns becomes very much greater, possibly due to the quantity of radioactive elements in the interior caused by transmutation. In such cases, relief valves in the form of sunspots, no longer take care of the excess energy increases and large portions blow apart, releasing astronomical quantities of radiation. After the explosion, the supernova becomes a burnt out body in comparison to its former state. Considering the countless billions of stars within our field of vision, and since only a few supernovas have been observed down through history, it is logical to conclude that it is not the fate of the great majority of stars.

One of the phenomena concerning the Sun, which completely baffles all of the scientists, is that it seems to rotate faster at the equator than it does in the higher latitudes. Sunspots in the vicinity of the equator make a revolution about the Sun in less time than those in the higher latitudes. This is an annoying paradox which can't be pushed aside by these scientists as it is out there for all to observe.

The part of the Sun which we see is a highly fluidic blanket. The region around the Sun's equator could rotate faster if, and only if, a steady external pull is exerted on that region. Otherwise, internal friction would eventually produce a uniform motion. This means that bodies in orbit near the equator and close to the surface, are generating a high concentration of gravity-inducing radiations. It becomes evident that such bodies could not consist of normal matter and are probably composed of atoms and molecules made up of softer particles which are little affected by the Sun's radiation. Such bodies could generate a concentration of gravity radiations considerably out of proportion to their masses. Being constructed of this kind of material, they would be practically invisible.

23. Errors have been made in determining the size and distance of planetary bodies. Charles Fort cited many instances of fiascos which belied astronomers' claims of extreme accuracy in determining stellar and
astronomical distances. His revelations did little to enhance their reputations as paragons of integrity.

The principles employed by astronomers in their measurements are essentially the same as those used by surveyors in measuring distances and elevations. However, some surveyors admit that they are unable to determine the height of mountains with any degree of precision and their measurements may be off by as much as 10%. Mr Cater has tested this using an altimeter which was set to zero at sea level and then driven to the top of a mountain at 42°30’ North latitude, which is supposed to have an elevation of 9,269 feet. The altimeter reading agreed closely with the established elevations of towns along the route ranging from 1,000 to over 4,000 feet. However, at the top of the mountain, the reading was only 8,800 feet. Mr Cater then reset the altimeter to the 9,269 feet attributed to the mountain and retraced his route. At every spot on the return trip, the altimeter consistently indicated elevations more than 400 feet higher than before. Even after several months, the altimeter reading was still more than 400 feet higher than it should be. A similar test was carried out on a mountain with a recorded elevation of 4,078 feet and at the top, the altimeter showed 3,750 feet although it agreed with other established elevations much lower down.

The fact that the altimeter was accurate at all places except the top of the mountain (whose official height was found by triangulation) shows that the methods employed by surveyors and astronomers are far from being accurate. The heights of mountains determined by triangulation will always be considerably more than the true value. There are two factors involved. First, the atmosphere becomes steadily denser as one descends from the top of the mountain. Second, the orgone concentration becomes greater closer to the ground. This means that light rays from a mountain top will be refracted and so appear to be originating from a point well above the top of the mountain. This was also confirmed by a barometric test at the top of Mount Everest which indicates that it is actually 27,500 feet in elevation and not the 29,000 feet previously supposed.

A friend of Mr Cater had his property surveyed to determine the acreage. Afterwards, he checked some of the distances determined by triangulation, using a tape measure, and found significant errors. Refraction of light is clearly throwing triangulation results off. The bulk of refraction effects are caused by orgone concentration. The measurement of mountain elevations taken at different times give different values and this is due to fluctuations in orgone concentrations, which are higher on hot sunny days than on cool cloudy days. Also, they are generally higher during summer months rather than at other times of the year.

The examples above show the unreliability of results obtained by triangulation. Astronomers are faced with additional factors when they try to apply triangulation, such as the Van Allen Radiation Belt, varying concentrations of orgone throughout space, etc. It is not realistic to assume that astronomers can determine planetary and astronomical distances with great precision.

There are several factors which astrophysicists and astronomers have not taken into consideration in their calculations. Perhaps the most important of these is the fact that all electromagnetic radiations including gravity in free space, suffer an attenuation effect which is well above that of the inverse square law. Everywhere in the universe is permeated with soft and hard particles of all kinds. These particles have been radiated by planetary systems for countless ages. This principle is demonstrated by fluctuations in the velocity of light and gravity attenuation.

There is a steady decline in the velocity of light as it travels through space. The reasons for this can be seen from the following considerations. Normal light, or light which has travelled a relatively short distance from it’s source, immediately resumes it’s original velocity after passing through a dense medium such as glass or water. As shown earlier, this is due to the close bunching of photons and soft electrons in any given ray. The concentrations of particles in a ray of light tends to decrease after travelling great distances. The father it travels, the more attenuated the ray becomes. This means that its ability to increase it’s velocity after passing from a medium of a given density to one of a lesser density, will be reduced. This is, of course, due to the scattering and dissipation of particles within the ray as it encounters the conglomeration of particles moving in random directions throughout space.

Since conglomerations of soft particles permeate all known space, and the distribution is not uniform, it follows that light will experience refraction effects, even when passing through free space. Therefore, even under the best conditions, with observations being made beyond the atmosphere, astronomical observations cannot be made with any degree of accuracy. The difficulty is, of course, compounded when the observations are made inside the atmosphere. It is small wonder that Charles Fort found a wealth of evidence that completely debunked the astronomer’s claims of great precision.

The fluctuation in soft particle distribution, along with the refraction effects of the atmosphere, rules out the possibility of averaging out errors by making many observations and applying the mathematical method of
least squares. Conventional statistical theory obliterates actual small variations and distorts data by such averaging out processes. The gross errors which crop up despite these methods speak for themselves.

In order to measure the orbital distance of various planets, it was necessary to find the distance of the Earth from the Sun. Originally, this was allegedly found by measuring the angles that two widely separated observation points on the Earth made with the Sun. This is known as the parallax method. The distance to the Sun was calculated from these angles and the distance between the observation points. The size of the Sun could then be determined, and knowing the orbital period of the Earth around the Sun, the Sun’s mass and surface gravity were calculated by applying the false Newtonian concept of gravitation.

More recently, the distance to the Sun, known as the “astronomical unit” was supposedly determined to a high degree of “precision” by measuring the distance of the body Eros by the parallax method when it was closest to the Earth. Knowing the period of Eros’ orbit, the distance to the Sun was calculated by the use of Kepler’s law which states that “the square of the periods of any two planets are proportional to the cube of their mean distances from the Sun.” Since the orbital periods of the planets are known to a reasonable degree of accuracy, most of the other unknowns within the solar system could be calculated by knowledge of the Sun’s alleged mass and surface gravity. By now, it should be apparent that it would be a miracle, or at least, one of the strangest coincidences ever, if the actual distances coincided even approximately with the calculated values.

If the Newtonian concept were valid and the planets were held in orbit by only the effects of the Sun’s surface gravity, then the orbital periods of the planets would be a reliable means of determining planetary distances. Since it has been proven that the concepts on which these calculations were made are false, it can be safely concluded that the size of the orbits is considerably different from what the astronomers claim. As a result of the dissipation effects of radiation, well beyond that which can be expected from the inverse square law, it follows that planetary distances are very much different from the accepted values.

This excessive attenuation of the gravity effects of the Sun is reflected in the alleged rapid increase of orbital distances of the outer planets. The supposed orbital distances are as follows:

It does not follow that the longer the orbital period, the greater the planetary distance. For example, within certain limits, the larger and more massive the planet is beyond a certain critical amount, the slower it must move in order to stay in a given orbit. This is because the total gravity effects of the Sun are unable to permeate and affect the entire mass to the extent that they would with a smaller planet. For example, a planet like Saturn could be placed in a stable orbit inside Earth’s orbit. Yet it would have to move so slowly in it’s orbit that it’s orbital period would be much greater than that of Earth. This means that orbital periods are not a reliable gauge for relative orbital distances.

Although planetary and stellar distances are completely unknown as far as astronomers are concerned, and at this time there are no reliable means available of determining them, the diameters of some of the inner planets, including Jupiter and Saturn, can be calculated far more accurately than any of the other values in the realm of astronomy. The orbital distances of the planetary satellites in proportion to planetary diameters as well as their periods can be accurately determined. The determination of these constants is not affected to any significant degree by the dissipating factors of light already mentioned since a planet and it’s satellites are about the same distance from the Earth. The main factor which makes it possible to approximate the diameter of any of these planets is the knowledge that they have practically the same surface gravity as Earth does.

If a satellite is very small as is the case with the satellites of Mars, a planetary diameter can be calculated with a high degree of accuracy. In fact, Mars is the only planet in the solar system whose diameter can be reliably determined. Astonishingly, Mars turns out to have a diameter of about 11,300 miles. Using unusual methods, Mr. Cater has estimated the diameter of the Sun as over 2,500,000 miles and at a distance of about 277,000,000 miles from Earth. The Moon diameter at 5,200 miles at an average distance of 578,000 miles, shell thickness 115 miles and surface gravity 98% that of Earth. With a lesser degree of accuracy, the diameter of Venus is assessed at 23,000 miles and Mercury at over 8,000 miles. Jupiter diameter about
230,000 miles and Saturn about 200,000 miles. It is most unlikely that the accepted distances to the stars are even approximately correct.

24. Hard electrons travel through metals more readily than through non-metals. This indicates that they encounter more extensive positive electrostatic fields between atoms and molecules than in non-metals. At the same time, the atoms in metals are usually more mobile or free to move around than is the case with solid non-metals. This is why the best conductors of electricity are also the best conductors of heat. It is significant that all of the heavier atoms are metals, with the exception of radon which is a gas. This means that such atoms have a higher net positive charge, which causes a stronger mutual repulsion for greater distances on atoms which are not directly connected to each other. This greater extension of the positive zone around such atoms gives them more freedom without breaking the bond which holds them together. The repulsive forces of nearby atoms, increases the mobility of any given atom.

The heavier atoms contain more protons and neutrons bunched together. The outside pressure needed to hold a group of mutually repulsive particles together is independent of the number of particles present.

One might conclude that the heaviest atoms make the best conductors, but this is not the case. Silver, copper and aluminium are the best conductors although their positive field zones are not as extensive, they have less inertia and so are more easily pushed out of the path of a flow of hard electrons. Electrons which flow along conductors are continually colliding with atoms in motion. Therefore, it require a steady application of electromotive force at the ends of the conductor in order to keep them flowing. The atoms of non-metals are more firmly locked into position and therefore do not have that much of a tendency to move out of the way and this is why they make good insulators. Electrons follow the lines of least resistance and so they tend to move on the surface of the conductor where there is less tendency to collide with atoms.

The rules governing the conductivity of soft electrons are somewhat different from those of hard electrons. Soft electrons are enormous when compared to hard electrons. This can be seen when considering that the average diameter of a particle is directly proportional to it’s so-called wavelength of the light comprising it (or inversely proportional to the frequency). The ethers associated with atoms and their fundamental particles are much higher in frequency than those associated with soft particles. This means that atoms will offer little resistance to the passage of soft electrons. However, the magnetic fields resulting from thermal agitation of certain atoms and molecules are involved with ethers which are closer in frequency to the ethers directly associated with soft electrons. Consequently, soft electrons will interact with these fields. This explains why metals in general offer greater resistance to the passage of soft electrons than do non-metals.

The ordinary electrical transformer presents an enigma. The secondary of the transformer continues to pour out or eject electrons from a seemingly unlimited source. There is a limited quantity of free electrons in conductors which should be exhausted quite quickly. The standard argument used to account for the source of current is that free electrons in the circuit supply the electrons and are used over and over again. A simple calculation demonstrates that free electrons in conductors are not the source of electricity.

Consider a wire two millimetres in diameter in which carries about 10 amps of current. The electron flow is concentrated near the surface of the wire. Since the electricity in a conductor travels at about the speed of light, such a wire 186,000 miles long would have 10 coulombs of electricity distributed over it’s surface at any instant. The surface area of this wire is 1,840,000 square metres. A parallel plate capacitor having this plate area and a separation of one millimetre, would have a capacity of 0.016 farads. Even with a potential across it’s plates of 100 volts, it would still only be able to concentrate an equivalent of 1.6 coulombs, and a good part of this electrostatic charge would be due to the displacement of the electrons and protons of the atoms. This voltage is more than enough to concentrate all of the free electrons on the surface of the plates. Similarly, all of the free electrons in the wire example would be involved if the current were maintained with 100 volts. Of course, a wire this long would have too much resistance to carry any appreciable current with 100 volts, but this has nothing to do with the argument just given. As a matter of fact, even 6 volts is far more than enough to produce a current of 10 amps in a wire of 2 mm diameter. Therefore, there aren’t enough free electrons in any conductor to supply any appreciable current. This means that the source of electrons in current flow is not coming from free electrons in the conductor. The conclusion is therefore that the hard electrons somehow manage to get through the insulation of the conductor and flow into the wire from outside.

By the law of action and reaction, since a current has inertia, any change in the primary current of a transformer produces a force in the opposite direction in the secondary. This reactive force produces a disturbance of the ethers which produce the voltage or Electromotive Force as a result of increased ether bombardment. The EMF induced in the secondary winding of the transformer, creates a temporary electric void in the wire which draws all kinds of negative charges to the wire. The softer electrons quickly penetrate
the insulation and stop at the surface of the wire as they do not travel as readily through a hard electron conductor. These softer electrons absorb most of the electrostatic forces in the insulation which impede the flow of hard electrons, allowing the hard electrons to pass through the insulation and enter the wire.

Electrical charges, composed of photons in nearly all the frequency ranges, permeate all space, since they are continually radiated by stars throughout the universe. They are no easily detected as they are in the form of conglomerates with the harder particles residing inside the softer ones. The resulting combinations are highly penetrating and it takes something like a voltage induced in a conductor to separate the harder particles from the softer ones. The performance of a transformer can be greatly impaired by completely shielding the secondary winding with a good conductor of electricity such as copper or pure aluminium. This is because the shield tends to impede the flow of soft particles to the secondary. This effect has been verified by experiment.

The terms “EMF” and “voltage” need clarification. The true nature of the phenomena associated with these terms has never been fully understood. All that has been known is that if a conductor is exposed to an EMF, a flow of electricity is produced. Also, voltage is associated with the amount of energy or work which a current is capable of producing. An EMF of a given value can induce a current with a definite voltage. The voltage produced is directly proportional to the EMF impressed on the conductor. Also, the energy of the current is directly proportional to the energy of the current flow. Therefore, Voltage is a measure of the average energy of the electrons flowing along the conductor. This in turn, is directly proportional to the square of the average velocity of the electrons. This simple definition of voltage is sadly lacking in all standard textbooks.

An EMF induces an accelerating force on an electron. What is the nature of this force? Basically, there are two methods of producing an EMF. One is by subjecting the conductor to a fluctuating magnetic field, and the other is by exposing the conductor to a difference of potential, such as connecting it between the opposite poles of a battery. In that instance, one battery pole has a negative charge while the opposite pole is positive. The flow of electrons is the result of an electron concentration at one point tending to flow to an area where there is a shortage.

The EMF is produced by direct electrostatic force, which in turn, has a dual nature. There is the tendency for negative charges to be attracted to positive charges, and then there is also the mutual repulsion between negative charges. The voltage attained is directly proportional to the difference of potential existing between the poles of that battery. The difference of potential is equal to the kinetic energy gained by the electrons in moving from one potential to the other.

The EMF produced by a fluctuating magnetic field gives the same results but the process is different. When a conductor is subjected to a fluctuating magnetic field, as with the secondary winding of a transformer, the “free” electrons of the conductor and the outer electrons of the atoms which are not as intimately associated with the atoms, are exposed to differential ether bombardments. It is equivalent to an electrostatic force. When a magnetic field changes, the change does not take place simultaneously throughout that volume of space occupied by the field but it progresses from one portion to another. This creates differential electrostatic ether particle bombardments on electrons within the field. When a conductor cuts magnetic lines as with an AC generator, the electrons are subjected to the same conditions experienced by electrons moving between the poles of a magnet. The accelerating force will be in a direction perpendicular to the direction in which the electrons in the conductor are found to move.

If there were even a small fraction of the free electrons existing in the matter as is believed by our physicists, the negative charge effects of matter would be so great that these bodies would be unable to get close to each other. Much of the charge on capacitors comes from outside the capacitor, as is the case with the flow of electricity in conductors. Actually, free electrons in a conductor are practically non-existent. Hard electrons which are not a part of the atoms are captured by soft particles which permeate matter. The soft particles release hard electrons when subjected to the EMF in a current, or the voltage across the plates of a capacitor.

The current in a straight wire is evenly distributed along the surface where the electron flow encounters the least resistance. The released hard electrons which are directly affected by the EMF, tend to move as a unit partially held together by mutual magnetic attraction. This unit leaves a temporary void behind it which is quickly filled by surrounding hard electrons. Many such groups are started almost simultaneously in a conductor at about the speed of light, although the electrons themselves travel at a much lower velocity.
When an EMF is applied to a conductor, something akin to the domino effect is set up in the ethers. This effect travels at the speed of light since it is produced in a similar manner.

That the source of electricity flowing in power lines as well as that produced by generators, comes from soft particles which permeate and surround the area, has been proven during auroral displays. When aurora activity is unusually high, transformers in Canada have been known to burn out and even explode. At the same time, increase of current flow in power lines has been great enough to trip circuit breakers as far south as Texas. As explained earlier, the concentration of soft electrons in the atmosphere is greatly increased during auroral phenomena. Some areas receive higher concentrations than others at the same latitude.

A loop of wire or a coil offers impedance to alternating current. This property is known as “inductance”. Since a single loop of wire has inductance, it follows that the effect can be explained in terms of one loop. Electrons tend to travel along the surface of a conductor as that is the path of least resistance. The major source of this electricity is the high concentration of soft electrons which gather around a conductor and permeate the material. This is due to the relatively high positive charge of the conductor. The greatest concentration is found at the surface and a short distance below the surface. When an EMF is applied to the conductor, free electrons are set in motion. During this process, soft electrons concentrated at and just below the surface tend to disintegrate and release more hard electrons. This is enhanced by the concentration of the soft electrons, which is turn causes an agitation of the soft particles, causing them to become highly unstable.

In a straight wire, most of this disintegration and nearly all of the electron flow takes place below the surface. This condition greatly shortens the mean free path of the electrons and the flow stops immediately after the applied EMF is shut off. Consequently, an alternating current will encounter the same ohmic resistance in a straight wire as will a direct current. However, the situation is different when the conductor is looped.

When an EMF is applied to a loop, the free or released hard electrons below the surface are forced to the outside by centrifugal force, whence a still greater disintegration of soft electrons occurs because the greatest concentration is at the surface. The mean free path of the electrons is greatly increased and the flow continues for a brief period after the EMF travelling in the direction of the current flow ceases. When the EMF continues in the opposite direction as in the case of an alternating current, the force must oppose the momentum of the electron flow still continuing in the opposite direction to that of the new EMF direction. It follows that this impedance will be directly proportional to the number of turns and to the frequency of the AC. It is logical to assume that the deceleration rate of the electron flow is a constant when the EMF is zero. This means that the more quickly that the EMF is applied in the opposite direction, the higher the velocity of flow that will be encountered. It will be a linear function.

It would now seem evident that when the AC is rectified of has been changed to a pulsed DC, the coil will produce an increase in amperage where a straight wire will not. Experiments have confirmed this. It was found that the input amperage of a current was greatly increased after it passed through a coil. The increase was greatest during the initial stage of the applied EMF and soon dropped to a lower value as the concentration of soft electrons around the wire was reduced. It follows that a coil will offer impedance only to an AC current. It follows that pulsed DC has numerous advantages over AC. It can be used to operate transformers as well as AC without suffering impedance.

A steady direct current experiences the same resistance in a coil as it does in a straight wire of the same length. The fluctuating EMF produces extreme agitation of the soft electrons around and inside the wire, resulting in the disintegration of a large percentage of them, and the release of a high concentration of hard electrons. This does not occur during the steady flow of direct current. During the initial application of DC there is a surge of additional current during the build-up of the EMF. When the current is shut off, there will be a momentary surge of current in the opposite direction. The excess of electrons on the surface of the conductor and in the coil will naturally flow towards the void outside the coil and in the opposite direction to which the current was flowing. The concepts just outlined can be applied when building a self-sustaining electric generator.

When an alternating current is applied to a coil, the EMF must overcome the impedance each time the EMF changes direction. The greatest amount of resistance occurs at the beginning of each change and then steadily decreases as the current builds up. The resistance will be at a minimum when the current reaches it’s maximum. With AC, the EMF changes direction very frequently and so the maximum resistance is encountered for a high percentage of the time.

The flow of electrons in a wire results in a circular magnetic flow around that wire. As mentioned previously, the magnetic effects between electrons moving together tend to cancel each other out. They are drawn
together and the resulting ethers encompass the entire group. This also occurs between adjacent wire segments in a coil. The magnetic effects are cancelled out between the segments and a continuous ether flow, encompassing the entire coil, perpendicular to the direction of the current flow, will occur. The solenoid will then behave like a bar magnet with continuous lines of force.

The Earth’s atmosphere produces geomagnetism in much the same way that a solenoid produces a magnetic field. Changes in the atmosphere move along with the Earth in a circular motion. Although there is little motion of the charges relative to the surface, a magnetic field is still created. Magnetic lines, or ethers, flow from the South magnetic region to the North magnetic region as a result of these rotating charges.

25. Despite the fact that our illustrious physicists have managed to develop as highly a destructive device as a nuclear bomb, they still have no concept of the nature and source of the energy released after a detonation. As with all other well-known phenomena, they try to create the illusion that they comprehend and have explained it. As a matter of fact, academic science has not yet supplied satisfactory explanations for any of the simplest and most common everyday phenomena. The energy released by nuclear devices is explained away by stating that it is a conversion of matter into energy in accordance with the false Einstein relation $E = mc^2$. Many readers, especially those steeped in orthodoxy, may be shocked to learn there is no conversion of mass into energy during such a process, nor by any process in which energy is released! The tremendous heat produced in a nuclear blast means that an abnormal quantity of hard electrons were suddenly released by the complete disintegration of all the soft electrons within the area of the explosion. The intense light that accompanies the blast is the result of the photons set free by the disintegration of those soft electrons.

The key to the triggering of the reaction is the neutron. As indicated earlier, a neutron is equivalent to a collapsed hydrogen atom, and yet it is more than this. A hydrogen atom has a strong net positive charge, while the neutron has no net charge. This means that a neutron has collected far more hard electrons than a hydrogen atom. Since a neutron has no charge, it cannot add to the weight of an atom, as is commonly believed.

The concepts introduced in this treatise render all of the old beliefs concerning atomic structure invalid. The weight of an atom is dependent almost entirely on the number of orbital electrons and the number of protons in its nucleus. This will be discussed in more detail later. There is an exception or two to the above rule in the case of certain radioactive elements where the presence of neutrons can actually reduce the weight of an atom. An interchange of excess electrons between protons and neutrons within the nucleus, and thus transformations of protons into neutrons and vice versa, can occur. The neutrons greatly outnumber the protons in the heavier atoms, especially those that are radioactive. During the interchanges between neutrons and protons, excess neutrons disintegrate into protons and hard electrons are ejected from some of the atoms. This results in a transformation of such atoms. Simultaneously, the tremendous interactions between electrons released in this manner as well as from the disintegration of soft electrons in the vicinity cause the higher ethers to be disturbed, ultimately resulting in the production of gamma rays.

The isotope of the more common uranium 238 atom known as U235 is lighter yet it is fissionable and more radioactive than the uranium 238. It is lighter because it supposedly has fewer neutrons than the ordinary uranium atom. The opposite is actually the case. The U235 having more neutrons is more radioactive. The greater interactions within the nucleus result in more hard electrons being released, which reduces the overall positive charge of it’s nucleus.

There is a continuous interchange of ejected protons transforming back into neutrons and vice versa among the U235 atoms. A similar but less violent interchange takes place among the atoms of U238. A low percentage of the U238 atoms receive more than their share of these interchanges and thus transform into U235 atoms. Most of the hard electrons released which contribute to such interchanges and transformations is the result of the disintegration of soft electrons which permeate the atoms. It follows that the main contributing factor of radioactivity is the presence of soft electrons which house the hard electrons! Therefore, if the soft electron concentration throughout the vicinity of a radioactive substance is reduced, it will lose much of it’s radioactivity. By now, it has no doubt occurred to the reader, that a Reich cloud-buster pointed at a radioactive material would cause it to lose it’s radioactivity! This has been proven to be the case. For example, a glowing piece of radium stops radiating when it is placed in front of a cloud-buster.

The source of the energy released during a nuclear blast is now becoming clear. When a fissionable material like U235 or plutonium is bombarded with additional neutrons, the increased activity in the nuclei causes even the most stable soft electrons in the vicinity to disintegrate. A chain reaction of soft electron disintegration in areas well beyond the confines of the fissionable material results. All of the hard electrons and protons originally camouflaged by the soft particles are suddenly released. A tremendous gamma ray
production also occurs. Adequate quantities of fissionable materials suddenly brought together can result in a sufficient increase of neutron bombardment of the interior atoms to produce such a result. It is known as the ‘critical mass’. The proper fusion of hydrogen atoms can also cause enough soft electron disintegration to produce a similar result. It is now apparent there is no conversion of mass into energy during the process. All of the fundamental particles of the atoms involved remain intact. In fact, there is even more mass following a blast than there was previously, as a result of the additional hard electrons and protons released. Once again, it is obvious that the Theory of Relativity is in no way concerned.

The monstrous hoax fostered on the public by the Defence Department of the Government, now becomes more than obvious. A Reich cloud-buster can completely deactivate nuclear devices for great distances by drawing away the soft electron concentration from the vicinity of such device. In fact, a cloud-buster can be used for downing fleets of planes carrying nuclear weapons. Combustion is also dependent on soft electron concentrations which of course includes jet engines. Therefore jet engines or missiles cannot function in an area affected by a cloud-buster. The fact that a simple cloud-buster can deactivate a nuclear reactor from a great distance has been proven on numerous occasions. For example, during the time Reich was carrying out intensive experiments with a cloud-buster in Arizona in the early 1950s, a large reactor several hundred miles to the southeast quit functioning. This means that hundreds of billions of tax dollars are being funnelled every year to support a multibillion dollar nuclear industry and other related industries which are rendered obsolete by the device used by Reich.

It is evident that the proper use of the cloud-buster could throw modern warfare back to the stone age. Obviously the drawing of soft particles away from any group would completely enervate each individual and even turn him into a block of frozen flesh. Although a cloud-buster could not completely deactivate a particle beam weapon it could bring down any craft carrying such a device before it could get into position. The potential of the cloud-buster is perhaps greater than even Reich himself realised. Since heat is transferred from one body to another by soft electrons which release harder electrons, the cloud-buster can be used as a highly efficient refrigeration system by drawing soft electrons away from a body. It has been made apparent that this simple device can render present fire fighting techniques obsolete. By use of the cloud-buster in the proper manner, the loss of life and property from fire and storms could become a thing of the past. It also provides dramatic proof of the validity of many of the new concepts introduced in this treatise.

Radioactivity was the subject of a ridiculous, if not amusing, fiasco more than two decades ago when two physicists, Lee and Yang, received the Nobel Prize in 1957. The incident, which was given wide publicity, concerned an error in the parity principle. The parity principle has been defined as "a mathematical concept impossible to define in physical terms". How such a concept could have any bearing on physical reality is not made clear. Generally, anything relating to reality can be defined in terms of reality, which is in conformity with the Law of Cause and Effect.

Incredibly, an experiment was devised to test the validity of this great revelation. It was based on the idea that a radioactive substance should eject more particles in one preferred direction, than in any other. Radioactive cobalt was chosen. It was cooled down to near absolute zero and exposed to a powerful magnetic field produced by a solenoid, in order to align the nuclei. Another physicist, a Dr. Wu, had devoted six months of hard work setting up the experiment. Indeed, it was found that more particles were ejected out of one pole of the solenoid than the other. Which pole was it? Of course, it was the pole out of which the magnetic lines flowed. Naturally, the experiment merely demonstrated that particles tend to travel down magnetic lines of force. The excess of particles that came out of the pole were those barely ejected from the atom. They had such a low initial velocity that, regardless of what direction they happened to be travelling initially, the magnetic field would dictate their final direction of travel.

Lee and Yang were accorded every scientific honour, including the Nobel Prize, as a result of this experiment. Instead of giving them the Nobel Prize, the awarding of an Oscar would have been more appropriate. Accompanying the extensive publicity given this comedy act was a photo appearing in a prominent magazine showing one of the recipients pointing to a grotesque mathematical equation containing over 100 terms! He was allegedly explaining the reasoning behind their great revelation.

The great nuclear scare scam should rate as the biggest lie of the century. This fabrication is so colossal even Mr Cater is somewhat embarrassed to admit he was also taken in by it, as everyone else was, except those directly involved in the conspiracy but Mr Cater never questioned it as he had other universally accepted beliefs. The long-hidden truth is this: radiation from radioactive substances is relatively harmless! One can actually swim in water from so-called high level nuclear waste, drink the water and actually thrive on it. Also one can handle pure U235 and even plutonium (the fuel for A-bombs) with bare hands all day long, and suffer no ill effects. Of course excessive exposure to this radiation can be inimical, as can occur from
any other type of radiation such as sunlight. The effects, however, are immediate and not long-lasting if the source of the trouble is removed. The popular belief that mutations can result from this radiation that effects future generations, is complete nonsense. A study of the effects on the victims of Hiroshima and Nagasaki bear this out. The only mutations are immediate damage to cells and subsequent malfunctions from ultrahigh concentrations.

For the above revelations we are indebted to a courageous and dedicated individual who worked for 35 years in the nuclear industry. He was intimately involved in every aspect of the production of nuclear fuels and the building of reactors. He is Galen Windsor, of Richland, Washington. The so-called lethal nuclear radiations are relatively harmless, with very limited penetration. In 1987, Galen had already lectured in 77 different cities over a two-year period. His credentials are impressive. He has worked in every major reactor decommissioning project in America. He was involved in the analytical process inventory control, which was responsible for measuring and controlling the nuclear fuel inventory for these projects. He has few peers in this field and all of them agree with him but are afraid to speak out. He is one of the world's greatest authorities of nuclear radiation measurement.

He and others did plutonium processing using their bare hands until radiation monitors were installed at every reactor. Rules were laid down as to the amount of exposure to radiation that must not be exceeded. If the rules were not followed, the worker disappeared and was never seen again by anyone. The reason is obvious. If word leaked out that radioactive materials below critical mass were harmless, then there would be widespread pilfering of such products. The lie that radioactive materials can be handled only with extreme safety precautions must be maintained at all costs. The high-level disposal act of 1982 calls for the permanent disposal of the so-called high level waste 3,000 feet underground. This high level waste consists of reusable uranium fuel and contains useful metal isotopes. Every ton of it is worth about 10 million US dollars.

Enough has been collected to pay off the National Debt. Portland General Electric owns the Trojan reactor and had a storage basin problem. Windsor offered to take all of their spent fuel off their hands. He would ship it, store it, and do everything that needed to be done at no expense to them, if they would give it to him. They told him "Go to Hell, Galen Windsor - we value it more than plutonium or gold. We are going to play the plutonium future ourselves".

Windsor was taken to California in 1965 to help design and build a nuclear fuel reprocessing plant. After it was built in 1973, a presidential order was issued which said the plant was not to be run. At that time, they had 170 metric tons of spent fuel stored in the basin. Also, the maximum allowed exposure was further reduced by a factor of 10. This was the beginning of Windsor's rebellion against "The Establishment". He began swimming in a 660,000 gallon pool containing the spent fuel. The radioactive materials it contained were enough to maintain a water temperature of 100° F and the water would glow with a bluish light in the dark. He discovered that the tank provided good drinking water.

Windsor was also asked about what was in the burial sites of so-called low-level nuclear waste. The answer was that there are no nuclear wastes, only materials produced in a reactor to be recovered and used beneficially. Low-level waste is an excuse for a Federally-mandated non-inspectable disposal system, so that organised crime can get rid of any evidence they want, and that it can never be dug up again. Also, so that no one finds out whose bodies are in those drums. This is what is contained in barrels that are dropped in the ocean.

Windsor also stated, (and he was in a position to know), that in 1947 the United States sent to the USSR all the necessary materials and technology to build A-bombs! This was under the approval of President Truman. In 1949, they exploded their first A-bomb. Later, the Rosenbergs were executed for allegedly turning over nuclear "secrets" to the Russians.

According to Windsor, by 1975 large reactors no longer had a future. They are being phased out. The notorious Three-Mile Island incident was no accident. It did no damage and no one was harmed. But, it did impress upon the public the alleged danger of reactors. Windsor advocated the use of many small reactors systematically distributed. They could be not only used for producing adequate quantities of electricity, but for obviating refrigeration of packaged foods. When briefly exposed to the radiation from such reactors they will keep indefinitely. A Federal energy cartel is the reason that the effective use of many smaller reactors is not implemented. They control the amount of electricity, the availability and the price. Windsor stated that no reactors have been built correctly. In any event, reactors can in no way, match the use of self-sustaining electric generators for electricity, but their use in preserving food is intriguing.

From the above, it becomes obvious that recent publicity concerning the danger of radon gas in homes is
another monstrous hoax! It could be mixed with oxygen in sizeable quantities and breathed for long periods without damage.

The question now arising is why are the radiations from radioactive sources relatively harmless? Three types of radiation emanate from them: alpha, beta and gamma rays. Alpha rays consist of helium nuclei or a small group of protons, neutrons and electrons. The number of neutrons and protons are still unknown despite the vaunted claims of nuclear physicists. Since they are totally ignorant as to their true nature, the nature of gravity and soft particle physics, they have no means of determining such values. Beta particles are the hard electrons of ordinary electricity, and gamma rays are negative charges comprised of ether particles in the same range as that of hard electrons. As such, they have no more penetrating ability than a stream of hard electrons and are no more damaging than the hard electrons when they do penetrate. Since they are comprised of the same ethers as atoms and molecules, it follows that they will not penetrate matter as readily as softer particles. This leaves the alpha rays. It has already been shown that positive charges are inimical to living tissues since they tend to absorb the negative charges living organisms require. However, alpha particles also have little penetrating ability for the same reasons as given above, and quickly absorb electrons to become harmless helium gas. Windsor gave demonstrations of such facts at his lectures by use of a Geiger counter.

The capture of large quantities of alpha particles by high concentrations of orgone energy is another matter. Reich termed it deadly orgone energy. The orgone enters the body and releases alpha particles throughout vital organs and produces what is known as radiation sickness. Reich and his assistants had this experience. When the source of the trouble was removed they quickly recovered. Occasionally, deadly orgone can remain in the body and at later periods, release the positive charges at various times, thus causing severe after-effects. This problem can be alleviated by treatments inside orgone accumulators or pyramids after being exposed to the deadly orgone. This is what Reich and his helpers did.

Galen Windsor also stated that the bomb dropped on Hiroshima contained 20 pounds of U235. The one exploded over Nagasaki had 2.5 kilograms or about 5 pounds of plutonium. This values were jealously guarded secrets for a long time. Windsor is likely the first one who has dared reveal it to the public. The author was acquainted with the late Stanislaw Ulam, a mathematician who had calculated the critical mass of these elements for bombs while working on the Manhattan project. It was a deep, dark secret and he would have parted with his life before he would reveal anything so sacred. The degree of the hang-up officialdom has on secrecy is of a magnitude difficult to comprehend, and the steps they have taken to insure it is even more mind-boggling. It is so infantile and childish that there are no words in the English language to describe it adequately.

Radioactive substances such as plutonium, produce their own heat and the larger the mass, the higher the temperature of the mass. This follows identically, the same principle by which the Sun generates its energy or the ratio between mass and surface area. The essential difference is that plutonium can do in a few cubic inches what ordinary matter does in a ball 2,500,000 miles in diameter!

Interestingly enough, Windsor looks about 30 years younger than his chronological age would indicate. He also stated he always sustained a healthy tan from his work with radioactive substances. It is significant that Reich and his assistant had a similar experience in their work with orgone energy. It is clear Windsor and Reich were exposed to the same energies, high concentrations of soft electrons. The constant exposure to high orgone concentrations during his working hours is what has kept Galen Windsor young. Of course the high orgone concentrations was produced by soft electrons clustering around the radioactive substances which produced a constant flow of positive charges.

You may wonder why Windsor and certain others could handle radioactive substances with impunity while others have either died or suffered from serious physical problems after being exposed to the radiation. As mentioned earlier, radioactive materials radiate highly positively charged particles which are extremely inimical. Some are absorbed by soft electrons and become DOR (deadly orgone energy). They can enter the body and remain for long periods before disintegrating and releasing the deadly particles. These particles are very sluggish when compared to negative particles including soft electrons.

The victims of radioactive fallout are not exposed for any significant period to high concentrations of positive charges. Also, the area of exposure is very large; consequently, the Coanda effect does not come into play and there is no rush of orgone energy to alleviate the situation as was the case with Windsor when he was directly exposed to ultra high concentrations of radioactive materials. Any victim of radioactive contamination can be cured by being exposed to high concentrations of orgone for extended periods as was Reich and his assistants after experiencing radioactive sickness. They had received a heavy dose of DOR as mentioned earlier. Being exposed to high concentrations of radioactivity is equivalent to being placed in
an orgone accumulator.

This is only a summary of part of Mr Cater's book which has 586 pages. A number of topics are not even mentioned here. Mr Cater also speaks of:

Superconductivity.
The properties of Helium at low temperatures.
Mystery spots on Earth, including the famous Oregon Vortex.
Gravitational anomalies.
The origin of the Van Allen Radiation Belt.
The research of William Reich.
Orgone energy.
The Oranur Experiment.
The Reich Cloud Buster (which is also a weapon of major power).
Atmospheric phenomena.
Three practical Free-Energy devices.
The great potential of crystals in the obtaining of Free-Energy.
The work of Nikola Tesla with Free-Energy.
The Searle Effect and many other topics.

If you wish to buy a copy of his book, it is supposedly available at these two outlets: http://www.healthresearchbooks.com/ or in the UK from http://www.amazon.co.uk. I have ordered and paid for a copy of this book on three occasions and every time, the supplier claimed to be unable to supply what was advertised for sale.

So, having absorbed some of what Mr Cater has to say, do you feel that you have been treated fairly, and that the true scientific details were presented to you as part of your general education?

Chapter 12: Basic Electronics

Introduction
This document is not an in-depth presentation of the subject of electronics. Instead, it is intended to give you sufficient (empirical) knowledge of the subject to be able to understand, design and build simple circuits such as the control circuits used with the ‘Free Energy’ devices described in the later parts of this eBook.

Disclaimer
This material is provided for information purposes only. Should you decide to attempt construction of some device based on information presented here and injure yourself or any other person, I am not liable in any way. To clarify this; should you construct something in a heavy box and drop it on your toe, I am not liable for any injury you may sustain (you should learn to be more careful). If you attempt to construct some electronic circuit and burn yourself with the soldering iron, I am not liable. Also, I strongly recommend that unless you are expert in electronics, you do not construct any device using, or producing more than 30 Volts - high voltage circuits are extremely dangerous and should be avoided until you gain experience or can obtain the help and supervision of a person experienced in constructing high voltage circuits.

Voltage.
Voltage is the key to understanding electronics. Without voltage, nothing happens in electronics. What is it? Nobody knows. We know how to generate it. We know what it does. We know how to measure it, but nobody knows what it actually is.

It is also called “Electro Motive Force” or “EMF” which is no help whatsoever in knowing what it is. That, is roughly equivalent to saying “the thing that pushes is the thing that pushes” - very true but absolutely no help whatsoever. OK, having admitted that we really don't know what it is, we can start to say the things we do know about it:

A new battery has a voltage between its terminals. This voltage is said to cause a current to flow through any complete electrical circuit placed across it. The current flowing through the circuit can cause various things to happen such as creating light, creating sound, creating heat, creating magnetism, creating movement, creating sparks, etc., etc.

By using the current caused by a voltage, a device called a ‘Voltmeter’ can indicate how big the voltage is. The bigger the voltage, the bigger the current and the bigger the display on the voltmeter. The voltmeter can have a numerical display where you read the voltage directly from the display, or it can be an ‘analogue’ voltmeter where the voltage is shown by the position of a needle on a scale. The size of the voltage is stated in ‘Volts’ which is a unit of measurement named after the man Volta who introduced voltage to the world (it was always there, we just did not know about it).

Voltages add up if they are connected the same way round, i.e. with the + terminals all facing the same way:

The physical size of the battery usually determines the length of time it can supply any given current - the bigger the battery, the longer it can provide any given current. A battery is constructed from a number of ‘cells’. The number of cells in the battery controls the voltage of the battery. For example, an ‘AA’ size battery (what used to be called a ‘penlight’ battery) has a single ‘cell’ and so produces 1.5 Volts when new. The very much larger and heavier ‘D’ battery also has just one cell and so it also produces 1.5 Volts when new. The difference (apart from the higher cost of the ‘D’ cell) is that the larger cell can provide a much higher current if both batteries are discharged over the same period of time.
There are several different types of battery construction. A rechargeable NiCad battery has a single cell but its construction method means that it produces about 1.35 Volts when fully charged. In passing, NiCad batteries have a ‘memory’ characteristic which means that if they are recharged before they are fully discharged, then the next time they are discharged they run out of power at the voltage level it had when the last charging was started. Consequently, it is a good idea to fully discharge a NiCad battery before charging it again.

Car and motorcycle batteries are described as Lead/Acid batteries. This type of construction is not very convenient being large, heavy and potentially corrosive. The big advantages are the ability to provide very high currents and giving 2.0 Volts per cell. These batteries are normally produced as 6 Volt or 12 Volt units. The Amp-Hours for lead/acid car batteries is usually quoted for a 20 hour discharge period, so a fully charged, new, 20 Ahr battery can provide 1 Amp for 20 hours of continuous use. That battery loaded to give 5 Amps, will not provide that current for 4 hours but might only last 2 hours, or perhaps a little better. The manufacturers literature should give an indication of the performance, but if it is important, run your own test to see how the battery actually works in practice.

“Mains units” are known in the electronics world as “Power Supply Units” or “PSUs” for short. These convert the mains voltage (220 Volts in UK, 110 Volts in USA) to some convenient low voltage; 12 Volts, 9 Volts, 6 Volts, or whatever is needed. A mains unit can provide several different voltages simultaneously.

**Resistance.**
Being familiar with Voltage and Resistance is the key to understanding electronic circuitry. Resistance is a measure of how difficult it is for current to flow through something. Some materials such as glass, ceramics, wood and most plastics do not easily carry a current and so are considered to be ‘insulators’. That is why you will see power lines hung from their pylons by a series of ceramic discs. Current flows easily through metals, especially along the surface of the metal, so cables are made from metal wires surrounded by a layer of plastic insulation. The higher grade cables have wire cores made up of many small-diameter strands as this increases the surface area of the metal for any given cross-sectional area of the metal core (it also makes the cable more flexible, and generally, more expensive).

There is a very important, third group of materials, silicon and germanium in particular, which fall between conductors and insulators. Not surprisingly, these are called ‘semi-conductors’ and the amount of current they can carry depends on the electrical conditions in which they are placed. Much, much more about this later on.

While a metal wire carries current very well, it is not perfect at the job and so has some ‘resistance’ to current flowing through it. The thicker the wire, the lower the resistance. The shorter the wire, the lower the resistance. The first researchers used this characteristic to control the way circuits operated. Sometimes, as higher resistances were needed, the researcher used to need long lengths of wire which would get tangled up. To control the wire, a board with nails along each side was used and the wire wound backwards and forwards across the board like this:

![Resistor symbol](image)

When drawing a circuit diagram, the researcher would sketch the wire on the board giving a zig-zag line which is still used today to represent a ‘resistor’ although different methods of construction are now used. An alternative symbol for a resistor is a plain rectangle as shown above.

If a resistor is connected across a battery, a circuit is formed and a current flows around the circuit. The current cannot be seen but that does not mean that it is not there. Current is measured in ‘Amps’ and the instrument used to display it is an ‘ammeter’. If we place an ammeter in the circuit, it will show the current flowing around the circuit. In passing, the ammeter itself, has a small resistance and so putting it in the circuit does reduce the current flow around the circuit very slightly. Also shown is a bulb. If the current flowing around the circuit is sufficiently high and the bulb chosen correctly, then the bulb will light up, showing that current is flowing, while the ammeter will indicate exactly how much current is flowing.
Shown on the right, is the way that this circuit would be shown by an electronics expert (the ‘Resistor’, ‘Ammeter’ and ‘Lamp’ labels would almost certainly not be shown). There are several different styles of drawing circuit diagrams, but they are the same in the basic essentials. One important common feature is that unless there is some very unusual and powerful reason not to do so, every standard style circuit diagram will have the positive voltage line horizontally at the top of the diagram and the negative as a horizontal line at the bottom. These are often referred to as the positive and negative ‘rails’. Where possible, the circuit is drawn so that its operation takes place from left to right, i.e. the first action taken by the circuit is on the left and the last action is placed on the right.

Resistors are manufactured in several sizes and varieties. They come in ‘fixed’ and ‘variable’ versions. The most commonly used are the ‘fixed’ carbon ‘E12’ range. This is a range of values which has 12 resistor values which repeat: 10, 12, 15, 18, 22, 27, 33, 39, 47, 56, 68, 82 and then: 100, 120, 150, 180, 220, 270, 330, 390, 470, 560, 680, 820 and then: 1000, 1200, 1500, 1800, 2200, 2700, 3300, 3900, 4700, 5600, 6800, 8200, etc. etc. Nowadays, circuits often carry very little power and so the resistors can, and are, made in very small physical sizes. The higher the resistance value of a resistor, the less current will flow through it when a voltage is placed across it. As it can be difficult to see printing on small resistors clustered together on a circuit board and surrounded by other larger components, the resistor values are not written on the resistors, instead, the resistors are colour-coded. The unit of measurement for resistors is the ‘ohm’ which has a very small size. Most resistors which you encounter will be in the range 100 ohms to 1,000,000 ohms. The higher the resistance of any resistor, the smaller the current which will flow through it.

The colour code used on resistors is:

0 Black
1 Brown
2 Red
3 Orange
4 Yellow
5 Green
6 Blue
7 Purple (Violet if your colour vision is very good)
8 Grey
9 White

Each resistor has typically, three colour bands to indicate its value. The first two bands are the numbers and the third band is the number of noughts:

Green: 5
Blue: 6
Red: 2 noughts
Value: 5,600 ohms or 5.6K or 5K6

Yellow: 4
Purple: 7
Green: 5 noughts
Value: 4,700,000 ohms or 4.7M or 4M7

The colour bands are read from left to right and the first band is close to one end of the body of the resistor. There is often a fourth band which indicates the manufacturing tolerance: you can ignore that band.
Examples:

Red, Red, Red: 2200 ohms or 2K2
Yellow, Purple, Orange: 47000 ohms or 47K
Brown, Black, Brown: 100 ohms or 100R
Orange, Orange, Orange: 33000 ohms or 33K
Brown, Green, Red: 1500 ohms or 1K5
Brown, Green, Black: 15 no noughts, or 15 ohms
Blue, Grey, Orange: 68000 ohms or 68K
Brown, Green, Green: 1500000 ohms or 1,500,000 ohms or 1M5
Yellow, Purple, Brown: 470 ohms

As there are only 12 standard resistor values per decade, there are only 12 sets of the first two colour bands:

10: Brown/Black,
12: Brown/Red,
15: Brown/Green,
18: Brown/Grey
22: Red/Red,
27: Red/Purple
33: Orange/Orange,
39: Orange/White
47: Yellow/Purple
56: Green/Blue
68: Blue/Grey
82: Grey/Red
The details above give you all the basic information on resistor colour codes but there are a few additional refinements. There is an extra colour band further down the body of the resistor as shown here:

This extra band is used to indicate the manufacturing tolerance of the construction of the resistor. Resistor values are never exact and this rarely has any significant effect on their use in circuits. If some circuit needs very accurate resistor values in it, then buy several resistors of the same nominal value and use an ohm-meter to measure that actual value of each particular resistor and if none are perfect, then use two or more resistors to give the exact value wanted.

The tolerance band has the following codes:

- Silver is ± 10% (i.e. a 10K resistor of this type should be between 9K and 11K)
- Gold ± 5% (i.e. a 10K resistor of this type should be between 9.5K and 10.5K)
- Red ± 2% (i.e. a 10K resistor of this type should be between 9.8K and 10.2K)
- Brown ± 1% (i.e. a 10K resistor of this type should be between 9.9K and 10.1K)
- Green ± 0.5% (i.e. a 10K resistor of this type should be between 9.95K and 10.05K)
- Blue ± 0.25% (i.e. a 10K resistor of this type should be between 9.975K and 10.025K)
- Purple ± 0.1% (i.e. a 10K resistor of this type should be between 9.99K and 10.01K)

This type of resistor in the 10% and 5% ranges are the most common as they are the cheapest to buy and so tend to be the most popular. Recently, however, two additions to the coding have been introduced in order to allow for very high specification resistors which the average constructor may never come across. Each of these additions involves one additional colour band. The first additional colour band allows an extra digit in the resistor value, and looks like this:
As before, the colour coding is exactly the same, with the fourth colour band specifying the number of zeros after the digits indicated by the colour bands in front of it. So, in the example shown above, the first band being Red indicates a "2". The second colour band being Purple indicates a "7". The third colour band being Green indicates a "5" and the fourth colour band being Red indicates "2 zeros", so putting those together it produces the value of 27,500 ohms, which can also be written as 27.5 K or more briefly as 27K5.

Another example of this is:

The fourth colour band coding has also been extended to include two other colours:
Gold: meaning "no zeros and divided by 10" so if the band in the example above had been gold, then the value would be 56.4 ohms.
Silver: meaning "no zeros and divided by 100" and if the example band had been silver then the value would have been 5.64 ohms.

So, for example, if the resistor had a fourth colour band which was silver, then the value would be:

Finally, for very high-quality applications (typically military applications), there can be a sixth colour band positioned outside the tolerance band, and that final colour band states how much the resistance value can be expected to alter with changes in temperature. This is not something which is likely to be of any interest to you, but the codes for that final colour band are:

Brown: 0.01% of the resistor value for each degree Centigrade change in temperature.
Red: 0.005% of the resistor value for each degree Centigrade change in temperature.
Yellow: 0.0025% of the resistor value for each degree Centigrade change in temperature.
Orange: 0.0015% of the resistor value for each degree Centigrade change in temperature.

To put this in context, the worst of these represents a change of 1% in the resistor value when moving from the temperature of ice to the temperature of boiling water. Is this something which you really care about? I don't.

Leaving the details of identifying individual resistors, we now come to the interesting part: what happens when there are several resistors in a circuit. The important thing is to keep track of the voltages generated within the circuit. These define the currents flowing, the power used and the way in which the circuit will respond to external events. Take this circuit:
What is the voltage at point ‘A’? If you feel like saying “Who cares?” then the answer is “you” if you want to understand how circuits work, because the voltage at point ‘A’ is vital. For the moment, ignore the effect of the voltmeter used to measure the voltage.

If R1 has the same resistance as R2, then the voltage at ‘A’ is half the battery voltage, i.e. 4.5 Volts. Half the battery voltage is dropped across R1 and half across R2. It does not matter what the actual resistance of R1 or R2 is, as long as they have exactly the same resistance. The higher the resistance, the less current flows, the longer the battery lasts and the more difficult it is to measure the voltage accurately.

There is no need to do any calculations to determine the voltage at point “A” as it is the ratio of the resistor values which determines the voltage. If you really want to, you can calculate the voltage although it is not necessary. The method for doing this will be shown you shortly. For example, if R1 and R2 each have a value of 50 ohms, then the current flowing through them will be 9 volts / 100 ohms = 0.09 Amps (or 90 milliamps). The voltage drop across R1 will be 50 ohms = Volts / 0.09 amps or Volts = 4.5 volts. Exactly the same calculation shows that the voltage across R2 is exactly 4.5 volts as well. However, the point to be stressed here is that it is the ratio of R1 to R2 which controls the voltage at point “A”.

If R1 has half as much resistance as R2, then half as much voltage is dropped across it as is dropped across R2, i.e. 3 Volts is dropped across R1, giving point ‘A’ a voltage of 6 Volts and that is what the voltmeter will show. Again, it does not matter what the actual value of R1 is in ohms, so long as R2 has exactly twice the resistance (shown by a higher number on the resistor).

If R1 has twice as much resistance as R2, then twice as much voltage is dropped across it as is dropped across R2, i.e. 6 Volts is dropped across R1, giving point ‘A’ a voltage of 3 Volts. Here are some examples with different resistors:

The same division of the supply voltage can be produced by positioning the slider of a variable resistor at different points by rotating the shaft of the device:
This determination of the voltage levels is the key factor to understanding electronic circuitry. The voltage levels control what currents flow and how every circuit will perform, so it is essential to understand what is happening. Stick with this section until you understand it, and if necessary, ask questions about what you find difficult.

First, please understand that a good battery is an unlimited source of voltage and that voltage does not get "used up" when a resistor or whatever is connected across it:

There can be some difficulty in understanding the “0-volt” connection in a circuit. All this means is that it is the return line for current flowing from the battery. Most conventional circuits are connected to both sides of the battery and that allows a current to flow around a closed “circuit” from one terminal of the battery to the other terminal.

It is normal practice to draw a circuit diagram so that the Plus terminal of the battery is at the top and the minus terminal is at the bottom. Many circuit diagrams show the negative line at the bottom connected to the ground or an "earth" connection, which is literally a metal rod driven into the ground to make a good electrical connection to the ground. This is done because the Earth is literally a vast reservoir of negative electricity. However, in reality, most circuits are not connected directly to the Earth in any way. The standard circuit diagram can be visualised as being like a graph of voltage, the higher up the diagram, the higher the voltage.

Anyway, when there is a circuit connected across the battery, the negative or “0V” line just indicates the return path to the battery for the current flow:
This principle applies immediately to the following circuit:

Here we encounter two new components. The first is ‘VR1’ which is a variable resistor. This device is a resistor which has a slider which can be moved from one end of the resistor to the other. In the circuit above, the variable resistor is connected across the 9 Volt battery so the top of the resistor is at +9 Volts (relative to the battery Minus terminal) and the bottom is at 0 Volts. The voltage on the slider can be adjusted from 0 Volts to 9 Volts by moving it along the resistor by turning the shaft of the component (which normally has a knob attached to it).

The second new device is ‘TR1’ a transistor. This semiconductor has three connections: a Collector, a Base and an Emitter. If the voltage on the base is below 0.7 volts, then the transistor is said to be “OFF” and in that state it has a very high resistance between the collector and the emitter, much higher than the resistance of resistor “R2”. The voltage dividing mechanism just discussed means that the voltage at the collector will therefore, be very near to 9 Volts - caused by the ratio of the transistor’s Collector/Emitter resistance compared to the resistor “R2”.

If the voltage on the base of the transistor is raised to 0.7 volts by moving the slider of the variable resistor slowly upwards, then this will feed a small current to the base which then flows out through the emitter, switching the transistor ON causing the resistance between the collector and the emitter to drop instantly to a very low value, much, much lower than the resistance of resistor ‘R2’. This means that the voltage at the collector will be very close to 0 Volts. The transistor can therefore be switched on and off just by rotating the shaft of the variable resistor.
If a bulb is used instead of R2, then it will light when the transistor switches on. If a relay or opto-isolator is used, then a second circuit can be operated:

If a buzzer is substituted for R2, then an audible warning will be sounded when the transistor switches on. If a light-dependent resistor is substituted for VR1, then the transistor will switch on when the light level increases or decreases, depending on how the sensor is connected. If a thermistor is used instead of VR1, then the transistor can be switched on by a rise or fall in temperature. The same goes for sound, wind speed, water speed, vibration level, etc. etc. - more of this later.

We need to examine the resistor circuit in more detail:

We need to be able to calculate what current is flowing around the circuit. If the circuit contains only resistors, then this can be done using “Ohm’s Law” which states that "Resistance equals Voltage divided by Current" or, if you prefer:

**Ohm’s Law (resistive Circuits only).**

“**Ohms = Volts / Amps**” which indicates the units of measurement.

In the circuit above, if the voltage is 9 Volts and the resistor is 100 ohms, then by using Ohm’s Law we can calculate the current flowing around the circuit as 100 Ohms = 9 Volts / Amps, or Amps = 9 / 100 which equals 0.09 Amps. To avoid decimal places, the unit of 1 milliamp is used. There are 1000 milliamps in 1 Amp. The
current just calculated would commonly be expressed as 90 milliamps which is written as 90 mA.

In the circuit above, if the voltage is 9 Volts and the resistor is 330 ohms, then by using Ohm’s Law we can calculate the current flowing around the circuit as \( \frac{330}{9} = \text{Amps} \). Multiplying both sides of the equation by “Amps” gives: Amps \( \times \) 330 ohms = 9 volts. Dividing both sides of the equation by 330 gives: Amps = 9 volts \( / \) 330 ohms which works out as 0.027 Amps, written as 27 mA.

Using Ohm’s Law we can calculate what resistor to use to give any required current flow. If the voltage is 12 Volts and the required current is 250 mA then as Ohms = Volts / Amps, the resistor needed is given by: Ohms = \( \frac{12}{0.25} \) Amps which equals 48 ohms. The closest standard resistor is 47 ohms (Yellow / Purple / Black).

The final thing to do is to check the wattage of the resistor to make sure that the resistor will not burn out when connected in the proposed circuit. The power calculation is given by: Watts = Volts \( \times \) Amps. In the last example, this gives Watts = 12 \( \times \) 0.25, which is 3 Watts. This is much larger than most resistors used in circuitry nowadays.

Taking the earlier example, Watts = Volts \( \times \) Amps, so Watts = 9 \( \times \) 0.027 which gives 0.234 Watts. Again, to avoid decimals, a unit of 1 milliwatt is used, where 1000 milliwatts = 1 Watt. So instead of writing 0.234 Watts, it is common to write it as 234 mW.

This method of working out voltages, resistances and wattages applies to any circuit, no matter how awkward they may appear. For example, take the following circuit containing five resistors:

As the current flowing through resistor ‘R1’ has then to pass through resistor ‘R2’, they are said to be ‘in series’ and their resistances are added together when calculating current flows. In the example above, both R1 and R2 are 1K resistors, so together they have a resistance to current flow of 2K (that is, 2,000 ohms).

If two, or more, resistors are connected across each other as shown on the right hand side of the diagram above, they are said to be ‘in parallel’ and their resistances combine differently. If you want to work out the equation above, for yourself, then choose a voltage across Rt, use Ohm’s Law to work out the current through Ra and the current through Rb. Add the currents together (as they are both being drawn from the voltage source) and use Ohm’s Law again to work out the value of Rt to confirm that the \( \frac{1}{Rt} = \frac{1}{Ra} + \frac{1}{Rb} \) equation is correct. A spreadsheet is included which can do this calculation for you.

In the example above, R4 is 1K5 (1,500 ohms) and R5 is 2K2 (2,200 ohms) so their combined resistance is given by \( \frac{1}{Rt} = \frac{1}{1500} + \frac{1}{2200} \) or Rt = 892 ohms (using a simple calculator). Apply a common-sense check to this result: If they had been two 1500 ohm resistors then the combined value would have been 750 ohms. If they had been two 2200 ohm resistors then the combined value would have been 1100 ohms. Our answer must therefore lie between 750 and 1100 ohms. If you came up with an answer of, say, 1620 ohms, then you know straight off that it is wrong and the arithmetic needs to be done again.

So, how about the voltages at points ‘A’ and ‘B’ in the circuit? As R1 and R2 are equal in value, they will have equal voltage drops across them for any given current. So the voltage at point ‘A’ will be half the battery voltage, i.e. 6 Volts.

Now, point ‘B’. Resistors R4 and R5 act the same as a single resistor of 892 ohms, so we can just imagine two resistors in series: R3 at 470 ohms and R4+R5 at 892 ohms. Common-sense rough check: as R3 is only about half the resistance of R4+R5, it will have about half as much voltage drop across it as the voltage drop across R4+R5, i.e. about 4 Volts across R3 and about 8 Volts across R4+R5, so the voltage at point ‘B’ should work out.
at about 8 Volts.

We can use **Ohm’s Law** to calculate the current flowing through point ‘B’:

\[
\text{Ohms} = \frac{\text{Volts}}{\text{Amps}}, \quad \text{(or } \text{Amps} = \frac{\text{Volts}}{\text{Ohms}} \text{ or } \text{Volts} = \text{Ohms} \times \text{Amps})
\]

\[(470 + 892) = 12 \div \text{Amps}, \text{ so}\]

\[
\text{Amps} = \frac{12}{(470 + 892)}
\]

\[
\text{Amps} = \frac{12}{1362} \text{ or }
\]

\[
\text{Amps} = 0.00881 \text{ Amps (8.81 milliamps)}.
\]

Now that we know the current passing through \(R4+R5\) we can calculate the exact voltage across them:

\[
\text{Resistance} = \frac{\text{Volts}}{\text{Amps}} \text{ so}
\]

\[
892 = \frac{\text{Volts}}{0.00881} \text{ or }
\]

\[
\text{Volts} = 892 \times 0.00881
\]

\[
\text{Volts} = 7.859 \text{ Volts}.
\]

As our common-sense estimate was 8 Volts, we can accept 7.86 Volts as being the accurate voltage at point ‘B’.

**The Potentiometer.**

Just before we leave the subject of resistors and move on to more interesting subjects, we come across the term ‘potentiometer’. This term is often shortened to ‘pot’ and many people use it to describe a variable resistor. I only mention this so that you can understand what they are talking about. A variable resistor is not a potentiometer and really should not be called one. You can skip the rest of this part as it is not at all important, but here is what a potentiometer is:

A fancy name for voltage is ‘potential’, so a circuit powered by a 12 Volt battery can be described as having a ‘potential’ of zero volts at the negative side of the battery and a ‘potential’ of plus twelve volts at the positive side of the battery. Ordinary folks like me would just say ‘voltage’ instead of ‘potential’.

When a voltmeter is used to measure the voltage at any point in a circuit, it alters the circuit by drawing a small amount of current from the circuit. The voltmeter usually has a high internal resistance and so the current is very small, **but** even though it is a small current, it **does** alter the circuit. Consequently, the measurement made is not quite correct. Scientists, in years gone by, overcame the problem with a very neat solution - they measured the voltage without taking any current from the circuit - neat huh? They also did it with a very simple arrangement:

They used a sensitive meter to measure the current. This meter is built so that the needle is in a central position if no current is flowing. With a positive current flowing, the needle deflects to the right. With a negative current flowing, the needle moves to the left. They then connected a variable resistor ‘VR1’ across the same battery which was powering the circuit. The top end of VR1 is at +12 Volts (they called that ‘a potential of +12 Volts’) and the bottom end of VR1 is at zero volts or ‘a potential of zero volts’.

By moving the slider of VR1, any voltage or ‘potential’ from zero volts to +12 Volts could be selected. To measure the voltage at point ‘A’ without drawing any current from the circuit, they would connect the meter as shown and adjust the variable resistor until the meter reading was exactly zero.
Since the meter reading is zero, the current flowing through it is also zero and the current taken from the circuit is zero. As no current is being taken from the circuit, the measurement is not affecting the circuit in any way - very clever. The voltage on the slider of VR1 exactly matches the voltage at point ‘A’, so with a calibrated scale on the variable resistor, the voltage can be read off.

The slick piece of equipment made up from the battery, the variable resistor and the meter was used to measure the ‘potential’ (voltage) at any point and so was called a ‘potentiometer’. So, please humour me by calling a variable resistor a ‘variable resistor’ and not a ‘potentiometer’. As I said before, this is not at all important, and if you want to, you can call a variable resistor a ‘heffalump’ so long as you know how it works.

**Understanding what circuit diagrams mean.**

Many people look at a circuit diagram and have no idea what it means, so let’s see if we can make the mystery go away. Take this circuit for example:

![Circuit Diagram](image)

This circuit has three components plus some wire. The symbol “B” represents a battery, or more strictly speaking, a battery made up of a number of cells. Batteries come in many different shapes and sizes. Here are some of them:

![Battery Images]

The symbol “R” represents a resistor as described above, and the “LED” is a Light-Emitting Diode which probably looks like this:

![LED Image]

The longer lead is the Plus. Many LEDs need more than 1.5 volts to light up, and while it is very easy to think of a single AA-size battery as being 1.5 volts, the very common AA-size NiMh batteries are only 1.2 volts. So, let us set up the circuit using a 9V battery and a 330 ohm resistor (Orange, Orange, Brown) to limit the current flowing through the LED. The circuit is:

![Modified Circuit Diagram](image)

And this indicates that the Plus of the battery gets connected to the resistor. This can be done using some wire, or the resistor can be connected directly to the battery.
Then the LED gets connected to the other end of the resistor:

And finally, the other side of the LED is connected to the Minus of the battery:

If the LED is connected the wrong way round, it will not damage anything but the LED will not light up. Poor quality connections can be made by twisting wires together. Better quality connections can be made using screw connectors:

The spacing of the connectors on the strip varies with the power rating of the connectors and there are four or five sizes commonly available, and so it is sometimes necessary to cut the strip and use individual connectors at times. Another option is to use a plug-in board although they are far from perfect. They used to be very good but then integrated circuits came along with their tiny pin spacing and the boards adapted to them by making the holes and the spacing between the holes small enough to suit the integrated circuits. Now, it is no longer possible to plug in quite ordinary components such as the fast UF5408 diode as the diode wires are too large to plug into the tiny holes:
The most effective method of connection is to solder the components together and that is not particularly difficult to do. Veroboard (stripboard) is convenient and there are several other board styles which can be used. When I was very young and almost no components were available, I used drawing pins and soldered components to them, killing the excessive heat using a wet cloth which is very effective in dropping temperature very rapidly. However, no matter what method of connection is used, you just follow along the connecting lines in any diagram to see what components are connected together.

Semiconductors.
This section deals with discrete semiconductors. A later section deals with ‘Integrated Circuits’ which are large-scale semiconductor devices.

ORP12 Light-dependent resistor. This device has a high resistance in the dark and a low resistance in bright light. It can be placed in a circuit to create a switch which operates with an increase in light level or a decrease in light level:

In this version, the voltage at point ‘A’ controls the circuit. In darkness, the ORP12 has a resistance ten times greater than that of R1 which is 12,000 ohms. Consequently, the voltage at point ‘A’ will be high. As the light level increases, the resistance of the ORP12 falls, dragging the voltage at point ‘A’ downwards. As the variable resistor ‘VR1’ is connected from point ‘A’ to the ground rail (the -ve of the battery), its slider can be moved to select any voltage between 0 Volts and the voltage of ‘A’. A slider point can be chosen to make the transistor switch off in daylight and on at night. To make the circuit trigger when the light level increases, just swap the positions of R1 and the ORP12.

The transistor shown is a BC109 although most transistors will work in this circuit. The BC109 is a cheap, silicon, NPN transistor. It can handle 100mA and 30V and can switch on and off more than a million times per second. It has three connections: the Collector, marked ‘c’ in the diagram, the Base, marked ‘b’ in the diagram and the Emitter, marked ‘e’ in the diagram.

As mentioned before, it has a very high resistance between the collector and the emitter when no current flows into the base. If a small current is fed into the base, the collector/emitter resistance drops to a very low value. The collector current divided by the base current is called the ‘gain’ of the transistor and is often called ‘hfe’. A transistor such as a BC109 or a BC108 has a gain of about 200, though this varies from actual transistor to actual
transistor. A gain of 200 means that a current of 200mA passing through the collector requires a current of 1mA through the base to sustain it. Specific information on the characteristics and connections of semiconductors of all kinds can be obtained free from the excellent website [www.alldatasheet.co.kr](http://www.alldatasheet.co.kr) which provides .pdf information files.

The BC109 transistor shown above is an NPN type. This is indicated by the arrow of the symbol pointing outwards. You can also tell by the collector pointing to the positive rail. There are similar silicon transistors constructed as PNP devices. These have the arrow in the transistor symbol pointing inwards and their collectors get connected, directly or indirectly, to the negative rail. This family of transistors are the earliest transistor designs and are called 'bi-polar' transistors.

These silicon transistors are so efficiently constructed that they can be connected directly together to give greatly increased gain. This arrangement is called a 'Darlington pair'. If each transistor has a gain of 200, then the pair give a gain of $200 \times 200 = 40,000$. This has the effect that a very, very small current can be used to power a load. The following diagram shows a Darlington pair used in a water-level detector. This type of alarm could be very useful if you are asleep on a boat which starts taking on water.

Here, (when the circuit is switched on), transistor TR1 has so little leakage current that TR2 is starved of base current and is hard off, giving it a high resistance across its collector/emitter junction. This starves the buzzer of voltage and keeps it powered off. The sensor is just two probes fixed in place above the acceptable water level. If the water level rises, the probes get connected via the water. Pure water has a high electrical resistance but this circuit will still work with pure water.

The odds are that in a practical situation, the water will not be particularly clean. The resistor R1 is included to limit the base current of TR1 should the sensor probes be short-circuited. Silicon bi-polar transistors have a base/emitter voltage of about 0.7V when fully switched on. The Darlington pair will have about 1.4V between the base of TR1 and the emitter of TR2, so if the sensor probes are short-circuited together, resistor R1 will have $6 - 1.4 = 4.6V$ across it. Ohm's Law gives us the current through it as $I = V / R$ or $47,000 = 4.6 / I$ or $I = 4.6 / 47,000$ amps. This works out at 0.098mA which with a transistor gain of 40,000 would allow up to 3.9A through the buzzer. As the buzzer takes only 30mA or so, it limits the current passing through it, and TR2 can be considered to be switched hard on with the whole battery voltage across it.

NPN transistors are more common than PNP types but there is almost no practical difference between them. Here is the previous circuit using PNP transistors:

Not a lot of difference. Most of the circuit diagrams shown here use NPN types but not only are these not critical, but there are several ways to design any particular circuit. In general, the semiconductors shown in any circuit are seldom critical. If you can determine the characteristics of any semiconductor shown, any reasonably similar
device can generally be substituted, especially if you have a general understanding of how the circuit works. Either of the two previous circuits can operate as a rain detector. A suitable sensor can easily be made from a piece of strip board with alternate strips connected together to form an interlacing grid:

![Rain Sensor Diagram](image)

Here, if a raindrop bridges between any two adjacent strips, the circuit will trigger and sound a warning.

The transistors in the circuit above are connected with their emitter(s) connected to the ground rail (the lower battery line shown in any circuit is considered to be “ground” unless it is specifically shown elsewhere). This connection method is called ‘common emitter’. The following circuit uses the transistor connected in ‘emitter follower’ mode. This is where the emitter is left to follow the base voltage - it is always 0.7V below it unless the base itself is driven below 0.7V:

![Light-operated switch Diagram](image)

This is almost the same as the light-operated circuit shown earlier. In this variation, the transistors are wired so that they work as an ‘emitter-follower’ which follows the voltage at point ‘A’ which rises as the light level drops and the resistance of the ORP12 increases. This causes the voltage across the relay to increase until the relay operates and closes its contacts. A relay is a voltage-operated mechanical switch which will be described in more detail later on.

The disadvantage of the above circuit is that as the light level decreases, the current through the relay increases and it may be a significant amount of current for some considerable time. If it was intended to power the unit with a battery then the battery life would be far shorter than it need be. What we would like, is a circuit which switched rapidly from the Off state to the On state even though the triggering input varied only slowly. There are several ways to achieve this, one of them being to modify the circuit to become a ‘Schmitt Trigger’:
Here, an additional transistor (‘TR2’) has changed the circuit operation significantly, with transistor TR3 switching fully on and fully off, rapidly. This results in the current through the relay being very low until the circuit triggers.

The circuit operates as follows. When the voltage at the base of TR1 is high enough, TR1 switches on, which causes the resistance between its collector and emitter to be so low that we can treat it as a short circuit (which is a nearly-zero resistance connection). This effectively connects the 10K and 1K8 resistors in series across the battery. The voltage at their connecting point (both the collector and emitter of TR1) will then be about 1.8 Volts. The two 18K resistors are in series across that voltage so the voltage at their junction will be half that; 0.9 Volts.

This puts the Base of TR2 at about 0.9 Volts and its emitter at 1.8 Volts. The base of TR2 is therefore not 0.7 Volts above its emitter, so no base/emitter current will flow in TR2, which means that TR2 is switched hard off. This means that the TR2 collector/emitter resistance will be very high. The voltage at the base of TR3 is controlled by the 1K8 resistor, the TR2 collector/emitter resistance (very high) and the 3K9 resistor. This pushes the base voltage of TR3 up to near the full battery voltage and as it is wired as an emitter-follower, its emitter voltage will be about 0.7 Volts below that. This means that the relay will have most of the battery voltage across it and so will switch hard on.

Some practical points: The current flowing into the base of TR3 comes via the 3K9 resistor. A 3K9 resistor needs 3.9 Volts across it for every 1 mA which flows through it. If the relay needs 150 mA to operate and TR3 has a gain of 300, then TR3 will need a base current of 0.5 mA to provide 150 mA of current through its collector/emitter junction. If 0.5 mA flows through the 3K9 resistor, there will be a voltage drop across it of some 2 Volts. The TR3 base/emitter voltage will be a further 0.7 Volts, so the voltage across the relay will be about 12.0 - 2.0 - 0.7 = 9.3 Volts, so you need to be sure that the relay will work reliably at 9 Volts.

If you used a Darlington pair of transistors, each with a gain of 300, instead of TR3, then their combined base/emitter voltage drop would be 1.4 Volts, but they would only need a base current of 150 mA / (300 x 300) = 1/600 mA. That current would only drop 0.007 Volts across the 3K9 resistor, so the relay would receive 10.6 Volts.

So, how do you work out the gain of any particular transistor? The main working tool for electronics is a multimeter. This is a digital or analogue meter which can measure a wide range of things: voltage, current, resistance, ... The more expensive the meter, generally, the greater the number of ranges provided. The more expensive meters offer transistor testing. Personally, I prefer the older, passive multimeters. These are looked down on because they draw current from the circuit to which they are attached, but, because they do, they give reliable readings all the time. The more modern battery-operated digital multimeters will happily give incorrect readings as their battery runs down. I wasted two whole days, testing rechargeable batteries which appeared to be giving impossible performances. Eventually, I discovered that it was a failing multimeter battery which was causing false multimeter readings.

Transistor Testers.
For the moment, let us assume that no commercial transistor tester is to hand and we will build our own (or at least, discover how to build our own). The gain of a transistor is defined as the collector/emitter current divided by the base/emitter current. For example, if 1mA is flowing through the collector and 0.01mA is flowing into the base to sustain that collector flow, then the transistor has a gain of 100 times at 1mA. The transistor gain may vary when it is carrying different current loads. For the circuits we have been looking at so far, 1mA is a reasonable current at which to measure the transistor gain. So let’s build a circuit to measure the gain:
With the circuit shown here, the variable resistor is adjusted until a collector current of 1mA is shown on the millimetre and the gain of the transistor is then read off the scale on the variable resistor knob. The circuit is built into a small box containing the battery and with a socket into which the transistor can be plugged. The question then is, what values should be chosen for the resistor R1 and the variable resistor VR1?

Well, we might choose that the minimum gain to be displayed is 10. This would correspond to where the variable resistor slider is taken all the way up to point ‘A’ in the circuit diagram, effectively taking the variable resistor out of the circuit. If the transistor gain is 10 and the collector current is 1mA, then the base current will be 0.1mA. This current has to flow through the resistor R1 and it has a voltage of (9.0 - 0.7) Volts across it as the base/emitter voltage is 0.7 Volts when the transistor is on. Ohms Law gives us Ohms = Volts / Amps, which for the resistor R1 means Ohms = 8.3 / 0.0001 or 83,000 ohms, or 83K.

Rule of thumb: 1K provides 1mA if it has 1V across it, so 10K will give 0.1mA if it has 1 Volt across it. With 8.3 Volts across it, it needs to be 8.3 times larger to hold the current down to the required 0.1mA so the resistor should be 83K in size.

As 83K is not a standard size, we need to use two or more standard resistors to give that resistance. Nearest standard size below 83K is 82K, so we can used one 82K resistor and one 1K resistor in series to give the required 83K.

Suppose that we say that we would like to have 500 as the highest gain shown on our tester, then when VR1 is at its maximum value, it and R1 should provide 1/500 of the collector current of 1mA, i.e. 0.002mA or 0.000002 Amps. From Ohms Law again we get VR1 + R1 = 4,150,000 ohms or 4M15. Unfortunately, the largest value variable resistor available is 2M2 so the circuit as it stands, will not be able to cope.

Rule of thumb: 1K provides 1mA if it has 1V across it, so 10K will give 0.1mA if it has 1 Volt across it. With 8.3 Volts across it, it needs to be 8.3 times larger to hold the current down to the required 0.1mA so the resistor should be 83K in size.

As 83K is not a standard size, we need to use two or more standard resistors to give that resistance. Nearest standard size below 83K is 82K, so we can used one 82K resistor and one 1K resistor in series to give the required 83K.

Suppose that we say that we would like to have 500 as the highest gain shown on our tester, then when VR1 is at its maximum value, it and R1 should provide 1/500 of the collector current of 1mA, i.e. 0.002mA or 0.000002 Amps. From Ohms Law again we get VR1 + R1 = 4,150,000 ohms or 4M15. Unfortunately, the largest value variable resistor available is 2M2 so the circuit as it stands, will not be able to cope.

Suppose we were to just use a 2M2 variable resistor for VR1, what transistor gain range could we display? Well Ohms Law ... lets us calculate the base current with 8.3 Volts across (83,000 + 2,200,000) ohms and from that the maximum transistor gain which would be 277.77 (at 1mA). You would buy a ‘linear’ standard carbon track variable resistor so that the change in resistance is steady as the shaft is rotated. The scale which you would make up would be in even steps and it would run from 10 at the minimum setting, to 278 at the highest setting.

But that is not what we wanted. We wanted to measure up to 500. But they don’t make variable resistors big enough, so what can we do? Well, if we wanted, we could lower the battery voltage, which in turn would lower the resistor values. As a 9V battery is very convenient for this kind of circuit, lets not go down that route. We could add extra circuitry to drop the 9V battery voltage down to a lower value. The most simple solution is to add an extra resistor and switch to give two ranges. If we switched in an extra 2M2 resistor above VR1 then the circuit would measure transistor gains from 278 to just over 500 and all we would need to do would be to add a second scale for the VR1 pointer knob to move over. We could, provide extra ranges which overlap and which have more convenient scales to mark. The design is up to you.
The design covered above is not the only way to measure the transistor gain. A second way, which accepts that it is not so accurate, picks a set base current and measures the collector current as a guide to the gain. In this simple method, one or more resistor values are chosen to give gain ranges, and the milliammeter used to read the corresponding gain:

Here, resistor R1 might be chosen to give a collector current of 1mA (which is a full-scale deflection on the meter) when the transistor gain is 100. Resistor R2 might be picked to give a full-scale deflection for a gain of 200, R3 for a gain of 400, R4 for a gain of 600, and so on. Generally speaking, it is not essential to know the exact gain but any reasonable approximation to it is sufficient. You are normally selecting a transistor where you need a gain of 180, so it is not important if the transistor you pick has a gain of 210 or 215 - you are only avoiding transistors with gains below 180.

How do you work out the values of the resistors R1 to R4? Well, you probably won’t expect this, but you use Ohms Law. Voltage drop is 8.3 Volts and the base current is given by the full-scale deflection’s 1mA divided by the transistor gain for each range, i.e. 1/100 mA for R1, 1/200 mA for R2,... 1/600 mA for R4,...

Emitter Followers
The transistor circuits show so far are known by the technical term “Common Emitter” because the emitters are generally connected to the ‘Negative rail’ or battery minus line. This method of use is very popular because when the transistor is switched on, all of the supply voltage is supplied to the load. Another common and very useful method is known as the ‘Emitter-Follower’ circuit where the load is connected to the negative rail instead of the emitter of the transistor. With this arrangement, the voltage at the emitter remains at 0.7 volts below the voltage of the transistor base and ‘follows’ that voltage no matter how it changes. Generally speaking, the transistor is being used to amplify the current which could be drawn from the point in the circuit where the transistor base is connected.

The circuit arrangement is like this:
If the battery is genuinely 12-volts, then the slider of the variable resistor VR1 can be moved from a voltage of zero volts to a voltage of +12 volts, or any desired value between those two values. That means that the voltage on the base of transistor TR1 can be any of those values. If the voltage on the transistor base is 0.7 volts or higher, then the transistor will conduct current and the voltage across the load will increase until the emitter is 0.7 volts below the base voltage. This means that the voltage across the load can be adjusted to any value from 0 volts to +11.3 volts. This circuit is known as an “Emitter-Follower” circuit.

The actual values encountered in ‘real life’ are that a battery marked as 12-volts is very seldom actually at that voltage and a common value is 12.8 volts. I have called the Base-to-Emitter voltage 0.7 volts but in reality, it may be anything from 0.6 volts to 0.75 volts. A common use for this type of circuit is to pass a constant voltage to a circuit, using a zener diode. The circuit is like this:

This circuit is supposed to have a fixed voltage at point “A” as the zener diode Z1 is supposed to produce a fixed voltage. That can work reasonably well if the battery voltage is fixed, but if the battery voltage alters either upwards or downwards, the voltage at “A” drifts, which means that the voltage across the load also alters. You will sometimes see this in constant-current circuits.

**Constant-Current circuits**

The generally recommended way to arrange a constant current flow through some load or other is to use an integrated circuit designed for the job. The arrangement is generally like this:

Here, the resistor R1 controls how much current will flow in the circuit and the resistor R2 needs to be ten times higher in value than R1. One snag is that the LM334Z drops about 4-volts when stabilising the current through the load. That is a lot of voltage sacrificed. An alternative arrangement is:
With this circuit, two ordinary diodes such as the 1N4007, are used to give a steady voltage due to the current flowing through them, supplied by resistor R1. Each diode has a voltage drop across it roughly equal to the voltage drop across the Base/Emitter junction of the transistor TR1. That means that the resistor R2 will have about the same voltage across it as one of the diodes. It is my experience that the voltage drop across the diodes is not affected much if the battery voltage changes as time goes by. The value of the resistor R2 is chosen to give the desired current flow through the load. The voltage drop across the transistor Collector/Emitter connections adjusts automatically to keep the current through the load at the constant required value.

**Substitute Transistors**

A recent question was how to find a substitute transistor for the T13009 transistor in this chapter 21 circuit, as there seemed to be no local supplier for it, and would a 2N2222 transistor do as a substitute?

That is a very reasonable question. So to answer it, we look at the circuit and we see that the Collector of the transistor is going to be pulled upwards until it exceeds the voltage of the battery chain. There are five 12-volt batteries in a chain going upwards from the transistor Emitter and while those batteries have “12 Volts” written on them, they can charge up to nearly 14 volts each. That means that the transistor collector may be dragged up to a voltage of $5 \times 14 = 70$ volts or more if the batteries are going to be charged. So, common sense says that any successful substitute transistor will have to have a voltage rating of at least 70 volts.

If we want to find out the characteristics of a transistor or diode, we can go to the [http://www.alldatasheet.com/](http://www.alldatasheet.com/) web site, although just Googling the transistor name often gets the needed information very quickly. Anyway, on the web site, the top of the page has an entry section like this:
And if you type in T13009 as the part name:

and click on the Search button, then it comes up with this:

**T13009 Datasheet, PDF**

<table>
<thead>
<tr>
<th>Shortcut</th>
<th>T13009(1) recommended result.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Match, Like</td>
<td>ST13009(1)</td>
</tr>
</tbody>
</table>

So you click on the blue ST13009 link and it then comes up with a slightly confusing advertisement display which offers information on some totally unrelated component. However, if you scroll down the page a little you reach a link to the datasheet for the transistor:

<table>
<thead>
<tr>
<th>Electronic Manufacturer</th>
<th>Part no</th>
<th>Datasheet</th>
</tr>
</thead>
<tbody>
<tr>
<td>STMicroelectronics</td>
<td>ST13009</td>
<td></td>
</tr>
</tbody>
</table>

If you then click on the PDF symbol, you get another screen offering the actual link to the pdf file:

<table>
<thead>
<tr>
<th>Part No.</th>
<th>ST13009</th>
</tr>
</thead>
<tbody>
<tr>
<td>Download</td>
<td>ST13009 Click to view</td>
</tr>
</tbody>
</table>

Clicking on the link actually provides you with the datasheet which you can store locally to save ever having to go through all that lot again.

**ST13009**

High voltage fast-switching
NPN power transistor

**Features**

- Low spread of dynamic parameters
- High voltage capability
- Minimum lot-to-lot spread for reliable operation
- Very high switching speed

**Applications**

- Switch mode power supplies
This is not an FET transistor and so our main interest is in the voltage it can withstand, the continuous current which it can carry, the peak current it can manage when fed sudden pulses, how much power overall it can handle, what DC-current gain (that is amplification) you can expect from it and how fast it can operate.

That sounds a lot but it really is quite simple. However, there is a manufacturing spread on transistors and most other electronic components, and so we are looking for just a ball-park number for these things. That is, you can have five identical-looking transistors in your hand but it is most unlikely that any two of them will actually be identical. However, let's look at this data sheet and see what we find out:

First, the maximum voltage that the transistor can withstand with the base unconnected is 400 volts which is a good deal more that is likely to be reached in our circuit.

Next, the current. The continuous current is stated to be 12 amps and 24 amps if in pulses. That is likely to be more than the circuit needs, as a sustained output of 40 watts from a 12-volt connection is a current of under 4-amps.

Next, the wattage is stated as being 100 watts (a heat sink is definitely needed for that – imagine holding a lit 100 watt light bulb in your hand and think how comfortable that would be). However, in our circuit, the transistor will be off for most of the time and so, wattage is not likely to be a problem.

Next, the switching speed, which is likely to be important in this circuit. The data sheet suggests that about 60 nanoseconds is likely for any T13009 transistor.

And finally, the DC current gain will probably be between 15 and 39 at a current of 5 amps. It is likely to be much better than that at lower currents.

Some people have difficulty visualising how a bipolar transistor works, so let me explain it in a bit more detail. When current is flowing through a bipolar transistor, then the base voltage of that transistor is pretty much fixed. It is a bit like having a large lake with a long horizontal dam wall holding the water in the lake. When the lake water level is below that of the dam, then no water flows over the dam. If the lake level rises, then water spills over the dam. The amount of that water flow is VERY much affected by the depth of water over the dam with even a small increase in depth causing a massive increase in water flow. The same goes for the transistor base and that is why the base current flow is limited by a resistor. Without a resistor, the current flow would very quickly become many amps and burn the transistor out through sheer heating of the base/emitter junction.

The base current flow is like the setting of a valve between the collector and the emitter. If the transistor gain is 200, then 1 mA flowing into the base allows 200 mA to flow between the collector and the emitter, unless there is a load between the collector and the battery – a load which chokes off that current flow, and that is the normal case. For example, if 0.5 mA flows into the base, then a maximum of 100 mA can pass between the collector and emitter. The gain of any transistor depends on the amount of current flowing through the transistor and it varies so much that the only way to specify it properly is to draw a graph of it. Because of that, printed gain figures are given for just one or two currents. Generally, the lower the current, the higher the actual gain, so if a gain is given as 20 at 1 amp and you are only intending to have 100 mA flowing through it, then you can expect a gain much higher than 20. The voltage on the base of a single transistor which is conducting will always be 0.7 volts (or something very close to that depending on how that particular transistor was actually manufactured). That 0.7 volts stays fixed even if the current flowing into the base increases from 0.1 milliamps to 100 milliamps. So back to our T13009 transistor.

Okay, we now know a bit about the T13009 transistor, and the question asked about the 2N2222 transistor, so we look it up on the All Data Sheet web site and we find that the maximum voltage is 40-volts. That rules it out of our circuit where the voltage goes to at least 70-volts and a 2N2222 transistor would die instantly. We then look at the current and see that it has a maximum of 0.8 of an amp which means that it is really not in the ball-park for this circuit.

We know that the TIP3055 (originally packaged as the 2N3055) is very popular with free-energy builders, so we look it up and find out that it can handle voltages up to 60 volts, 90 watts of power and 15 amps of current. While it is a powerful transistor, it looks as if its voltage rating is too low for this circuit.

So, what do we do now? One way is to ask an electronics expert to suggest a suitable alternative. Another way is to look up the transistors offered by your local supplier, which for me is www.esr.co.uk which leads to this table which is one of many and which has far more entries:
We want an NPN transistor and so the MJ11016 looks possible with a 100 volt capacity, 30 amp current and 200 watt dissipation. It is a Darlington pair in a single case and so will switch on around 1.4 volts as opposed to 0.7 volts on the base, but that should not make any difference in our circuit. With a gain of 1000 a simple carbon variable resistor could be used to control the base current. There are many other transistors to choose from.

Another way to find a suitable transistor might be to go on eBay and search on “transistor” and see what transistors are popular and how much they cost. An alternative might be to try the circuit with a FET transistor such as the IRF740 which is high voltage, very powerful and not expensive. However, FET transistors trigger on voltage and draw almost no current through their “grid” connection which is the equivalent to a bipolar “base” connection and so some experimentation with the circuit may be needed.

It might also be worthwhile looking to see what transistors were chosen by Alexkor in his 5-battery circuits in chapter 6. If we do that we find the MJE13009 which has an identical specification and so is almost certainly the same as a T13009 transistor and the MJE version is readily available on eBay. Another of his transistors is the 2SC3552 transistor with 500V capability and 150 watt capacity and described as “fast acting”.

The Diode

One component which has been shown but not described is the diode or ‘rectifier’. This is a device which has a very high resistance to current flowing in one direction and a very low resistance to current flowing in the opposite direction. The base/emitter junction of a transistor is effectively a diode and, at a push, can be used as such. A proper diode is cheap to buy and has far greater voltage and current handling capacities than the base/emitter junction of a transistor.

Diodes are mainly made from one of two materials: germanium and silicon. Germanium diodes are used with very small alternating currents such as radio signals coming from an aerial. This is because a germanium diode needs only 0.2 Volts or so to carry a current while silicon needs 0.6 to 0.7 Volts (same as a silicon transistor base/emitter junction). Germanium diodes (and transistors) are very sensitive to temperature change and so are normally restricted to low power circuits. One very neat application for a silicon diode is as an ‘un-interruptible power supply’ where mains failure is caught instantly:

![Mains Unit Back-up Circuit](image)

In this circuit, the mains voltage drives the Power Supply Unit which generates 12 Volts at point ‘A’. This provides current to the Load. The diode has +12 Volts at ‘A’ and +12 Volts at point ‘B’ so there is no voltage drop across it and it will not carry current in either direction. This means that the battery is effectively isolated when the mains is...
functioning. If the Power Supply Unit output were to rise above its design level of +12 Volts, then the diode would block it from feeding current into the battery.

If the mains fails, the Power Supply Unit (‘PSU’) output will fall to zero. If the battery and diode were not there, the voltage at point ‘A’ would fall to zero, which would power-down the Load and possibly cause serious problems. For example, if the load were your computer, a mains failure could cause you to lose important data. With a battery back-up of this type, you would have time to save your data and shut your computer down before the battery ran out.

The circuit operates in a very simple fashion. As soon as the voltage at point ‘A’ drops to 0.7 Volts below the +12 Volts at point ‘B”, the diode starts feeding current from the battery to the Load. This happens in less than a millionth of a second, so the Load does not lose current. It would be worth adding a warning light and/or a buzzer to show that the mains has failed.

Diodes are also supplied packaged as a diode bridge, with four diodes enclosed inside. Usually intended for power supply rectification, they are not particularly fast-acting diodes, but are cheap and can carry a good deal of current. A common size is with the diodes rated at 1000 volts and able to carry 35 amps. Although there are many package types, a very common package looks like this:

The alternating signal is connected between two opposite corners and the pulsating DC is taken off from the other two terminals. The symbols shown above are normally marked on the flat face which is not seen in this picture. The package has a hole in the centre so that the metal case can be bolted to a heat-sink in order to keep the device reasonably cool when carrying large currents. The connections inside the package are like this:

It is possible to connect the bridge in a different way and use it as a higher voltage double diode arrangement as shown here:
By skipping the alternating current ability and connecting to just the Plus and the Minus terminals, the package provides two pairs of diodes in connected in series. This gives twice the voltage handling in both current paths and the rated current handling capacity in both of those two paths which are now connected across each other, which doubles the current handling capacity. The diagram shows how three ordinary, cheap 1000V 35 amp bridges can be connected to give one 70 amp 6000V composite diode. You could, if you wish, raise the specification of a 1000V 35A diode bridge to 2000V 70A by using four of them like this:

Diodes are specified by their voltage handling capacity and their current-carrying capacity and the speed at which they can switch on and off. For power supplies where the frequency is very low, any diode will do, but there are circuits where the switching is needed hundreds of thousand times per second and so the diode specification sheets need to be checked to see what frequency can be handled by any particular diode. Those data sheets can be downloaded free from [http://www.alldatasheet.co.kr/](http://www.alldatasheet.co.kr/).

One other thing which needs to be checked for some circuits is the voltage needed to get the diode to switch on. Two common materials used when making diodes are silicon and germanium. Germanium types have a low forward voltage of around 0.2 volts typically which silicon has about a 0.6 volt threshold generally. These voltage figures vary enormously as the current through the diode increases. Circuits which use very low voltages need germanium diodes such as the 1N34.

**Light-Emitting Diodes.**

There is a widely used variation of the diode which is extremely useful, and that is the Light Emitting Diode or ‘LED’. This is a diode which emits light when carrying current. They are available in red, green, blue, yellow or white light versions. Some versions can display more than one colour of light if current is fed through their different electrical connections.

LEDs give a low light level at a current of about 8 or 10 mA and a bright light for currents of 20 to 30 mA. If they are being used with a 12 Volt system, then a series resistor of 1K to 330 ohms is necessary. LEDs are robust
devices, immune to shock and vibration. They come in various diameters and the larger sizes are very much more visible than the tiny ones.

**Thyristors ("SCR"s) and Triacs.**

Another version of the diode is the Silicon Controlled Rectifier or ‘Thyristor’. This device carries no current until its gate receives an input current. This is just like the operation of a transistor but the SCR once switched on, stays on even though the gate signal is removed. It stays on until the current through the SCR is forced to zero, usually by the voltage across it being removed. SCRs are often used with alternating voltages (described below) and this causes the SCR to switch off if the gate input is removed. SCRs only operate on positive voltages so they miss half of the power available from alternating power supplies. A more advanced version of the SCR is the ‘Triac’ which operates in the same way as an SCR but handles both positive and negative voltages.

**Opto-Isolators.**

Another very useful variation on the LED is the Opto-Isolator. This device is a fully enclosed LED and light-sensitive transistor. When the LED is powered up, it switches the transistor on. The big advantage of this device is that the LED can be in a low voltage, low power sensing circuit, while the transistor can be in a completely separate, high voltage, high power circuit. The opto-isolator isolates the two circuits completely from each other. It is a very useful, and very popular, low-cost device.

**Alternating Current.**

A battery provides a constant voltage. This is called a Direct Current or ‘DC’ source of power. When a circuit is connected to a battery, the positive rail is always positive and the negative rail is always negative.

If you connect a battery to a circuit through a double-pole changeover switch as shown here:

![Diagram of changeover switch and alternating current voltage](image)

When the changeover switch is operated, the battery is effectively turned over or inverted. This circuit is called an ‘inverter’ because it repeatedly inverts the supply voltage. If the switch is operated on a regular, rapid basis, the graph of the output voltage is as shown on the right. This is a ‘square wave’ voltage and is used extensively in electronic equipment. It is called alternating current or ‘AC’ for short. SCRs and Triacs can be used conveniently with supply voltages of this type. Mains voltage is also AC but is rather different:

![Diagram of mains voltage wave](image)

Mains voltage varies continuously in the form of a sine wave. In Britain, the mains voltage is described as ‘240 Volts AC’ and it cycles up and down 50 times per second, i.e. 50 positive peaks and 50 negative peaks in one
second. It would be reasonable to assume that each voltage peak would be 240 Volts but this is not the case. Even though the supply is described as 240 Volts, it peaks at the square root of 2 times greater than that, i.e. 339.4 Volts. The actual supply voltage is not particularly accurate, so any device intended for mains use should be rated to 360 Volts. In America, the supply voltage is 110 Volts AC and it cycles 60 times per second, peaking at plus and minus 155 Volts. Later on, you will see how one or more diodes can be used to convert AC to DC in a unit which is sold as a ‘mains adapter’ intended to allow battery operated equipment be operated from the local mains supply.

**Coils (“Inductors”) and Solenoids.**
If you take a cardboard tube, any size, any length, and wind a length of wire around it, you create a very interesting device. It goes by the name of a ‘coil’ or an ‘inductor’ or a ‘solenoid’.

![Coil Diagram](image)

This is a very interesting device with many uses. It forms the heart of a radio receiver, it used to be the main component of telephone exchanges, and most electric motors use several of them. The reason for this is if a current is passed through the wire, the coil acts in exactly the same way as a bar magnet:

![Magnetic Force Diagram](image)
The main difference being that when the current is interrupted, the coil stops acting like a magnet, and that can be very useful indeed. If an iron rod is placed inside the coil and the current switched on, the rod gets pushed to one side. Many doorbells use this mechanism to produce a two-note chime. A ‘relay’ uses this method to close an electrical switch and many circuits use this to switch heavy loads (a thyristor can also be used for this and it has no moving parts).

A coil of wire has one of the most peculiar features of almost any electronic component. When the current through it is altered in any way, the coil opposes the change. Remember the circuit for a light-operated switch using a relay?:

You will notice that the relay (which is mainly a coil of wire), has a diode across it. Neither the relay nor the diode were mentioned in any great detail at that time as they were not that relevant to the circuit being described. The diode is connected so that no current flows through it from the battery positive to the ‘ground‘ line (the battery negative). On the surface, it looks as if it has no use in this circuit. In fact, it is a very important component which protects transistor TR3 from damage.

The relay coil carries current when transistor TR3 is on. The emitter of transistor TR3 is up at about +10 Volts. When TR3 switches off, it does so rapidly, pushing the relay connection from +10 Volts to 0 Volts. The relay coil reacts in a most peculiar way when this happens, and instead of the current through the relay coil just stopping, the voltage on the end of the coil connected to the emitter of TR3 keeps moving downwards. If there is no diode across the relay, the emitter voltage is forced to briefly overshoot the negative line of the circuit and gets dragged down many volts below the battery negative line. The collector of TR3 is wired to +12 Volts, so if the emitter gets dragged down to, say, -30 Volts, TR3 gets 42 Volts placed across it. If the transistor can only handle, say, 30 Volts, then it will be damaged by the 42 Volt peak.

The way in which coils operate is weird. But, knowing what is going to happen at the moment of switch-off, we deal with it by putting a diode across the coil of the relay. At switch-on, and when the relay is powered, the diode has no effect, displaying a very high resistance to current flow. At switch-off, when the relay voltage starts to plummet below the battery line, the diode effectively gets turned over into its conducting mode. When the voltage reaches 0.7 Volts below the battery negative line, the diode starts conducting and pins the voltage to that level until the voltage spike generated by the relay coil has dissipated. The more the coil tries to drag the voltage down, the harder the diode conducts, stifling the downward plunge. This restricts the voltage across transistor TR3 to 0.7 Volts more than the battery voltage and so protects it.

Solenoid coils can be very useful. Here is a design for a powerful electric motor patented by the American, Ben Teal, in June 1978 (US patent number 4,093,880). This is a very simple design which you can build for yourself if you want. Ben’s original motor was built from wood and almost any convenient material can be used. This is the top view:
And this is the side view:

Ben has used eight solenoids to imitate the way that a car engine works. There is a crankshaft and connecting rods, as in any car engine. The connecting rods are connected to a slip-ring on the crankshaft and the solenoids are given a pulse of current at the appropriate moment to pull the crankshaft round. The crankshaft receives four pulls on every revolution. In the arrangement shown here, two solenoids pull at the same moment.

In the side view above, each layer has four solenoids and you can extend the crankshaft to have as many layers of four solenoids as you wish. The engine power increases with every layer added. Two layers should be quite adequate as it is a powerful motor with just two layers.

An interesting point is that as a solenoid pulse is terminated, its pull is briefly changed to a push due to the weird nature of coils. If the timing of the pulses is just right on this motor, that brief push can be used to increase the power of the motor instead of opposing the motor rotation. This feature is also used in the Adams motor described in the ‘Free-Energy’ section of this document.
The strength of the magnetic field produced by the solenoid is affected by the number of turns in the coil, the current flowing through the coil and the nature of what is inside the coil ‘former’ (the tube on which the coil is wound). In passing, there are several fancy ways of winding coils which can also have an effect, but here we will only talk about coils where the turns are wound side by side at right angles to the former.

1. Every turn wound on the coil, increases the magnetic field. The thicker the wire used, the greater the current which will flow in the coil for any voltage placed across the coil. Unfortunately, the thicker the wire, the more space each turn takes up, so the choice of wire is somewhat of a compromise.

2. The power supplied to the coil depends on the voltage placed across it. Watts = Volts x Amps so the greater the Volts, the greater the power supplied. But we also know from Ohm’s Law that Ohms = Volts / Amps which can also be written as Ohms x Amps = Volts. The Ohms in this instance is fixed by the wire chosen and the number of turns, so if we double the Voltage then we double the current.

For example: Suppose the coil resistance is 1 ohm, the Voltage 1 Volt and the Current 1 Amp. Then the power in Watts is Volts x Amps or 1 x 1 which is 1 Watt.

Now, double the voltage to 2 Volts. The coil resistance is still 1 ohm so the Current is now 2 Amps. The power in Watts is Volts x Amps or 2 x 2 which is 4 Watts. Doubling the voltage has quadrupled the power.

If the voltage is increased to 3 Volts. The coil resistance is still 1 ohm so the Current is now 3 Amps. The power in Watts is Volts x Amps or 3 x 3 which is 9 Watts. The power is Ohms x Amps squared, or Watts = Ohms x Amps x Amps. From this we see that the voltage applied to any coil or solenoid is critical to the power developed by the coil.

3. What the coil is wound on is also of considerable importance. If the coil is wound on a rod of soft iron covered with a layer of paper, then the magnetic effect is increased dramatically. If the rod ends are tapered like a flat screwdriver or filed down to a sharp point, then the magnetic lines of force cluster together when they leave the iron and the magnetic effect is increased further.

If the soft iron core is solid, some energy is lost by currents flowing round in the iron. These currents can be minimised by using thin slivers of metal (called ‘laminations’) which are insulated from each other. You see this most often in the construction of transformers, where you have two coils wound on a single core. As it is convenient for mass production, transformers are usually wound as two separate coils which are then placed on a figure-of-eight laminated core.

However, while all that information is a useful, gentle introduction to what an inductor is, it does not convey the most important feature of a coil, which is that every coil stores energy when it is connected to a power source and it returns almost all of that energy when disconnected from the power source. The return of the stored energy happens in a very short period of time and that feature can produce powerful systems if you have the expertise to capture and use that power.

For example, it is not unusual for a simple 12-volt system to generate a rapid series of 400-volt pulses which can be used to recondition and charge car batteries. There are many examples of this in chapter 6.

Paul Babcock (www.paulmarlobabcock.com) destroyed more than a thousand transistors when developing his magnetic motor system as the return of coil energy is so fast that it produces high current flows, and if the capacitor into which the current return is being fed is of a low capacity, voltages higher than the supply voltage are produced. For the last hundred years or so, this sort of information has been suppressed, so take what is said in standard textbooks as being a mixture of half truths and downright lies.

As ‘Kone’ has demonstrated, if you short-circuit a powered coil, it causes multiple magnetic pulses as the power in the coil oscillates backwards and forwards through the closed circuit containing the coil:
Magnetism is a field which has not been taught or generally researched for many decades. It is not a simple subject. The magnetic strength produced by any coil increases as the number of turns in the coil increases (if the current flowing through the coil remains the same). That means that a coil with many turns can produce a higher magnetic field at a lower current than a high-current coil with few turns. However, other coil characteristics are also altered. The power loss due to the resistance of the wire in the coil increases with increased turns as they need a longer length of wire. That power loss results in the coil heating up when in use. The speed with which the magnetic field develops and decays is slower for a coil with many turns. Surprisingly, because of this, the best coil for many jobs ends up having relatively few turns.

Transformers.
Transformers are used to alter the voltage of any alternating current power source. If the alteration increases the output voltage, then the transformer is called a ‘step-up’ transformer. If the output voltage is lower than the input voltage then it is called a ‘step-down’ transformer. If the voltages are the same, it is called an ‘isolation’ transformer. A common construction looks like this:

The Coil bobbin sits on the section of the laminations marked ‘A’ above. The coil is wound on its bobbin former, first one winding and then the second winding. The bobbin is then placed on the central part of the ‘E’ shaped laminations and then completely surrounded by the laminations when the crossbar is placed on the top. The mounting strap is used to hold the two sets of laminations together and provide mounting lugs for attaching the transformer to a chassis. There are typically, twenty laminations in each set and every lamination is insulated from the adjoining laminations.

If you want to change the voltage of a battery supply, it is possible to build an electronic circuit to generate an alternating voltage and then use a transformer to change that alternating voltage to whatever voltage you want. The most common form of this, is for generating mains voltage from a 12 Volt car battery, so that mains equipment can be run in remote locations, such as boats, caravans, etc. These circuits are called ‘inverters’ and they are very popular pieces of equipment. The voltage in the secondary coil of any transformer is determined by the ratio of the turns in the primary and secondary windings.

For example; if there is a 10 Volt alternating voltage available and you have a transformer which has 100 turns in the primary coil and 1000 turns in the secondary coil. If you connect the 10 Volts across the primary, there will be 100 Volts generated across the secondary coil.
Instead, if you connect the 10 Volts across the secondary coil, a voltage of 1 Volts will be generated across the primary winding. This is because there is a 10:1 ratio between the two windings. The Law of Conservation of Energy applies to transformers as it does to everything else. The power input to the primary winding will be the same as the power in the secondary winding minus the losses. The losses, in this case, will be a temperature rise of the whole transformer. If the current passed through the transformer is well below its rated capacity, then the losses will be small. The important point is that 10 Volts at 1 Amp into the primary winding will generate 100 Volts in the secondary, but at somewhat less than 0.1 Amps: Power Input is 10 Watts and Power Output is almost 10 Watts. The voltage has been raised to 100 Volts but the potential current draw has been reduced from 1 Amp to 0.1 Amps (100 mA).

In practice, the thickness of the wire used in the windings is very important. If the voltage to be placed across the winding is high, then the wire diameter will be small. Coil windings have fairly low resistances but this is not critical in circuits as coils operate in a peculiar way. Coils have AC ‘impedance’ in addition to their DC ‘resistance’. While Direct Current (from a battery, say) can flow quite easily through a coil with low resistance, Alternating Current may have a hard job getting through the coil due to its high ‘impedance’. Sometimes, coils are used to choke off any AC ripple (interference) coming along a DC power cable. When a coil is used for this purpose it is called a ‘choke’. Each coil has its own resonant frequency and at that frequency it is very difficult for AC to get through the coil. Crystal set radios work on that principle:

In practice, the thickness of the wire used in the windings is very important. If the voltage to be placed across the winding is high, then the wire diameter will be small. Coil windings have fairly low resistances but this is not critical in circuits as coils operate in a peculiar way. Coils have AC ‘impedance’ in addition to their DC ‘resistance’. While Direct Current (from a battery, say) can flow quite easily through a coil with low resistance, Alternating Current may have a hard job getting through the coil due to its high ‘impedance’. Sometimes, coils are used to choke off any AC ripple (interference) coming along a DC power cable. When a coil is used for this purpose it is called a ‘choke’. Each coil has its own resonant frequency and at that frequency it is very difficult for AC to get through the coil. Crystal set radios work on that principle:

Here, the aerial picks up every radio station broadcasting in the area. These are all at different frequencies and they all head down the aerial wire, looking for the easiest path to the earth connection. Most of them run through the coil with no problem whatsoever. If the resonant frequency of the coil matches the frequency of one of the radio stations, then that radio signal (and only that signal) finds it very hard to get through the coil and looks for an easier path to earth. The next easiest path is through the diode and the headphones, so the signal goes that way. The diode blocks part of the signal which generates the sound of the radio broadcast in the headphones.

This system works very well indeed if there is a good radio signal. A germanium diode is used as the radio signal voltage is very small and a germanium diode operates on 0.2 Volts while a silicon diode needs 0.7 Volts to operate. That difference is significant at these very low voltages. The resonant frequency of the coil depends on the number of turns in the coil. In this design, the coil has a slider which allows the number of turns to be altered and so, different radio stations to be tuned in.

Rectification and Power Supplies.
We now have the question of how do we turn an alternating voltage into a constant ‘direct’ voltage. The crystal radio set operates by chopping off half of the alternating radio signal. If we were to do this to the output from a mains transformer with an output of say, 12 Volts AC, the result is not very satisfactory:
Here, we have the situation shown in the upper diagram. The output consists of isolated pulses at 50 per second. You will notice that there is no output power for half of the time. The negative part of the waveform is blocked by the high resistance of the diode while the positive part of the waveform is allowed through by the low resistance of the ‘forward-biased’ diode. It should be remembered that the diode drops 0.7 Volts when conducting so the output of the half-wave rectified transformer will be 0.7 Volts lower than the transformer’s actual output voltage.

If four diodes are used instead of one, they can be arranged as shown in the lower diagram. This arrangement of diodes is called a ‘bridge’. Here the positive part of the waveform flows through the upper blue diode, the load ‘L’ and on through the lower blue diode. The negative part flows through the left hand red diode, the load and then the right hand red diode. This gives a much better output waveform with twice the power available. The output voltage will be 1.4 Volts less than the transformer output voltage as there are two silicon diodes in the supply chain.

The output from even the full-wave rectifier is still unsatisfactory as there is a voltage drop to zero volts 100 times per second. Only a few devices operate well with a power supply like that, an incandescent bulb as used in a car can use this output, but then, it could use the original AC supply without any rectification. We need to improve the output by using a reservoir device to supply current during those moments when the voltage drops to zero. The device we need is a **Capacitor** which used to be called a ‘condenser’. The circuit of a mains unit using a capacitor is shown here:
This produces a much better result as the capacitor stores some of the peak energy and gives it out when the voltage drops. If the load on the unit is light with not very much current taken from it, the output voltage is quite good. However, if the current drain is increased, the output voltage gets dragged down 100 times per second. This voltage variation is called ‘ripple’ and if the unit is supplying an audio system or a radio, the ripple may well be heard as an annoying hum. The larger the capacitor for any given current draw, the smaller the ripple.

To improve the situation, it is normal to insert an electronic control circuit to oppose the ripple:

This circuit uses one new component, a new variety of diode called a ‘Zener’ diode. This device has an almost constant voltage drop across it when its current-blocking direction breaks down. The diode is designed to operate in this state to provide a reference voltage. The circuit merely uses a tiny current from the top of the zener diode to drive the Darlington pair emitter-follower transistors used to provide the output current.

With this circuit, when the output current is increased, the resistance of the transistor pair automatically reduces to provide more current without varying the output voltage. The 1K resistor is included to give the transistors a completed circuit if no external equipment is connected across the output terminals. The zener diode is chosen to give 1.4 Volts more than the required output voltage as the two transistors drop 1.4 Volts when conducting.

You should note that the output transistor is dropping 6 Volts at the full supply current. Watts = Volts x Amps so the power dissipated by the transistor may be quite high. It may well be necessary to mount the transistor on an aluminium plate called a ‘heat sink’ to keep it from overheating. Some power transistors, such as the 2N3055, do
not have the case isolated from the active parts of the transistor. It is good practice to use a mica gasket between the transistor and the heat-sink as it conducts heat without making an electrical connection to the metal heat-sink.

A capacitor, being an electrical reservoir, can be used as part of a timer circuit. If the current flow into it is restricted by passing it through a resistor, the length of time between starting the flow on an empty capacitor, and the voltage across the capacitor reaching some chosen level, will be constant for a high-quality capacitor.

As the voltage increase tails off, it becomes more difficult to measure the difference accurately, so if the capacitor is to be used for generating a time interval, it is normal to use the early part of the graph area where the line is fairly straight and rising fast.

**The Voltage Doubler.**

It is possible to increase the output voltage of a transformer although this does reduce its ability to supply current at that voltage. The way that this is done is to feed the positive cycles into one storage capacitor and the negative cycles into a second reservoir capacitor. This may sound a little complicated, but in reality, it isn't. A circuit for doing this is shown here:

![Diagram of the Voltage Doubler](image)

With this circuit, the transformer output is some voltage, say "V" volts of AC current. This output waveform is fed to capacitor "C1" through diode "D1" which lops off the negative part of the cycle. This produces a series of positive half-cycles which charge up capacitor "C1" with a positive voltage of "V".

The other half of the output is fed to capacitor "C2" through diode "D2" which cuts off the positive part of the cycle, causing capacitor "C2" to develop a voltage of -V across it. As the two capacitors are 'in series' and not placed across each other, their voltages add up and produce twice the transformer output voltage.

A word of warning here. The transformer is producing an AC waveform and these are marked with the average voltage of the waveform, which is usually a sine wave. The peak voltage of a sinewave is 41% greater than this, so if your transformer has an AC output of 10 volts, then the peaks fed to the capacitors will be about 14.1 volts. If there is no current draw from the capacitors (that is, with the load switched off), then each capacitor will charge to this 14.1 volts and the overall output voltage will be 28.2 volts and **not** the 20 volts which you might expect. You need to understand that as this is only a half-wave supply, there will be considerable ripple on the output voltage if the current draw is high.

Using one additional smoothing capacitor and paying attention to the voltage ratings of the capacitors, the 28 volts supply circuit might be like this:
Multivibrators: The Bistable.

The number of electronic circuits which can be built with basic components such as resistors, capacitors, transistors, coils, etc. is limited only by your imagination and needs. Here is a circuit where two transistors operate as a pair:

This circuit has two stable states and so it is called a “bi” “stable” or “bistable” circuit. It is important to understand the operation of this simple and useful circuit.

If press-button switch ‘A’ is pressed, it short-circuits the base/emitter junction of transistor TR1. This prevents any current flowing in the base/emitter junction and so switches TR1 hard off. This makes the voltage at point ‘C’ rise as high as it can. This leaves transistor TR2 powered by R1 and R2 which have 11.3 Volts across them and switches TR2 hard on.

This pulls point ‘D’ down to about 0.1 Volts. This happens in less than a millionth of a second. When the press-button switch ‘A’ is released, transistor TR1 does not switch on again because its base current flows through resistor R3 which is connected to point ‘D’ which is far, far below the 0.7 Volts needed to make TR1 start conducting.

The result is that when press-button ‘A’ is pressed, transistor TR2 switches on and stays on even when press-button ‘A’ is released. This switches transistor TR3 off and starves the Load of current. This is the first ‘stable state’.

The same thing happens when press-button ‘B’ is pressed. This forces transistor TR2 into its ‘off’ state, raising point ‘D’ to a high voltage, switching transistor TR3 hard on, powering the Load and holding transistor TR1 hard off. This is the second of the two ‘stable states’.

In effect, this circuit ‘remembers’ which press-button was pressed last, so millions of these circuits are used in computers as Random Access Memory (‘RAM’). The voltage at point ‘C’ is the inverse of the voltage at point ‘D’, so if ‘D’ goes high then ‘C’ goes low and if ‘D’ goes low, then ‘C’ goes high. In passing, the output at ‘D’ is often called ‘Q’ and the output at ‘C’ is called ‘Q-bar’ which is shown as the letter Q with a horizontal line drawn above it. This is shown on the next circuit diagram.

A minor variation of this circuit allows a load to be energised when the circuit is powered up:
When powered down, the capacitor ‘C1’ in this circuit is fully discharged through resistor ‘R6’. When the 12 Volts supply is connected to the circuit, capacitor C1 does not charge instantly and so holds the base of TR2 down below 0.7 Volts for much longer than it takes for transistor TR1 to switch on (which, in turn, holds TR2 hard off). Mind you, if it is not necessary to have the Load held powered on indefinitely, then an even more simple circuit can do this:

Here, when the switch is closed, both sides of the capacitor C1 are at +12 Volts and this causes the 1K8 resistor to conduct heavily, driving the transistor and powering the load. The capacitor charges rapidly through the transistor and reaches the point at which it can no longer keep the transistor switched on. When the battery is switched off, the 1M resistor discharges the capacitor, ready for the next time the battery is connected.

**the Monostable Multivibrator.**

The monostable has one stable state and one unstable state. It can be flipped out of its stable state but it will ‘flop’ back into its stable state. For that reason, it is also known as a ‘flip-flop’ circuit. It is similar to a bistable circuit, but one of the cross-link resistors has been replaced by a capacitor which can pass current like a resistor, but only for a limited amount of time, after which, the capacitor becomes fully charged and the current flow stops, causing the ‘flop’ back to the stable state once more.

In this circuit, the ‘R’ resistor and the ‘C’ capacitor values determine how long the monostable will be in its unstable state. The circuit operates like this:

1. In the stable state, transistor TR1 is off. Its collector voltage is high, pushing the left hand side of capacitor ‘C’ to near +12 Volts. As the right hand side of capacitor ‘C’ is connected to the base of TR2 which is at 0.7 Volts, the capacitor gets charged to about 11.3 Volts.
2. The press-button switch is operated briefly. This feeds current through its 10K resistor to the base of transistor TR1, switching it hard on. This drops the collector voltage of TR1 to near 0 Volts, taking the left hand side of the capacitor with it.

3. As the voltage across a capacitor can't change instantly, the right hand side of the capacitor drives the base of transistor TR2 down below 0.7 Volts, causing TR2 to switch off.

4. The circuit can't hold TR2 in its 'off' state for ever. The resistor 'R' feeds current into the capacitor, forcing the voltage at the base of TR2 steadily upwards until the voltage reaches 0.7 Volts and transistor TR2 switches on again, forcing TR1 off again (provided that the press-button switch has been released). This is the stable state again. If the press-button switch is held on, then both transistors will be on and the output voltage will still be low. Another output pulse will not be generated until the press-button is let up and pressed again.

This circuit could be used to switch a microwave oven on for any chosen number of seconds, create a delay on your home-built burglar alarm, to give you time to switch it off after walking through your front door, operate a solenoid valve to feed a pre-determined quantity of beverage into a bottle on a production line, or whatever...

**The Astable Multivibrator.**

The astable circuit is the monostable with a second capacitor added so that neither state is stable. This results in the circuit flopping backwards and forwards continuously:

The rate of switching is controlled by the R1/C1 and R2/C2 combinations. The load's ON time to its OFF time is called the 'mark-space' ratio, where the ON period is the 'mark' and the OFF period is the 'space'. If you choose to use electrolytic capacitors which have their own polarity, then the +ve end of each capacitor is connected to the transistor collector.

While it is good to understand how these multivibrator circuits operate and can be built, nowadays there are pre-built circuits encased in a single package which you are much more likely to choose to use. These are called Integrated Circuits or 'ICs' for short. We will be discussing these shortly. Before we do, notice that in the circuit above, transistor TR3 has been changed to a new variety called a Field Effect Transistor ('FET'). This type of transistor is newer than the 'bipolar' transistors shown in the earlier circuits. FETs come in two varieties: 'n-channel' which are like NPN transistors and 'p-channel' which are like PNP transistors.

FETs are more difficult to make but have now reached a level of cost and reliability which makes them very useful indeed. They require almost no base current (called 'gate' current with this type of transistor) which means that they have almost no effect on any circuit to which they are attached. Also, many of them can handle large currents and boast major power handling capabilities. Because of this, it is usual to see them packaged with a metal plate mounting, ready to be bolted to an aluminium heat-sink plate to help dissipate the heat generated by the large amount of power flowing through them. The ‘RFP50N06’ shown above can handle up to 50 Volts and carry up to 60 Amps, which is serious power handling.

**Inverters and Truth Tables.**

Consider the following circuit:
If neither of the press-button switches are operated, the transistor has no base/emitter current flow and so it is off. This places the collector voltage at 'C' near the positive rail (+5 Volts).

If press-button switch 'A' is operated, the base voltage tries to rise to half of the battery voltage but doesn't make it because the transistor base pins it down to 0.7 Volts. This feeds base current to the transistor, switching it hard on and causing the output at 'C' to drop to nearly 0 Volts.

If press-button switch 'B' is operated (don't do this when switch 'A' is closed or you will get a very high 'short-circuit' current flowing directly through the two switches) it has no effect on the output voltage which will stay high.

If we re-draw the circuit like this:

We can see that if the voltage at the input 'A' is taken high, then the output voltage at 'C' will be low. If the voltage at the input 'A' is taken low, then the output voltage at 'C' will be high. A circuit which does this is called an 'Inverter' because it 'inverts' (or 'turns upside down') the input voltage.

We can summarise this operation in a table. Personally, I would call the table an 'Input/Output' table, but for no obvious reason, the standard name is a 'Truth' table. The purpose of this table is to list all of the possible inputs and show the corresponding output for each input.

Another standard, is to substitute ‘1’ for ‘High Voltage’ and ‘0’ for ‘Low Voltage’. You will notice that many items of electrical and electronic equipment have these symbols on the ON / OFF switch. In computer circuitry (hah! you didn’t notice that we had moved to computer circuits, did you?), the ‘0’ represents any voltage below 0.5 Volts and the ‘1’ represents any voltage above 3.5 Volts. Many, if not most, computers operate their logic circuits on 5 Volts. This Inverter circuit is a ‘logic’ circuit.

A criticism of the above circuit is that its input resistance or ‘impedance’ is not particularly high, and its output impedance is not particularly low. We would like our logic circuits to be able to operate the inputs of eight other logic circuits. The jargon for this is that our circuit should have a ‘fan-out’ of eight.

Let's go for a simple modification which will improve the situation:
Here, The input impedance has been increased by a factor of 100 by using a Darlington pair of transistors which need far less base current, and so can have a much higher input resistor.

Unfortunately, the output impedance is still rather high when the transistors are in their OFF state as any current taken from the positive line has to flow through the 1K8 (1800 ohm) resistor. But we need this resistor for when the transistors are in their ON state. We really need to change the 1K8 resistor for some device which has a high resistance at some times and a low resistance at other times. You probably have not heard of these devices, but they are called ‘transistors’.

There are several ways to do this. We might choose to use PNP transistors (we normally use NPN types) and connect these in place of the 1K8 resistor. Perhaps we might use a circuit like this:

This circuit is starting to look complicated and I don’t like complicated circuits. It is not as bad as it looks. The NPN transistors at the bottom are almost the same as the previous circuit. The only difference is that the collector load is now two 100 ohm resistors plus the resistance of the two transistors. If the PNP transistors are OFF when the NPN transistors are ON, then the circuit loading on the NPN transistors will be negligible and the whole of the NPN transistors output will be available for driving external circuits through the lower 100 ohm resistor (a large ‘fan-out’ for the ‘0’ logic state). To make sure that the PNP transistors are hard off before the NPN transistors start to switch on, the resistor ‘R1’ needs to be selected carefully.

The PNP transistors are an exact mirror image of the NPN side, so resistor R2 needs to be selected carefully to ensure that the NPN transistors are switched hard OFF before the PNP transistors start to switch ON.

You need not concern yourself unduly with that circuit, because you will almost certainly use an Integrated Circuit rather than building your own circuit from ‘discrete’ components. An Integrated Circuit containing six complete inverters is the 7414 which is shown above. This comes in a small black case with two rows of 7 pins which make it look a bit like a caterpillar. Because there are two row of pins, the packaging is called “Dual In-Line” or “DIL” for short.

Now, consider the following circuit:
This circuit operates the same way as the Inverter circuit, except that it has two inputs ('A' and 'B'). The output voltage at 'C' will be low if either, 'A OR B' or both, of the inputs is high. The only time that the output is high, is when both Input 'A' and Input 'B' are low. Consequently, the circuit is called an "OR" gate. Strictly speaking, because the output voltage goes Down when the input voltage goes Up, it is called a "Not OR" gate, which gets shortened to a "NOR" gate. In this context, the word "not" means "inverted". If you fed the output 'C' into an inverter circuit, the resulting circuit would be a genuine "OR" gate. The digital circuit symbols for an AND gate, a NAND gate, an OR gate and a NOR gate are:

<table>

Gating.
These common chips are usually supplied with 2, 4 or 8 inputs. So, why is it called a “Gate” - isn't it just a double inverter? Well, yes, it is a double inverter, but a double inverter acts as a gate which can pass or block an electronic signal. Consider this circuit:

Here, transistors ‘TR1’ and ‘TR2’ are connected to form an astable (multivibrator). The astable runs freely, producing the square wave voltage pattern shown in red. Transistor ‘TR3’ passes this voltage signal on. TR3 inverts the square wave, but this has no practical effect, the output being the same frequency square wave as the signal taken from the collector of TR2.

If the press-button switch at point ‘A’ is operated, a current is fed to the base of TR3 which holds it hard on. The voltage at point ‘C’ drops to zero and stays there. The square wave signal coming from the collector of TR2 is blocked and does not reach the output point ‘C’. It is as if a physical ‘gate’ has been closed, blocking the signal from reaching point ‘C’. As long as the voltage at point ‘A’ is low, the gate is open. If the voltage at point ‘A’ goes high, the gate is closed and the output is blocked.

There is no need for a manual switch at point ‘A’. Any electronic switching circuit will do:
Here, a slow-running astable is substituted for the manual switch. When the output voltage of ‘Astable 2’ goes high, it switches the gate transistor ‘TR3’, holding it hard on and blocking the square-wave signal from ‘Astable 1’. When the output voltage of ‘Astable 2’ goes low, it frees transistor ‘TR3’ and it then passes the ‘Astable 1’ signal through again. The resulting gated waveform is shown in red at point ‘C’ and it is bursts of signal, controlled by the running rate of ‘Astable 2’. This is the sort of waveform which Stan Meyer found very effective in splitting water into Hydrogen and Oxygen (see Chapter 10).

This circuit could also be drawn as:

The small circle on the output side of logic devices is to show that they are inverting circuits, in other words, when the input goes up, the output goes down. The two logic devices we have encountered so far have had this circle: the Inverter and the NAND gate.

If you wish, you can use a NAND gate chip which has the circuitry also built as a Schmitt trigger, which as you will recall, has a fast-switching output even with a slowly moving input. With a chip like that, you can get three different functions from the one device:
If the two inputs of a NAND gate are connected together, then the output will always be the opposite of the input, i.e. the gate acts as an inverter. This arrangement also works as a Schmitt Trigger due to the way the NAND gate circuitry is built. There are several packages built with this type of circuitry, the one shown here is the “74132” chip which contains four “dual-input” NAND gates. Gates can have almost any number of inputs but it is rare to need more than two in any given circuit. Another chip with identical pin connections is the 4011 chip (which is not a Schmitt circuit). This ‘quad dual-input’ NAND gate package uses a construction method called “CMOS” which is very easily damaged by static electricity until actually connected into a circuit. CMOS chips can use a wide range of voltages and take very little current. They are cheap and very popular.

The number of devices built into an Integrated Circuit is usually limited by the number of pins in the package and one pin is needed for one connection to ‘the outside world’. Packages are made with 6 pins (typically for opto-isolators), 8 pins (many general circuits), 14 pins (many general circuits, mostly computer logic circuits), 16 pins (ditto, but not as common) and then a jump to large numbers of pins for Large Scale devices such as microprocessors, memory chips, etc. The standard IC package is small:

Prototype circuits are often built on ‘strip board’ which is a stiff board with strips of copper running along one face, and punched with a matrix of holes. The strips are used to make the electrical connections and are broken where necessary. This strip board is usually called “Veroboard”:

Nowadays, the strip board holes are spaced 2.5 mm (1/10”) apart which means that the gaps between the copper strips is very small indeed. I personally, find it quite difficult to make good solder joints on the strips without the solder bridging between two adjacent strips. Probably, a smaller soldering iron is needed. I need to use an 8x magnifying glass to be sure that no solder bridging remains in place before a new circuit is powered up for the first
time. Small fingers and good eyesight are a decided advantage for circuit board construction. The narrow spacing of the holes is so that the standard IC DIL package will fit directly on the board.

Circuits built using computer circuitry, can experience problems with mechanical switches. An ordinary light switch turns the light on and off. You switch it on and the light comes on. You switch it off and the light goes off. The reason it works so well is that the light bulb takes maybe, a tenth of a second to come on. Computer circuits can switch on and off 100,000 times in that tenth of a second, so some circuits will not work reliably with a mechanical switch. This is because the switch contact bounces when it closes. It may bounce once, twice or several times depending on how the switch is operated. If the switch is being used as an input to a counting circuit, the circuit may count 1, 2 or several switch inputs for one operation of the switch. It is normal to “de-bounce” any mechanical switch. This could be done using a couple of NAND gates connected like this:

**The NAND Latch.**

Here, the mechanical switch is buffered by a ‘latch’. When the ‘Set’ switch is operated, the output goes low. The unconnected input of gate ‘1’ acts as if it has a High voltage on it (due to the way the NAND gate circuit was built). The other input is held low by the output of gate ‘2’. This pushes the output of gate ‘1’ high, which in turn, holds the output of gate ‘2’ low. This is the first stable state.

When the ‘Set’ switch is operated, the output of gate ‘2’ is driven high. Now, both inputs of gate ‘1’ are high which causes its output to go low. This in turn, drives one input of gate ‘2’ low, which holds the output of gate ‘2’ high. This is the second stable state.

To summarise: pressing the ‘Set’ switch any number of times, causes the output to go low, once and only once. The output will stay low until the ‘Reset’ switch is operated once, twice or any number of times, at which point the output will go high and stay there.

This circuit uses just half of one cheap NAND gate chip to create a bistable multivibrator which is physically very small and light.

**Gate Circuits.**

NAND Gates can be used as the heart of many electronic circuits apart from the logic circuits for which the package was designed. Here is a NAND gate version of the rain alarm described earlier. The ‘4011B’ chip is a CMOS device which has a very high input impedance and can operate at convenient battery voltages (3 to 15 Volts):
This circuit is comprised of a rain sensor, two astable multivibrators and a power-driver feeding a loudspeaker:

1. The rain sensor is a wired-up strip board or similar grid of interlaced conductors, forming a voltage-divider across the battery rails.

2. The output voltage from this, at point 'A' in the circuit diagram, is normally low as the strip board is open-circuit when dry. This holds the first NAND gate locked in the OFF state, preventing the first astable from oscillating. This first astable is colour-coded blue in the diagram. Its frequency (the pitch of the note it produces) is governed by the values of the 47K resistor and the 1 microfarad capacitor. Reducing the value of either of these will raise the frequency (note pitch). If rain falls on the sensor, the voltage at point 'A' goes high letting the astable run freely. If the voltage at 'A' does not rise sufficiently when it rains, increase the value of the 1M resistor.

3. The output of the first astable is a low voltage when the sensor is dry. It is taken from point 'B' and passed to the gating input of the second astable, holding it in its OFF state. The speed of the second astable is controlled by the value of the 470K resistor and the 0.001 microfarad capacitor. Reducing the value of either of these will raise the pitch of the note produced by the astable. The rate at which this astable operates is very much higher than the first astable.

When it rains, the voltage at point 'A' rises, letting the first astable oscillate. As it does so, it turns the second astable on and off in a steady rhythmic pattern. This feeds repeated bursts of high speed oscillations from the second astable to point 'C' in the diagram.

4. The Darlington-pair emitter-follower transistors cause the voltage at point 'D' to follow the voltage pattern at point 'C' (but 1.4 Volts lower voltage due to the 0.7 Volts base/emitter voltage drop for each transistor). The high gain of the two transistors ensures that the output of the second oscillator is not loaded unduly. These power-driver transistors place the output voltage across an eighty ohm loudspeaker, padded with a resistor to raise the overall resistance of the combination. The voltage pattern produced is shown at point 'D' and is an attention-grabbing sound.

So, why does this circuit oscillate?:

The circuit will not oscillate if the gating input is low, so assume it to be high. Take the moment when the output of gate 2 is low. For this to happen, the inputs of gate 2 have to be high. As the output of gate 1 is wired directly to the inputs of gate 2, it must be high, and for that to be true, at least one of its inputs must be low. This situation is
shown on the right.

There is now a full voltage drop between point ‘A’ and point ‘B’. The 47K resistor and the capacitor are in series across this voltage drop, so the capacitor starts to charge up, progressively raising the voltage at point ‘C’. The lower the value of the resistor, the faster the voltage rises. The larger the value of the capacitor, the slower the voltage rises.

When the voltage at point ‘C’ rises sufficiently, the 100K resistor raises the input voltage of gate 1 far enough to cause it to change state. This creates the following situation:

Now, the voltage across ‘A’ to ‘B’ is reversed and the voltage at point ‘C’ starts to fall, its rate governed by the size of the 47K resistor and the 1 microfarad capacitor. When the voltage at point ‘C’ falls low enough, it takes the input of gate 1 low enough (via the 100K resistor) to cause gate 1 to switch state again. This takes the circuit to the initial state discussed. This is why the circuit oscillates continuously until the gating input of gate 1 is taken low to block the oscillation.

Now, here is a NAND gate circuit for a sequential on/off switch:

This circuit turns the Light Emitting Diode on and off repeatedly with each operation of the press-button switch. When the on/off switch is closed, capacitor ‘C1’ holds the voltage at point ‘A’ low. This drives the output of gate 1 high, which moves the inputs of gate 2 high via the 100K resistor ‘R1’. This drives the voltage at point ‘B’ low, turning the transistor off, which makes the LED stay in its off state. The low voltage at point ‘B’ is fed back via the 100K resistor ‘R2’ to point ‘A’, keeping it low. This is the first stable state.

As the output of gate 1 is high, capacitor ‘C2’ charges up to that voltage via the 2M2 resistor. If the press-button switch is operated briefly, the high voltage of ‘C2’ raises the voltage of point ‘A’, causing gate 1 to change state, and consequently, gate 2 to change state also. Again, the high voltage at point ‘B’ is fed back to point ‘A’ via the 100K resistor ‘R2’, keeping it high, maintaining the situation. This is the second stable state. In this state, point ‘B’ has a high voltage and this feeds the base of the transistor via the 4.7K resistor, turning it on and lighting the LED.

In this second state, the output of gate 1 is low, so capacitor ‘C2’ discharges rapidly to a low voltage. If the press-button switch is operated again, the low voltage of ‘C2’ drives point ‘A’ low again, causing the circuit to revert to its original stable state.

We could, if we wished, modify the circuit so that it would operate for three or four minutes after switch-on but then stop operating until the circuit was turned off and on again. This is accomplished by gating one of the gates instead of just using both as inverters. If we gated the second gate, then the LED would be left permanently on,
so we will modify the first gate circuit:

![Image of modified gate circuit]

This circuit operates exactly the same way as the previous circuit if, and only if, the voltage at point 'C' is high. With the voltage at point 'C' high, gate 1 is free to react to the voltage at point 'A' as before. If the voltage at point 'C' is low, it locks the output of gate 1 at the high level, forcing the output of gate 2 to the low level and holding the LED off.

When the circuit is first powered up, the new 100 microfarad capacitor 'C3' is fully discharged, which pulls the voltage at point 'C' to nearly +9 Volts. This allows gate 1 to operate freely, and the LED can be toggled on and off as before. As time passes, the charge on capacitor 'C3' builds up, fed by the 2M2 resistor. This causes the voltage at point 'C' to fall steadily. The rate of fall is governed by the size of the capacitor and the size of the resistor. The larger the resistor, the slower the fall. The larger the capacitor, the slower the fall. The values shown are about as large as are practical, due to the current 'leakage' of 'C3'.

After three or four minutes, the voltage at point 'C' gets driven low enough to operate gate 1 and prevent further operation of the circuit. This type of circuit could be part of a competitive game where the contestants have a limited time to complete some task.

**The NAND Gate as an Amplifier.**

Gates can also be used as amplifiers although they are not intended to be used that way and there are far better integrated circuits from which to build amplifiers. The following circuit shows how this can be done:

![Image of NAND gate as amplifier]

This circuit operates when there is a sudden change in light level. The previous light-level switching circuit was designed to trigger at some particular level of increasing or decreasing level of lighting. This is a shadow-detecting circuit which could be used to detect somebody walking past a light in a corridor or some similar situation.

The voltage level at point 'A' takes up some value depending on the light level. We are not particularly interested
in this voltage level since it is blocked from the following circuitry by capacitor ‘C1’. Point ‘B’ does not get a voltage pulse unless there is a sudden change of voltage at point ‘A’, i.e. there is a sudden change in light level reaching the light-dependent resistor ORP12.

The first gate amplifies this pulse by some fifty times. The gate is effectively abused, and forced to operate as an amplifier by the 10M resistor connecting its output to its input. At switch-on, the output of gate 1 tries to go low. As its voltage drops, it starts to take its own inputs down via the resistor. Pushing the voltage on the inputs down, starts to raise the output voltage, which starts to raise the input voltage, which starts to lower the output voltage, which ....... The result is that both the inputs and the output take up some intermediate voltage (which the chip designers did not intend). This intermediate voltage level is easily upset by an external pulse such as that produced by the ORP12 through capacitor ‘C1’. When this pulse arrives, an amplified version of the pulse causes a voltage fluctuation at the output of gate 1.

This voltage change is passed through the diode and variable resistor to the input of gate 2. Gates 2 and 3 are wired together as a makeshift Schmitt trigger in that the output voltage at point ‘D’ is fed back to point ‘C’ via a high value resistor. This helps to make their change of state more rapid and decisive. These two gates are used to pass a full change of state to the output stage transistor. The variable resistor is adjusted so that gate 2 is just about to change state and is easily triggered by the pulse from amplifier gate 1. The output is shown as an LED but it can be anything you choose. It could be a relay used to switch on some electrical device, a solenoid used to open a door, a counter to keep track of the number of people using a passageway, etc. etc. Please note that an operational amplifier chip (which will be described later) is a far better choice of IC for a circuit of this type. A gate amplifier is shown here only to show another way that a gate can be utilised.

The NE555 Timer Chip.

There is an exceptionally useful chip designated by the number 555. This chip is designed to be used in oscillator and timer circuits. Its use is so widespread that the chip price is very low for its capability. It can operate with voltages from 5 Volts to 18 Volts and its output can handle 200 mA. It takes 1 mA when its output is low and 10 mA when its output is high. It comes in an 8-pin Dual-In-Line package and there is a 14-pin package version which contains two separate 555 circuits. The pin connections are:

```
0 Volts Trigger Output
1 555 Discharge
2 Threshold
4 Reset
5 Control Voltage
```

This device can operate as a monostable or astable multivibrator, a Schmitt trigger or an inverting buffer (low current input, high current output).

Here it is wired as a Schmitt trigger, and for variation, it is shown triggering a triac which will then stay on until the circuit is powered down (an SCR could be used just as well with this DC circuit):
And here, a monostable:

```
Monostable multivibrator
```

And here are two astables, the second of which has fixed, equal mark/space ratio and the first a high output voltage time determined by $Ra + Rb$ and a low voltage output time determined by $Rb$ (2:1 in this case):

```
Astable multivibrators
```

Frequency = \( \frac{0.72}{C \times R} \)
Astable Frequencies

Note: The high leakage of large value electrolytic capacitors prevents them being used with high value resistors in timing circuits. Instead, use a smaller capacitor and follow the timing circuit with a “divide-by-N” chip to give accurately timed long periods. Not all 555 chips have a manufacturing quality sufficient for them to operate reliably above 20,000 Hz, so for the higher frequencies the chip needs to be selected after testing its actual performance.

We can also wire the 555 to give a variable mark/space ratio while holding the frequency of the oscillation fixed:

The output waveform changes drastically as the variable resistor is adjusted, but the frequency (or pitch of the note) of the output stays unaltered.

A variable-frequency version of this circuit can be produced by changing the 33K resistor to a variable resistor as shown here:
Here, the 33K resistor has been replaced by two variable resistors and one fixed resistor. The main variable resistor is 47K in size (an almost arbitrary choice) and it feeds to a second variable resistor of 4.7K in size. The advantage of this second variable resistor is that it can be set to its mid point and the frequency tuning done with the 47K variable. When the frequency is approximately correct, the 4.7K variable can be used to fine tune the frequency. This is convenient as the small variable will have ten times more knob movement compared to the main variable (being just 10% of its value).

Obviously, it is not necessary to have the fine-tuning variable resistor, and it can be omitted without changing the operation of the circuit. As the 47K variable resistor can be set to zero resistance and the 4.7K variable resistor can also be set to zero resistance, to avoid a complete short-circuit between output pin 3 and the 50K Mark/Space variable resistor, a 3.3K fixed resistor is included. In this circuit, the frequency is set by your choice of the resistor chain 47K + 4.7K + 3.3K (adjustable from 55K to 3.3K) and the 100nF (0.1 microfarad) capacitor between pin 6 and the zero volt rail. Making the capacitor larger, lowers the frequency range. Making the resistors larger, also lowers the frequency range. Naturally, reducing the size of the capacitor and/or reducing the size of the resistor chain, raises the frequency.

One 555 chip can be used to gate a second 555 chip via its pin 4 ‘Reset’ option. You will recall that we have already developed a circuit to do this using two astables and a transistor. We also generated the same effect using four NAND gates. Here, we will create the same output waveform using the more conventional circuitry of two 555 chips:

Both of the NE555 circuits can be bought in a single 14-pin DIL package which is designated ‘NE556’:

There are many additional circuit types which can be created with the 555 chip. If you wish to explore the possibilities, I suggest that you download the free pdf “50 555 Projects” from the web site:
The 555 chip can also produce a sine wave output:

Or, if you wish, a bi-stable multivibrator:

All right, suppose that we want to design and build a circuit to do the same as Bob Beck’s pulser circuit mentioned in chapter 11. The requirements are to produce a square wave output pulsing four times per second using a 27 volt power supply, the circuit being powered by three small PP3 size batteries. An obvious choice for the circuit seems to be a 555 timer chip which is small, robust and cheap and a suitable circuit would appear to be:

This leaves us with choosing a value for the capacitor and the resistor. We need to pay attention to the fact that the circuit will be running on 27 volts and while the capacitor will not charge up to anything like that voltage, we still will pick one which will survive 27V. Looking on the local eBay shows that a pack of ten capacitors of 1 microfarad rated at 50V can be bought for just £1 including postage, so take that as the value for “C”. Looking at the 555 table of frequencies above shows:
Which indicates that to get the circuit switching four times per second (4 Hz) the resistor “R” will need to be somewhere between 100K and 470K. With my capacitor, 120K is about right. While the switching frequency does not have to be exact, let’s aim at getting it correct. Most reasonably priced components have a tolerance of around 10% so we need to select our resistor/capacitor combination for the exact values of the actual components which we will use. For this, it is worth building the circuit on a solder-less ‘breadboard’, so looking on eBay again we find that a suitable small plug-in board can be bought and delivered for £3. It looks like this:

These type of boards allow ICs to be plugged in spanning the central divide, leaving up to five extra connections on every pin. Short lengths of solid-core wire can be used to connect between any two socket holes. This will allow us to plug in one of our capacitors and find what resistor (or what two resistors) make the circuit switch forty times in ten seconds.

However, if we go to http://www.alldatasheet.co.kr/ and download the data pdf for the NE555 chip, we find that the maximum 555 chip voltage is quite limited:

This means that the chip is liable to burn out instantly if it is fed more than 16 volts. As we need to run our circuit on 27V this is a problem. As the 27V is being provided by three separate batteries, we could supply the 555 chip from just one of the batteries and run it on 9V which would be ok from the point of view of the chip as the table above shows that it can operate correctly with a supply voltage as low as 4.5 volts. The disadvantage of that arrangement is that one of the batteries will run down more quickly than the others and it would be nice to avoid that.

The table also shows that the current draw just to keep the 555 running can be anything from 6 to 15 milliamps. This is not a large current but the PP3 batteries have been chosen for their small size, allowing the whole circuit to be strapped to a person’s wrist. A quick search on the internet shows that cheap PP3 batteries have a capacity of 400 milliamp-hours and the very expensive alkaline types 565 milliamp-hours. These ratings are the “C20” values, based on the battery being discharged at a constant current over a period of twenty hours, which would be ten days of use if Bob Beck’s two hours per day protocol is followed.

This means that the ‘cheap’ batteries should not be discharged at more than one twentieth of their 400 mAh rating, which is 20 mA. The expensive alkaline batteries should be able to be discharged at 28 mA for twenty hours.

Our current draw is made up of two parts. The first part is supplying the circuit with the current which it needs to run. The second part is the current flowing through the body of the user. This second part is limited by the 820
ohm resistor in the output line which limits that part of the current to a maximum of 33 milliamps (Ohm’s Law: Amps = Volts /Resistance). This neglects the body resistance and assumes that the output control variable resistor is set to minimum resistance, which is unlikely.

Checking these values shows that the 555 chip is liable to draw as much current as the circuit supplies through the output electrodes. However, let’s go ahead with the circuit, after all, we might decide to use rechargeable PP3 batteries which would overcome the need to buy new batteries every few days.

The first essential requirement is to provide the 555 chip with a voltage of, say, 10 volts when it is running in the completed circuit. That could be done with one of the voltage-stabiliser integrated circuits:

![Diagram of voltage-stabiliser circuit]

That is not a particularly expensive option, but those chips draw a current in order to provide the voltage stabilisation and an absolutely steady voltage is not needed by the 555 chip. Alternatively, we could use a resistor and a 10V zener diode:

![Diagram of resistor and zener diode circuit]

But that method does waste some current flowing through the zener in order to provide the wanted voltage. The most simple method is to use a resistor and a capacitor:

![Diagram of resistor and capacitor circuit]

Considerable care is needed when selecting the resistor value “R”. If the value is too low, then the voltage passed to the 555 chip will be too high and the chip will burn out. When selecting the resistor “R”, start with a higher value than expected and then substitute slightly lower value resistors while monitoring the voltage across the capacitor to make sure that it stays low enough. The resistor value can be assessed using Ohm’s Law. Assuming a current of about 6 mA, the voltage drop across the resistor being \((27 - 10) = 17\) volts, then a resistor of about 2.83K (as Ohms = Volts / Amps) which suggests that starting with a 4.7K resistor is likely to be ok, and then picking each lower standard resistor in turn until a satisfactory voltage across the capacitor is reached.

The capacitor could be 12V or 15V rated, but if one rated at a higher voltage is used, then if it is accidentally connected across the full 27V it will not be harmed in any way. The larger the capacitance, the better, say 220 microfarads which can be got for a few pence on eBay. If you want to play safe, you could connect a 12V zener diode across the capacitor. It will not draw any current under normal working conditions, but if anything should cause the voltage on the capacitor to rise, then it will fire up and hold the voltage down to a safe 12V level. I would be inclined to see the zener as being unnecessary, but the choice is always yours.

So what resistor power rating is needed? Well, if the resistor turns out to be a 2.7K and the capacitor voltage ends up as 9.5 volts, then the average voltage across the resistor is 17.5V which makes the current through it 6.48 mA and as Watts = Volts x Amps, the power rating needs to be 113 milliwatts, so the typical quarter-watt (250 mW) resistor should be perfectly ok. If two (nearly equal value) resistors in parallel are used to get some intermediate value of “R” then that increases the overall resistor wattage.
The output of the 555 chip is then used to drive the remainder of the circuit which operates at 27V. A BC109C transistor costs only a few pence, can handle the voltage and has a minimum gain of 200 although the gain can be anything up to 800 and a BC109 can handle the current quite easily. If you need to find out any of these things, then download a datasheet for the transistor from the internet.

The output of the 555 timer is on pin 3 and it can easily supply 200 mA which is far, far more current than we would ever need for this circuit. We can feed the 555 square-wave output to the 27V electrodes using a transistor:

As the transistor is made of silicon, the switch-on voltage is when the base voltage is about 0.7 volts above the emitter voltage. That means that when the transistor is switched on, the top of resistor “R1” will be at around 10 volts and the bottom of “R1” will be at about 0.7 volts, which means that the voltage across “R1” will be \((10 - 0.7) = 9.3\) Volts. When that voltage is present across “R1” we want it to feed sufficient current to the transistor to switch it on fully. The transistor supplies a 100K resistor (which will carry 0.27 mA when 27 volts is across it) and the electrodes which will have a minimum resistance of 820 ohms across them (causing a current of 33 mA through them). So, the transistor might have to supply about 33 mA maximum. The BC109C transistor has a minimum gain of 200 so the current flowing into the base needs to be \(33 / 200 = 0.165\) mA and the resistor which will carry that current when it has 9.3 volts across it is 56.3K. A somewhat smaller resistor will suit.

A commonsense check that the resistor calculation is correct is:
- A 1K resistor carries 1 mA per volt and so will carry 9.3 mA with 9.3 volts across it.
- A 10K resistor will carry one tenth of that amount, or 0.93 mA with 9.3 volts across it.
- A 100K resistor will carry one tenth of that again, or 0.093 mA with 9.3 volts across it.

This indicates that for a current of 0.165 mA which is about twice the 100K current, a resistor of about half of 100K should be about the right value, so 56.3K looks correct.

Considering that the gain of 200 is the minimum and three or four times that is typical, we could perhaps choose to use a 47K resistor for “R1”

As the electrode current is likely to be considerably less than 33 mA and as the BC109C gain is likely to be very high, it could be quite difficult to get the transistor to switch off as it can operate on very tiny amounts of input current. To get it to switch on and off cleanly when the 555 output voltage is say, about 5 volts, (at which point the NE555 voltage will be changing very rapidly), “R2” is included. With it in place, the output voltage of the NE555 is divided between “R1” and “R2” in the ratio of their resistances. The situation we want is:

When The transistor is not switched on, it draws almost no current and so looks like a very high value resistor to the circuit. This allows the “R1” and “R2” resistors to act as a voltage-divider pair. This causes the voltage at point “A” to be determined by the ratio of “R1” to “R2” and the transistor can be ignored provided that the voltage at point “A” is below 0.7 volts. If the voltage at that point rises to 0.7 volts then the situation changes dramatically and Ohm’s Law no longer holds as the transistor is not a passive resistor but instead, is an active semi-conductor device. If the voltage at point “A” tries to rise further it can’t because the transistor base clamps it solidly there by appearing to be an ever lower resistor between the base and the emitter of the transistor. So for higher input voltages, resistor “R2” might as well not be there for all the difference it makes.
So, what value do we need for \( R2 \) in order for the voltage at point \( A \) to be 0.7V when pin 3 of the NE555 reaches 5V? Well, that part of the circuit is acting in a resistive fashion and so Ohm’s Law can be used. The resistor \( R1 \) is 47K and has 4.3 volts across it, which means that the current through it must be 0.915 mA. That means that \( R2 \) has 0.7V across it and 0.915 mA flowing through it which means that it has a value of 7.65K. A standard 8.2K or 6.8K resistor could be used as there is nothing dramatically important about the 5V switching point. If you were fussed about getting exactly 7.65K (and you shouldn’t be), then you can get that value by combining two standard resistors, either in series or in parallel.

A common sense method of working out the value of \( R2 \) is to use the fact that as the same current flows through them (no matter what that current happens to be), then the ratio of the voltage will be the same as the ratio of the resistors. That is: \( 0.7V / 4.3V = R2 / 47K \) or \( R2 = 47K \times 0.7 / 4.3 \) which is 7.65K.

We have now reached the point where we can determine the resistor value needed to provide a reasonable voltage for the NE555 timer chip, the circuit being:

The \( Rx \) value is going to be fairly close to 270K so you can use that value when testing to find a suitable value for \( R \) (2.2K in my case). The capacitor across the NE555 chip should be as large a capacitance as is convenient, bearing in mind that the entire circuit, batteries, etc. is to fit into a small case to be strapped to a wrist. One way that the components could be positioned on the plug-board is:

Remember that when trying various resistors for \( R \) you need to start high at about 4.7K and the resulting voltage on the capacitor shows the voltage drop across your first resistor choice and so, the actual current being drawn by your particular NE555 chip. That calculated current will allow you to calculate the resistor value needed to give 10 volts or so, allowing your next resistor to be tested to be almost exact in value.

For checking the frequency produced by the circuit, any ordinary LED can be used as a temporary measure. It can be connected across the 100K ‘load’ resistor between the transistor collector and the +27V positive supply.
A current-limiting resistor is essential to stop the LED burning out instantly. If we allow a current of 5 mA to flow through the LED then since the current-limiting resistor has some 26.3 volts across it, then its value will be about 5.4K (1K would give 26 mA, 2K would give 13 mA, 3K would give 9 mA, 4K would give 6.5 mA) and so a 4.7K resistor works well. This LED and resistor are shown in the layout above. Please remember that if your BC109C transistor has a metal case, then that case is normally connected internally to the collector and so, care must be taken that the case does not short-circuit to anything else.

If it is considered important to maximise battery life by reducing the current draw to a minimum, then perhaps using an astable circuit might be a good choice. In common with most electronic circuits, there are many different ways to design a suitable circuit to do the required job. The BC109C transistor can handle the 27V and so we might aim at a current draw for the circuit of just 3 mA. If 2 mA were to flow through the astable transistors when they are switched on, then with 27V across them, the resistors would be 13.5K which is not a standard value. We might select 12K to give a 2.25 mA current, or 15K to give 1.8 mA. Either should be satisfactory. The circuit might then be:

As the voltage swing feeding the output transistor has now risen from 10V to 27V the voltage-divider resistors can now increase in value by 2.7 times, giving around 127K and 22.1K for these resistors. However, the situation is not the same as for the NE555 chip which can supply at least 200 mA at the voltage-high output level. Instead, the transistor becomes such a high resistance that it can be ignored, but the 12K remains in the path which supplies the base current for the output transistor and it will in fact, add to the upper resistor of the voltage-divider pair. So while a 100K resistor is shown, it is effectively 112K due to that extra 12K resistor between it and the +27V supply line. The astable transistors will be switching fast at the point where the output transistor changes state, so the output square wave should be good quality. The BC109C transistor can switch on and off a hundred million times per second, so its performance in this circuit should be very good. A test breadboard layout might be:

We now need to choose the timing components. For an even 50% duty cycle where each transistor is ON for half the time and OFF for half the time, the two timing capacitors can be the same size and then the two timing resistors will have the same value, in my case, 330K but it depends on the actual capacitors used.
Bob Beck’s design calls for the LED display to be running when the unit is switched on and then be disconnected when the electrodes are plugged into a 3.5 mm socket mounted on the case containing the circuit. The switched socket looks like this:

When the plug is not inserted into the socket, pin 1 connects to pin 2 and pin 3 is not connected to anything. When the plug is inserted, then pin 1 is isolated, pin 2 is connected to plug pin 4 and pin 3 is connected to plug pin 5.

The Beck circuit is connected to the output socket like this:

This arrangement will give a 27V 4Hz square wave output through the jack socket. But, Bob Beck’s original circuit did not do that. Instead, it was like this:

Here, a relay operates two change-over switch contacts which are used to reverse the battery bank contacts four times per second. That is different from just producing a positive-going square wave voltage between the two output terminals. If you were to consider a resistor connected across the output socket, then with the relay switching, the direction of the current reverses four times per second, but with the square wave, while it starts and stops four times per second, the direction of the current is always the same and there is no reversal of direction.

As Bob wanted to avoid using a relay which clicks four times per second all the way through the two-hour treatment described in chapter 11 and in the “Take Back Your Power” pdf on the [http://www.free-energy-info.tuks.nl/](http://www.free-energy-info.tuks.nl/) web site, he redesigned the circuit using the very impressive LM358/A integrated circuit:
This chip draws only half of one milliamp, has two very high-gain operational amplifiers and can operate with a wide range of supply voltages. It is also inexpensive.

Bob displays the circuit as:

Bob states that the first section acts as a 4Hz square-wave signal generator, the frequency being controlled by the 2.4M resistor “R1” and the 100nF capacitor “C1”. The data sheet for the LM358 states that the output voltage swing is between zero volts and 1.5V less than the supply voltage “Vcc” (which is +27V in this case). That implies that, as would be expected, the pin 1 output voltage from the first stage will switch sharply from 0V to +25.5V and sharply back again, four times per second.

It is difficult to follow the circuit as it is drawn, so it might be a little easier to follow when drawn like this:

The output from the first amplifier inside the LM358 package is on pin 1 and it can supply a large amount of current (if a large current is ever needed). That output goes straight to one of the jack socket connections. It also goes the pin 6 input of the second amplifier inside the chip and that causes the high-power output of that amplifier on pin 7 to be the opposite of the pin 1 voltage. When pin 1 goes high to +25.5 volts, then pin 7 goes low, to about zero volts. That output is also fed to the other jack socket connection, placing 25.5 volts across the electrodes when they are plugged in to the jack socket.

When the oscillator circuitry connected to the first amplifier causes the voltage on pin 1 to go low, then the output on pin 7 inverts it and so it goes to +25.5 volts. You will notice that while the overall voltage of 25.5 volts is applied again to the jack socket, the polarity is now reversed, achieving what the relay circuit does (although 1.5 volts is lost in the process). This is a neat solution.

Bob uses a two-colour LED to confirm that the circuit is working correctly before the electrodes are plugged in. He chooses to do it this way:
The two 18V zener diodes drop off 18.7 of the 25.5 volts as one will be forward biased dropping 0.7 volts and the other reversed biased, dropping off 18 volts. That leaves a 7V drop for the LED, which is a bit excessive, so Bob says that he uses a capacitor to limit the current. As there is already an 820 ohm resistor in the LED current path through the socket, the capacitor is not needed. The variable resistor need to be set to it's minimum resistance by rotating it's shaft fully clockwise so that it does not affect the LED brightness as the zeners also show when the battery voltage has dropped as there will no longer be sufficient voltage to light the LED brightly, indicating that the batteries need to be replaced (or recharged if they are rechargeable batteries). When testing the circuit, an alternative to the two zeners is to use a 4.7K resistor and if a bi-colour LED is not to hand, then two ordinary LEDs can be used back to back like this:

With this arrangement, the two LEDs flash alternately. In any circuit, a capacitor with a higher voltage rating can always be used if the capacitance values are the same. The Beck external circuit is completed through the body of the user, so there is just one electrode connected to each side of the output jack socket. A possible plug-board layout is:
The 4.7K resistor and LEDs are only on the board for testing purposes and when the circuit is built in permanent form, then the LED chain connects to pin 1 of the jack socket so that the LEDs are disconnected during the two hours of daily treatment recommended when using the device.

One stripboard layout using the standard 9-strip 25-hole board and incorporating the two 18V zener diodes for voltage sensing is:

When using a Beck device, it is very important to pay attention to the precautions which Bob sets out. These are in his “Take Back Your Power” pdf document: [http://www.free-energy-info.tuks.nl/Beck.pdf](http://www.free-energy-info.tuks.nl/Beck.pdf) which includes the following, which, while it refers to treatment to deal with HIV, presumably applies to all treatments with his device:

**EXPANDED INSTRUCTIONS FOR EXPERIMENTAL / THEORETICAL HIV BLOOD NEUTRALIZATION**

**HYPOTHETICAL PROTOCOLS FOR EXPERIMENTAL SESSIONS**

**PRECAUTIONS:** Do NOT use wrist to wrist current flow with subjects who have cardiac pacemakers. Any applied electrical signals may interfere with 'demand' type heart pacers and cause malfunction. Single wrist locations should be acceptable. Do NOT use on pregnant women, while driving or using hazardous machinery.

Users MUST avoid Ingesting anything containing medicinal herbs, foreign or domestic, or potentially toxic medication. nicotine, alcohol, recreational drugs. laxatives, tonics. and certain vitamins etc., for one week before starting because blood electrification can cause electroporation which makes cell membranes pervious to small quantities of normally harmless-chemicals in plasma. The effect Is the same as extreme overdosing which might be lethal. See [Electroporation: a General Phenomenon for Manipulating Cells and Tissues; J.C. Weaver, Journal of Cellular Biochemistry 51:426-435 (1993).](#) Effects can mimic increasing dosages many fold. Both the magnetic pulsar and blood purifier cause electroporation.

Do NOT place electrode pads over skin lesions, abrasions, new scars, cuts, eruptions, or sunburn. Do NOT advance output amplitude to uncomfortable levels. All subjects will vary. Do NOT fall asleep while using. The magnetic pulsar should be safe to use anywhere on body or head.

Avoid ingesting alcohol 24 hours before using. Drink an 8 oz. glass of distilled water 15 minutes before and immediately following each session end drink at least four additional glasses daily for flushing during 'neutralization' and for one week thereafter. This Is imperative. Ignoring this can cause systemic damage from unflushed toxic wastes. When absolutely essential drugs must be ingested, do so a few minutes after electrification then wait 24 hours before next session.

If subject feels sluggish, faint, dizzy, headache, light-headed or giddy, nauseous. bloated or has flu-like symptoms or rashes after exposures, reduce pulsing per session and/or shorten applications of electrification. Drink more water-preferably ozonized -to speed waste oxidation and disposal. Use extreme caution when treating patients with impaired kidney or liver function. Start slowly at first like about 20 minutes per day to reduce detoxification problems.
To avoid shock liability, use batteries only. Do NOT use any line-connected power supply, transformer, charger, battery eliminator, etc. with blood clearing device. However line supplies are OK with well-insulated magnetic pulse generators (strobe lights).

Health professionals: Avoid nicotine addicts, vegans, and other unconsciously motivated death-wishers and their covert agendas of ‘defeat the healer’. Tobacco, the most addictive (42 times more addictive than heroin) and deadly substance of abuse known, disrupts normal cardiovascular function. True vegetarian diets are missing essential amino acids absolutely necessary for the successful rebuilding of AIDS-ravaged tissues. Secondary gains (sympathy / martyrdom, work avoidance, free benefits, financial assistance, etc.) play large roles with many AIDS patients. "Recovery guilt" as friends are dying has even precipitated suicide attempts masked as 'accidents'. Avoid such entanglements, since many have unconscious death wishes.

SUPERIOR ELECTRODES: Excellent, convenient and vastly superior electrodes, reusable indefinitely can be made by butt-soldering lead wires to ends of 1” long by 3/32” dia. blanks cut from type 316 stainless steel rods available from welding supply stores (Cameron Welding Supply. 11061 Dale Ave., Stanton, CA 90680). Use 'Stay Clean' flux before soldering (zinc chloride/hydrochloric acid). Shrink-insulate TWO tight layers of tubing over soldered joints to prevent flexing/breaking and lead/copper ions from migrating. Wrap three or four turns of 100% cotton flannel around rods. Spiral-wrap with strong thread starting from wire side to end, tightly pinch cloth over the rod’s end so as to leave no metal exposed by wrapping 6 or 7 turns of thread TIGHTLY just off end of rod, then spiral wrap back to start and tie tightly with four knots then cut off excess cloth at end close to pinch -wraps. Treat end windings and knots with clear fingernail polish or Fray Check® (fabric & sewing supply stores) to prevent ravelling. Soak in a strong solution of sea salt (not table salt) containing a little wetting agent like Kodak Photo Flow, ethylene glycol, or 409 kitchen cleaner. Add a few drops of household bleach, silver colloid, etc., for disinfectant. Store solution for reuse. Tape soaking-wet electrodes tightly over pulse sites with paper masking or Transpore™ tape or with 1 inch wide stretch elastic bands with tabs of Velcro® at ends to fasten. Electrodes should closely conform precisely along blood vessels, not skewing ever so slightly over adjacent flesh. This insures better electrical conductivity paths to circulating blood and insures very low internal impedance. (~2000W). Rinse and blot-dry electrodes and skin after each use. NEVER allow bare metal to touch skin as this will cause burns manifested as small red craters that heal slowly. The objective is to get maximum current into blood vessels, not leak it over to adjacent tissue. Therefore never use any electrode wider that about 1/8 inch (3 mm).

ELECTRODE PLACEMENTS: Locate maximum pulse position (NOT to be confused with acupuncture, reflexology, Chapman, etc. points) on feet or wrists by feeling for maximum pulse on inside of ankle about 1 inch below and to rear of ankle bone, then test along top centre of instep. Place electrode on whichever pulse site on that foot that feels strongest. Scrub skin over chosen sites with mild soap and water or alcohol swab. Wipe dry. Position the electrodes lengthwise along each left and right wrists blood vessel. Note: with subjects having perfectly healthy hearts and not wearing pacers, it is convenient to use left wrist to right wrist exactly over ulnar arterial pulse paths instead of on feet. Recent (Dec. 1995) research suggests that placing both electrodes over different arteries on the same wrist works very well (see pg. 7), avoids any current through heart, and is much more convenient and just as effective. An 8” long, 1” wide elastic stretch-band with two 1.5” lengths of 3/4” wide Velcro® sewn to ends of opposite sides makes an excellent wrist band for holding electrodes snugly in place. With electrode cable unplugged, turn switch ON and advance amplitude control to maximum. Push momentary SW. 2 'Test' switch and see that the red and green light emitting diodes flash alternately. This verifies that polarity is reversing about 4 times per second (frequency is NOT critical) and that batteries are still good. When LED’s don’t light replace all three 9V batteries. Zener diodes will extinguish the LEDs when the three 9V battery’s initial 27V drops below 18V after extended use. Never use any electrode larger than 1.125” (28 mm) long by 1/8” wide to avoid wasting current through surrounding tissue. Confine exactly over blood vessels only. Apply drops of salt water to each electrode’s cotton cover ~every 20 minutes to combat evaporation and insure optimum current flow. Later devices are solid-state, use only three batteries and no relays, and are much smaller.

Now rotate amplitude control to minimum (counter-clockwise) and plug In electrode cable. Subject now advances dial slowly until he feels a “thumping” and tingling. Turn as high as tolerable but don’t advance amplitude to where it is ever uncomfortable. Adjust voltage periodically as he adapts or acclimates to current level after several minutes. If subject perspires, skin resistance may decrease because of moisture, so setting to a lower voltage for comfort is indicated. Otherwise it is normal to feel progressively less sensation with time. You may notice little or no sensation at full amplitude immediately, but feeling will begin building up to maximum after several minutes at which time amplitude must be decreased. Typical adapted electrode-to-electrode impedance is on the order of 2000W. Typical comfortable input (to skin) is about 3 mA, and maximum tolerable input (full amplitude) is about 7 mA but this ‘reserve’ margin although harmless is unnecessary and can be uncomfortable. Current flowing through blood is very much lower than this external input because of series resistance through skin, tissue and blood vessel walls, but 50 to 100 µA through blood is essential.

Apply blood neutralizer for about 2 hours daily for ~2 months. Use judgment here. The limiting factor is...
detoxification. Carefully monitor subject’s reactions (discomfort, catarrh, skin eruptions, weeping exudates, rashes, boils, carbuncles, coated tongue, etc.). With very heavy infections, go slower so as not to overload body’s toxic disposal capability. With circulation-impaired diabetics, etc., you may wish to extend session times. Again, **have subject drink lots of water.** Recent changes in theoretical protocol being currently tested suggest following up the three weeks of treatments with a 24 hours per day (around the clock) continuous electrification of blood for two days to deal a knockout blow to the remaining HIV’s 1.2 day life cycle. (A. Perelson; Los Alamos Biophysics Group, Mar. 16, 1996 “Science” Journal.) Remember to remoisten electrodes regularly. If you absolutely must ingest prescription drugs, do so immediately after turning off instrument and allow 24 hours before next treatment to let concentrations in blood plasma decay to lower levels.

Remember, if subjects ever feel sleepy, sluggish, listless, nauseous, faint, bloated, or headachy, or have flu-like reactions they may be neglecting sufficient water intake for flushing toxins. We interpret this as detoxification plus endorphin release due to electrification. Let them rest and stabilize for about 45 minutes before driving if indicated. If this detoxing becomes oppressive, treat every second day. Treating at least 21 times should ‘fractionate’ both juvenile and maturing HIV to overlap maximum neutralization sensitivity windows and interrupt ‘budding’ occurring during HIV cells' development cycles. Treatments are claimed to safely neutralize many other viruses, fungi, bacteria, parasites, and microbes in blood. See patents US 5,091,152 US 5,139,684 US 5,188,738 US 5,328,451 and others as well as numerous valid medical studies which are presently little known or suppressed. Also, ingesting a few oz. of about 5 parts per million of silver colloid solution daily can give subjects a ‘second intact immune system’ and minimise or eliminate opportunistic infections during recovery phase. This miracle substance Is pre-1938 technology, and unlike ozone is considered immune from FDA harassment. Silver colloid can easily be made at home electrolytically in minutes and in any desired quantities and parts per million strength for under 14 cents per gallon plus cost of water. It is ridiculous to purchase it for high prices. Colloid has no side effects, and is known to rapidly eliminate or prevent hundreds of diseases. Silver colloids won’t produce drug resistant strains as will all other known antibiotics. No reasonable amount can overdose or injure users either topically, by ingestion, or medical professional injection.

**The 741 Operational Amplifier.**

An important and very useful group of Integrated Circuits is the “Operational Amplifier” or “op-amp” group. These devices have a very high gain, an ‘inverting’ input and a ‘non-inverting’ input. There are many op-amps but we will look at just one popular type called the “741” which has an ‘open-loop’ gain of 100,000 times. All operational amplifiers work in the same way in theory. The way they operate in a circuit is controlled by the external components attached to them. They can operate as inverting amplifier, a non-inverting amplifier (i.e. a ‘buffer’), a comparator, an astable multivibrator, and various other things. The symbol and connections for a 741 op-amp are:

![741 Operational Amplifier Diagram](image)

We can connect the 741 chip to act as an amplifier with any set gain level that we choose:
Here, the gain is set by the ratio of the 220K resistor to the 22K resistor. This circuit has a gain of 10 times, so the input signal at point 'B' will generate an output signal at point 'C' which is ten times larger, provided that the output signal does not approach the battery voltage. If it does, then clipping will occur with the top and the bottom of the output waveform chopped off at about a volt away from the battery voltage levels, approximately 1 Volt and +11 Volts in this example.

Operational amplifiers are generally designed to operate from a dual power supply. In the above example, the supply would be created by using two 6 Volts batteries instead of one 12 Volt battery. To avoid the inconvenience of this, a mid-point voltage is generated at point ‘A’ by using two equal resistors in series across the battery. This gives a central voltage of +6 Volts which is fed to the IC.

This circuit can be used in many applications. Here is a circuit for a meter to measure sound intensity:

This circuit is two copies of the previous circuit. Each 741 chip has a reference voltage of half the supply voltage created by a voltage-divider pair of 1K resistors. This voltage is fed to pin 3 of the chip, which is the non-inverting input.

At point ‘A’, a microphone or small loudspeaker is used to generate a signal voltage when sound reaches it. This voltage is fed to the 741 op-amp via a 1 microfarad blocking capacitor. This passes the audio signal through while blocking the +4.5 Volts DC on pin 3. The first 741 has a gain of 22, set by the 10K and 220K resistors (220/10 = 22).

Point 'B' then receives an audio signal 22 times larger than the signal produced by the microphone. This signal is still quite small, so the second 741 boosts it further. The gain of the second 741 is variable and depends on the resistance set on the 1M variable resistor. If the variable resistor is set to zero ohms, then the gain of the second 741 will be controlled by the 4K7 resistor at point ‘C’ alone and so will be 1 (4.7/4.7 = 1). If the variable resistor is set to its maximum value, then the gain of the second 741 will be some 214 (1,004,700/4,700 = 213.8).

The two op-amps together have a combined gain which ranges from 22 to 4702. The amplified audio signal arrives at point ‘D’ and it can be adjusted to a respectable value. This alternating voltage is now rectified via the diodes at point ‘E’ and it builds up a DC voltage across the 47 microfarad capacitor there. This voltage is displayed on a voltmeter. The result is that the voltmeter shows a reading directly proportional to the sound level reaching the microphone.

The 741 can be wired as a buffer. This is the equivalent of an emitter-follower circuit when using transistors. The set up for the 741 is:
Difficult circuit - huh! Are you sure you can afford all the extra components? This circuit utilises the full gain of the 741 chip. The output follows the input waveform exactly. The input requires almost no current, so the circuit is described as having a 'high input impedance'. The output can drive a serious load such as a relay, so the circuit is described as having a 'low output impedance'.

The 741 chip can be wired to act as a comparator. This is the circuit:

Are you sure you are up to such a difficult circuit? Bit complicated - huh! This is the basic operational form for an operational amplifier.

If the voltage at point 'A' is higher than the voltage at point 'B' then the output goes as low as it can go, say 1 or 2 volts.

If the voltage at point 'A' is lower than the voltage at point 'B' then the output goes as high as it can go, say 10 volts or so.

Having seen how transistor circuits work, you should be able to understand why the 741 chip circuitry (which is a transistor circuit inside the 741 package) needs some voltage inside the supply rails to provide an efficient high-current output drive.

Here is a 741 version of the light-operated switch:
This circuit is set up as evening falls. We want the relay to have minimum voltage across it in daylight, so the voltage at point ‘A’ needs to be higher than the voltage at point ‘B’. As the 1K variable resistor is across the supply voltage, its slider can be set to any voltage between 0 Volts and +12 Volts. To make this easy to do, we choose a ‘linear’ variable resistor as the logarithmic variety would be hard to adjust in this application. With the ‘linear’ version, each 1 degree of rotation of the resistor shaft causes the same change in resistance, anywhere along the range. This is not the case for the logarithmic variety.

Anyhow, we adjust the variable resistor downwards until the relay voltage drops to a minimum. When the light level has fallen to the level at which we wish the circuit to trigger, we adjust the variable resistor to make the relay click on. The 741 chip has a very rapid output voltage swing when the input voltages swap over, so the relay switching will be decisive. The switching can be made even more positive by adding a resistor between the output and point ‘B’. This acts like a Schmitt trigger when switching occurs by providing some additional positive feedback, lifting the voltage at point ‘B’.

If you wish the circuit to trigger on a rising light level, just swap the positions of the 10K resistor and the ORP12 light-dependent resistor. The same circuit will operate as a temperature sensing circuit by substituting a ‘thermistor’ (which is a temperature-dependent resistor) for the ORP12.

If we would like the circuit to act as a burglar alarm, we could use the same circuit like this:

The circuit is still controlled by the voltage at point ‘A’. Under normal circumstances, this voltage will be near +6 Volts (produced by the two 10K resistors and the 100K resistor). The upper switch marked ‘NC’ for ‘Normally Closed’, represents a chain of, say, magnetic switches attached to doors and windows. If any of these are opened, then the voltage at point ‘A’ will be dictated by the lower 10K resistor in series with the 100K resistor. This will cause the voltage at ‘A’ to fall instantly to a low value, triggering the circuit.

The ‘NO’ switch (‘Normally Open’) represents one or more pressure-operated switches under carpets or rugs and/or switches which get brushed when doors are swung open, etc. These switches are wired in parallel across each other and if any of them is closed for even a millionth of a second, the voltage at point ‘A’ will be pulled down by the 1K resistor and the circuit will be triggered.

The circuit can be latched on in any one of a variety of ways. One relay contact can be used to hold the relay on or hold the voltage at ‘A’ low. A transistor can be wired across the relay to hold the circuit on, etc. etc. If this is done, the circuit will remain in its triggered state until the supply voltage is interrupted. You might prefer to use a 555 chip to limit the length of time the alarm sounds to three minutes or so.

The SCR and Triac.
An alternative to using a relay or semiconductor latch is to use a Silicon Controlled Rectifier usually referred to as an ‘SCR’ or ‘Thyristor’. This device is normally “off” with a very high resistance to current flow. If it is switched on by applying a voltage to its Gate connection, it stays continuously on until some external device stops current flowing through it. The following circuit shows how it operates:
When the voltage is first applied to the circuit by closing switch S2, the SCR is in its OFF state so no current is supplied to the load. If the press-button switch S1 is pressed, a current is fed into the Gate of the SCR, turning it ON. When switch S1 is allowed to open, the SCR remains in its ON state and it will stay that way until the current through it is cut off. Opening switch S2 cuts off the current to the load and the SCR returns to its OFF state. A very valid question would be: “Why have an SCR at all and just turn the load on and off with switch S2?” The answer is that switch S1 might be the under-carpet pressure pad of a burglar-alarm and it might be operated some hours after switch S2 was closed to activate the alarm system. Stepping off the pressure pad does not stop the alarm sounding.

While this sort of DC latching action is useful, it is more common for an SCR to be used in an AC circuit. For example, take the circuit shown here:

![Diagram 1](image1.png)

When the voltage is first applied to the circuit by closing switch S2, the SCR is in its OFF state so no current is supplied to the load. If the press-button switch S1 is pressed, a current is fed into the Gate of the SCR, turning it ON. When switch S1 is allowed to open, the SCR remains in its ON state and it will stay that way until the current through it is cut off. Opening switch S2 cuts off the current to the load and the SCR returns to its OFF state. A very valid question would be: “Why have an SCR at all and just turn the load on and off with switch S2?” The answer is that switch S1 might be the under-carpet pressure pad of a burglar-alarm and it might be operated some hours after switch S2 was closed to activate the alarm system. Stepping off the pressure pad does not stop the alarm sounding.

While this sort of DC latching action is useful, it is more common for an SCR to be used in an AC circuit. For example, take the circuit shown here:

![Diagram 2](image2.png)

The 555 chip is connected to form a monostable multivibrator and the timing components (the 120K resistor and the 10nF capacitor) cause it to output a 1 millisecond pulse which is long enough to trigger the SCR into its ON state, but short enough to have finished before the mains pulse reaches its zero-voltage level again. The 555 chip is triggered by the rising mains voltage being passed to its pin 2 through the voltage-divider 100K and 120K pair of resistors, and that synchronises it with the AC waveform. Pin 4 of the 555 chip can be used to switch the load power on and off.

In the circuit shown above, the diode bridge is needed to convert the incoming AC waveform to pulsing DC as shown in red in the diagram, as the SCR can only handle current flowing in one direction. The AC load equipment works just as well with the pulsing DC as with a full blown AC waveform. A better semiconductor construction is the 'Triac' which acts like two SCR devices back-to-back in a single package. It is shown like this in circuit diagrams:
There are three connections to the device: Main Terminal 1, Main Terminal 2 and the Gate. When switch ‘S’ shown in the diagram is closed, the triac conducts on both positive and negative voltages applied to its MT1 and MT2 terminals. When the switch is open, the device does not conduct at all.

If the external circuit containing switch ‘S’ is placed inside the device as a permanently closed circuit, then the device becomes a 'Diac' which can be used to trigger a Triac and give a very neat circuit for controlling the power to an item of AC mains equipment as shown here:

Here, the variable resistor/capacitor pair controls the point on the AC waveform that the Triac is triggered and so controls how much of each sinewave cycle is passed to the mains equipment, and so it controls the average power passed to the equipment. A very common use for a circuit of this type is the ‘dimmer-switch’ used with household lighting.

To return now to the 741 chip. The 741 can also be used as an astable multivibrator. The circuit is:

The rate of oscillation of this circuit is governed by the Resistor marked ‘R’ in the diagram and the capacitor marked ‘C’. The larger the resistor, the lower the rate of oscillation, the larger the capacitor, the lower the rate of oscillation.

When the output goes high, capacitor ‘C’ charges up until the voltage on it exceeds the mid-rail voltage on pin 3, at which time the 741 output goes low. The capacitor now discharges through resistor ‘R’ until the voltage on it drops below the voltage on pin 3, at which time the output goes high again. The 10K resistor connecting the output to pin 3 provides some positive feedback which makes the 741 act quite like a Schmitt trigger, sharpening up the switching.

The same arrangement of resistor and capacitor applied to a Schmitt inverter or Schmitt NAND gate causes exactly the same oscillation:
If you would like to see additional ways of using 741 and 555 chips, I can recommend the excellent book “Elementary Electronics” by Mel Sladdin and Alan Johnson ISBN 0 340 51373 X.

A Hex Inverter Signal Generator.
Here is a very well tested and highly thought of, low-cost oscillator circuit, using a 74HC14 Schmitt inverter chip (or the 40106B higher voltage CMOS chip). It allows fine tuning control of the frequency and the pulse width produced. Three of the inverters are connected together to give a more powerful output current drive:

The 4022 Divide-by-Eight Chip.
One very useful CMOS integrated circuit is the ‘4022’ chip which is a 16-pin ‘divide by 8’ chip with built-in decoding. The connections are:
If pin 14 is provided with the output from some variety of astable multivibrator, on the first pulse, this chip sets the “0” output on pin 2 to High while the other outputs are Low. On the next pulse, the “0” output goes Low and the “1” output on pin 1 goes High. On the next pulse, output “1” goes Low and the “2” output on pin 3, goes High. And so on until on the eighth pulse, output “7” on pin 10 goes Low and output “0” goes high again.

The chip can also divide by lower numbers:

For ‘Divide by 7’ operation, connect pin 10 to pin 15 (this resets the output to ‘0’)
For ‘Divide by 6’ operation, connect pin 5 to pin 15
For ‘Divide by 5’ operation, connect pin 4 to pin 15
For ‘Divide by 4’ operation, connect pin 11 to pin 15
For ‘Divide by 3’ operation, connect pin 7 to pin 15
For ‘Divide by 2’ operation, connect pin 3 to pin 15

If you want a ‘Divide by 1’ circuit, I suggest you cut down on the amount of alcohol you drink.

Here is an illustration of a ‘Divide by 4’ setup:

![Image of a 'Divide by 4' setup]

Clock Input:  
Output "0":  
Output "1":  
Output "2":  
Output "3":  

There are a number of things to notice in the above diagram. Firstly, the practical arrangements for circuitry have not been stressed before. If the circuitry has a pulsing circuit drawing heavy current, as shown by the thick red arrows, then it should be physically connected to the battery and any low-current circuitry should be further away from the battery. The supply from the battery should have a fuse or circuit breaker and a switch in the line before anything else is connected, so that if any component develops a fault and goes short-circuit, the fuse will blow and prevent any significant problems.

Secondly, it is a good idea to provide the other circuitry with a smoothed power supply as shown by the blue components in the diagram. This minimises the effect if the battery voltage gets pulled down by the pulsing of the...
high-current circuitry. The diode (silicon, 1 Amp, 50 V) stops the heavy current circuit drawing current from the large smoothing capacitor. The 100 ohm resistor limits the current into the large capacitor on switch-on and provides a little more smoothing. This circuitry is called “de-coupling” as it de-couples the low current circuitry from the high current circuitry.

Thirdly, notice capacitor “C1” which is wired physically as close to the power supply pins of the integrated circuit as is possible. If a spike is superimposed on the battery supply, then this capacitor soaks it up and prevents it damaging or triggering the integrated circuit. A spike could be caused by a very strong magnetic pulse nearby as that can induce an extra voltage in the battery wires.

The lower part of the diagram shows the output voltages produced as the clock pulses reach pin 14 of the chip. The positive-going part of the clock signal triggers the change in state of the outputs. If necessary, a positive-going pulse on the reset pin, pin 15, causes output “0” to go high and the other outputs to go low.

The 4017 Divide-by-Ten Chip.

Now, to take this output sequencing a little further. For example, the Charles Flynn magnet motor shown in Chapter 1 needs coils to be powered up, one after the other and only one should be on at any one time. This calls for a circuit which has a large number of outputs. The CD4022BC chip gives up to eight outputs one after the other. The CD4017B chip gives up to ten outputs one after the other but there is no need to be limited by these numbers as more than one chip can be used. If you find this section difficult to understand, then just skip past to the next section as it is not important for you to understand these larger circuits.

The pin connections for the divide-by-ten CD4017B chip is shown here:

While this shows outputs 1 to 10, the manufacturers and some people who draw circuits, prefer to label the outputs as “0 to 9” which correspond to digital displays. In our style of operation, it is easier to think of the ten outputs as being from 1 to 10.

You will notice that there are two pin labels which we have not come across before, namely, the “Carry-out” pin and the “Clock Enable” pin. These allow us to use several of these chips in a row to give a much larger “divide-by” number. The “Clock Enable” pin can be used to block the clock input. The operation is like this:
In this example, the sequence is started by the Reset pin being given a high voltage as shown by the green shading. This pushes the output pin 1 to a high voltage and all of the other outputs to a low voltage and holds those voltages as long as the reset voltage is high.

When the Reset voltage drops, the next rising edge of the clock pulse (marked “1” in the diagram) causes the output 1 to go low and output 2 to go high. Each of the successive clock pulses “2” to “9” moves the high voltage steadily along the outputs until output pin 10 is high.

The next clock pulse rising edge (marked “10” in the diagram) starts the sequence again with output 10 going low and output 1 going high again. If nothing changes, then that sequence of output voltage changes will continue indefinitely.

However, in the diagram above, the Clock Enable pin voltage is driven high on clock pulse “11”. Output 2 has just gone high and would have gone low when the rising edge of clock pulse “12” occurred, but in this case, the Clock Enable feature blocks the clock pulse and prevents it reaching the rest of the circuitry. This causes the output 2 voltage to stay high as long as the Clock Enable remains high. In this example, the Clock Enable voltage stays high for just one clock pulse, causing the output 2 voltage to be high for twice it's usual length, and then the sequence continues as before.

**A Divide-by-Twenty-five Circuit.**

Here is one way to get a large “divide-by” number. This example is divide-by-25 because there is only one ‘intermediate stage’ but there can be any number and each additional one adds another eight outputs to the total:
At startup, output 10 of the first stage (which is physical pin 11 of the chip) is at a low voltage. This holds the Clock Enable (pin 13) low, allowing the clock pulses to enter the first stage. Because the output 10 voltage is low, one input to the first AND gate is held low, preventing it from letting the clock pulse flow through it, i.e. the “gate” is closed to through traffic.

The first stage chip then operates as normal, producing outputs 1 to 9 in order as you would expect. The next clock pulse sets the first stage output 10 high, allowing the clock pulses through the first AND gate and holding the Clock Enable (pin 13) high, which in turn locks the output 10 high, dropping the first stage chip out of the operation.

As the output 1 of the first stage is connected to the Reset (pin 15) of the second chip, it will have been cleared and its output 1 set high, which in turn Resets the third chip and closes the second AND gate. So, when the first pulse gets through to the second chip, it pushes it from state 1 to state 2 where the output 2 goes high. For that reason, output 1 of the second chip is not one of the outputs which can be used by whatever following circuitry you choose to connect to this system. Consequently, only eight of the ten outputs of the second chip are available as counter outputs. That is, outputs 1 and 10 are taken up in passing the switching sequence between the various chips in the chain.

The same applies to all following chips in the chain, each extra chip adding up to eight extra sequential outputs. On the final stage chip, if you connect the red Reset wire (which goes back to fire up the first chip again) to output 9 instead of output 10 of the final chip, then you get a divide-by-24 result.

If the Reset is taken from output 8 of the final chip, then you get a divide-by-23 result, and so on. Using this method, you can have a divide-by-circuit for any number you want. These chips are very popular and so their cost is low, making the entire circuit cheap to make. The pin connections for the AND gates is shown here:

The PIC Revolution.
Over the years, there have been advances in the way that circuitry can be put together, prototypes built and tested. Initially, "valves" or "vacuum tubes" were used and circuits required a good deal of electrical power in order to operate. Mechanical vibrators or "reeds" were used to generate the switching needed to convert DC into AC. Then the transistor became widely available and the transistor replaced the mechanical vibrator reed, the circuit being called an "astable multivibrator" and comprising of two transistors wired back to back (as described in chapter 12). Then came the digital integrated circuit with it’s "NOR gates" which could also be wired back to back to make a multivibrator. This was done so often that a special integrated circuit called the "555 chip" was designed to do the job all on its own. That chip has been a tremendous success and is now found in all sorts of different circuits, being very easy to use, very robust and very cheap. Surprisingly, the dominant position of the "555" chip is being challenged by a completely different type of chip, one which is essentially, a computer on a
single chip, and which is called a "PIC controller".

This new type of chip is not expensive, is easy to use, and can be changed to perform a different task in just a few seconds. It can perform timing tasks. It can act as a multivibrator. It can act as a "Divide-by-N" chip. It is a very impressive chip which is very useful. The reason that I mention it here is because it is at the heart of the fastest working Tesla Switch research forum around (the "energetic forum" group). The chip is something you need to know about as it will certainly take over more and more circuit applications in the coming years.

There is a whole family of these processor chips, but I will select just one for this description, and that will be the one being used by the "energetic forum" members, and I have to thank Jeff Wilson for his help in describing this circuitry, the programming and the methods which he uses.

First, however, some information on this new design of chip and the methods used with it. The one used by Jeff is called the "PICAXE-18X" and it looks like the chip shown here. From which you can see, it looks just like any other chip, although with eighteen pins. The powerful performance comes from the way that it operates. You are probably familiar with the "555" chip and understand that it operates by changing the voltage on just one of its pins (pin 3) the output pin, from a low voltage to a high voltage. The PIC chip can do that as well, but even better still, it has more than one output pin and it can alter the voltage on any of those pins to either a high or a low voltage and it can do that in any order and with any timing that you choose. This makes it a very versatile chip indeed and one which is very well suited to be the central controller for a Tesla Switch test environment.

The chip is used by wiring it into a circuit in the same sort of way that a 555 chip would be used, except that the PIC has its own internal timing clock and can operate in intervals of one thousandth of a second, that is, one millisecond.

![PICAXE-18X Chip Diagram](image)

The top eight pins are for making the chip work. The next two are for providing the chip with electrical power. The bottom eight pins are separate outputs, any one of which can operate switches, timers, etc., just as the output from a 555 chip can. Having been named by computer people, instead of the eight output pins being numbered from 1 to 8 as any rational person would do, they have numbered them from 0 to 7.

The voltage on those output pins will be either High or Low. PIC switching can be used with a wide range of different free-energy designs. The PIC chip is generally supplied with a socket, a connecting cable and a program for feeding instructions into the chip. The feed is generally from an ordinary PC. The programming instructions are very simple and anyone can learn how to use them in just a few minutes.

So let's look at a circuit which has been used by Jeff when he tests prototype circuitry. The first part of the circuit is for connecting the standard PC socket to the PIC chip and it looks like this:
A standard 9-pin computer socket has its pin 2 connected to the PIC's pin 2, pin 3 connected to the PIC's pin 3 via a 10K / 22K voltage divider resistor pair (which lowers the incoming signal voltage), and pin 5 is connected to the PIC's pin 5. That is all that's needed to feed information into the PIC chip.

The chip is supplied from a 12-volt battery but as it needs a 5-volt supply, the 100 / 150 ohm (2 watt) resistor pair is used to drop the 12 volts down to about 7 volts and then the 5.1-volt zener diode clamps the voltage at 5.1 volts, which is just what the chip needs. The tiny 10 nF (0.01 microfarad) capacitor is there to trap any voltage spikes should any be picked up from some outside influence. Finally, the press-button switch used to short between pins 4 and 5 is used to wipe out the program inside the PIC, ready for a new program to be loaded.

The actual programming is not difficult and the feed into the chip is handled by the program supplied with the chip and which is run on your home computer. Let's take an example. Suppose we want the output on pin 10 to act as a clock signal. The people who made the chip expect that pin to be called "Output 4" in the program. Please don't ask me why it isn't called "10" in the program as I have no answer for you other than "it takes all sorts of people to make a world".

All right, suppose we want to produce an output signal like a 555 chip running at 50 Hz. We choose one of our output pins, say, the physical pin 10, that being the bottom right hand pin on the chip. As you can see from the pin diagram of the chip shown above, pin 10 is called "Output 4" in a set of commands, or just "4" to save typing. The program might be:

```
Main:
high 4
pause 10
low 4
pause 10
goto Main
```

Wow - really difficult stuff!! Only a genius could manage to program! Well, we'll see if we can struggle along with this "difficult" stuff.

The "Main:" at the start is a "label" which can be jumped to and that is done by the "goto Main" command which sends the chip back to repeat the commands in the loop indefinitely (or until the chip is powered down).

The second line "high 4" tells the chip to put the maximum possible voltage on the "Output 4" which is the physical pin 10 of the chip. The chip does this immediately, with no time delay.

If we want the output to give a 50 Hz output signal, then the voltage on our chosen output pin will have to go high, pause, go low, pause and go high again, 50 times each second. As there are 1,000 milliseconds in one second, and the chip's clock runs with 1 millisecond ticks, then we need our complete cycle of "up, pause, down, pause" to happen 50 times in those 1,000 clock ticks. That is, once every 20 ticks, so each delay will be 10 clock ticks long.

The third line "pause 10" tells the chip to sit on it's hands and do nothing for the next 10 ticks of it's internal clock (which ticks 1,000 times per second).

The fourth line "low 4" tells the chip to lower the output voltage on it's "Output 4" (pin 10 in real life) to it's minimum value.

The fifth line "pause 10" tells the chip to wait for 10 milliseconds before doing anything else.
The last line "goto Main" tells the computer to go back to the label "Main:" and continue with whatever instructions follow that label. This puts the chip into an 'infinite loop' which will make it generate that output waveform continuously. The output will look like this:

![Graph showing a waveform with 50% Duty Cycle.]

This gives an even waveform, that is, one with a Mark/Space ratio of 50:50 or a Duty Cycle of 50%. If we want the same rate of pulsing but a Duty Cycle of just 25% then the program would be:

```
Main:
  high 4
  pause 5
  low 4
  pause 15
  goto Main
```

which produces this waveform:

![Graph showing a waveform with 25% Duty Cycle.]

If you wanted "Output 7" (physical pin 13) to do the reverse of this at the same time - that is, when Output 4 goes high we want Output 7 to go low, and vice versa, then, for a 20% Duty Cycle the program would be:

```
Main:
  high 4
  low 7
  pause 4
  low 4
  high 7
  pause 16
  goto Main
```

These output voltages are then used in exactly the same way as the output voltages on pin 3 of a 555 chip, or any of the outputs of NAND gates, Hall-effect sensor chips, Schmitt triggers, or whatever. If the device to be powered requires very little current, then the easiest method is to connect the load directly to the output pin.

If, as is most often the case, the device to be powered needs a large current to make it work, then the output voltage is used to power a transistor, perhaps like this:
Here, the resistor "R1" limits the current fed into the base of the transistor when pin 10 goes high, but allowing enough current for the transistor to switch on fully, powering the load. The resistor "R" makes sure that the transistor switches off fully when the output on pin 10 goes low. The circuit as shown restricts the load to some piece of equipment which can operate on just five volts, so an alternative circuit could be:

This allows whatever voltage the load needs to be applied to the load, while the PIC chip remains running on it's normal 5-volt supply. However, the equipment to be powered may not be able to have a common zero voltage connection with the PIC. To deal with this, an optical isolation chip can be used like this:

Here a high output voltage on pin 10 of the PIC chip lights up the LED inside the opto-isolator chip, causing a major drop in the resistance between the other two pins. This causes a current controlled by the resistor "R" to be fed into the base of the transistor, switching it on and powering the load.

Recently, a very popular programmable chip has been introduced. It is called the "Arduino" and it is fast and versatile and very popular with experimenters. There is an extensive set of English-language Video tutorials on the Arduino chip, the first in the series by Jeremy Blum is [http://www.youtube.com/watch?v=fCxzA9_kg6s](http://www.youtube.com/watch?v=fCxzA9_kg6s). The board looks like this:
Capacitors.
We have avoided mentioning capacitors in any detail as it has not been necessary for understanding the circuitry covered so far. Capacitors come in many sizes, types and makes. Their size is stated in ‘Farads’ but as the Farad is a very large unit, you are unlikely to encounter a capacitor marked in anything larger than a microfarad, which is a millionth of a Farad. The symbol for a microfarad is μF where ‘μ’ is the letter of the Greek alphabet. This is a pain for normal text production as Greek letters do not occur in your average font. Some circuit diagrams give up on ‘μ’ and just write it as uF which looks like μu-F slightly mis-printed where the descender of the μ has not printed.

Anyway, very large capacitors which you may encounter range from 5,000 microfarads to maybe as much as 20,000 microfarads. Large capacitors range from 10 microfarads to 5000 microfarads. Medium sized capacitors run from 0.1 microfarad to about 5 microfarads and small capacitors are those below 0.1 microfarad.

1000 nanofarads (‘nF’) = 1 microfarad.
1000 picofarads (‘pF’) = 1 nanofarad

So:

0.01 microfarad can be written as 10nF
0.1 microfarad can be written as 100nF
0.1nF can be written as 100pF

Capacitors larger than 1 microfarad tend to be ‘polarised’. In other words, the capacitor has a ‘+’ connector and a ‘-’ connector, and it does matter which way round you connect it. The larger capacitors have a voltage rating and this should not be exceeded as the capacitor can be damaged and possibly even totally destroyed. Capacitors can be added together, but surprisingly, they add in the reverse way to resistors:

Example 1

100μF 16V + 100μF 16V = 50μF 32V

Example 2

100μF 16V + 100μF 16V = 33μF 48V
If two capacitors are wired in series, as shown in Example 1 above, the overall capacity is reduced while the voltage rating increases. The reduction in capacitance is given by:

\[
1/C_t = 1/C_1 + 1/C_2 + 1/C_3 + \ldots
\]

In Example 1, then, \(1/\text{total capacitance} = 1/100 + 1/100\) or \(1/C_t = 2/100\) or \(1/C_t = 1/50\)

so the overall capacitance reduces from 100 microfarads to 50 microfarads. The advantage in wiring the capacitors like this is that the voltage rating has now increased to 32V (16V across each of the capacitors).

In Example 2, the overall capacitance has reduced to a third of 100 microfarads but the voltage rating has tripled.

In Example 3, the capacitors are wired in parallel. The voltage rating is unchanged but the overall capacitance is now the sum of the three capacitors, namely 300 microfarads.

There is no need for the capacitors to have similar values, there are merely shown that way in the examples to make the arithmetic easier and not distract you from the ways in which the capacitors interact together.

Occasionally, a circuit needs a large capacitor which is not polarised. This can be provided by placing two polarised capacitors back-to-back like this:

When the capacitors are connected this way, it does not matter which end of the pair is connected to the positive side of the circuit and which to the negative side.

Large capacitors usually have their capacitance and voltage printed on the outside of the capacitor, but small capacitors are usually far too tiny for that to be an option. So, a code very much like that used for resistors is used for small capacitors. The code is a 2-digit code for capacitors up to 100 picofarads and for higher values it is a 3-digit code where the first two digits are the numerical value of the capacitor in picofarads and the third digit is the number of zeros following the two digits. One thousand picofarads (pF) is one nanofarad (nF) and one thousand nanofarads is one microfarad. These are some common values:

The time has come for a serious warning: High voltages are very, very dangerous. Do not become so familiar with them that you treat them casually. **High voltages can kill you.** Capacitors are capable of building up high voltages and some good makes can hold the charge for several days.

In particular, do **not** try to make adjustments to, or take parts from, the inside of a TV set. A black and white TV set uses 18,000 Volts on the magnetic coils used to create the moving picture on the tube. A capacitor inside the set may well have that voltage on it three days after the set was last used. Don't fool around inside a TV set, it could kill you quick, or if you are really unlucky, it could injure you for life. A colour TV set uses 27,000 Volts to operate the coils inside it and that will fry you in jig time if you touch it.

Also, please don’t think that you are safe if you don’t quite touch it; 27,000 volts can jump across a gap to your hand. If you try to discharge a TV capacitor using a metal screwdriver with a wooden handle, please ensure that you medical insurance is up to date before you do it. You can receive a hefty shock through the screwdriver handle.

Voltages up to 24 Volts should be quite safe. **However,** some circuits will generate very high voltages even though the battery driving the circuit is low voltage. A standard off-the-shelf inverter circuit produces 240 Volts AC from a 12 Volt battery. Just because the battery is only 12 Volts does **not** mean that the circuit is not dangerous. Circuits which have inductors in them can produce high voltages, especially if they contain large capacitors. The voltage which produces the spark in your car engine is very high and it comes from the 12-volt car battery. You know enough about this by now, so **pay attention**!

**The more advanced stuff:**

You do not need to bother with this section if you are just starting out with some basic switching circuits of the type already described in this tutorial, so please feel free to skip this section and move on to the “Prototype Construction” section which you will find immediately useful.

This section is a lightweight introduction to Alternating Current circuits and pulsed DC circuits. Let me stress again that I am mainly self-taught and so this is just a general introduction based on my present understanding.

**AC Power Factors.**

Alternating Current, generally called “AC” is called that because the voltage of this type of power supply is not a constant value. A car battery, for instance, is DC and has a fairly constant voltage usually about 12.8 volts when in it’s fully charged state. If you connect a voltmeter across a car battery and watch it, the voltage reading will not change. Minute after minute it says exactly the same because it is a DC source.

If you connect an AC voltmeter across an AC power supply, it too will give a steady reading, but it is telling a lie. The voltage is changing all the time in spite of that steady meter reading. What the meter is doing is **assuming** that the AC waveform is a sine wave like this:

![Sine Wave](image)

and based on that assumption, it displays a voltage reading which is called the “Root Mean Square” or “RMS” value. The main difficulty with a sine wave is that the voltage is below zero volts for exactly the same length of time as it is above zero volts, so if you average it, the result is zero volts, which is not a satisfactory result because you can get a shock from it and so it can’t be zero volts, no matter what the arithmetical average is.

To get over this problem, the voltage is measured thousands of times per second and the results squared (that is, the value is multiplied by itself) and then those values are averaged. This has the advantage that when the voltage is say, minus 10 volts and you square it, the answer is plus 100 volts. In fact, all of the answers will be positive, which means that you can add them together, average them and get a sensible result. However, you end up with a value which is far too high because you squared every measurement, and so you need to take the square root of that average (or “mean”) value, and that is where the fancy sounding “Root Mean Square” name comes from – you are taking the (square) root of the (average or) mean value of the squared measurements.

With a sine wave like this, the voltage peaks are 41.4% higher than the RMS value which everyone talks about. This means that if you feed 100 volts AC through a rectifier bridge of four diodes and feed it into a capacitor the
capacitor voltage will **not** be 100 volts DC but instead it will be 141.4 volts DC and you need to remember that when choosing the voltage rating of the capacitor. In that instance I would suggest a capacitor which is made to operate with voltages up to 200 volts.

You probably already knew all of that, but it may not have occurred to you that if you use a standard AC voltmeter on a waveform which is **not** a sine wave, that the reading on the meter is most unlikely to be correct or anywhere near correct. So, please don’t merrily connect an AC voltmeter across a circuit which is producing sharp voltage spikes like, for instance, one of John Bedini’s battery pulsing circuits, and think that the meter reading means anything (other than meaning that you don’t understand what you are doing).

You will, hopefully, have learned that power in watts is determined by multiplying the current in amps by the voltage in volts. For example, 10 amps of current flowing out of a 12 volt power supply, represents 120 watts of power. Unfortunately, that only holds true for circuits which are operating on DC, or AC circuits which have only resistors in them. The situation changes for AC circuits which have non-resistive components in them.

The circuits of this type which you are likely to come across are circuits which have coils in them, and you need to think about what you are doing when you deal with these types of circuit. For example, consider this circuit:

![Diagram](attachment:diagram.png)

This is the output section of a prototype which you have just built. The input to the prototype is DC and measures at 12 volts, 2 amps (which is 24 watts). Your AC voltmeter on the output reads 15 volts and your AC ammeter reads 2.5 amps and you are delighted because 15 x 2.5 = 37.5 which looks much bigger than the 24 watts of input power. **But**, just before you go rushing off to announce on YouTube that you have made a prototype with COP = 1.56 or 156% efficient, you need to consider the real facts.

This is an AC circuit and unless your prototype is producing a perfect sine wave, then the AC voltmeter reading will be meaningless. It is just possible that your AC ammeter is one of the few types that can accurately measure the current no matter what sort of waveform is fed to it, but it is distinctly possible that it will be a digital meter which assesses current by measuring the AC voltage across a resistor in series with the output, and if that is the case, it will probably be assuming a sine wave. The odds are that both readings are wrong, but let’s take the case where we have great meters which are reading the values perfectly correctly. Then the output will be 37.5 watts, won’t it? Well, actually, no it won’t. The reason for this is that the circuit is feeding the transformer winding which is a coil and coils don’t work like that.

The problem is that, unlike a resistor, when you apply a voltage across a coil the coil starts absorbing energy and feeding it into the magnetic field around the coil, so there is a delay before the current reaches it's maximum value. With DC, this generally doesn’t matter very much, but with AC where the voltage is changing continuously, it matters a great deal. The situation can be as shown in this graph of both voltage and current:

![Graph](attachment:graph.png)

At first, this does not look like any great problem, but it has a very significant effect on the actual power in watts. To get the 37.5 watts output which we were talking about earlier, we multiplied the average voltage level by the average current level. But these two values do not occur at the same time and that has a major effect.

As this can be a little difficult to see, let’s take the peak values rather than the averages as they are easier to see. Let’s say that in our example graph that the voltage peak is 10 volts and the current peak is 3 amps. If this were
DC we would multiply them together and say that the power was 30 watts. But with AC, this does not work due to the timing difference:

When the voltage is peaking, the current is nowhere near it’s peak value of 3 amps:

As a result of this, instead of getting our expected peak power at the top of the voltage peak, the actual power in watts is very much lower – less than half of what we were expecting. Not so good, but it gets worse when you look at the situation more closely. Take a look at what the voltage is when the current crosses the zero line, that is, when the current is zero. The output power is zero when the current is zero but this occurs when the voltage is at a very high value:

The same goes for when the voltage is zero. When the voltage is zero, then the power is also zero, and you will notice that this occurs when the current is at a high value:

The power is not the average current multiplied by the average voltage if there is a coil involved in the circuit – it will be less than that by an amount known as the “power factor” and I’ll leave you to work out why it is called that.

So, how do you determine what the power is? It is done by sampling the voltage and current many times per second and averaging those combined results:
Both the voltage and the current are sampled at the times indicated by the vertical red lines and those figures are used to calculate the actual power level. In this example, only a few samplings are shown, but in practice, a very large number of samples will be taken. The piece of equipment which does this is known as a wattmeter as it measures watts of power. The sampling can be done by windings inside the instrument, resulting in an instrument which can be damaged by overloading without the needle being anywhere near full deflection, or it can be done by digital sampling and mathematical integration. Most digital sampling versions of these meters only operate at high frequencies, typically over 400,000 cycles per second. Both varieties of wattmeter can handle any waveform and not just sine waves.

The power company supplying your home measures the current and assumes that the full voltage is present all of the time that the current is being drawn. If you are powering a powerful electric motor from the mains, then this current lag will cost you money as the power company does not take it into account. It is possible to correct the situation by connecting one or more suitable capacitors across the motor to minimise the power loss.

With a coil (fancy name “inductor” symbol “L”), AC operation is very different to DC operation. The coil has a DC resistance which can be measured with the ohms range of a multimeter, but that resistance does not apply when AC is being used as the AC current flow is not determined by the DC resistance of the coil alone. Because of this, a second term has to be used for the current-controlling factor of the coil, and the term chosen is “impedance”. The wire in any coil has a resistance and that opposes current flow through the coil irrespective of whether the voltage applied to the coil is DC or AC. The capacitance between the neighbouring turns of wire in a coil, introduces a feature of the coil which “impedes” AC current flow through the coil and the amount of that impedance depends on the frequency of the AC voltage being applied to the coil.

The impedance of a coil depends on it’s size, shape, method of winding, number of turns and core material. If the core is made up of iron or steel, (usually thin layers of iron which are insulated from each other), then it can only handle low frequencies. You can forget about trying to pass 10,000 cycles per second (“Hz”) through the coil as the core just can’t change its magnetisation fast enough to cope with that frequency. A core of that type is ok for the very low 50 Hz or 60 Hz frequencies used for mains power, which are kept that low so that electric motors can use it directly.

For higher frequencies, ferrite can be used for a core and that is why some portable radios use ferrite-rod aerials, which are a bar of ferrite with a coil wound on it. For higher frequencies (or higher efficiencies) iron dust encapsulated in epoxy resin is used. An alternative is to not use any core material and that is referred to as an air-core coil. These are not limited in frequency by the core but they have a very much lower inductance for any given number of turns. The efficiency of the coil is called it’s “Q” (for “Quality”) and the higher the Q factor, the better. The resistance of the wire lowers the Q factor.

A coil has inductance, and resistance caused by the wire, and capacitance caused by the turns being near each other. However, having said that, the inductance is normally so much bigger than the other two components that we tend to ignore the other two. Something which may not be immediately obvious is that the impedance to AC current flow through the coil depends on how fast the voltage is changing. If the AC voltage applied to a coil completes one cycle every ten seconds, then the impedance will be much lower than if the voltage cycles a million times per second.

If you had to guess, you would think that the impedance would increase steadily as the AC frequency increased. In other words, a straight-line graph type of change. That is not the case. Due to a feature called resonance, there is one particular frequency at which the impedance of the coil increases massively. This is used in the tuning method for AM radio receivers. In the very early days when electronic components were hard to come by, variable coils were sometimes used for tuning. We still have variable coils today, generally for handling large currents rather than radio signals, and we call them “rheostats” and some look like this:
These have a coil of wire wound around a hollow former and a slider can be pushed along a bar, connecting the slider to different winds in the coil depending on its position along the supporting bar. The coil connections are then to the slider and to one end of the coil. The position of the slider effectively changes the number of turns of wire in the part of the coil which is in the circuit. Changing the number of turns in the coil, changes the resonant frequency of that coil. AC current finds it very, very hard to get through a coil which has the same resonant frequency as the AC current frequency. Because of this, it can be used as a radio signal tuner:

![Diagram of a radio signal tuner with an aerial, coil, tuning capacitor, Germanium diode, and headphones.]

If the coil’s resonant frequency is changed to match that of a local radio station by sliding the contact along the coil, then that particular AC signal frequency from the radio transmitter finds it almost impossible to get through the coil and so it (and only it) diverts through the diode and headphones as it flows from the aerial wire to the earth wire and the radio station is heard in the headphones. If there are other radio signals coming down the aerial wire, then, because they are not at the resonant frequency of the coil, they flow freely through the coil and don’t go through the headphones.

This system was soon changed when variable capacitors became available as they are cheaper and more compact. So, instead of using a variable coil for tuning the radio signal, a variable capacitor connected across the tuning coil did the same job:

![Diagram of a radio receiver circuit with an aerial, coil, tuning capacitor, Germanium diode, and headphones.]

**Resonance.**

While the circuit diagram above is marked “Tuning capacitor” that is actually quite misleading. Yes, you tune the radio receiver by adjusting the setting of the variable capacitor, **but**, what the capacitor is doing is altering the resonant frequency of the coil/capacitor combination and it is the resonant frequency of that combination which is doing exactly the same job as the variable coil did on its own.

This draws attention to two very important facts concerning coil/capacitor combinations. When a capacitor is placed across a coil “in parallel” as shown in this radio receiver circuit, then the combination has a very high impedance (resistance to AC current flow) at the resonant frequency. But if the capacitor is placed “in series” with the coil, then there is nearly zero impedance at the resonant frequency of the combination:

![Diagram showing very high resistance at resonance and very low resistance at resonance.]

This may seem like something which practical people would not bother with, after all, who really cares? However, it is a very practical point indeed. In Chapter 3, some of the very high-power devices produced by Don Smith are described. Typically, he uses an off-the-shelf neon-tube driver module as an easy way to provide a high-voltage, high-frequency AC current source, typically, 6,000 volts at 30,000 Hz. He then feeds that power into a Tesla Coil which is itself, a power amplifier. The arrangement is like this:
People who try to replicate Don’s designs tend to say “I get great sparks at the spark gap until I connect the L1 coil and then the sparks stop. This circuit can never work because the resistance of the coil is too low”.

If the resonant frequency of the L1 coil does not match the frequency being produced by the neon-tube driver circuit, then the low impedance of the L1 coil will definitely pull the voltage of the neon-tube driver down to a very low value. But if the L1 coil has the same resonant frequency as the driver circuit, then the L1 coil (or the L1 coil/capacitor combination shown on the right, will have a very high resistance to current flow through it and it will work well with the driver circuit. So, no sparks, means that the coil tuning is off. It is the same as tuning a radio receiver, get the tuning wrong and you don’t hear the radio station.

Choosing components which are not specified.

Some people find it difficult to select a suitable component where the exact component is not specified or where an alternative has to be selected, so perhaps a few general pointers might be helpful. The reason why component values are omitted may well be because a very wide range of alternative values can be used and if one particular is specified, the newcomers to electronics feel that they have to use that one value or the circuit will not work, (which is almost never the case). For example, I have been asked if a capacitor rated at 25V could be used instead of the same value capacitor rated at 16V shown in the circuit, to which the answer is ‘yes, most definitely’. The lower voltage rating is adequate and the component cheaper to buy, but if one of a higher voltage rating is available, then it can be used.

With capacitors, you need to consider the physical size and wire connections, the capacitance, the voltage rating, and the leakage. The cost and size of a capacitor is directly related to it’s voltage rating, and once the voltage rating exceeds that normally used, the price shoots up rapidly as the sales volume reduces rapidly, which in turn, discourages further sales. This sometimes causes circuit builders to connect chains of cheaper capacitors together to make a smaller-capacity high-voltage capacitor. In the case of Tesla Coil builders, they then may connect several of these chains in parallel to boost the capacitance.

If the voltage rating is exceeded (usually by a very large amount), the capacitor will be damaged and become either a short-circuit, or more likely, an open circuit. Either way, it will never work as a capacitor again. In a household circuit, where the capacitor is being used as part of the power supply to the circuit, the voltage rating does not need to be much higher than the supply voltage, with say, 16V being used for a 12V circuit. You could use a capacitor rated at 25V, 40V, 63V, 100V or 400V and it would work perfectly well, but it will be much larger and have cost much more. But, if you have one sitting around and not being used, there is no reason why you should not use it rather than paying to buy another one.

If the capacitor is being used in a timing circuit where a high-value resistor is feeding current to it, then the leakage current of the capacitor becomes very important. Electrolytic capacitors are seldom suitable for such an application as they have a small, unpredictable leakage current which will vary with the age of the capacitor. For accurate timing with a capacitor, ceramic, polypropylene, mylar or tantalum should be used.

The voltage rating for an electrolytic capacitor is for DC, so if you use it for limiting current in an AC power supply, that is, where the current flows through the capacitor rather than the capacitor being placed across the supply and is acting to combat ripple, then great care is needed. The capacitor will heat up due to the power flowing through it, and it is possible for an electrolytic capacitor used in that way to rupture or ‘explode’ due to the electrolyte boiling. Instead, you need to use the very much more expensive oil-filled can capacitors (as shown near the end of chapter 10). That style of usage is unusual for home constructors.

With bi-polar transistors, you need to use commonsense. Suppose a 555 timer chip is required to power a transistor which controls a relay:
For the moment, we will ignore the fact that the 555 could drive the relay directly without the need for a transistor. Let’s say that the relay draws a current of 30 mA when connected to a 12V supply. Therefore, the transistor needs to be able to handle a current of 30 mA. Any small switching transistor such as the BC109 or 2N2222 can easily handle that current. The transistor also needs to be able to handle 12 volts. If in doubt, look up the characteristics of your choice of transistor at [http://www.alldatasheet.co.kr/](http://www.alldatasheet.co.kr/) by entering the transistor name ‘BC109’ or whatever in the entry box at the top of the screen and clicking on the button to the right of it. Eventually, it will let you download a pdf document specifying the transistor, and that will show you the voltages which the transistor can handle. Both of the above transistors can handle far more than 12V.

The next question is, ‘can the transistor switch fast enough to work in this circuit?’ and the data sheet will show that they can switch on and off a million times per second. As the relay can only switch on and off a few times per second, the transistor can easily operate fast enough to handle the switching.

Next, we need to know what size of resistor would be suitable. The data sheet will also show the DC current gain of the transistor. This is usually marked as “hfe” and for these transistors is likely to be a minimum of, say, 200. This means that the current flowing into the base of the transistor needs to be one two-hundredth of the relay’s 30 mA which is 0.15 mA. The resistor will have about +11 volts at pin 3 of the 555 timer and around +0.7 volts at the base of the transistor when it is switched fully on. That means that the resistor will have about 10.3 volts across it when the relay is switched on:

So, what size of resistor will have 0.15 mA flowing through it when there is a 10.3-volt drop across it? We know that a 1K resistor passes 1mA per volt and so would pass 10.3 mA with 10.3 volts across it. That is far more than we need. A 10K resistor would pass 1.03 mA which is still far too much but certainly could be used. As it is a resistor, we can use Ohm’s Law: \( R = \frac{V}{A} \) (Ohms equals Volts over Amps), or \( R = \frac{10.3}{0.00015} \) which is 68K. So, any resistor between 68K and perhaps 15K should work well.

The diode is there to protect the transistor from excessive voltage caused by the coil of the relay. When a coil is switched off suddenly, it generates a reverse voltage which can be hundreds of volts, pulling the collector of the transistor far above the +12V power supply line. When that starts to happen, it effectively reverses the diode direction, allowing it to conduct and short-circuit that big voltage spike:
Due to the short-circuiting, the voltage can't get any higher and the current through the diode is not large, so most diodes such as the popular and cheap 1N4001 or 1N4007 types can be used.

When a transistor is connected like that and switched on, it is effectively a short-circuit between it's collector and emitter, and that places the full 12 volts across the relay, powering it very solidly. This connection method is called a “common-emitter” circuit because all of the transistors used have their emitters all wired in common to the 0V line. An alternative arrangement is the “emitter-follower” circuit:

With this circuit arrangement, the emitter of the transistor “follows” the voltage on pin 3 of the 555 timer. It is always a constant voltage below it, typically about 0.7 volts. The output of the 555 timer has a maximum of about 0.7V below the supply voltage, and so it’s maximum value is about 11.3V in this circuit. The transistor drops that by a further 0.7V, which means that the relay only gets about 10.6V across it instead of the full 12V of the supply, which means that it should be a 10-volt relay rather than a 12-volts relay.

Those are the easy cases because the 555 timer can supply at least 200 mA through it’s output pin, while keeping the output voltage steady. That is not the case with simple transistor circuits. Take a situation like this:

For audio work - microphone pre-amplifiers and the like – the rule of thumb is that the current flowing through the first transistor should be at least ten times the current required by the base of the second transistor in order not to drag down and distort the audio waveform.
Relay switching is not so critical but the same general principle applies and attention needs to paid to the collector resistor of the preceding transistor. For example, if the current flowing through the preceding transistor is small, say, 0.5 mA and the output transistor needs 1.5 mA flowing into it's base, then there can be a problem. In this circuit, for example:

Here, the voltage at point “A” goes high because the first transistor switches off and so becomes the same as a resistor of 1Meg or more. Normally, that resistance is so much greater than the 27K of it's resistor, that the voltage at point “A” would be nearly +12V, but if you were to connect the resistor “R” of just 1K in value, then the situation is changed completely. the base of “Tr” can’t rise above 0.7V. The first transistor can be ignore due to its very high resistance. That leaves a voltage-divider pair of resistors, the 27K and the 1K, with 11.3 volts across them, slopping the voltage at point “A” from rising above 1.13V instead of the original 12V and transistor “Tr” will only get 0.43 mA instead of the 1.5 mA which was wanted. The transistor “Tr” has effectively a 28K resistor feeding it current from the +12V rail.

One solution would be to raise the current through the first transistor by using a resistor a good deal smaller than the present 27K. Another option is to lower the input current requirement of transistor “Tr” by making it a Darlington pair or by using a transistor with a much higher gain.

Constructing Prototypes.
The main options for building a prototype circuit are:

1. A (plug-in) breadboard
2. Electrical screw connector strips.
3. Stripboard
4. A printed circuit board.

1. The typical breadboard unit consists of a matrix of clip holes wired in strips, into which component leads can be pushed to make a circuit. In my opinion, they are best avoided as it takes quite some effort to implement any significant circuit using them, some components do not fit well in the sockets which are small enough to take DIL IC packages, and when you do get a circuit working well on the breadboard, there is no guarantee that it will work well when you attempt to move it to a permanent soldered board:

While a plastic board of this type looks as if it should be quick and easy to use, I have never found it to be so ever since the boards were scaled down in size to take the closely-spaced pins of integrated circuits (“chips”). It is generally difficult to lay the components out in the same pattern as the circuit diagram, and if they are not, then it becomes slow to follow the circuit through on the breadboard layout.
2. The local hardware shop has cheap screw connectors which can be very effective. These come in several sizes and the smaller ones are very convenient for constructing transistor circuitry. They look like this:

Circuits can be assembled very easily, using these connectors and an example might be one of the John Bedini battery pulsing circuits which might have a layout like this:

I have built this circuit using this style of construction and it was very successful indeed, being very quick and easy to construct and it proved to be very tough and effective over a long period of use. The plastic strip has a hole between each connector strip and that allows you to bolt the strip to a base board on which you mount other components, in this case, the pulsing coil and the rotor with the magnets attached. Each connection block can take two or three wires. The wires need to have the insulation removed and the wires scraped clean and shiny if they are not already in that state. If more than one multi-strand wire is being put into one side of a connector, then it is usually best to twist the wires together before tightening the clamping screw. If you want, you can give the twisted wires a thin coat of solder, but this has to be done neatly to avoid producing a joint which is too large to fit into the connector. One connector can be cut out of the strip quite easily, using a pair of scissors or a craft knife. Single connectors can join two wires very effectively without the need to solder them.

While the wire trigger switch is shown as a thin line in the diagram above, it is suggested that it is more convenient to use wires of identical diameter, and if it is not clear which is the beginning and end of a single wire, then, an ohmmeter may be used to identify the ends. It is suggested that the cables are stretched out in a long length and then twisted together using an electric drill. I have found that doing that is not very good because the cable near the drill is twisted much more strongly than the rest of the wire. Also, it needs a considerable distance outside to lay out a sufficient length of wire. If you really want to twist the wires together (it is not immediately obvious why you would want to do that), then use two coils of wire and twist them together for a short length by turning the reels over as a pair, then wind the twisted length on to a third spool or temporary holder. This method does not need for you to set long cables (which tangle and catch on things very easily) and it gives uniformly twisted wires which can be prepared when sitting in a small workspace. The coil of 850 turns is wound like this:
The first strand of the coil starts at point “C” at the base of the coil and finishes at point “A” at the top of the coil. This is the coil which drives the motor with point “A” connected to the Plus of the drive battery. The second strand starts at point “D” at the base of the coil and finishes at point “B” with point “B” connected to the transistor’s base resistor. This arrangement generates a magnetic North field at the top of the coil and that pushes against the rotor’s permanent magnet’s North pole which is the one facing the coil. With the implementation which I used to charge a car battery, the wheel rotation was gentle, giving perhaps 200 to 300 pulses per minute to the battery. The speed of the wheel reduced as the battery charge increased and so a glance at the wheel showed the charge state of the battery. It is recommended that the coil core be made up from lengths of 1.5 millimetre diameter copper coated welding rod, but as copper is highly conductive electrically, I prefer to coat each rod with enamel paint to block sideways eddy currents which waste power.

3. Stripboard, usually called ‘Veroboard’ even if it is not made by Vero, is a quick and satisfactory method, although you have to make very tiny solder joints. Please be aware that the fumes from the burning resin when soldering are most definitely not good for your health and should be avoided by making sure that the ventilation is adequate.

4. A printed circuit board is feasible for a one-off prototype and making one will increase your production skills, so it is also a reasonable option if you have the etching and drilling equipment to hand. Buying all of the necessary equipment if you do not have any, can cost a fair amount, but the skills gained are significant and the finished boards looks very professional.

There are several other methods of construction, and many varieties of construction board and stripboard. Simple stripboard will be used in the following descriptions, although the method does apply to many different styles of construction.

The first step is to produce a layout for the components on the board. When designing the layout provision should be made for drilling holes to allow the completed board to be bolted to its case using bolts and insulating pillars to keep the soldered joints clear of all other surfaces.

The circuit diagram of the circuit to be built is the starting point. You might wish to draw a light grid of lines to represent the matrix of holes in the strip board. This helps to visualise the run of the copper strips and the sketch can be made to show the exact number of holes available on the piece of strip board to be used. The strip board looks like this:

So you might wish to produce a layout sketch re-usable drawing like this:
where the horizontal strips are numbered and the vertical lines of holes are also numbered. In this sketch, where the lines cross, represents a hole in the board. The sketch of a possible physical layout can then be prepared and it might look like this when seen from the top although the copper strips on the underside of the board are shown in the sketch:

\[\text{TIMING SECTION}\]

It is very important when producing a sketch like this, that the copper strips making up the circuit are not accidentally used to connect components further along the board, without breaking the copper strip between the two sections of the board. It helps to mark a copy of the circuit diagram when you are sketching a possible physical layout on the strip board. It might be done like this:

Here, the components just below the diode are ringed to show that they have been marked on the layout sketch and, if necessary, the copper strip broken to isolate the components. A component worth mentioning in passing, is the capacitor marked with red in the circuit diagram. This is a decoupling capacitor, fed from the 12V battery via a resistor and a diode (a diode is not normally used in this part of the circuit).
The decoupling is to provide the 555 chip and drivers with a supply which is reasonably isolated from the heavy current-draw circuit not shown in this small section of the circuit diagram. The pulsating heavy current draw of the rest of the circuit is capable of pulling the battery voltage down slightly many times per second. This creates a voltage ripple on the positive supply line from the battery and to smother the ripple, the resistor and diode are used to feed a large reservoir capacitor which smoothes out the ripple.

The circuit itself is not beyond criticism. Transistor ‘TR2’ and its associated components are redundant since pin 3 of the 555 chip already supplies the required signal (and with higher drive capacity) so the second output line should be taken directly from pin 3 of the 555 chip. This snippet of circuit is only shown here as an example of marking up a circuit diagram when making a components layout sketch.

As the layout sketch is produced, the circuit diagram should be marked off with a highlighting pen to make sure that every part of the circuit diagram has been successfully copied to the sketch. In the example below, not all of the highlighted strip is shown, since it runs off the small section of the board being shown here:

![TIMING SECTION](image)

Many electronic components can be damaged by the high temperatures they are subjected to when being soldered in place. I personally prefer to use a pair of long-nosed pliers to grip the component leads on the upper side of the board while making the solder joint on the underside of the board. The heat running up the component lead then gets diverted into the large volume of metal in the pair of pliers and the component is protected from excessive heat. On the same principle, I always use a DIL socket when soldering a circuit board, that way, the heat has dissipated fully before the IC is plugged into the socket. It also has the advantage that the IC can be replaced without any difficulty should it become damaged.

If you are using CMOS integrated circuits in any construction, you need to avoid static electricity. Very high levels of voltage build up on your clothes through brushing against objects. This voltage is in the thousands of volts range. It can supply so little current that it does not bother you and you probably do not notice it. CMOS devices operate on such low amounts of current that they can very easily be damaged by your static electricity. Computer hardware professionals wear an earthing lead strapped to their wrists when handling CMOS circuitry. There is no need for you to go that far. CMOS devices are supplied with their leads embedded in a conducting material. Leave them in the material until you are ready to plug them into the circuit and then only hold the plastic body of the case and do not touch any of the pins. Once in place in the circuit, the circuit components will prevent the build up of static charges on the chip.

Soldering is an easily-acquired skill. Multi-cored solder is used for electronic circuit soldering. This solder wire has flux resin contained within it and when melted on a metal surface, the flux removes the oxide layer on the metal, allowing a proper electrical joint to be made. Consequently, it is important that the solder is placed on the joint area and the soldering iron placed on it when it is already in position. If this is done, the flux can clean the joint area and the joint will be good. If the solder is placed on the soldering iron and then the iron moved to the joint, the flux will have burnt away before the joint area is reached and the resulting joint will not be good.

A good solder joint will have a smooth shiny surface and pulling any wire going into the joint will have no effect as the wire is now solidly incorporated into the joint. Making a good solder joint takes about half a second and certainly not more than one second. You want to remove the soldering iron from the joint before an excessive
amount of heat is run into the joint. It is recommended that a good mechanical joint be made before soldering when connecting a wire to some form of terminal (this is often not possible).

The technique which I use is to stand the solder up on the workbench and bend the end so that it is sloping downwards towards me. The lead of the component to be soldered is placed in the hole in the strip board and gripped just above the board with long-nosed pliers. The board is turned upside down and the left thumb used to clamp the board against the pliers. The board and pliers are then moved underneath the solder and positioned so that the solder lies on the copper strip, touching the component lead. The right hand is now used to place the soldering iron briefly on the solder. This melts the solder on the joint, allowing the flux to clean the area and producing a good joint. After the joint is made, the board is still held with the pliers until the joint has cooled down.

Test Equipment.
When developing new circuitry, it may be convenient to try different values of resistor in some position in the circuit (the resistor value may be dependent on the gain of a transistor or the actual resistance of an ORP12, or some such other situation). For this, it is very convenient to have a resistor-substitution box which allows you to select any standard resistor at the turn of a switch.

These are not readily available on the market. In years gone by, it was possible to buy custom wafer switches, where the number of wafers could be built up to whatever switch size was required, but these do not seem to be available any more. A slightly less convenient method of construction is to use four of these, selected by a second wafer switch:

![Diagram of resistor-substitution box](image)

In the above diagram, all of the resistors in one range (100 ohms to 820 ohms, 1K to 8K2, 10K to 82K or 100K to 820K) are wired to a single 12-way switch. The output wires then have any of these standard resistors across them, depending on the setting of the switch. A second switch can then be used to select several of these groups, while still using the same output wires. When boxed, it might look like this:
It can also be useful to have a versatile signal generator. You can easily construct your own with variable frequency, variable mark/space ratio and optional variable gating. If you do, you might as well make it with a low output impedance so that it can drive devices under test directly rather than having to provide additional buffering. It might look like this:

![Signal Generator Image]

The really essential item of equipment is a multimeter. These come in many shapes, sizes and varieties and the cost varies enormously. The reliability also varies a great deal. The most reliable and the cheapest is the analogue type which does not use a battery (other than for the occasional measurement of resistance). Although these types are looked down upon nowadays, they are 100% reliable:

![Multimeter Image 1]

The meter shown above is rated at 2,000 ohms per volt, so connecting it to a circuit to make a measurement on the 10V range is the same as connecting a 20K resistor to the circuit. The big brother of this style of equipment is about five times larger and has 30,000 ohms per volt performance, so connecting it on a 10V range is the same as connecting a 300K resistor to the circuit being measured. This one is battery driven, so if you get one of these, may I suggest that you check its accuracy on a regular basis:

![Multimeter Image 2]
The really excellent non-battery (ex-professional) Avo meter multimeters are still available through eBay at affordable prices. These have 30,000 ohms per volt performance and are robust and accurate, having been built to very high standards.

A multimeter uses a 1.5V battery to measure resistance. Ohm’s Law is used as the working principle and the operation is:

The meter shown in the diagram has a small resistance of its own. This has a small variable resistor added to it. This variable resistor will have a small knob mounted on the face of the multimeter, or it will be a thumbwheel knob projecting slightly from the right hand side of the multimeter case. The 1.5V battery will be positioned inside the multimeter case as is the 1K resistor. To use the resistance ranges, the multimeter probes are touched firmly together to form a short-circuit and the variable resistor adjusted so that the meter points to zero.

For the purpose of this discussion, let us assume that the internal resistance of the meter, when correctly adjusted, is exactly 1K. If the resistor under test is exactly 1K in value, then the current through the meter will be halved and the meter will show a needle deflection half way across the scale. If the resistor under test is 2K, then the current will be one third and the scale marking will be at the 1/3 position from the left. If the resistor is 4K, then there will be one fifth (1K + 4K = 5K) of the full-scale current and the 4K mark will be 20% from the left hand side of the scale.

Two things to notice: firstly, the scale has to read from right to left which can take some getting used to, and secondly, the scale is not linear, with the markings getting closer and closer together and consequently, more difficult to mark and read, the higher the value of the resistor being measured. The bunching up of the scale markings is why the more expensive multimeters tend to have more than one range.

A mains-operated oscilloscope is an excellent piece of equipment to own but they are expensive when new. It is possible to pick one up at a reasonable price second-hand via eBay. An oscilloscope is by no means an essential item of equipment. One of its most useful features is the ability to measure the frequency, and display the shape of a waveform. Most waveforms are of known shape so the frequency is the major unknown. The following meter is not expensive and it displays the frequency of a signal on a digital readout:
So, when you are deciding what multimeter to buy, consider the following points:

1. How reliable is it? If you are opting for a battery driven unit, what happens to the accuracy if the battery starts to run down. Does it display a warning that the battery needs to be replaced? Mains-operated digital multimeters are brilliant but are a problem if you want to make measurements away from the mains.

2. What DC voltage ranges does it have? If you are intending to work mainly with 12V circuits, it is inconvenient for the ranges to be 9V and 30V as successive ranges. Digital meters do not have this problem but the question then is, how accurate are they going to be in day to day use?

3. Transistor testing options you can ignore - you are better off making your own dedicated unit to check transistors if you think you will ever need to do this - you probably won't.

4. Measuring current can be very useful so see what ranges are offered.

5. Measuring capacitance is very useful, especially since many capacitors are not well marked to indicate their value.

6. Measuring the frequency of a waveform could be a significant bonus but the question is; are you every likely to need it?

7. Measuring resistance is very useful. Every meter has it. There is no need to be over fancy on measurement ranges as you usually only need to know the approximate answer - is it a 1K resistor or a 10K resistor?

Look around and see what is available, how much it costs and what appeals to you. It might not be a bad idea to buy a really cheap multimeter and use it for a while to see if it has any shortcomings which are a nuisance, and if so, what improvements you personally want from a more expensive meter.

The ‘Bench’ Power Supply.
It might be worth getting a fancy bench power supply which allows you to set any voltage you want and which displays the current being drawn by your development circuit:
However, there is no need to spend money on a fancy unit when you can build an excellent unit of your own with voltage stabilisation, adjustable output, metered current, etc. etc. Personally, if developing a circuit to be used with a battery, I believe you are better off powering the development from a battery, that way the characteristics of the battery are included in any tests which you carry out.

If you wish, you can construct a very convenient development test bed power supply system. This has the advantage that you can make it in the most convenient style for your own use. You can also make the protection ultra-sensitive and build in additional circuitry such as transistor tester and resistor substitution box to produce an integrated test bed. You could perhaps use a circuit like this:

![Diagram of power supply system]

Here, the power is supplied by a pack of re-chargeable Ni-Cad batteries or possibly, a mains unit with voltage stabilisation. As in all actual circuits, the next thing in the circuit is always an on/off switch so that the power source can be disconnected immediately should any problem arise. Next, as always, comes a fuse or circuit breaker, so that should the problem be serious, it can disconnect the circuit faster than you can react. If you wish, you can build your own super-accurate adjustable circuit breaker to use in this position.

The two transistors and three resistors form an adjustable, stabilised output. The FET transistor has a high output power handling capacity and a very low input power requirement and so is good for controlling the output voltage.
Resistor ‘VR1’ is padded with the 4K7 resistor solely to reduce the voltage across the variable resistor. VR1 is adjusted to control the output voltage. If the current draw is increased and the output voltage is pulled down slightly, then the voltage on the base of the BC109 transistor is reduced. This starts to turn the transistor off, raising the voltage at point ‘A’, which in turn, raises the output voltage, opposing the variation caused by the load.

The output is monitored, firstly by a large milliammeter to show the current draw and secondly, on the output side of the milliammeter, a voltmeter. This allows very close monitoring of the power supplied to the prototype, especially if the milliammeter is placed alongside the prototype. You can build this circuit into a wide flat box which provides a working surface beside the milliammeter.

At point ‘B’ in the above diagram, a method for altering the current range of the milliammeter by placing a ‘shunt’ resistor across it. When the switch is closed, some current flows through the resistor and some through the milliammeter. This resistor has a very low value, so you are better off making it yourself. Let’s say we wish to double the range of the meter. Solder the switch across the meter and for the resistor use a length of enamelled copper wire wound around a small former. Put a load on the output so that the meter shows a full-scale deflection. Close the switch. If the current displayed is exactly half of what it was, if not, switch off, remove some wire to lower the reading or add some wire to raise the reading and repeat the test until exactly half the current is displayed. The lower the value of the shunt resistor, the more current flows through it and the less through the meter, which then gives a lower reading.

Please note: it is very important to have a fuse or circuit breaker in the power being delivered to your test circuit. Any error in building the prototype can cause a major current to be drawn from the supply and this can be dangerous. Remember, you can’t see the current. Even if you have a meter on the current being delivered, you may not notice the high reading. The first sign of trouble may be smoke! You can easily fry the circuit you are building if you do not have a safety cut-off, so use a fuse or other device which limits the current to twice what you are expecting the circuit to draw.

So, after all that, what equipment do you really need? You need a small soldering iron and multicore solder, a pair of long-nosed pliers and a multimeter. One other thing is some tool to cut wires and remove the insulation prior to soldering. Personal preferences vary. Some people prefer one of the many custom tools, some people use a knife, I personally use a pair of straight nail scissors. You pick whatever you are comfortable with.

Not exactly a vast array of essential equipment. The other items mentioned are not by any means essential so I suggest that you start by keeping things simple and use a minimum of gear.

If you are not familiar with electronics, I suggest that you get a copy of the Maplin catalogue, either from one of their shops or via the [http://www.maplin.co.uk](http://www.maplin.co.uk) web site. Go through it carefully as it will show you what components are available, how much they cost and often, how they are used. The specifications of almost any semiconductor can be found free at [http://www.alldatasheet.co.kr](http://www.alldatasheet.co.kr) in the form of an Adobe Acrobat document.

Finally, because it is not important, all of the circuitry shown so far has indicated current flowing from the + of a battery to the - terminal. The discovery of voltage was made by Volta but he had no way of knowing which way the current was flowing, so he guessed. He had a 50 - 50 chance of getting it right but he was not lucky and got it wrong. Electrical current is actually a flow of electrons, and these flow from the battery minus to the battery plus. So, who cares? Almost nobody, as it has no practical effect on any of the circuitry. Some useful websites:

- [http://www.esr.co.uk](http://www.esr.co.uk) for components
- [http://www.maplin.co.uk](http://www.maplin.co.uk) for components
- [http://www.alldatasheet.co.kr](http://www.alldatasheet.co.kr) for semiconductor specifications
- [http://www.cricklewoodelectronics.com](http://www.cricklewoodelectronics.com) for components
- [http://www.greenweld.co.uk](http://www.greenweld.co.uk) for components

### The Oscilloscope.

If you do decide that you are going to research new equipment, design and possibly invent new devices, then an oscilloscope is useful. Let me stress again that this is not an essential item of equipment and most certainly is not needed until you are quite familiar with constructing prototypes. It is quite easy to misread the settings of an oscilloscope and the methods of operation take some getting used to. The low-cost book “How to Use Oscilloscopes and Other Test Equipment” by R.A. Penfold, ISBN 0 85934 212 3 might well be helpful when starting to use a ‘scope.

It is possible to get an oscilloscope at reasonable cost by buying second-hand through eBay. The best scopes are ‘dual trace’ which means that they can display the input waveform and the output waveform on screen at the same time. This is a very useful feature, but because it is, the scope which have that facility sell at higher prices.
The higher the frequency which the scope can handle, the more useful it is, but again, the higher the selling price. Not all scopes are supplied with (the essential) ‘test probes’, so it might be necessary to buy them separately if the seller wants to keep his. Getting the manual for the scope is also a decided plus. A low cost scope might look like this:

![Image of a scope]

**Measuring Magnetic Field Strength.**

People who experiment with permanent magnets, can make use of an instrument which displays the strength of a magnetic field. Professionally made devices to do this tend to be well outside the purchasing power of the average experimenter who will already have spent money on materials for his prototypes. Here is a design for a simple and cheap circuit, powered by four AA dry cell batteries, and utilising a Hall-effect semiconductor as the sensor:

![Circuit diagram of the magnetic field strength meter]

This design uses an OP77GP operational amplifier chip to boost the output signal from the A1302 chip which is a Hall-effect device. The gain of the DC-connected operational amplifier is set by the ratio of the 1K and 1M fixed resistors shown shaded in the circuit diagram, giving a gain of 1,000.

The circuit operation is simple. The six-volt battery charges the 10 microfarad capacitor which helps iron out any supply line fluctuations caused by varying current draw by the circuit. The 10K variable resistor is used to set the
output meter display to zero when the Hall-effect device is not near any magnet. The 1K variable resistor is there to make fine tuning adjustments easier.

When the A1302 chip encounters a magnetic field, the voltage on it's output pin 3 changes. This change is magnified a thousand times by the OP77GP amplifier. It's output on pin 6 is connected to one side of the display meter and the other side of the meter is connected to point “A”. The voltage on point “A” is about half the battery voltage. It would be exactly half the voltage if the two 4.7K resistors were exactly the same value. This is rather unlikely as there is a manufacturing tolerance, typically around 10% of the nominal value of the resistor. The exact value of the voltage on point “A” is matched by the OP77GP tuning and so the meter reads zero until a magnetic field is encountered. When that happens, the meter deflection is directly proportional to the strength of the magnetic field.

The Weird Stuff.
You don’t need to know the following information, so please feel free to skip it and move on to something else.

The presentation shown above is based on the conventional view of electronics and electrical power as taught in schools and colleges. This information and concepts works well for designing and building circuits, but that does not mean that it is wholly correct. Unfortunately, the world is not as simple as is generally made out.

For example, it is said that current is a flow of electrons passing through the wires of a circuit at the speed of light. While it is true that some electrons do actually flow through the metal of the wires, the small percentage of electrons which actually do that, do it quite slowly as they have to negotiate their way through the lattice of the molecules of metal making up the body of the wires.

In spite of this, when the On/Off switch of a circuit is flipped on, the circuit powers up immediately, no matter how long the wires are. The reason for this is that electrical current flows along the wires at very high speed indeed, but it flows rapidly along the outside of the wires, not rapidly through the wires. One thousandth of a second after switching on a circuit, the electrons flowing through the wires have hardly got started, while the current flowing along the outside of the wires has gone all around the circuit and back:

The above sketch does not show the proportions correctly, as the current flow spiralling along the outside of the wire should be hundreds of thousands of times longer than shown, which is not practical in a diagram.

The actual path taken by current flow makes the surface of the wire of particular importance, and the insulation material is also of great importance. In years gone by, wire manufacturers used to anneal (cool down) copper wires in air. This created a layer of cupric oxide on the outer surface of copper wires, and that layer gave the wire different characteristics than copper wire has today. William Barbat in his patent application claims that the cupric oxide layer can be utilised in making devices with greater power output than the power input from the user.

Unfortunately, the world is not quite as simple as that, as power flowing in a circuit has at least two components. The electrical current which we measure with ammeters is as described above and is sometimes referred to as “hot” electricity as when it flows through components, it tends to heat them up. But there is another component referred to as “cold” electricity, so named because it tends to cool components down when it flows through them. For example, if the output wires of Floyd Sweet's VTA device were short circuited together, frost would form on the device due to the heavy flow of “cold” electricity, and getting a “shock” from it could give you frostbite instead of a burn.

“Cold” electricity is not something new, it has always been there as it is just one aspect of “electricity”. It has not been investigated much by conventional science because none of the instruments used to measure “hot” electricity, react to “cold” electricity at all. (Actually, “hot” electricity, “cold” electricity and magnetism are all features of a single entity which should really be called “electromagnetism”).

Now the spooky bit: “cold” electricity does not flow along or through the wire at all. Instead, it flows in the space around the wire, possibly riding on the magnetic field caused by the “hot” current. Thomas Henry Moray is famous for building a device which captured “cold” electricity and produced a massive power output capable of powering a whole host of ordinary electrical pieces of equipment. In his many public demonstrations before he was intimidated into silence and his equipment smashed, he invited members of the audience to bring a piece of ordinary glass with them. Then, when his circuit was powering a row of lights, he would cut one of the wires and
insert the piece of glass between the cut ends of the wires. This had no noticeable effect on his circuit, with the power flowing happily through the glass and on through his circuit, powering the lights just as before. That does not happen with “hot” electricity, but as the “cold” electricity is not flowing through or along the surface of the wire, a break in the wire is not a major obstacle to it.

We still do not know very much about “cold” electricity. Edwin Gray snr. demonstrated light bulbs powered by “cold” electricity being submerged in water. Not only did the bulbs continue to operate unaffected by the water, but Edwin often put his hand in the water along with the lit bulb, suffering no ill effects from doing so. Neither of those two effects are possible with conventional electricity, so please don’t try them to check it out.

Another interesting item is the water-powered car system produced by an American man Nathren Armour. His system, (among other things) involves feeding extra electrical power to the spark plugs. One thing which has always puzzled him is that the engine will not run with just one wire going to the spark plug cap. He has to have a second wire running from his extra power supply to the body of the plug where it screws into the engine block. Take that wire away and the engine stops. Put it back again and the engine runs. But according to conventional electrics, that wire cannot possibly be needed, because the engine block is grounded and the power supply output is grounded, so in theory, there is no voltage difference between the ends of the wire, therefore no current can flow along the wire, hence the wire is not needed and has no function. Well, that is true for “hot” electricity, but it seems possible that the Nathren Armour system is using “cold” electricity as well as “hot” electricity and the “cold” electricity needs the extra wire as a flow guide to the spark plug.

Enough about that for now. Let’s go one step further into the “weirdness” of the actual world. If, three hundred years ago, you had described X-rays, gamma rays, nuclear energy and TV signals to the average well-educated person, you would have run considerable risk of being locked up as being mad. If you do it today, your listener would probably just be bored as he already knows all this and accepts it as a matter of fact (which it is). Please bear that in mind when you read the following information. If it seems strange and far-fetched, that is only because conventional science today is lagging badly behind and still teaching things which have been conclusively proven to be wrong decades ago.

If you lived in a desert and every day a company drove in with a lorry-load of sand and sold it to you for a large amount of money, what would you think about that? Not a very good deal for you, is it? What’s that you say, you would never do that? But you already do, because you don’t realise that the sand is all around you ready for the taking at next to no cost at all. Several people have tried to publicise the fact, but the sand company has immediately silenced them by one means or another. The company does not want to lose the business of selling you the sand and definitely doesn’t want you to start picking it up for yourself for free.

Well... to be perfectly fair, it is not actually sand, it is energy, and it is all around us, free for the taking. Sound a bit like X-rays did three hundred years ago? Doesn’t mean that it is not true. It is perfectly true. The design of all computers made today is based on the equations of Quantum Mechanics, and while those equations are not yet perfect, they are easily good enough for practical purposes. The snag is that the world seen at the level of the quantum is not much like the world we think that we see around us and which we think that we understand fully. Examining the world at the quantum level shows that we live in a seething mass of incredible energy. Einstein is famous for stating that Mass equals a very large amount of Energy, a fact that is shown clearly when an atomic bomb is detonated. Put in different words, a small amount of matter is the equivalent of a very large amount of energy. Actually, Energy and Matter are two different aspects of a single thing (which could reasonably be called “Mass-Energy”).

At the quantum level, it can be seen that particles of matter pop into existence and drop out again into energy on a continuous basis, everywhere in the whole of the universe. The whole universe is seething with energy. That energy doesn’t bother us any more than water bothers a fish, as we evolved in this sea of energy and we just don’t notice it. It doesn’t harm us, but if we wanted, and knew how, we could use as much of that energy as we wanted for ever and ever. The amount of that energy is unbelievable. It has been calculated that one cubic centimetre anywhere in the universe contains enough energy to create all of the matter we can see in the whole of the universe. Think how many cubic centimetres there are in the Earth ... the Solar System ... our Galaxy ... If every person on Earth were to run their vehicles, power their homes, fly their planes, etc. etc. for the next million years, it would not make the slightest dent in the energy contained in one cubic millimetre of the universe. This is not a flaw, it is a fact. (Would you like to buy a big pile of sand? - I’ve got a load just over here...). This big energy field has gone under different names over the years. A popular name at the present time is the “Zero-Point Energy Field” and it is responsible for everything that happens in the universe. It powers life itself. It balances out in equilibrium everywhere, which is one reason which makes it hard to realise that it is all around us.

Tom Bearden is an American man with very considerable abilities and considerable in-depth knowledge of how the world actually operates. His statements are generally based on laboratory-proven criteria backed up by his high level of mathematical skills which give him an additional grasp of things. He explains how electricity actually works in circuits, and it is nothing like the system taught in schools and colleges. We think that when we attach a
battery to an electrical circuit, the battery forces a current through the wires of the circuit. Sorry Chief - it is actually nothing like that at all. The power in the circuit comes directly from the Zero-Point Energy Field and has very little to do with the battery at all. We tend to think of “using up” power, but that is just not possible. Energy cannot be destroyed or “used up” the most you can do to it is to change it from one form to another. It will perform “work” (power equipment, generate heat, generate cold...) when it changes from one form to another, but if you reverse the process and convert it back to it’s original form, it will perform another lot of “work” during the conversion and end up back in exactly the same state as it started out from, in spite of having performed two lots of “work” during the operation.

A battery does not provide energy to power a circuit. Instead, what happens is that the chemical action inside the battery causes negative charges to gather at the “minus” terminal of the battery and positive charges to gather together at the “plus” terminal of the battery. These two close-together “poles” of the battery are called a “dipole” (two opposite poles near each other) and they have an effect on the Zero-Point Energy Field which is everywhere. The “Plus” pole of the battery causes a massive cluster of Zero-Point Energy Field negative charges to cluster around it. In the same way, the “Minus” pole of the battery causes a massive gathering of ZPE (“Zero-Point Energy”) positive charges to gather around it. Not only do these charges gather around the poles of the battery, but an imbalance in the energy field is created and the ZPE charges continue to arrive at the poles and they radiate out in every direction in a continuous stream of incredible energy.

So, there is your shiny new battery sitting there, not connected to anything and yet it causes massive energy streams to radiate out from its terminals in every direction. We don’t notice it, because the energy flows freely through us and we can’t feel it and none of our conventional instruments, such as voltmeters, ammeters, oscilloscopes, etc. react to it at all.

The situation changes immediately if we connect a circuit to the battery. The circuit provides a flow path for the ZPE energy to flow along, and a significant amount of energy flows near the wires of the circuit, actually powering the circuit for a split second until it reaches the battery “pole” at the far end of the circuit. When it gets there it promptly wipes out the pole, destroying it completely. The ZPE field calms down and the energy flow ceases. But our trusty battery immediately does it all again, using it’s chemical energy to create the “dipole” once more, and the imbalance of the ZPE field starts again. It is because the battery has to use it’s chemical energy all the time, creating and re-creating, and re-creating it’s “dipole” that it runs down and eventually ceases to be able to create the dipole any more - result: no more power in the circuit.

Sorry to spoil the illusion, but the battery never did power the circuit itself, it merely acted as channelling device for the Zero-Point Energy Field. In passing, Direct Current (“DC”) is actually not a continuous current at all, but instead it is a stream of DC pulses at an incredibly high frequency - way higher than we can measure at present. The speed of the pulses is so great that it looks continuous to us, a bit like the individual still pictures which are the frames of a movie, appear to be a moving image to us if they are played one after the other at a rate of 25 per second - it looks like continuous movement to us, but in reality, it is a rapid series of still pictures.

The way that a battery “dipole” works on the Zero-Point Energy Field is rather like the way that a magnifying glass acts on sunlight. The rays of the sun get concentrated into a point, focused by the lens. You can start a fire with the lens, and it would be easy to think that the lens started the fire, when in actual fact, it is the rays of the sun that started the fire and the lens just influenced a local area of the large “field” of sunlight, raising the temperature at just one point.

While we tend to think of a “dipole” being generated by a battery, the same effect is also created by a magnet, whether an electromagnet or a permanent magnet - remember that electricity and magnetism are two faces of the same entity. It is possible, but not easy, to capture the energy streaming out from the interference with the ZPE field caused by the poles of a magnet. For example, Hans Coler managed to do this with a completely passive device which, when set up correctly, could produce electrical power, hour after hour from apparently “nothing” (well, actually, the ZPE field). Roy Meyers also did it with his patented array of magnets and zinc plates - completely passive, with no moving parts at all, no battery and no circuitry.

Patrick Kelly

Chapter 13: Doubtful Devices

This chapter covers a number of devices which either are unlikely to work, or which have too little practical information available to assist replication attempts. This selection, is of course, a matter of opinion.

Paul Baumann’s “Thestatika” Machine.
This device is a perfect example of a free-energy device as it powers itself and provides kilowatts of excess mains electrical power. It is in this section, not because its operation is "doubtful" in any way, but because the design has never been fully disclosed. It was developed by the late Paul Baumann who was part of a Swiss commune which is not willing to explain its operation. This “Thestatika” or “Testatika” machine works beautifully and has a very high quality of workmanship. It has two electrostatic discs which are initially rotated by hand and which then continue to rotate driven by the power produced by the device.

There are various ideas as to how the device operates. The Swiss commune no longer shows this device to people as they have the theory that "mankind" is not ready to have, or use free-energy. They have always refused to show what is inside the large cylinders mounted on each side of the device. D. A. Kelly's 1991 document provides some very perceptive comments on this device. He says:

The "Swiss M-L Converter" is a fully symmetrical, influence-type energy converter which is essentially based on the Wimshurst electrostatic generator with its twin counter-rotating discs where metallic foil sectors generate and carry small charges of electricity to be stored in matched capacitors. In Wimshurst units, diagonal neutralising brushes on each opposite disc distribute the correct charges to the sectors as they revolve, but in the M-L converter this is carried out by a crystal diode which has a higher efficiency.

Two brushes collect the accumulating charges and conduct them to the storage capacitor located at the top of this device. The device has two horseshoe magnets with matched coils and a hollow cylindrical magnet as part of the diode function, and two Leyden jars which apparently serve as the final capacitor function for the converter. The use of top grade components such as gold-plated contacts, control electrodes and dual capacitor stages, insure much higher conversion efficiencies than those available with a Wimshurst machine. The details of the operating prototype are:

1. Efficiency: The unit is started by hand and no other input power is required.
2. Constant power output: 300 volts at 10 amps = 3 kilowatts.
3. Dimensions: 43.31" (1100 mm) wide, 23.62" (600 mm) tall, 17.72" (450 mm) deep.
4. Weight: 44 lbs (20 Kg).
5. Operating speed: 60 rpm. (low speed - one revolution per second).

The twin discs are made of acrylic (plastic) and the metallic segments are steel, which causes the Searle Effect with electromagnetic conversion made at the rim of the discs through passive electromagnets. This is an ideal converter since both high voltage AC and moderate AC amperage can be generated simultaneously via two separate electrical circuits from the discs. The conventional conductive brushes pick off the high voltage AC while the rim electromagnet coils produce useful amperage. When permanent horseshoe magnets with coils are used, then the output power is enhanced to a considerable extent as shown by the above output specifications.

The self-propulsion after hand-starting the discs is achieved through the adoption of the Poggendorff principle (a German scientist of the 1870s) in which slanted conductive brushes produce self-rotation in electrostatic motors (not generators).

The special crystal diode module probably provides the dual functions of frequency regulation and capacitance amplifier - to the two Leyden jars - as part of the electrical resonance circuit, since it is connected with the horseshoe magnet coils.

This device is comprised of three separate electrical circuits:
1. The high voltage AC output from the twin electrostatic discs.
2. A moderate AC amperage circuit provided by the dual horseshoe magnet coils (Searle Effect) as the plus and minus discs pass by them. (Pulsed DC output at 50 Hz).
3. A resonant circuit in which the horseshoe magnet coils are connected to the diode capacitor so that frequency regulation is assured. The diode capacitor is then connected to the Leyden jar, transmitter unit.
The major physical principles involved in this outstanding composite unit are:
1. Electrostatic conversion using twin discs for positive output from one and negative output from the other.
2. The evidence of the Searle Effect from the use of multiple, identical steel segments inducing and EMF in electromagnets at the rim of the discs.
3. The Ecklin principle is also in evidence, since the steel segments pass by permanent horseshoe magnets, as in Ecklin's S.A.G. units.
4. The Poggendorff self-rotating electrostatic motor principle as described above.
5. The crystal capacitance function of the crystal diode module. The full operation of this unique component with its hollow cylindrical permanent magnet, is a composite component with the dual functions of distributing the correct charges to the sectors, and maintaining the output frequency at the desired value.

The M-L Converter is completely symmetrical with two acrylic discs, a light metal lattice, insulated copper wires, a secret crystal-diode rectifier, and gold-plated electrical connections. These machines have been developed over a period of twenty years.

In electrostatic generators, the air molecules between the two acrylic discs which counter-rotate closely side by side, become electrically activated by friction. This causes the discs to be continually charged until a flashover equalises the charge on them. To limit the voltage to the desired amount, the positively charged
particles on one of the discs and the negatively charged particles on the other disc are each extracted by means of separately adjustable lattice-electrodes, and are fed into a Leyden jar which collects the energy. The speed of the discs which have 50 lattice electrodes, is 60 rpm which produces a 50 Hz pulsed DC output. This speed is synchronised by magnetic impulses.

The unit is hand started by revolving the two discs in opposite directions until the Converter is charged up enough to synchronise itself and continues to rotate smoothly and noiselessly without any external source of input power. A centrally mounted disc of about 4" (100 mm) in diameter glimmers with all the colours of the rainbow. After a few seconds the Leyden jars are ready for operation and 300 volts DC with a current of 10 amps can be drawn from the device for any desired length of time. On many occasions, demonstrations have been made of the power available from the device. Heating elements, lights and hand power tools can be run from the device.

This suggested explanation of the M-L Converter contains a number of very interesting points. It has seemed mysterious that the electrostatic discs continued to rotate on their own without any visible motor driving them. Mr Kelly, who has seen the device and its operation, suggests that there are sloping brushes pressing against the front and rear faces of the twin electrostatic discs and that these are supplied with electrical current from the horseshoe magnet coils and that acts as a motor which drives the discs onwards once they have been started. He also suggests that the fifty steel segments per second which pass between the poles of the horseshoe magnets cause a rapidly fluctuating magnetic field through the magnet coils, which makes them operate as an Ecklin electrical generator, as described elsewhere in this eBook.

Mr D. A. Kelly also suggests that the two cylinders seen on the M-L Converter, are Leyden jar capacitors and that they work together as described by Sir Oliver Lodge (whose book is on this website). This is a very interesting suggestion, but it does not explain why the people in the Swiss commune refuse point-blank to let anyone see what is inside those cylinders.

There is a video produced by Don Kelly (presumably, a different person) which puts forward another theory of operation. He suggests that each of the cylinders contains a bi-filar coil on a barium ferrite magnet:

However, he describes the barium ferrite magnet as being the same type as used in radio receivers, and they are standard "ferrite rods" which are not permanent magnets as far as I am aware. Don suggests that the output from the high-voltage electrostatic discs gets fed directly to these coils and then on via a series connection to the coils around the horseshoe magnets. He envisages the bi-filar coil amplifying the current and the electrostatic discs being rotated by a standard low-voltage DC motor.
Another possibility is that the jars also contain a spark gap and surrounding copper pick-up shells and as the machine operates silently, the jars have a vacuum inside them. That would provide silent operation and explain why the people in the commune could not open them for inspection. It seems very clear that we just don't know exactly how this device operates.

One very interesting fact which has been reported by the Swiss group is that if a series of copper, aluminium and Perspex sheets are placed in a magnetic field, they generate a high voltage. This is worth investigating. It is not clear if the magnetic field should be constant or oscillating. The sequence of plates is said to be: cpacepacpacpa ("c" being copper, "p" being ‘Perspex’ (acrylic or ‘Plexiglas’) and “a” being aluminium).

The following set-up might be worth investigating:

There is good information on the Testatika at [http://peswiki.com/index.php/PowerPedia:Testatika](http://peswiki.com/index.php/PowerPedia:Testatika) but unfortunately, the bottom line is that nobody knows how to replicate Paul Baumann’s excellent machine.

**The Homopolar or “N-Machine”**.

This device was the brainchild of Michael Faraday in 1831 and has an intriguing method of operation and a remarkably large output.

The principle of operation is incredibly simple:
If a copper disc is rotated in a magnetic field, then power is developed between the shaft and the outer edge (or any intermediate position). It was then found that the device will still operate even if the magnet is attached to the copper disc and rotates with it - not something which is intuitively obvious. The power output is tremendous with the capability of extracting 1000 Amps but at a low voltage of less than 1 Volt. The power take-off can be from one face of the disc near the shaft rather than having to have a copper shaft integral with the copper disc. This device also works with a magnet just attached to the copper disc and rotating with it.

This looks like a very viable starting point to develop a device which can run itself and provide useful additional output, since a motor to rotate the disc will not require anything remotely like 1000A to drive it. The snag is, it is very difficult to provide reliable sliding contacts capable of handling large currents for extended periods of time. The second picture above shows the disc with its outer edge immersed in a bath of mercury. This is sufficient for a brief demonstration at low power but not realistic for a serious working device.

It might just be possible to get a reasonable working device by accepting that the current output is not going to be anything like 1000A. Long-life brushes could be made from solid copper bar and spring-loaded against the copper disc in matching pairs so that the brush thrusts oppose each other and so do not generate a sideways load. These could be made in multiple sets for each disc, say four or eight per disc, so that the effective electrical resistance between the brushes and the disc is reduced and the possible current draw increased.

Similar multiple brushes could be applied to the central shaft cylinder. Multiple discs could then be mounted on a non-conducting, non-magnetic shaft and their brushes wired in series as shown, to raise the output voltage:
However, when this is done, the brush drag is a serious problem. In 1987, three of the Borderlands Science team, Michael Know, Peter Lindemann, and Chris Carson experimented with this design and found that a much more satisfactory version could be produced. Their version produces sawtooth AC instead of DC and so the output could be fed directly into a step-up transformer. Their design has four ferrite magnets glued between two metal discs, and for additional mechanical strength, copper wire wound around the outer edges of the magnets in order to prevent magnets flying outwards if the glue bond should fail. Their arrangement is like this:
This appears to contradict the “laws” of conventional electricity as there is a very low resistance short-circuit directly across the brushes which pick up the AC voltage output. The output current from a small prototype was estimated at 100 amps. The frequency of the AC is directly proportional to the shaft speed of the motor, but the output voltage was almost independent of the shaft speed of the motor, increasing only very slightly with much greater speed. It was also found that putting the brushes at 90 degrees apart on the metal shaft of the motor gave the same output in spite of the contacts nearly touching each other. This design appears to have considerable potential for construction in a larger size and further investigation.

While the operation of these devices looks impossible at first glance, it needs to be understood that copper has some very unusual characteristics when interacting with magnetic fields. This is explained in the web site http://magnetism.vfedtec.com/SpinningCylinder.htm where it can be seen that a spinning copper cylinder exerts a large sideways force on a permanent magnet placed near it. This does not happen with spinning cylinders made from other metals.

**Paramahamsa Tewari** received an Indian patent (397/Bom/94) in 1994 for a COP=2.5 version, details of which can be seen at [http://www.rexresearch.com/tewari/tewari.htm](http://www.rexresearch.com/tewari/tewari.htm).

**Nikola Tesla** took Faraday’s 1831 design further as can be seen from his 1889 US patent No. 406,968. He remarked that to get any kind of useful power from the device would require a copper disc of very large diameter, or a disc which is spun very fast. A large copper disc would be an inconvenient size, and a high rate of rotation makes it very difficult to get a good, long-lasting, sliding contact at the outside edge of the disc. He also pointed out that current flowed from the shaft out to the outside edge if the magnetic field passing through the disc was in one direction, but if the direction of the magnetic field were reversed, then the current flow would be from the outer edge inwards to the shaft. The same change of direction of the current flow also happens if the direction of rotation of the disc is reversed.

Using those facts and considerable ingenuity, Tesla proposed an arrangement where the power take-off is from the axle alone, by using two separate copper discs and magnetic fields which moved in opposite directions. This arrangement has the advantage that it has an output voltage which is the sum of the two separate voltages. This basic concept uses four ring-shaped magnets and two discs of copper, brass or iron. Both of the discs are given a wide flange, as shown here:
The circuit shown here is broken by the gap between the discs and Tesla dealt with that by using a flexible metal belt linking the two discs together:

While it is possible to use the belt to drive one of the discs, Tesla did not use that method. The belt overcomes the need for a sliding contact at the outside edge of the discs and so both sliding contacts are at the axles which is an easy place to have a sliding contact. Tesla shows the contact against the end of the axles as that is just a rotary movement with respect to the stationary contact, but even if the contact pressed against the outer face of the axle, the sliding movement would still be relatively slow. In spite of this clever design from Tesla, I have never heard of anybody building this style of generator in spite of the large currents which it can generate.

The ‘Romag’ and ‘Mini-Romag’ Generators.
These generators have been displayed on the internet for some considerable time now. They can be found on the Jean-Louis Naudin website: http://jnaudin.free.fr/html/mromag.htm
The Mini Romag generator from Magnetic Energy uses the principle of moving magnetic flow named "the magnetic current" for generating electrical power. According to Magnetic Energy, this generator is able to produce 3.5 volts, 7A DC (24 Watts) of free electricity plus sufficient power to sustain itself.

This generator needs to be started by using an external motor to rotate it at 2,100 rpm for some 42 seconds. After this, the energy flow is established in the Romag generator and the external motor can be removed and the free electrical energy output can be used.

The starting procedure generates magnetic energy within the six coils of copper wire, the copper tube supporting these coils and the copper coated steel wires wrapped around the magnets. This charging is accomplished while the six coil connection wires, (shown as 22 in the above drawing), are making contact and setting up their alternating magnetic poles. After the 42 second start-up time one of these coil connection wires is opened by switch (24 above) leaving the working load in its place. The load (23 above) can draw 7 amps. As current is drawn from the six coils, it sets up magnetic poles which react with the rotor magnets maintaining the rotation. The main shaft is rotated by the 12 permanent magnets as they attract...
and build a release field. Then the driver unit (hand crank or motor) is disconnected allowing the unit to continue rotating with the load being the **activating** driving force.

**Construction:**

If you decide to attempt to build one of these units we suggest using the stated materials:

1. Aluminium Base Plate
2. Sleeve Bearing of oil impregnated brass, 1" long, 0.5" inside diameter.
3. Brass Shaft, 4" long, 0.5" outside diameter
4. Rotor, brass 1.75" long, 2" diameter,
5. Six rotor slots, each 1.75" long, 0.26" deep, 0.72" wide. These slots are spaced exactly 60 degrees apart.
6. One slot cut in centre of Brass Rotor, 360 degrees around, 0.25" wide by 0.313" deep.
7. 12 slots (produced from the six slots when the 360 degree cut is made). Each slot is lined with mica insulation, 0.01" thick.
8. A total of 228 pieces of U-shaped copper coated steel wires, 0.04" thick. Each slot (7 above) has 19 pieces of these wires fitted into the Mica, thus these wires do not contact the Brass rotor. The leading edge of these wires is flush with the Rotor’s outer surface and the trailing edge protrudes 1/8" above the Rotor’s outer diameter.
9. Each of the 12 magnets receives eleven complete turns of 0.032" thick copper coated steel wire. These 11 turns or ‘wraps’ accumulate to 3/8" wide and the same pattern is placed around all 12 magnets. When placed into the bent wires (8 above), they form a snug fit making firm contact.
10. Twelve pieces of mylar insulation, 0.005" thick, are inserted into the cores of the wires (9 above).
11. The twelve permanent magnets, insulated with the mylar, must not contact wires of 9). These magnets measure 3/4" long, 5/8" wide, 3/8" thick and are made of a special composition and strength. Alnico 4, M-60; 12 AL, 28 Ni, 5 Cobalt Fe, Isotropic permanent magnet material cooled in magnetic field, Cast 9100 TS. 450 Brin, 2.2 Peak energy product. When inserted in the rotor the outer faces of these 12 magnets are not to be machined to a radius. The centre of these magnets pass the centre of the coils with 3/32" clearance. The edges, where the wires are wrapped, pass 1/32" away from the coils. This ‘changing magnet spacing’ aids in not only the release cycle but also contributes to rotational movement. (Sharp magnet edges which are facing the coils are to be sanded to a small smooth radius.)
12. Make sure that the magnets are placed in the Rotor with the polarity shown in the diagram.
13. The 12 magnet wire wraps are divided into two sections; 6 upper and 6 lower. There are no connections between these sections. The magnetic flow direction between the upper 6 wraps and the lower 6 wraps is attained by the ‘flow direction’. The wires are wrapped around the magnet starting at the top ‘north’ half and then after 11 complete turns the wire exits at the lower ‘south’ half. As this wire then goes to the next magnet it arrives at an attract wire which is its ‘north’ side. Thus all wires get interconnected from south to north magnet half or north to south magnet half. The actual connections should be crimped copper clips (**not** solder) with insulation tubing to prevent contact to the Rotor body.
14. A 0.03" thick copper tube (stiff material) 2" long by 2½" inside diameter.
15. Six slots are cut at the top of tube #14. These slots are 5/8" wide by 1/32" deep spaced at 60 degrees apart.
16. Six slots are cut at the bottom of tube #14. These slots are 5/8" wide by 5/16" deep and in line with the upper slots #15.
17. There are six copper tube mounting points.
18. An acrylic ring is used to hold Part #14, measuring 3.75" outer diameter and 2.25" inner diameter, 3/8" thick, bolted directly to Part #1. This ring has a 0.03" wide groove cut 0.25" deep to allow the six copper tube mounting points to be inserted (part 17).

19. Plastic insulation paper, 0.002" thick, is to be placed around the inside and outside of Part #14.

20. There are six coils of insulated copper wire, each coil having 72 turns of .014 thick wire. Each coil is wound with two layers, the bottom layer completely fills the 5/8" wide slot with 45 turns and the top layer spans 5/16" wide with 27 turns. To be sure each coil has the exact wire length of 72 turns, a sample length wire is wrapped then unwound to serve as a template for six lengths. A suggested coil winding method is to fill a small spool with one length then by holding the copper tube at the lower extension, then start at the plus wire in Figure 2 and temporarily secure this wire to the outer surface of the tube.

21. Next, place the pre-measured spool of wire inside the tube, wrapping down and around the outside advancing clockwise until the 5/8" slot is filled with 45 turns. Then, return this wire back across the top of the coil for 15/32" and winding in the same direction again advance clockwise placing the second layer spanned for 5/16" with 27 turns. This method should have the second layer perfectly centered above the first layer. After winding this coil, repeat the process, filling the small spool with another length of pre-measured wire. A very important magnetic response happens as all six coils have their second layers spaced in this way.

22. Item 22 above shows the connection pattern for six coils. When the unit is driven at start-up (hand crank) for 42 seconds at 2100 RPM, all six jumper wires must be together which means the plus wire goes to the minus wire connected by the start switch. After 42 seconds the load is added to the circuit and the start switch is opened. To double check your connections between the coils, note that the finish wire of coil #1 goes to the finish wire of coil #2, which is top layer to top layer. This pattern then has start of coil 2 (bottom layer) going to start of coil 3 (also bottom layer). When the copper tube with the coils is placed around the rotor, the distance from any magnet to any coil must be identical. If it measures different, acrylic holding shapes can be bolted to the aluminum base, protruding upward, and thus push the copper tube in the direction needed to maintain the spacing as stated.

23. Wires to load.
24. Wires to start switch.
25. Rotational direction which is clockwise when viewing from top down.
27. Coating of clear acrylic to solidify rotor. **Do not use standard motor varnish.** Pre-heat the rotor and then dip it into heated liquid acrylic. After removal from dip tank, hand rotate until the acrylic hardens, then balance rotor. For balancing procedure, either add brass weights or remove brass as needed by drilling small holes into rotor on its heavy side.

28. Insulation tubing on all connections.
29. Shaft for start purposes and speed testing (if desired).

The reason that this generator is included in this chapter is because the construction is quite complex. Also, the plans have been around for several years without my being aware of anyone constructing or operating one of these units other than J.L. Naudin.

**The Frolov / Moller Atomic Hydrogen Generator.**

One already successful experiment has been shown at the J.L. Naudin website where many successful tests were performed. Alexander Frolov remarks that due to the water pump being externally powered, the results shown by J.L. Naudin are not quite accurate although the error is not significant for power levels below one kilowatt, and so the performance is actually very slightly less than that reported.

This system started with William Lyne’s concept which he published in his book “Occult Ether Systems” in 1997. In 1999, Nikolas Moller bought a copy of Lyne’s book and drew the attention of Alexander Frolov to the idea. Alexander then worked on the idea and produced both the present theory and design. A joint project was then started between Alexander’s Faraday Company Ltd. of St. Petersburg in Russia ([www.faraday.ru](http://www.faraday.ru)) and Nikolas’ company Spectrum Ltd.

The prototype shown in the photograph below, was then built by Alexander and passed to Nikolas where it was tested extensively. The exact process involved in the energy gain has only recently been fully disclosed in Alexander’s book entitled “New Energy Sources”.

The technique used involves repeatedly converting a quantity of hydrogen gas from its diatomic state (H₂ where two hydrogen atoms are bonded together to form a stable molecule), to its monatomic state H-H (where two hydrogen atoms remain as separate atoms, not closely bonded together) and back again to it’s original form.
No hydrogen is consumed. No additional gas is required. The gas is just converted from one state to the other, repeatedly. The problem for conventional science is that the output power measured in tests is considerably greater than the input power in carefully measured tests which were run for periods of more than half an hour each. The additional power is flowing in from the Zero-Point Energy field due to an energy extraction mechanism caused by the collision of molecules which have very different atomic weights. This is explained by Dr Frolov in his paper: http://alexfrolov.narod.ru/mac.html where the energy imbalance is described in detail. In it, he observes that the theory shows clearly that an input of 1,400 watts is capable of producing an output of 7,250 watts due to the impact energy imbalance between high-mass and low-mass molecules when they collide.

Here is a photograph of the development assembly built by Alexander Frolov and then used in the testing phase of the system:

Muammer Yildiz’s “Ocean Star” Electrical Generator.
This is a purely mechanical device which is self-powered and which can provide electric current to drive other equipment. This device was designed and built in Turkey. It was demonstrated in Dortmund on 17th October 2005 where the demonstration was conducted by J. L. Duarte who ran an independent test and produced a report dated 17th July 2005 on behalf of the Department of Electrical Engineering, Electromechanics and Power Electronics of the Eindhoven Technische Universiteit. Muammer has obtained Patent Application WO2004091083 for his design. The demonstration was of his portable unit which outputs some 12 volts DC:
During the demonstration was used to light a car light bulb very brightly:

Muammer has also produced a larger version capable of powering a house:

The demonstration unit was started using a 16 Ahr battery for a few seconds. Once the unit reaches its running speed, it becomes self-powered and capable of delivering substantial electrical power and the starting battery is then disconnected. In theory, no mechanical system can produce 100% efficiency, let
This technical note aims at describing a test which I personally conducted in Izmir, Turkey on 17th July 2005. The purpose of the experiment was to check the energy balance with respect to input and output of an apparatus which was the embodiment of the invention described in the international patent WO 2004/091083 A1 (shown below).

The apparatus was confined inside a metallic box sized 550 x 380 x 270 mm, weighing some 20 Kg, and I was allowed to inspect everything outside this box. However, in order to protect the core ideas of the invention, I was not supposed to check all the details of the internal parts. According to the inventor, the apparatus is predominantly a mechanical system, without any kind of energy storage inside the box (such as batteries, accumulators, flywheels, combustion motors, chemical or radioactive reactions). I believe the intentions of the inventor to be in good faith.

The experimental set-up was quite simple, as shown schematically in Fig.1. It consisted of placing the box with unknown contents, from which DC voltages and currents were expected to be generated, on a table in the middle of the room. A cable with two terminal contacts was run from the box and instruments were placed between the box and the load, which was a standard DC/AC inverter driving an incandescent lamp. The output power from the box was measured before the load connection as shown here:

![Experimental Set-up Diagram](image1)

The circuit connection method used is shown here:

![Circuit Connection Diagram](image2)

After a short start procedure, the metallic box and the load were both fully isolated from the environment, ensuring that there was no physical contact or connection to external power sources such as the public electric mains supply, at any time during the whole duration of the measurements. As the start-up energy input to the apparatus was quite modest, the main issue was then to measure the delivered energy output.

I had prepared the power measurements with care, by using reliable instruments which I personally brought with me from my own University laboratory. In order to measure the DC voltage directly out of the positive
and negative terminals, I used two different voltmeters connected in parallel. One voltmeter was an analogue type, constructed with permanent magnets and wires, while the other was a digital voltmeter. To measure the DC current I used two ammeters in series, one analogue and one digital. If electromagnetic waves should interfere with the measurements, then they would disturb one or other instrument, but not all four pieces at the same time and in the same way.

Before starting the test, no audible sound was being produced by the apparatus. The measured voltage and current at the terminals were zero. So, as far as I could observe, the apparatus was completely at rest.

The start-up procedure consisted of connecting a small 12V DC lead-acid battery to two contact points inside the box for a few seconds. I checked the time using my own watch and it was more than 5 seconds but less than 10 seconds. I consider it reasonable to consider the time to have been 8 seconds. After that time, no energy input was connected to the box by means of cables.

Immediately after the start-up procedure, I could hear noise such as would be produced by parts rotating inside the box. The inventor said that some ten minutes should be allowed to elapse before the load was connected. During that time, both of the voltmeters showed the output voltage dropping slowly from 12.9 volts to 12.5 volts. The two voltmeters matched accurately. In the following hours, I observed and recorded by hand, the voltage and current values displayed by the instruments. The displayed values were quite stable, so I initially decided to note them at 15 minute intervals, but later on at 30 minute intervals.

From time to time, using my hands, I attempted to find a temperature gradient inside the box, but I could not detect any variation or increase in the temperature compared to the room temperature. After five hours, I took the decision to stop the measurements. The results are shown in the following table:

</table>

As far as I am concerned, the above table of results raises serious doubts. The voltage readings are absolutely typical of an inverter powered by a lead-acid battery. I have tested many batteries in exactly the same way and the table looks 100% familiar. If the box contained a genuine self-powered generator, then I would expect the output voltage to remain constant under the constant current drain. In my opinion, it was wholly irresponsible to have stopped the test after just five hours with the output voltage falling steadily. If the output voltage had been rock steady at 12.5 volts for the whole five hours, then that would not have been quite so bad but with it going down 12.3, 12.2, 12.1, 12.0 in the last four 30-minute intervals, and with a lead-acid battery voltage of 11.5 for a fully discharged battery, it was wholly unrealistic to stop the test. A further ten hours of testing should have been undertaken.

However, early in 2010, Muammer demonstrated a permanent magnet motor/generator of his own design. That type of device is notoriously difficult to get functional, let alone producing the 250 watts of power which Muammer demonstrated at Delft University. As part of the demonstration, Muammer took the motor apart
completely to show that there was no hidden power source. This shows clearly that Muammer is a man of very considerable ability, and that lends considerable credibility to his earlier device shown here. Unfortunately, the patent application is not in English and some of the terms produced by a rough translation are not at all clear. Consequently, although the design appears quite simple, it can’t be rated as a design which could be confidently replicated from the information here and for that reason, the OceanStar information remains here, among the “Unlikely to Result in a Workable Device” section.

Here is the information from the Patent Application WO2004091083 although the quality of reproduction and the clarity of the wording is not particularly good:

A SYSTEM WHICH GENERATES ELECTRICAL POWER VIA AN ACCUMULATOR THAT PROVIDES THE INITIAL MOTION FOR THE SYSTEM

ABSTRACT
This is a portable system that generates electrical power via an accumulator that provides the initial motion for the system. Two batteries are used in this system and the system is kept working via the initial motion provided by these batteries. There is no need for another transformer. This device works using its own mechanism and there is no need for additional devices. In this way, a continuous electrical power generation is possible. This device can work without connecting it to a network so it is possible to use it at places where electricity does not exist. Moreover, when connected to the entry of a building, the need for a network is avoided. This system generates electrical power independent of a network.

DESCRIPTION
A system which generates electrical power via an accumulator that provides the initial motion for the system
This is a portable system that generates electrical power via an accumulator that provides the initial motion for the system. Already existing systems can generate electric power of whose duration depends on the lifetime of the battery. In these systems, the battery has to be reloaded in order to restart the system. 12V electrical power provided by the batteries used in cars is increased to 220 V via transformers.

Two accumulators are used in our invention. The system works on a continuous basis after the initial start up via these accumulators. There is no need for another transformer. Our system, which generates electrical power, does not need any other devices and it keeps on generating energy via its own mechanism. Also, the system works without connecting it to a network.

Thus, it can be used at any place where no electricity exists. Nevertheless, when this system is connected to the entry of the buildings, there is no need for an additional network. The system can produce electrical power independent of a network.

DESCRIPTION OF THE DRAWINGS
Below are the explanations of the figures that provide a better understanding about this invention.
Fig. 1 is a schematic view of the system.
Numbers used on the schematic:
1- Accumulator
2- Regulator
3- Big Gear 3/1-Starter dynamo
4- Small gear 4/1-2-Feedback dynamo
5- Small gear 5/1-2-3-Feedback dynamo
6- Contactor

26- Pulley
27- Pulley
28- V pulley
29- 380V current output
30- 220 V current input
DESCRIPTION

This invention is a system that starts working via the motion of alternator. There exist two accumulators (1), and the first motion provided by the accumulator is carried to the regulator. Contactor (6) keeps the starter dynamo working by disconnecting the accumulator (1) once the regulator (2) is put in. The voltage coming from the accumulator (1) passes through the regulator and the start dynamo (3/1) starts working and thus the feedback alternators via the gears (4/1-2-5/1-23-3). Feedback dynamo start sending pure DC current to regulator via shunt (12), capacitor (14) and diode (13). It connects all the currents that reaches to the regulator in 4 seconds and sends to the contactor (6). Accumulator (1) is put out by this current that reaches to the regulator. This current is transformed to the started dynamo (3/1). There becomes a transformation within the system. In case of electricity shortage, it keeps on working by using the current generated by the commutatis (7/1).

Via the starter dynamo (3/1), DC is generated in the alternators which are connected to the gears and this current is transformed to the commutatis (7/1 and 7/2) and DC voltage is generated at commutatis (7/1 and 7/2).

Second System: 3x24 DC voltage is transformed to the second starter dynamo (22). Once the start dynamo works (22), a feedback dynamo (23) having a pulley system and a feedback dynamo (24) generating alternating current starts working. The feedback dynamo (23) starts feeding back; the feedback dynamo (24) which generates alternating current is independently generating 6 KV, 18 Amp, 50 Hz current. Moreover, first system produces 24 DC and 580 DC current on its own. The bigger the gears are, the more the generated current is.

This system, which is the subject of our invention, can be used at any place. You can use it at places where there exist no electricity, or at places such as villages, cities, buildings, greenhouses where there is no network. Moreover, network is no longer a must. Instead of a network, you can use our system. There is no need for gasoline when this system is used in vehicles.

Jesse McQueen’s System.

There is a US patent which was granted to Jesse McQueen in 2006. This system looks too good to be true and, on the surface, appears impossible, even taking into account that it has been said that ordinary vehicle alternators have a Coefficient Of Performance over one (i.e. output energy is greater than the energy that the user has to put into the device to make it operate). I am not aware of anybody who has tried this system, so I have no evidence that it doesn’t work - just a lack of belief in a system of this type being able to operate as described. As against that, it is not far from the proven system of Chas Campbell (chapter 4) and the US Patent office has granted this patent and they have a reputation of being highly opposed to admitting that there is any such thing as a “perpetual motion machine”, which this system appears to be. So, I leave it up to you to make up your own mind, and test the system if you wish, which should be easy to do as it involves no real construction, but instead, uses off-the-shelf manufactured products which are readily available and not particularly expensive. Here is the patent:

US Patent 7,095,126 22nd August 2006 Inventor: Jesse McQueen

INTERNAL ENERGY-GENERATING POWER SOURCE

ABSTRACT

An external power source such as a battery is used to initially supply power to start an alternator and generator. Once the system has started it is not necessary for the battery to supply power to the system. The battery can then be disconnected. The alternator and electric motor work in combination to generator electrical power. The alternator supplies this electrical power to the two inverters. One inverter outputs part of it’s power to the lamp, and part back to the electric motor/generator. This power is used to power the electric motor. The second inverter supplies power to the specific load devices which are connected to the system.

BACKGROUND OF THE INVENTION

Electrical energy occurs naturally, but seldom in forms that can be used. For example, although the energy dissipated as lightning exceeds the world's demand for electricity by a large factor, lightning has not been put to practical use because of its unpredictability and other problems. Generally, practical electric-power-generating systems convert the mechanical energy of moving parts into electrical energy. While systems that operate without a mechanical step do exist, they are at present either excessively inefficient or expensive because of a dependence on elaborate technology. While some electric plants derive mechanical energy from moving water (hydroelectric power), the vast majority derives it from heat engines in which the working substance is steam. Roughly 89% of power in the United States is generated this way. The steam is generated with heat from combustion of fossil fuels or from nuclear fission.

In electricity, a machine is used to change mechanical energy into electrical energy. It operates on the principle of electromagnetic induction. When a conductor passes through a magnetic field, a voltage is induced across the ends of the conductor. The generator is simply a mechanical arrangement for moving the conductor and leading the current produced by the voltage to an external circuit, where it actuates devices which require electricity. In the simplest form of generator, the conductor is an open coil of wire rotating between the poles of a permanent magnet. During a single rotation, one side of the coil passes through the magnetic field first in one direction and then in the other, so that the induced current is alternating current (AC), moving first in one direction, then in the other. Each end of the coil is attached to a separate metal slip ring that rotates with the coil. Brushes that rest on the slip rings are attached to the external circuit. Thus the current flows from the coil to the slip rings, then through the brushes to the external circuit. In order to obtain direct current (DC), i.e., current that flows in only one direction, a commutator is used in place of slip rings.

A commutator is a single slip ring split into left and right halves that are insulated from each other and are attached to opposite ends of the coil. It allows current to leave the generator through the brushes in only one direction. This current pulsates, going from no flow to maximum flow and back again to no flow. A practical DC generator, with many coils and with many segments in the commutator, gives a steadier current. There are also several magnets in a practical generator. In any generator, the whole assembly carrying the coils is called the armature, or rotor, while the stationary parts constitute the stator. Except in the case of the magneto, which uses permanent magnets, AC and DC generators use electromagnets. Field current for the electromagnets is most often DC from an external source. The term dynamo is often used for the DC generator; the generator in automotive applications is usually a dynamo. An AC generator is called an alternator. To ease various construction problems, alternators have a stationary armature and rotating electromagnets. Most alternators produce a polyphase AC, a complex type of current that provides a smoother power flow than does simple AC. By far the greatest amount of electricity for industrial and civilian use comes from large AC generators driven by steam turbines.

SUMMARY OF THE INVENTION

It is an objective of the present invention to provide an energy source that generates more energy than the energy source requires in order to operate.

It is a second objective of the present invention to provide a system that uses the excess energy produced by the energy source to power other various devices.

It is a third objective of the present invention to provide an energy source for supplying power to various devices without the reliance on an external energy source for supplying power to the energy source of the present invention.

The present invention provides an energy source that is capable of producing more energy than it requires to operate. The excess energy is used to power devices. A feedback loop approach is used to channel a portion of the energy produce by the generator back to the generators power input port. This feedback loop approach enables the generator to use its own generated energy to operate. The additional energy generated by the generator is used to power other devices that can be connected to the generator.

In the method of the invention an external power source such as a battery is used to initially supply power to start an alternator and generator. Once the system has started it is not necessary for the battery to supply power to the system. The battery can then be disconnected. The alternator and electric motor work in combination to generate electrical power. The alternator supplies this electrical power to the two inverters. One inverter outputs part of its power to the lamp load device and part back to the electric motor/generator.
This power is used to power the electric motor. The second inverter supplies power to the specific load devices that are connected to the system.

DESCRIPTION OF THE DRAWINGS

Fig.1 is a configuration of an implementation of the internal power generating system of the present invention.

Fig.2 is a configuration of an alternate embodiment of the internal power generating system of the present invention.

DESCRIPTION OF THE INVENTION

This invention is an electric power-generating device that produces several times more power than it takes to operate this system. This invention comprises a first power source that is connected to a second power source. Referring to Fig.1, the system of the present invention comprises a battery source 10 (12 volt DC) that connects to an electrical alternator 20. The battery supplies the initial power to the system to initiate/start the operation of the alternator. The present invention can implement other power sources in addition to the illustrated battery to supply the initial power to the system. In the initial model of the present invention incorporated an alternator from a 1997 Isuzu Trooper. The invention incorporates an electric motor 30 (148 watt AC). The electric motor connects to an inverter 40 (400 watt AC). The system also comprises a second inverter 50. The battery 10 also connects to both inverters 40 and 50. Each inverter has two outputs. For the first inverter 40, one output feeds into the electric motor 30 to provide to the motor and alternator combination. The other output feeds into a lamp device 60. The lamp device is a 60-watt AC lamp. This lamp device alters the current travelling from the inverter 40 such that the current feeding into the electric motor 30 is not purely inductive.

Although, Fig.1 shows a lamp device, other loads can be used to accomplish this same a task. The inverter 40 has an input from which the inverter receives power from the alternator 20. The second inverter 50 also has an input that also receives power from the alternator.

In operation, initially, the battery 10 is used to supply power to start the alternator 20 and generator 30. Once the system has started, it is not necessary for the battery to supply power to the system. The battery can then be disconnected. Once started, the alternator 20 and electric motor 30 work in combination to generate electrical power. The alternator supplies this electrical power to the two inverters 40 and 50. Inverter 40 outputs part of this power to the lamp 60 and part to the electric motor 30. This power is used to
power the electric motor. The second inverter 50 supplies power to the specific load devices which are connected to the system. These load devices can be any devices which operate by using electrical power.

The key aspect of the present invention is the loop between the alternator 20, electric motor 30 and the first inverter 40. A portion of the power generated by the electric motor is recycled and is used to power the electric motor. In this way the system produces the power internally that is used to power the system. This concept makes this system a self-power generating system.

Fig. 2 shows an alternative embodiment of the power generating system of the present invention. This embodiment incorporates a gear box 70, a car starter 72, and a head brush generator 74, and buck booster 76. Initially, the car starter 72 works with the battery to supply power to the generator. This process is similar to the process of starting a car. The gearshift 70 increases the rpm of the generator. The Buck Booster 76 serves as the output to supply power to the various loads. This configuration also incorporates a DC converter 78.

The “Nitro” Cell.
This document was originally produced at the request of an Australian man who said that the cell worked well for him but that he was afraid to publish the details himself. This document was prepared, approved by him and published. It proved very popular and an enthusiast group was set up to build and test this “Nitro Cell”.

The results of this building and testing have been most unsatisfactory. As far as I am aware, not a single cell proved successful in powering an engine. I therefore, withdrew the document, since even though I believe it to be capable of working, the fact that many people failed to get it working indicates to me that this document should not be in a “practical” guide. I have been assured by two separate independent sources, both of which I rate as being reliable sources, that there are “hundreds” of these cells working in Australia and the USA. I have repeatedly been asked for copies of this document, so I am publishing it again, but requesting
you, the reader, to be aware that should you make one of these devices, that it is unlikely that you will get it operational. Having said that, I understand that it may work very well as a booster.

Simple arithmetic applied to the claimed performance of this device, shows that much of the claimed mileage has to have been covered without using any fuel at all. While this sounds impossible, in actual fact it is not, but that sort of operation comes from the Joe Cell which is notoriously difficult to get operational, requiring at least a week of fiddling around to get the metalwork of the vehicle aligned with the energy field used to provide the motive power. Also, each person acts as a “dipole” which produces an energy field around that person. Most people have a polarity which opposes the Joe Cell energy, and they will never get a Joe Cell to operate as they can disrupt such a cell from several paces away from it. Chapter 9, which describes the Joe Cell, includes information on how to reverse your own personal polarity, to stop blocking the cell performance.

This definitely sounds unbelievable, but as it happens to be the way that things actually are, there is little point in pretending otherwise. Personally, I never recommend anybody to build a Joe Cell for powering a vehicle, as the likelihood of success is so low. However, having said that, a friend of mine in the USA has his Joe Cell connected to his truck in “shandy” mode where the carburettor is left connected to it’s normal fossil fuel supply. The vehicle is perfectly capable of drawing in fossil fuel to run the engine, but it just doesn’t. His fuel consumption is literally zero and he is driving around powered solely by the energy channelled into the engine by the Joe Cell. This is most unusual, and I do not recommend you spending time and money on building such a cell. I mention these cells so that you can know all about them, but I would leave it at that.

Here is the original “D18” document, which is followed by important update information:

A Different Fuel

In the early days of heavier than air flight, observations were made and based on those observations, practical operating rules were deduced. After a time, those rules became called the “laws” of aerodynamics. These “laws” were applied to the design, building and use of aircraft and they were, and are, very useful.

One day it was observed that if you apply those laws of aerodynamics to bumble bees, then according to those laws, it was not possible for a bee to fly since there was just not enough lift generated to get the bee off the ground. But simple observation shows that bees do in fact fly and they can rise off the ground when they choose to do so.

Does that mean that the “laws” of aerodynamics are no good? Of course not, as they have been shown to be of great practical use when dealing with aircraft. What it did show was that the existing laws did not cover every instance, so research was done and the laws of aerodynamics were extended to include the equations for lift generated by turbulent flow. These show how a bee can develop enough lift to get off the ground. Do bees care about this? No, not at all, they just go on flying as before. What has changed is that the understanding of scientists and engineers has been extended to better fit the world around us.

Today, people who are trained in science and engineering are fed the idea that internal combustion engines need to consume a fossil fuel in order to operate. That is not strictly true and at the present time, engines using hydrogen gas as a fuel are becoming commonplace. Unfortunately, most of the hydrogen produced for this use, comes from fossil fuels, so these vehicles are still running on a fossil fuel, though only indirectly.

The “laws” of engineering say that it is not possible for an internal combustion engine to run without consuming some sort of fuel. Unfortunately, Josef Papp has demonstrated an internal combustion engine which has had it’s intake and exhaust systems blanked off. Filled with a mixture of inert gasses, during one demonstration, that Volvo engine ran for half an hour, producing a measured 300 horsepower from the nominally 90 horsepower motor, and apparently consuming no fuel at all. Josef received US patent 3,680,432. Robert Britt designed a similar sealed motor filled with a mixture of inert gasses, and he received US patent 3,977,191 for it. However, Heinrich Klostermann has shown that the same effect is produced with just air as the gas: https://www.youtube.com/watch?v=IHSAXbZfnbE and that is certainly much more simple than using inert gas, although several people have replicated the Papp design strategy as can be seen in various videos, such as https://www.youtube.com/watch?v=3kQ9MdoKt7I.

Does this mean that the current laws of engineering are of no use? Certainly not, they are vital for everyday life today. What it does mean, however, is that the present laws need to be extended to include the effects shown by these engines.
Another thing widely accepted today is that an internal combustion engine can’t use water as a fuel. Well..., let’s leave that to one side for the moment and look at it from a slightly different angle. Engines can definitely run using air and hydrogen as the fuel, there is no argument about that as there are many vehicle around which do just that. If you pass a current through water, the water breaks up into hydrogen gas and oxygen gas, this mixture is called “hydroxy” gas and that can most definitely be used, along with air, as the fuel for an internal combustion engine. But... this gas came from water, so is it really correct to say that water cannot be used as the fuel for an internal combustion engine?

Ah, says somebody with relief, that is not the case, because you are using water and electricity to get the fuel for the engine. But... the average vehicle powered by an internal combustion engine, has an alternator which produces electricity when the engine is running, so there is a source of electricity to do the electrolysis of the water and produce the gas to run the engine.

But the laws of engineering say that you can’t get enough electricity from the alternator to produce enough gas to run the engine. Engineers will point to the work of Faraday who examined the process of electrolysis in great detail and produced the “laws” of electrolysis. These laws show that you can’t get enough electrical power from an engine to make enough gas to run the engine.

Unfortunately, there have been several people who have done just that, so we have reached the point in time when these “laws” need to be extended to cover cases not covered by the work of Faraday. People have got from 300% to 1,200% of the gas output which Faraday considered to be the maximum possible. Several people have run vehicles on hydroxy gas produced by electrolysis of water using electricity generated by the vehicle’s alternator. This shows clearly that it can be done, and as a consequence, the “laws” need to be extended to include the newer techniques.

Leaving that aside for the moment, there have been at least two people who have managed to power an engine with water as the only fuel, and without using electrolysis. In this instance, a fine spray of water droplets inside the cylinder is acted on by the spark, and a secondary electrical supply from an inverter boosts the spark, forming a plasma discharge. The result is a power stroke nearly as powerful as using a fossil fuel. For the moment, let us also ignore that style of operation.

This document describes another system which uses water and air as the primary fuels, but again, does not use electrolysis to generate hydroxy gas for use in the engine. Instead, the objective is to create a continuous supply of Nitrogen Hydroxide (NHO2) for use as the fuel. This system has worked well for a number of people but there has been considerable intimidation and most of these people are very reluctant to pass the information on. This document is an attempt to present those details clearly enough to allow the system to be replicated by anyone who wishes to do so.

So, how exactly is this fuel generated? The production method is described as the fuel gas being synthesised by a mixture of stream water and rock salt (the mineral "halite") in the presence of air, being acted on by engine “vacuum”, electrolysis and a strong magnetic field. This fuel is said to be more powerful than hydrogen and is a much more viable fuel source as less of it is needed to run an internal combustion engine.

This system may be used with any internal combustion engine, whether used in a vehicle or stationary when powering an electrical generator or other equipment. The additional equipment consists of one, or more, horizontal cylinders mounted near the engine. A single, horizontally mounted, cylinder can generate sufficient gas to power an internal combustion engine up to two litres in capacity. Larger engines will need two cylinders to generate enough gas for them to operate.

It must be stressed that this is not a hydroxy gas electrolysis cell. One test vehicle has been run on this system for a distance of 3,000 miles (4,800 kilometers) and the liquid fuel used was only 2 litres of water and 2 gallons of petrol. Two litres of water converted to hydroxy gas will definitely not power a vehicle engine for anything like 3,000 miles, so let me stress again that the fuel being generated in this cell is Nitrogen Hydroxide (NHO2). It should be noted that if the cell described here is used as a booster for the original fossil fuel, then it will not be necessary to upgrade the engine by fitting stainless steel valves, piston rings, exhaust system, etc.

The person using this system which is shown in the following photograph, has opted for an exceptionally long generation tube attached to his stationary generator:
The versions of this cell design shown in the previous photograph and the following photograph, are early models which were in use before it was discovered that there was a considerable enhancement in gas production if a coil is wrapped around the cylinder.

For vehicle operation, it is more normal to have a shorter cylinder, (or pair of cylinders if the engine capacity is large) as can be seen in the following photograph of a 4-litre, 8-cylinder vehicle engine which uses this system. Engines of up to 2 litre capacity can be powered by a single horizontal cell, while two cells are used for larger engines.

The construction details are not difficult to follow and the materials needed are not particularly difficult to find nor expensive to buy. The main body of the device is constructed as shown in the following diagram. A chamber is constructed from a piece of 316L Grade (food quality) stainless steel pipe, 300 mm (12 inches) long and 100 mm (4 inches) in diameter. The length of 300 mm is chosen for convenience of fitting in the engine compartment of a vehicle. If there is plenty of room there, the length can be extended for better gas performance and water capacity. If that is done, keep the 100 mm cylinder diameter and all of the clearance dimensions mentioned below.

The chamber is sealed at each end with 12 mm (half inch) thick discs made from “Lexan” (a very strong polycarbonate resin thermoplastic). These discs have a 3 mm (1/8”) deep groove cut into their inner faces. The groove is there for the cylinder to fit into when the discs are clamped in place and held by stainless steel
nuts tightened on a 10 mm (3/8") stainless steel threaded rod. To combat engine vibration, a lock nut is used to clamp the retaining nuts in place. The threaded rod also provides the contact point for the negative side of the electrical supply and a stainless steel bolt is TIG welded to the outside of the cylinder to form the connection point for the positive side of the electrical supply.

This basic container is modified in a number of ways. Firstly, a small 3 mm (1/8 inch) diameter air intake pipe is provided in one of the Lexan discs. This air intake is provided with a needle-valve which is screwed tightly shut for the early stages of testing and only eased slightly open when the engine is actually running.

Also fitted is a 12 mm (1/2") stainless steel pipe, attached to the stainless steel cylinder to form a gas supply feed to the engine. A one-way valve is placed in this pipe as the design calls for the cylinder to be maintained at a pressure which is less that the outside atmosphere. The lower the pressure inside the cell, the greater the rate of gas production. The one-way valve allows flow into the engine but blocks any flow from the engine into the cylinder. This valve is the same type as is used in the vehicle's vacuum brake booster system.

The gas outlet pipe is continued from the one-way valve using plastic tubing for a few inches. This is to prevent an electrical connection between the stainless steel cylinder which is connected to the positive side of the electrical supply, and the engine manifold which is connected to the negative side of the electrical supply. If this pipe were metal all the way, then that would create a direct electrical short-circuit. The pipe running to the engine intake manifold needs to be made of metal in the area near the engine, due to the high engine temperature, so stainless steel pipe should be used for the last part of the gas supply pipe running to the engine. The gas supply pipe fitting is made to the most central of the bungs fitted to the manifold.

For the initial testing period, a filling port with a screw cap is mounted on the top of the cylinder, in order to allow the water inside to be topped up as necessary. Later on, if long journeys are made on a regular basis,
then it is worth fitting a separate water tank, water-level sensor and water injection system using a standard vehicle windscreen washer water pump. The topping up is done with water alone as the rock salt additive does not get used in the process and so does not need to be replaced. With these additional features, the gas generation cell looks like this:

There is one further step, and that is to add an inner cylinder of 316L grade stainless steel. This cylinder is 274 mm (10.75 inches) long and 80 mm (3.15") in diameter. Both cylinders have a wall thickness of 1 mm. The inner cylinder is supported on the central threaded bar and it is clamped in place with retaining nuts. A supporting lug is created by making two cuts at each end of the cylinder, drilling a hole and then bending the lug up inside the cylinder at right angles to its axis. This needs to be done accurately, otherwise the inner cylinder will not lie parallel to the threaded rod, or alternatively, not be centred on the threaded rod. The centre of the 10 mm (3/8") hole is positioned 8 mm (5/16") in from the end of the cylinder. Two 48 mm (1.9") long cuts are made each side of the hole, positioned to be about 5 mm (3/16") clear of the hole - this measurement is not critical. This is done at each end of the cylinder and the holes are positioned exactly opposite one another, along the axis of the cylinder, as shown here:

The inner cylinder is secured in position by two bolts as shown here:
The inner nuts are manoeuvred on inside on of the lugs by hand and then the threaded rod is rotated to move one nut to the inside of the other lug, while the nearer nut is held to prevent it rotating. When the rod is positioned correctly and the inner nuts are pressed up hard against the lugs, then a box spanner is used to lock the outer nuts tightly against the lugs, forming a strong mounting lock.

The inner cylinder is inserted inside the outer cylinder, the Lexan end discs are then added and the outer lock nuts added to produce this arrangement:

This gives a 9 mm clearance between the two cylinders and this gap stretches 360 degrees around the cylinders. The inner cylinder is located 10 mm clear of the Lexan end discs.

The units is completed by winding a coil of 2 mm diameter insulated copper wire tightly around the full length of the outer cylinder and filling the unit with electrolyte to a level of 3 mm (1/8 inch) above the top of the inner cylinder as shown here:
The wire used for the coil is heavy duty copper wire with an inner diameter of 2 mm, i.e. British 14 SWG wire or American 12 AWG wire. The coil is held in position at the ends of the cylinder, with plastic cable ties, as these are non-magnetic. This coil is of major importance in this design as the strong magnetic field produced by it has a very marked effect on the performance of the cell. The magnetic field produced by this coil, increases the gas production by anything from 30% to 50% and increases the production of Nitrogen Hydroxide by a factor of ten times. The electrical connection of the coil is in series with the cell, so the battery positive is not taken directly to the bolt welded to the outer cylinder, but instead it passes through the coil winding before being connected to the outer cylinder.

**Installation and Use**

The gas outlet pipe is connected directly to a vacuum port directly below the carburettor on the manifold of the engine. This connection is important as the cell relies on the “vacuum” (actually reduced air pressure) produced by the engine intake stroke, as part of it’s gas-forming process.

The exact method of mounting the cell in a vehicle depends on the vehicle, so this is something which you will need to think out for yourself. Be sure that you insulate the cell from the metal bodywork of the vehicle and I would suggest that you keep it away from the high-voltage electrical wiring (coil, distributor, spark plug leads, etc.).

The electrical connection arrangement is as shown here:

---

### SINGLE — CYLINDER ARRANGEMENT

![Diagram of single-cylinder arrangement](image1.png)

---

### TWIN — CYLINDER ARRANGEMENT

![Diagram of twin-cylinder arrangement](image2.png)

---

The method of electrical connection is important. It is vital that the electrical supply is disconnected when the engine is not running. For that reason, the power to the cell(s) is taken via the vehicle’s ignition switch. In order not to load that switch unduly, a standard automotive relay is used to carry the main current, leaving
just the relay current to be handled by the ignition switch. Also, a 30 amp circuit-breaker or fuse is placed in
the circuit, immediately after the battery connection. In the unlikely event of some physical problem with the
cell occurring, this device will disconnect the power instantly and avoid any possibility of a short-circuit
causing a fire, or of excess gas being produced when it is not needed.

The water to be used in this cell needs to be selected carefully. Tap water is not acceptable as it will be
contaminated with several additives - fluorine, chlorine, etc. put in it when going through the purification
process of the supply company and many other chemicals picked up along the way. It is considered very
important that the water be taken from a stream, preferably from where it rises, as that is the point of
greatest purity. May I also suggest that the water be transported in either glass containers or stainless steel
containers as these help to maintain the purity. Avoid plastic containers, because while these appear to be
completely inert, they frequently are most definitely not and chemicals from their manufacture can, and do,
enter any liquid contained in them.

The cell is filled to a depth of 25 mm (1 inch) below the top of the outer cylinder and then (on the first
occasion only) one or two grains of rock salt are added to the cell. This addition needs to be minimal as it
controls the current draw from the electrical system and the strength of the magnetic field created by that
current. After using the cell for at least a week, if the gas rate is not adequate, then add one more grain of
rock salt.

Getting the cell attuned to the vehicle is likely to take at least a week of use. The cell is put in place and the
vehicle run using it's normal fuel. The needle valve on the cell's air intake is kept completely closed during
this period. The inventor opted to continue running his engine on very small amounts of petrol plus this new
gas fuel - the result being 3,000 miles covered on just two gallons of petrol. If you consider this as still being
a petrol powered vehicle, then getting 1,500 mpg is quite an achievement - I certainly would settle for that.

When the cell is first connected, you will notice that the engine ticks over faster and tends to rev more than it
did before. It will take several days for the system to settle down. Part of this is believed to be the effect of
the new magnetic coil in the engine compartment. It may be that the metal parts of the vehicle have to take
up a magnetic alignment which matches the magnetic field produced by the cell. Whether that is so or not, it
will take a few days before the system settles down into its final state.

It should be realised that if the vehicle has a fuel-control computer with an oxygen sensor mounted in the
exhaust stream, then the oxygen sensor signal will need to be adjusted. The D17.pdf document of this
series, shows in detail how to do this, should it be necessary. If the vehicle has a carburettor, then there is
an advantage in fitting a one inch bore carburettor of the type found on lawnmowers, as this promotes lower
pressure inside the manifold and promotes good cell operation as the lower the pressure (or the greater the
"vacuum"), the higher becomes the rate of gas production.

Practical Details
The original end pieces were cut and grooved using a lathe. Most people do not own or have access to a
lathe so an alternative method of cutting the discs needs to be used. The essential part of this operation is
to cut an accurate groove to take the 100 mm stainless steel outer cylinder. The groove needs to be cut
accurately as it needs to form an airtight seal on the end of the cylinder. Consequently, the end of the
cylinder and the bottom of the groove, both need to be straight and true if they are to mate securely.

An alternative method is to use an adjustable hole-cutter drill attachment. If this is used with a drill press or
a vertical stand adaptor for an electric hand drill, then if care is taken, an accurate groove of the correct
dimensions can be cut. As an extra precaution, a thin layer of marine grade white “SikaFlex 291” bedding
compound can be used in the bottom of the groove. Two things here. Firstly, only use the genuine SikaFlex
291 compound even though it is far more expensive than other products which claim to be equivalents - they
aren’t, so pay for the genuine product. Secondly, we do not want the slightest trace of the SikaFlex
contacting the electrolyte if we can avoid it, so be very sparing in the amount put into the groove, no matter
what you paid for it. Make sure that the bedding compound is placed only in the very bottom of the groove
and not on the sides. When the cylinder is forced into the groove, a very small amount of the compound will
be driven into any gap between the cylinder and the sides of the groove.

What is needed is a result which looks like this:
The other important part of this joint is the end of the outer cylinder. It is recommended that the cylinder be cut by hand with a hacksaw to avoid generating excessive heat which can affect the structure of the metal.

To get the end exactly square, use a piece of printer paper. This has straight edges and square corners, so wrap it flat around the cylinder and manoeuvre it into place so that the overlapping edges match exactly on both sides. If the paper is flat and tight against the cylinder and the edges match exactly, then the edge of the paper will be an exact true and square line around the cylinder. Mark along the edge of the paper with a felt pen and then use that line as a guide to a perfectly square cut. To avoid excessive heat, do not use any power tool like an angle grinder on the cylinder. Just clean the edges of the cut gently with a hand file.

In the diagrams shown earlier, the gas pipe, water-filler cap and the battery positive connection bolt have all been shown on the top of the cylinder. This is only to show them clearly, and there is no need to have them positioned like that. You will notice that they all get in the way of the wire coil, which is not an advantage.

It is necessary for the gas pipe to be positioned at the top as that gives the best clearance above the water surface. The clearance should be maintained at 25 mm (1 inch). The water-filler cap which was shown on top of the cylinder, would be better positioned on one of the end caps as that would keep it out of the way of the coil of wire:

This arrangement has the advantage that it does not require a filler hole to be drilled through the steel cylinder.

It is necessary for the electrical connection to be welded to the cylinder, but it is not necessary to have a head on the bolt as that just gets in the way of the electrical coil. The best strategy is to use a longer bolt of small diameter, remove the head and weld the shaft in place with spot welds which will not get in the way of the coil, as shown below. Spot welds are very quick to make, but even they generate a good deal of heat in the pipe. Some people prefer to silver-solder the bolt shaft to the cylinder as the heating is less.
The bolt is kept just clear of the end cap to avoid fouling it when it is clamped on to the cylinder. A lock nut is used to keep the solder tag assembly clear of the outer edge of the end cap. This allows the wire coil to be wound right up to the bolt. It does not matter which end of the coil is connected to the outer cylinder, but common sense suggests that the end nearest the bolt is connected to the bolt. It is, however, important that once connected, the electrical connections to the coil are maintained ever afterwards, to ensure that the magnetic field stays in the same direction. Remember that the surrounding metal parts of the vehicle will take up a magnetic orientation matching that of the coil's magnetic field, so you do not want to keep changing the direction of the coil's magnetic field.

When welding the bolt to the outer cylinder, be sure you use stainless steel wire. The joint needs to be made with a MIG or TIG welder. If you don't have one and can't hire one, then your local metal fabrication shop will make the spot welds for you in less than a minute and probably not charge you for doing them.

The grade of stainless steel in the cylinders is important. Grade 316L is nearly non-magnetic, so if you hold the cylinder with it's sides vertical and place a magnet against the cylinder, the magnet should fall off under its own weight. Try this test no matter what grade the stainless steel is supposed to be, as some steels are not labelled correctly. There is a good chance that you will be able to find suitable tubing at your local scrap yard, but be careful on sizing. The 9 mm gap between the outer 100 mm diameter cylinder and the inner cylinder's 80 mm diameter, is very important indeed. This gap needs to be 9 mm (11/32 inch) so if really necessary to vary the diameters slightly up or down, be sure to pick material which gives the correct gap between the cylinders. Seamless piping is usually preferred to pipes which have seams as the seam welding tends to generate a magnetic effect in the steel. However, if a seamed pipe passes the magnet test with the magnet falling off it, it is definitely good material for the cell.

If you can get it, a good material for the 12 mm (1/2 inch) pipe running to the carburettor manifold, is aluminium. Please remember that the one-way valve on the cell's output pipe needs to be connected to this pipe with a material which insulates the two metal components. The suggested piping is therefore: the cell output is via a stainless steel pipe connector, connected directly to the one-way valve, which then has a plastic pipe connection to the aluminium tube which runs all the way to the manifold. Please remember to insulate the cell from the vehicle chassis and components to avoid a short-circuit.

An alternative to using the rather expensive “Lexan” for the end caps, is to use “UHMWP” - Ultra-High Molecular Weight Polyethylene which is cheap and easy to obtain as plastic food-chopping boards are usually made from it. The advantage of Lexan is that it is transparent and so the level of the electrolyte can be seen without the need for removing the water-filler cap.

It has been suggested that the topping up of water in the cell can be automatic if you wish it to be so. For this, a water-level sensor circuit is used to drive a standard windscreen-washer water pump when the level of the electrolyte falls below the design level. The sensor itself, can be a bolt running through one of the end caps as shown here:
When the electrolyte level drops below the upper bolt, the circuit contact to the control circuit is broken and the circuit responds by powering up the water pump, which injects a little water to bring the electrolyte level back up to where it should be. When the vehicle is moving, the surface of the electrolyte will not be steady as shown in the diagram, so the control circuit needs to have an averaging section which prevents the water pump being switched on until the circuit input has been missing for several seconds.

Circuitry suitable for this is shown in Chapter 12, and there is no reason why you should not design and build your own circuit for this.

In the initial stages of testing and installation, when adding rock salt, be very sparing indeed. Add just one grain at a time because the salt ions are very effective in carrying current through the electrolyte solution. Also, if too much is added, it is difficult to reduce the concentration as more water needs to be added, which involves draining off some of the water already in the cell. It is much easier to take your time and add very, very little salt. Give the salt grain plenty of time to dissolve and spread out throughout the electrolyte before checking the cell performance again.

Let me remind you that during the initial cell testing, the air intake needle valve is closed completely and it is not eased open until the engine is running satisfactorily. In the engine acclimatisation period, the engine should be run on it’s normal fuel and the cell just used as a booster. Remember that it will take at least a week for the vehicle to settle down to it’s new method of operation. There is no particular hurry, so take your time and don’t rush things.

If the vehicle is fitted with computer control of the fuel supply, it may be necessary to apply some control to the unit by adjusting the signal coming from the oxygen sensor placed in the vehicle’s exhaust system. The information on how to do this is shown in considerable detail in Chapter 10.

Some questions have been asked about this cell:

1. Does petrol have to be used or can the engine be run on the cell alone?
   Answer: No, you can eventually eliminate petrol altogether but the engine runs so cleanly that old carbon deposits around the piston rings and elsewhere will get cleaned away and the components may rust. These parts can eventually be replaced with stainless steel versions or instead of that, it is probably possible to avoid replacements by the use of the oil additive called “Vacclaisocryptene QX and Molybdenum Disulfide” - see [http://www.clickspokane.com/vacclaisocryptene/](http://www.clickspokane.com/vacclaisocryptene/) for details. This additive reduces wear to such a degree that engine life may be doubled, no matter what fuel is being used.

2. Why is the unit 300 mm long?
   Answer: Just for convenience in fitting it into the engine compartment. It can easily be longer if space allows it. The longer the unit, the greater the gas production and that is why two 300 mm cells are needed for engines over 2 litres in capacity.

3. Does the cell body need to be made from seamless pipe?
   Answer: Seamless 316L-grade stainless steel is preferred.
4. How do you determine the amount of rock salt to add to the water in the cell?
   Answer: The amount varies with the type and size of engine being dealt with. You want the minimum current through the coil so start with one grain and increase it only very gradually with tiny amounts. If the cell is being mounted in the engine compartment of a vehicle, then the make, model and size of the vehicle will affect the amount due to the magnetic effect of metal components near the cell.

5. Does it matter which end of the coil is attached to the outer cylinder?
   Answer: No, it can be either end.

6. Is the pipe diameter shown from the cell to the engine the best size?
   Answer: The 1/2 inch diameter is very good as it increases the "vacuum" inside the cell as the engine runs. When first testing the engine, remember that the needle valve is completely shut off, and when it is opened during tuning, it is only opened to a minimal setting.

7. Are the exhaust emissions damaging to the environment?
   Answer: Some years ago, a Mercedes car dealer ran his own emissions test on a new Mercedes diesel, using his own equipment. He found that the emissions were reduced by 50% and the engine power increased by 12%. The engine ran better, cleaner and quieter. He was fired for doing this.

   Other independent gas-analyser tests showed that there is an increase in water emissions and a drop in carbon emissions as less fossil fuel is used. It was also noted that the volume of gas produced by the cell was affected by where it was mounted in the engine compartment. This is thought to be due to the magnetic effect on the cell.

**Update Information:**

**Question 1:** Where do we connect the outlet hose from the D18 fuel system to the engine on a late model car with fuel injection system?

**Response:** There is a throttle body on the engine and it is connected to a rubber hose which goes to the air filter. Typically, the rubber hose attaches to the throttle body and is clamped in place. A hole needs to be punched through the rubber housing approximately two inches (50 mm) from the throttle body. A brass fitting needs to be put into this opening. It will have a flange on one end and the other end with be threaded to accept a nut to hold it in place. This brass fitting will be the attachment point for the incoming fuel line from the D18 system and/or any other booster. For the D18 horizontal system, the size of the fitting should be half-inch (12 mm) so as to be able to maintain the proper vacuum pressure to the D18 fuel system.

**Important Note:** Since the practice of using alternate fuels by the public is not widely accepted it would be expedient to locate the fuel inlet opening on the under side of the hose out of plain view. This will help the user pass vehicle inspections and keep inquisitive persons from asking too many questions.

**Question 2:** What do I do I have to do to make the on-board computer function properly with my new booster?

**Response:** You need to install an electronic mixer control system. Plans for such a system used to be downloaded from http://www.better-mileage.com. This control system will fool the on-board ECU into thinking that all is okay and it will continue to work as normal with no problems. There are two corrections that need to be made to the system to make it work properly. They are outlined in red on this diagram:
Note: In this application the D18 cell is only being used as a booster. Therefore the engine still is using a hydrocarbon fuel. There are numerous systems available such as “megasquirt”, which allow for tweaking the amount of fuel being injected into the engine, and for making numerous other on-board computer adjustments to your Electronic Control Unit, for those of you who want to use nitrogen hydroxide as your only fuel and/or want to reduce the amount of petrol being injected into the engine.

Air Inlet Port: None required!

Ageing of Cell / Cell Break In: Use only the proper water as described below. The cell needs to be drained every day during the ageing process. Filter the water five to seven times through a cotton T-shirt. Collect the water only in glass jars, and do not touch it with your bare hands. Re-use the water and top the cell up with the proper water. Use absolutely no electrolytes (such as salt or potassium hydroxide). You can use natural water which has not seen light and that has not been charged such as, well, cave, or spring water at its source. Age the cell until it becomes a slight bronze in colour and does not generate any more gunk inside the cell. The purpose of the break-in period is to purge impurities from the cell.

Cell Current: The peak electrical current with the proper water is approximately 10 amps.

The Positive Electrode: the inner cylinder should be connected to the battery positive. This should be done via an automotive relay to assure proper shutdown of the cell when the engine has been switched off.

The Negative Electrode: This is the outer cylinder, which is connected via a metal strap to the chassis.

Construction: The inner cylinder is separated from the outer cylinder by spacers made out of ebonite or any other material which will not deteriorate within the cell. The objective is to keep the plates at an equal 9 mm spacing throughout the cell. The inner cylinder is connected to the threaded rod via a stainless steel wire strap, which is silver soldered in place at both ends of the cylinder. The threaded rod forms the battery positive connection point on the outside of the cell.

Drain: There should be a drain at the bottom of one of the end plates, so that you can drain the cell without having to remove it from the vehicle. The water will need to be drained and filtered at least once every three weeks. Drain the cell contents into a glass container. Do not touch the water with your bare hands. Filter the water at least five times (seven is better). Use a cotton T-shirt for filtering. Never throw the water away but just filter it. Put the water back in the cell and top the cell off using only pre-charged water.
**Electrical Generation:** The cell will continue to produce electricity after engine shutdown which will also lead to gas production, so take the precaution of discharging the cell.

**Electrolyte:** Use absolutely no electrolyte (including salt) at any time. This has been found to decrease the fuel output of the cell and also to have caused unnecessary damage to the plates of the cell.

**Engine Timing:** Yes, you have to adjust it to your engine. This is a very important aspect of getting high mileage with this system. Each engine is different and therefore each engine has a different adjustment.

**Fuel Outlet Piping:** Copper piping is recommended as unlike plastic or rubber, it will reduce condensation of water into the fuel lines and thereby reduce the level of water getting into the engine.

**Fuel Outlet Ports:** There are two of them positioned on opposing ends of the cell. If you are using a 12” cell, then they are positioned 3” in from each end of the cell. If you are using an 8” cell then they are positioned 2” in from each end of the cell. Make one outlet port half-inch (12 mm) in diameter and the other three-quarter of an inch (18 mm) in diameter. Make sure that the piping from the ports extends into the cell by at least an eight of an inch (3 mm). This is to prevent water vapour accumulating at the top of the cell from entering the fuel outlet ports. This measure has been found to reduce water reaching the engine.

**Leak Prevention:** Use rubber gaskets - these can be the type used for domestic plumbing.

**One-way Valves:** One-way valves are not used on the fuel outlet pipes.

**Outlet Pipe Connections:** The half-inch (12 mm) pipe is connected to the engine after the butterfly valve, while the three-quarters of an inch (18 mm) pipe is connected to the engine before the butterfly valve.

**Cylinder Preparation:** The inside of the 4” (100 mm) outer cylinder and the outside of the inner cylinder, which are the opposing cell plates should be sanded very well with medium grit sand paper to rough up the surface. Two sanding directions at right angles to each other should be used. This will insure better cell productivity later. It is important that there should be no direct contact between the cell plates and your bare hands, so wear rubber gloves when sanding and then assembling the cell.

**Voltage:** Only 12 volts is required to run the cell, a typical car battery is all you need to power the cell.

**Water Selection:** Use only natural water that has come out of the ground and not seen light such as well, cave, or spring water at it’s source. **Important:** Only add charged water to the cell. Water being used must have a pH of somewhere between 6.4 & 6.5 (slightly acidic). Do not use water with a pH of 7 or higher. The water is charged using a regular Joe Cell with electrodes separated by 3/16” (5 mm) for best results. The details of a Joe Cell can be found in D10.pdf which is a document in this series.

**Water Level:** Maintain the water level at approximately half full, that is, just covering the threaded rod.

E-mail from a contact:

Hi,

Thanks so much for shedding light into my cell cleaning concerns. I haven't been posting lately since right now the cell is already hooked up in my test car and I've been doing some tests with it day and night.

For once, I can personally tell you that the cell in fact works! However, with my results, it is hard to believe that the Nitrogen Hydroxide produced is enough to make the car get 1500 mpg. When the Nitrogen Hydroxide is allowed to enter the engine, the car starts to rev erratically for 2-3 minutes and then steadies itself thereafter. I noticed an increase of about 800-1400 rpm in my ECU data-logger once the Nitrogen Hydroxide cell is put into the equation. I then adjusted my Engine Management System and removed 15% of the petrol going into the system and drove around the block for a good 15 minutes or so. My exhaust gas temperature rose from 90 Celsius to 97 Celsius which is still fairly acceptable.

I went back to the garage and further adjusted the petrol to less 20% in total and at this point, the car began to vibrate erratically as if it was gasping for air. Upon noticing this, I concluded that not enough NOH must be getting into the ICE or something. The next thing I did was I mounted my old 304L cell alongside with the 316L currently installed. With two cells in the equation, petrol at 20% less did not cause vibrations at all, but mind you that even at 50% less petrol and without Nitrogen Hydroxide cells installed, the car will still run by petrol alone. It was getting dark and so I maxed out my engine management and removed 50% petrol from...
the equation with the two NOH cells running side by side. Again, there were vibrations and it was very
evident but my brother and I drove the car around the block anyway. Within just five minutes of leaving
the garage, the engine temperature rose from 97 Celsius to 111 Celsius and was still rising. I also noticed
that the car was underpowered to say the least. We drove up and down a parking complex to test out the
non-sloshing design and from my guess it performed pretty well.

To cut a long story short, the cell produced some kind of fuel (NOH or HHO), but it was not enough to power
the car when 50% petrol was removed even with 2 cells running. I am currently getting 22 mpg with this test

and it was very
car so I assume that 50% less petrol should give me something like 44 mpg on city driving and probably 60
mpg for long trips. These number are very small as compared to the 1500 mpg that the inventor reported.
Maybe the cell needs more time to acclimatise to the test car... but I've been getting same results for 3 days
now.

I am currently building two new 316L cells which will incorporate my non-slosh design and which have a
vacuum-powered water top up system. I also believe that the gap inside the 3" cell should be sealed off
since there is no reaction happening in this part of the cell and it only increases the resistance of the water to
electricity. I also included this in my new cell design. I will probably publish it if I find that it produces more
gas that the D18 design.

By the way, I've contacted someone in my city who sells 914L stainless steel. However, he told me that
914L requires special handling and special tools and it is much much harder to work on with hand tools
alone. He gave me a 1" diameter tube as a sample to see if I can work with it. It's really, really expensive.
One cut of a 4" diameter 914L will cost just as much as 2 years worth of gasoline (around 70 FULL TANKS).

And: Bore water is water pump out of the ground. It is similar to well water, the only difference being in the
way the water is gathered. Well water is dug from the ground while bore water is SUCKED out of the
ground by means of an electric or manual pump.

What I noticed so far is that there is really a lot of steaming going on inside the cell. Converting steam into
Hydroxy Gas requires less power than water, so I suspect that this steaming is good. The suggestion to only
fill the cylinder half-way actually makes sense as this would allow a greater storage space for the steam and
pretty much eliminates water sloshing problems. I have also tried switching the polarities on my 304L cell a
couple of times but it did not make any noticeable difference. I will try to make a test run with a half-filled cell
and tell you my results.

And: The outlet tubes are positioned at 3" on both ends as this might be the optimum position where less
water will accidentally splash into the ports. I was also told that these tubes extend inwards into the cell for
about 3 mm so that the water building up in the top surface will not be allowed to slide accidentally into the
outlet tubes. It makes sense because with the tubes positioned at 3" away from the edge, it actually gives
you about 30 degrees of angle before one of the ports are completely submerged in the water. Also, if the
cell is just half-filled, this could actually give us 45 degrees which is relatively a very steep slope to say the
least.

The 1/2" and the 3/4" remains a mystery for me. The only reason I can think of is that one of these tubes
might be directed before the butterfly valve and the other one placed after the butterfly valve. I would
suspect
that the smaller tube (1/2") was placed after the butterfly valve and the larger tube was placed before the
butterfly valve. This will make sense because the negative pressure during idle is naturally constant would
only require less NOH, while stepping on the accelerator will result in variable pressures which will require
larger amounts of NOH. This is only my theory and I am in no position to declare that this is in fact the
reason behind the different tube sizes.

I cannot measure the amount of air entering my cell because my end caps are not see-through plexiglass. I
only open my Air Inlet Valve halfway through. At this position, I could see a difference in the rpm and at the
same time no water could be seen creeping into the tubes. If I open the valve all the way, the rpm will
continue to increase but at the same time so does the water in the tubes.

This is my third installation and probably the most successful one. It has been on my test car for five days
now but it was not switched on all the time. I found too much water creeping in into the tubes and so I had to

shut it off and run the car normally just to make sure no rusting will occur in my engine. I estimate that I have
the cell switched on and running for a total of maybe 12 to 14 hours as of today.
From another user:

Hi,

thanks for the info about the EFI thing! it worked on my wife's Passat. After a few weeks of searching we were able to find smaller injectors for the car as the variable resistor trick only gave us CEL errors. I do notice that the engine's rpm is changing somewhat with every turn of the variable resistor but the relationship is far from linear.

The cell will in fact continue to produce fuel for some time after the power source has been cut. This will tell you that you have the correct water in your cell and you should be happy! What you should do, is to mount a small 12V computer fan beside your cell so that this fan will feed on the power created by cell and reduce the fuel build-up. If you want to be totally safe, then you should put another outlet port on top of the cell and open this every time you park your vehicle. If you want to automate things to avoid constant accessing of the cell, then you can get an electronic valve which will also feed on the excess power produced by the cell. I will not explain further on how this can be achieved, but basically, the valve and fan should only be activated when the engine is off. A few switches here and there will do the trick.

Regarding outlet ports, you are correct to assume that you should have separate lines. One line before the butterfly valve and another line after it, is quite correct and this is what I am doing right now. You should however, have the means to regulate these lines as you will soon realise that too much fuel is actually bad for the engine's health. Also make sure to top up the water regularly as too much empty space inside the cell will make the cell into a bomb!

My concern right now is that if our cells were made half-filled, then it would mean that more than a litre of empty space would be left inside the cell. One litre of Hydroxy or Nitrogen Hydroxide will definitely turn our D18s into a bomb. We should therefore provide a means of venting the NOH build-up when the car is parked. My cell does not produce 13v when shut off as of this moment, which obviously explains the inefficiency I am getting.

Another person:

Hi,

I've seen your set-up pictures at photobucket and I am surprised at the level of professionalism that you are dedicating into this project. I am even more surprised that you claim that your current set-up doesn't work at all! What gives???

Now for my take on your set-up: it seems that the pipes you are using are too small... is it 1/4"? If so, try to use 1/2" as the minimum. Your fuel output on the end caps should be placed on top of the cell, as I previously stated in my messages. Your water inlet valve should be placed lower. I think the main problem of your set-up is that the introduction of air is placed very near your fuel output. Try to keep these two as far away from each other as possible.

Do not rely on the inventor's set-up as shown on the famous picture on his V8. This picture circulated years ago and to my knowledge, this is not the current set-up that gave him extreme mileage. Last I heard about this guy was that he also used a petrol vaporiser and this was one of the key components in achieving unimaginable mileage on his truck. I for one am not getting even half the mileage that this guy claims. With years of tweaking an old carby truck, I was able to get 225 mpg and this was good enough for me because sometimes I get 300+ on long drives to the country. You should also bear in mind that the longer that petrol stays in your tank, the more evaporation will take place. Upon installing a high mileage device, I realised that most of the petrol is wasted by just sitting in the tank and evaporating.

The air inlet port should be kept as far away from the output ports as possible. It is the water that does the work and not the stainless steel. It should be possible to drain the water completely without removing the cell from the car. The air inlet is a dual purpose port which is placed on the dead bottom of the end caps. Tuning the car to work efficiently with the cell can take a very long time. Make sure that the cell is producing gas aggressively before mounting it on the car.

If you always have the fuel tank full at all times, it reduces fuel loss through evaporation, since on a hot summer day, you are probably losing 12-18% of the fuel through evaporation and what will be left inside the
tank will be less volatile, with bigger molecule sizes which won't combust completely in the engine, which in turn, shortens the life of the catalytic converter and causes more pollution.

**System Summary by Contact:** I use two 8” cells on my truck with two gas ports on each cell for a total of four ports. Two Ports to Manifold and two Ports to air intake, and there are no one-way valves, instead I use small fuel filters to make sure that water entering the engine is minimised, and at the same time oil is prevented from going into the cell.

I drilled a small hole on the bottom of both fuel filters and sealed them with a small screw plus a rubber ring. From time to time, I remove the screw to drain the water from the filters. The water inside the filters is dirty and should not be recycled for use in the cell. No salt or KOH is used because once the cell is aged and ready, catalysts are no longer required as they will only produce more dirt inside the cells.

Now here comes the most controversial part... NO AIR INLET PORT OPENING!! I don't have an opening for air in my cells. I'm sorry that I've been keeping this from you since day one. I know I told you about properly proportioning your air to the amount of gas that your cell produces. This was the same information that I got from another guy years ago. Although this might be true, you can never be precise on how much gas your cell is producing as the temperatures and pressures you get in the engine vary from time to time...

Right now you might be thinking that I may be using a different system all along... this is what I was wanting to avoid that is why I withheld this information from you. But don't worry, there's an explanation for everything...

Simple analysis of the cell design will tell you that it is plainly impossible to remove all the air inside the cell. Air will always enter the weakest point in your cell no matter how air-tight you think your cell is. Take your tires for example: air is continuously escaping your tires no matter how air-tight you may think they are. Needless to say, your cell is not air-tight to begin with so why the hell would you need another air opening? As controversial as I may sound, I found this design to the most efficient.

I use a Joe Cell to charge/clean my water. I don't have a working Joe Cell, I just use it for electrolysis to remove the junk out of the water before putting it in the cells in my car. I have a drain valve on the bottom of one cap and I usually drain and filter my cell water whenever I feel like it. If you have good water and an aged cell, you will produce hydroxly in no time. 304, 316, 317 stainless steel - it does not matter, just as long as you are able to produce gas and that it does not rust quickly. More expensive s/s will tend to outperform cheaper s/s but cheap s/s will still work!

I don't have a magnetic coil and I never heard of this until you pointed it out to me. It did not take me weeks to age the cell, the hard part is really the water. You can use plain old tap and maybe get some gas... hooray! You have just made a hydrogen booster! Or you can follow my lead, and use good water and make fossil fuel nearly obsolete. The water level inside the cell may not matter, but I find that the cell will produce more gas when there is less water is inside it. However, for safety reasons, I almost always make sure that the cell is 3/4 filled with water and 1/4 empty space. Another important thing to bear in mind is the steaming inside the cell. If you use plastic or rubber tubes, the steam might condense back into water before getting into the engine. Use copper tubes to make sure that steam will not condense. To my knowledge, the salt is just used to remove the protective layer on the s/s which actually prevents the bubbles from dislodging quickly. You can also age your cells in many other ways and this won’t be a problem.

That main idea is, get your cells to produce hydroxyl without using catalysts. The nitrogen part will come as an accident and I cannot explain how this happens. I am still a little sceptical about the nitrogen actually bonding with the hydroxide. Sometimes I think that it is only the hydroxyl and steam which are doing all the work... You are entitled to your own opinion.

The wife gets around twice her previous mileage on the Passat. The injector change can only do so much. I only installed one 10” cell to keep all the stock parts intact. She is happy with it and so my EFI project stops here.

**Please let me stress again that many people have built this device and tried to get it to work without any success whatsoever, and that is why it is in this chapter.**

However, having emphasised those concerns and provisos, I was informed early in 2010, that Jim Bundock in the UK has had considerable success using this design as a booster. He estimates that using this device has saved him about £500 over a two year period. Here is some detail from him:
These two cells have been in use in two different vehicles for more than a year now. The vehicles are Ford Transit vans with 2.5 litre diesel engines. One is sixteen years old and the other is seventeen years old and the Nitro Cells have given a 10 mpg improvement from the day that they were installed in spite of the vans being heavily loaded when being used. The original mpg was 25, so the resulting 35 mpg represents a 40% improvement over a long period.

Jim says: these cells were built from the plans shown above, the only variation being that instead of bending the tabs for the inner tube, tabs were silver-soldered at the end of the inner tubes as shown here:

These cells are run without salt and they work equally well without the wire wrap suggested in the design. The vertical cell is 18 inches tall and 4 inches in diameter and it has a rubber diaphragm on top which acts both as a seal and as an anti-slosh device. The inner cylinder gives a 9 mm gap between the inner and outer cylinders. The cell ends and spacers are made from plastic food-chopping board. The top spacers are about 30 mm long as it was found that vibration tended to dislodge shorter ones. This vertical “slow” cell is very easy to build.
On one of the “fast” horizontal units, there is a length of blue pipe:

This prevents water from entering the engine when a certain boy-racer tries to negotiate corners at the speed of light. The horizontal cell was plumbed in using a plastic 12mm pipe connected to the inlet manifold. Personally, I don’t think these cells like speed and they seem to respond best when driving around 50 mph – this is for a single cell on a diesel engine. The cell is wired in as standard, only on a diesel, the relay is connected to the fuel cut-off valve, making it very easy to wire, and when the engine is switched off, then the cell is turned off at the same time. Using a miniature version of the upright cell, the bore-hole water which I use, is pre-charged on the bench for as long as I feel it needs to be, just to remove some of the material suspended in it. Topping up with water is done every 750 miles or so and takes about an egg cup full of water. All in all, the Nitro Cell is a good honest working device, it is a simple drive-and-go piece of kit that has saved me around £500 in two years and will carry on doing that for ever.

The “HydroStar” and “HydroGen” Systems.
There are various sets of plans for car conversions and many of them are worthless and intended to waste the time and money of people who are interested in moving away from fossil fuel products. It is not possible for anyone to say with assurance that these plans do not work since even if you construct in exact accordance with the plans and your replication fails to come anywhere close to working, all that can be truthfully said is that your own replication was useless. We need to avoid this sort of comment, since for example, the Joe Cell does indeed work and can power a vehicle in a completely fuel-less mode, but, most people fail to get it operational. Consequently, it is completely wrong to write off the Joe Cell, but warnings on the difficulty of getting it working should always be given.

In the case of the HydroStar and HydroGen plans, I have never heard of anyone who has ever got either of them working. Also, experienced people are quite convinced that the design is seriously flawed and never worked in the first place. Still, it is up to you to make up your own mind on this, and so these plans are mentioned in this chapter.

The plans shown here can be downloaded free from http://www.free-energy-info.tuks.nl/P62.pdf and they are intended for free use by anyone who wants to use them. Please remember that should you decide to undertake any work of this nature, nobody other than yourself is in any way responsible for any loss or damage which might result. The full manual for an essentially updated version of the design is included under the name “HydroGen” and can be downloaded free from http://www.free-energy-info.tuks.nl/P61.pdf.

It is recommended that should experimental work be undertaken on a car, then the car chosen should be of little value and that all existing parts be kept so that the vehicle can be restored to its present fossil-oil
burning status should you choose to do so. It is also suggested that you use a car which is not important to your present transport needs. It is claimed that the modified car will travel 50 to 300 miles per gallon of water depending on how well it is tuned. The system is set up like this:

Here, the car has an extra tank installed to contain a reserve of water. This is used to maintain the water level in the reaction chamber which contains the electrode plates. The electrodes are driven by the electronics which applies a pulsed waveform to them in the 0.5 to 5.0 Amp range. The electronics box is powered directly from the existing car electrics. The Hydrogen/Oxygen mix which is the output from the reaction chamber is fed directly into the existing carburettor or fuel-injection system.

The start-up procedure is to power up the electronics and wait for the gas pressure to reach the 30 - 60 psi range. Then the car ignition is operated as normal to start the engine. The accelerator pedal is wired into the electronics to give more power to the electrode plates the further the pedal is pressed. This increases the gas production rate as the throttle is operated.

**Electronic Control Circuit**

The diagrams show a simple circuit to control and drive this mini-system. You are going to make a 'square-pulse' signal that you can watch on an oscilloscope. The premise given by the literature is: the faster you want to go down the road, the 'fatter' you make the pulses going into the reaction chamber. Duty cycle will vary with the throttle from a 10% Mark/Space ratio (10% on and 90% off) with the pedal up, to a 90% Mark/Space ratio with the pedal fully down.

There are many ways to generate pulses. This circuit uses an "NE555" integrated circuit. The output switching transistor must be rated at 5 Amps, 12V for pulsed operation.
The output of the 741 integrated circuit is adjusted via its 2K variable resistor, to give an output voltage (at point 'B' in the circuit diagram) of 1 Volt when the car throttle is fully up, and 4 Volts when the throttle is fully down.

The CD4069 is just an IC containing six inverters. It can handle a supply voltage of up to 18V and is wired here as an oscillator. Its four capacitors are likely to be used in just four combinations: C1, C+C2, C+C2+C3, and C1+C2+C3+C4 as these are the most widely spaced tuning ranges. There are, of course, eleven other capacitor combinations which can be switched with this arrangement of four switches.

**Important Note**
Gary of G. L. Chemelec commenting on "The HydroStar" circuit which sounds to be based on the same style of circuitry, states that the circuit and design are riddled with serious errors, some of which are:
1. The use of the 741 WILL NOT WORK! Pin 5 is a Voltage Control pin that already has its own voltage of 2/3 of the Supply voltage so it requires a pull down resistor, not an IC to control it.
2. The 2K Pulse width adjust will blow the 555 timer if adjusted all the way down. It needs an additional resistor to limit current to those pins on the IC.
3. The output of the 555, Pin 3 is fed to the CD4059 as well as a TC4420CPA (Mosfet Driver). This driver is a waste of money as it is not needed.
4. The Output of the TC4420CPA is then fed to the IRF510 Mosfet which is now obsolete, however you can use an RFP50N06 (50V, 60A).
5. There is no schematic of the CD4059. They should have shown pin 1 as in, pin 23 as out, pins 3, 10, 13, 14, and 24 connected to 12 volts and pins 2, 4, 5, 6, 7, 8, 9, 11, 12, 15, 16, 17, 18, 19, 20, 21, and 22 connected to ground.
6. The "Strength Adjust" Only Needs the variable resistor connected to Pin 5 and the Ground. The Connection of this control to the Supply Voltage Make Absolutely No Difference in the Output Waveforms, as the IC only needs a 2/3’s voltage on this Pin and this is supplied internally, Within the IC.
7. The "Frequency Adjust", Connects to Pins 6 & 7 of This 555. Supply to the battery Will Destroy the 555. so another resistor is needed to prevent this from happening.

This is just a small list of what is wrong. There is MUCH MORE and even after the thing is built it does NOT WORK! If you want to experiment then please do, but I would suggest you just make your own Pulse Width Modulator.
There are also many problems with the design of the reaction chamber and simply put, even if you did get it to work you would need more of these units than you could ever fit in your car to even think about running the engine. Simply put, the unit will NOT create enough gas to run much of anything. Don't get me wrong, I do think that the idea is GREAT and that it can be done.

**Reaction chamber:**
The suggested reaction chamber arrangement is:

![Diagram](image)

It is suggested that you use a section of 4" PVC waste pipe with a threaded screw-cap fitting on one end and a standard end-cap at the other. Make sure to drill-and-epoxy or tap threads through the PVC components for all fittings. Set and control the water level in the chamber so that the pipe electrodes are well covered and there is still ample headroom left to build up the hydrogen/oxygen gas pressure. Use stainless steel wires inside the chamber or otherwise use a protective coating; use insulated wires outside. Ensure that the epoxy seals are perfect or alternatively, lay down a bead of water-proof silicone sufficient to hold the pressure.

The screw fitting may require soft silicone sealant, or a gasket. Its purpose is to maintain the pressure in the cylinder and yet allow periodic inspection of the electrodes. Make sure that there are no leaks and you will have no problems. Make sure you get a symmetric 1.5 mm gap between the 2 stainless steel pipes. The referenced literature suggests that the closer to 1 mm you get, the better. Check that the chamber water-level sensor is working correctly before you epoxy its cap in place. Make your solder connections at the wire/electrode junctions nice, smooth, and solid; then apply a waterproof coating, e.g. the epoxy you use for joining the pipes to the screw cap. This epoxy must be waterproof and be capable of holding metal to plastic under pressure.

The suggested circuit for the reaction chamber water-level pump control is:

![Circuit Diagram](image)
Hydrogen from Aluminium.
Since 2003 Rothman Technologies of Canada have been running a 12 HP petrol motor on hydrogen produced by a chemical process. This is a cheap process in which metal is consumed and so, although of great interest, this is not a ‘free-energy’ engine. A recent patent application by William Brinkley proposes a system where aluminium pipes are consumed by a 25% solution of Potassium Hydroxide heated to 180 degrees Fahrenheit. William remarks on the non-polluting nature of the system, but this is not really so in that a very large amount of energy has to be put into producing the aluminium metal in the smelting and refining process, and the pollution is just moved from the end user to the industrial plant, and much more importantly, the aluminium oxide produced is said to be highly toxic and cause a wide range of serious illnesses including Alzheimer’s, although I have seen this disputed. Francis Cornish of the UK has a system where electrolysis of water is combined with a chemical process consuming aluminium wire. The system works well, but I have reservations about using consumables which tie you to industrial manufacturing, also concerns about the reliability of mechanical feed systems when they are being used by non-technical people (most car drivers). There is also the issue of removing and recycling the chemical residue generated by the process.

I personally am not keen on chemical processes and I do NOT recommend that you construct anything based on the following description. However, it might be possible to adapt the Brinkley system so that it operates with no moving parts:

Here, there is a header tank containing a 25% mixture of Potassium Hydroxide (KOH) in water. This tank is positioned higher than the pressure tank where the hydrogen gas is generated and the venting pipe is protected by a baffle. The venting pipe should provide an outlet to the air outside the vehicle or building which contains the system.

Initially, the KOH solution in the pressure tank is heated by the heating element, but when the process gets started, it generates heat to maintain the chemical reaction. The gas generation then builds up pressure in the strongly-built pressure tank. The raised pressure pushes some of the KOH solution back into the header tank, against gravity. This reduces the area of aluminium exposed to the KOH solution and reduces the rate of gas production. This effectively creates an automated gas production rate control which has no moving parts.

If the rate of gas taken by the engine increases, that lowers the pressure in the pressure tank, allowing more KOH solution to run into the pressure tank, increasing the rate of gas production. When the engine is stopped completely, then the KOH solution gets pushed into the header tank until all gas production stops, as shown here:
This looks as if the pressure tank is under considerable pressure, but that is not so, as the header tank is open to atmospheric pressure. I have concerns about controlling purely chemical processes rapidly enough for practical use. The above system would be more suited to a fixed engine, such as an electrical generator, where the gas requirement does not fluctuate greatly. The KOH tank shown above should be large enough to contain all of the KOH solution in case the gas production just does not stop when it should. The vent from the header tank should be capable of venting excess hydrogen with no possibility of it ponding on a ceiling and forming an explosive mixture with air. As far as I am aware, the above system has never been constructed and it is just shown here for discussion purposes.

Only 5 pounds per square inch of pressure is needed for electrolyser systems to feed a car engine satisfactorily, so a relatively low pressure is quite satisfactory, provided that the piping is of reasonable internal diameter. It should be remembered that the car engine will be applying a slight vacuum through the bubbler. As with all of these systems, it is vital that at least one bubbler is used between the gas production and the engine, to guard against flashback from the engine ignition if faulty ignition should occur. All bubblers should have a tightly fitting pop-off cap which can ease the effect of an explosion, and they should contain only a small amount of gas. The method of connection to the engine and the necessary timing adjustments are shown and explained in Chapter 10.

Francois Cornish Hydrogen System.
The method of using aluminium for a fuel in an on-demand hydrogen system for vehicle propulsion has been presented in detail by several people. One of the best known is the 1987 US Patent 4,702,894 by Francois Cornish, where he uses a feed mechanism for aluminium wire to maintain an underwater electrical arc which raises the water temperature high enough to make the aluminium react with the water. The rotating drum is made of aluminium but as it has a much larger thermal capacity than the aluminium wire being fed towards it, the drum temperature is much lower than that of the wire. As a result of this, the wire reaches the temperature required to make the aluminium react with the water. The chemical reaction releases hydrogen and converts the aluminium wire to aluminium oxide powder, which settles on the bottom of the tank, passing through a grid just above the bottom of the tank.

The bubbles of hydrogen gas released by the reaction tend to stick to the rotating aluminium drum, so a wiper blade is provided to sweep the bubbles off the drum. The bubbles then rise to the surface of the water and are directed into the gas collection chamber by a funnel located above the arc. If the engine demand drops and the pressure in the gas collection tank rises, a sensor located in the tank causes the wire-feed control electronics to stop the wire feed which cuts off the gas production.

At first glance, a system like this appears to have limited appeal. It uses aluminium wire which requires manufacturing by a process which uses substantial amounts of energy and while a vehicle using hydrogen produced by this method will generate very little pollution, the pollution occurs at the point of manufacture. Also, the device uses a mechanical wire feed and any device of that nature will need regular maintenance and may not be 100% reliable. In addition, the aluminium oxide powder will have to be cleaned out of the generating tank on a routine basis.

But, having said all that, the system has some very significant advantages. It does not use any fossil fuel (directly). It can be readily installed in a vehicle and the consumption of aluminium wire is surprisingly low. Figures quoted indicate that typical consumption is of the order of 20 litres of water, plus one kilogram of aluminium used to cover 600 kilometers distance (1 pound per 170 miles). This is probably a good deal cheaper than using fossil fuel to drive the vehicle. However, the aluminium oxide produced by this system is
a serious pollutant as it is highly toxic, producing a wide range of serious illnesses, including Alzheimer's. The system is set up like this:

Another system of interest is the self-powered electrolysis system of the 1992 US Patent 5,089,107 granted to Francisco Pacheco where sacrificial anode plates of magnesium and aluminium are placed in seawater opposite a stainless steel cathode. Electrical power is generated and hydrogen produced on demand. There is also surplus electrical power available to run a standard electrolyser if so desired.

**An Ultrasonic System for Producing Hydrogen.**
I have been told (by a rather doubtful source) of a very high-performance water-splitting system which produces enough hydroxy gas to power a vehicle engine while only drawing 3 milliwatts at 3 volts which is a mere 9 milliwatts of power. I have never seen one of these units, and I have no evidence that the system works, other than word of mouth, so please treat the following entry as just a suggestion rather than a matter of hard fact.

The system is so interesting and simple that it is very attractive. Basically, you have two stainless steel pipes placed in a bath of tap water:
The objective is to get two stainless steel tubes resonating together at the same frequency. That is, they should both produce the same “musical” note when suspended on a thread and tapped. As the inner tube is smaller diameter, it will have a higher note than the larger diameter tube if they are the same length, so for them to match, it would be necessary for the inner tube to be longer, or the outer tube have a slot cut in it as Stan Meyer did and which is discussed in Chapter 10.

The piezo transducers are presumably glued to the cylinders, perhaps as shown above, and they are fed with a 2.24 MHz signal. The tubes need to resonate with the electronics signal, so they are ground down very slowly and carefully until they do resonate. This will presumably be at a much lower harmonic of the electronics signal, one in the standard ultrasonics range. Presumably, there will be three spacers top and bottom, maintaining the gap between the tubes. If the frequency were down in the mains region of about 50 Hz or 60Hz, then the device would just act as a water heater of the type designed by Peter Davey. At ultrasonic frequencies, the result is quite different as cavitation bubbles form in the water. A highly respected textbook on ultrasonics points out that these cavitation bubbles have a positive charge on one side and a negative charge on the other side and these charges cause electrolysis of the water surrounding the bubbles. Lots of bubbles - lots of hydroxy gas produced. So, background theory supports the possibility of this device working, however, I am not aware of anyone who has attempted to replicate it.

What we have not been told is:

1. The size, length and thickness of tubes which work well.
2. The gap between the tubes.
3. The specific transducers used in the prototype.
4. What type of spacers were used.
5. Where and how the transducers were fixed to the cylinders.

However, even without this information, this could be an interesting investigation project using absolutely minimal power at trivial voltage levels.

The “MEG” Motionless Electricity Generator.
Tom Bearden, Stephen Patrick, James Hayes, Kenneth Moore and James Kenny were granted US Patent 6,362,718 on 26th March 2002. This patent is for an electromagnetic generator with no moving parts. This device is said be self-powered and is described and illustrated on JL Naudin’s web site at http://jnaudin.free.fr/meg/megv21.htm where test results are shown. While this device has been claimed to have a greater output than its input and an output five times higher than the input has been mentioned, I am not aware of anyone who has attempted to replicate this device and achieved a COP>1 performance, and so, for that reason, it is described in this section describing devices which are unlikely to be worthwhile for the home-constructor to attempt to replicate.

The “Motionless Electromagnetic Generator” or “MEG” consists of a magnetic ring with output coils wound on it. Inside the ring is a permanent magnet to provide a steady magnetic flux around the ring. Superimposed on the ring are two electromagnets which are activated one after the other to make the magnetic flux oscillate. This is very much like Floyd Sweet’s “VTA” device.
The external power source shown above is intended to be disconnected when the circuit starts operating, at which time, part of the output from one of the pick-up coils is fed back to power the circuit driving the oscillator coils. The circuit then becomes self-sustaining, with no external input but with a continuous electrical output.

If you should construct one of these, please be warned that it should not be started up unless there is an external load across the pick-up coils, otherwise dangerous, potentially lethal voltages can be produced. Don't get yourself killed or injured - please be very careful.

A re-worded excerpt from the patent for this system, is in the Appendix and it gives the construction details of the prototype: dimensions, number of turns, materials used, drive frequency, monostable pulse durations, etc. The prototype produced two outputs of 48 watts for one input of 12 watts. This allowed the input power to be taken from one of the outputs, while that same output was powering other loads.

This device is essentially, a custom-built transformer with two primary windings (the oscillator coils) and two secondary windings (the pick-up coils), with a permanent magnet inserted to create a standing magnetic field through the yoke (frame) of the transformer. However, a permanent magnet has two separate energy streams coming from it. The main field is the magnetic field which is very well known. It normally flows out in every direction, but in the MEG, a very good conducting path is provided by the frame of the device. This traps the magnetic energy flow and channels it around inside the frame. This prevents it masking the second energy field which is the Electrical energy field. With the magnetic field moved out of the way, it is now possible to tap this energy field for additional power output.

The MEG looks like a very simple device, but in actual fact, it is not. To act as a successful device with a Coefficient of Performance (COP) over 1, where the input power which is provided is less than the useful power output of the device, then Tom says that the frame needs to be made from a nanocrystalline material. This material has special properties which give the MEG it's exceptional output.

Care has to be taken with this device as the output power can be so high that it can burn the insulation off the wires and destroy the device if the output power is not controlled carefully. The output power is normally limited to a COP of 5.4 for practical reasons. If the necessary input power is taken from the output power via a rigorous control circuit which prevents runaway, then the device can provide output power while no outside input power is needed.

The output power is controlled by the waveform being sent to the oscillator coils. The power is controlled by the exact shape of the "square wave" drive:

This waveform is adjusted carefully to keep the COP down to 5.4 for safety sake. The waveform is also adjustable for frequency and Mark/Space ratio.

As it is some years since this device was patented, the question can be asked as to why it is not in production and offered for sale everywhere. The reason is that the MEG is a laboratory prototype which needs careful adjustment and tweaking. It has been replicated by others and it's performance verified as being COP>1, but it is not yet ready for production where it is necessary to have the design enhanced to the stage that it can be assembled in a factory and work immediately without the need for manual adjustments. That development is in hand and may be completed in the next year or two.

Some further explanation is in order. The MEG has an overall efficiency, well below 100% in spite of having a Coefficient Of Performance well in excess of 1. The COP of 5.4 mentioned earlier is an arbitrary figure selected by the designers to prevent the insulation being burnt off the output wires. The actual maximum output is almost unlimited, certainly a COP of 100 is perfectly possible, but quite unnecessary in practical terms.
If a standard laminated iron yoke is used for the MEG, it will never have a COP>1 as input power will be needed to make it operate. The magnetic flux from a permanent magnet consists of two components. One component is rotary and it spreads out in every direction. The second component is linear and it gets swamped and hidden by the rotary field. If a toroidal yoke wound with an input winding over its whole length is used, then that traps all of the rotating magnetic field inside the toroid. The snag is that this requires considerable input power to energise the toroidal winding. The big advance with the MEG is that the inventors have discovered some standard off-the-shelf nanocrystalline materials which have the property of trapping the rotational magnetic field inside a toroid formed from them, without the need for any energising coil. This is a major boost to the functioning of the device.

Now, with the rotational magnetic field trapped inside the toroid, the linear field becomes accessible, and it is a very useful field indeed. It is electrical in nature. In actual fact, magnetism and electricity are not two separate things, but instead, they are different aspects of the same thing, so both should really be referred to as “electromagnetism”. Anyway, the linear field is easy to access once the rotational field has been removed. All that is necessary is to pulse it sharply. When that is done, real electricity is introduced into the MEG from the surrounding environment. The sharper the waveform, the greater the additional electrical input becomes. This is what makes the MEG have a COP of say, 5.4 which is a practical working output. If the output is then manipulated to provide the input power needed for the pulsing, the COP effectively becomes infinite as you do not have to provide any power to make it work and you have a substantial power output. The power output divided by the power input you have to provide to make the device operate, gives the COP rating, so any output divided by zero input, always gives infinity.

Dave Lawton has experimented with the MEG arrangement, using a professionally constructed custom laminated iron yoke. He found that using the standard arrangement, he found no difference when he removed the permanent magnet. Testing various configurations, he found that the most effective set-up for his components is:
Here, the drive coils are both put asymmetrically on one side of the frame and wired so that their pulses complement each other. Then two pairs of button magnets are placed on the other side of the centreline, each side of the yoke, and bridged together with two straight vertical sections of laminated iron bar. This arrangement is sensitive to the exact position of these magnets and tuning is achieved by moving the group of four magnets and two bars (effectively two “horseshoe” magnets) slightly left or right to find the optimum position. Introducing or removing these magnets then made a considerable difference to the operation of the device.

While most people find it very difficult to get COP>1 operation from the MEG, I am reliably informed that WITTS have succeeded in producing self-powered replications. There is, on the web, an exceptionally well-written presentation by Jacco van der Worp entitled “The Hitchhiker’s Guide to the ‘Free Energy’ MEG” at http://yowusa.com/scitech/2002/scitech-2002-06a/1.shtml and it explains how and why it can work. By kind permission, it is reproduced here:

**A Hitchhiker's Guide to the "Free Energy" MEG**

YOWUSA.COM, 25-June-02
Jacco van der Worp

**Foreword by Marshall Masters**

This article by Jacco van der Worp a Dutch physicist, explains the “free energy” Magnetic Energy Generator MEG simply, in layman’s terms. I worked closely with Jacco on this project and sent a polite request to Lee Kenny, one of the MEG principals for assistance. His quick response was controlling and reeked of paranoia. "You are NOT AUTHORIZED by MEL to publish any information regarding the MEG." *(Readers can view and comment on the full text via the YOWUSA message board post, MEG -- Masters and Kenny.)* At first, his paranoid reply puzzled me, but as we further investigated the MEG we came to understand the paranoia and it chilled our blood. Perhaps this particular genie should be left in the bottle.

My first reaction to Kenny's suppressive controlling behavior was to shoot back a reply reminding him that there is a funny little piece of paper called The Constitution. After that, the urgent paranoia in Kenny's response continued to task me.

An obvious and simplistic explanation is that Bearden et al. are busy subscribing to Yachting Magazine and setting up bank accounts in offshore tax havens for their new to be wealth. The problem is that is too simplistic an explanation, because after working with engineers for twenty-five years I’ve learned to recognize a knee-jerk paranoid reaction when I see one. Kenny's reply was quintessential a knee-jerk
paranoid reaction. Perhaps, I would have reached this conclusion early on, were I not so enamored with the MEG technology. But as dug deeper, I found more tangible reasons for Kenny's paranoia.

The process of invention is a passionate one. At the end of the process are the hopeful financial rewards, but for something as complex as the MEG there is an equally large reward -- peer recognition. "Damn your eyes, but you did it." In this heat of invention the post reality dimensions are discussed but at a lower level and with less emphasis. I believe this is what may have happened to the MEG inventors. They simply got so carried away with the passion of invention that it clouded their view beyond the moment they would receive their patent, which in turn would embrace their paradigm shifting theories with plausibility.

However, once the patent was issued, the types of articles one would expect to see in magazines like Popular Science and Popular Mechanics failed to materialize. Further, what was made available by Bearden et al. was such geeky technobabble that it usually sails over the head of the average man. I now believe there was a reason for this.

The MEG opens a doorway into a new future, filled with new applications that will build upon the fundamental concepts of the MEG. Like the nuclear genie America unleashed upon Japan, the MEG genie offers us both a new and better world as well as a dead world all in the same breath. I believe this explains Kenny's paranoia. Now that he and his fellow MEG/MEL partners are looking at the practical applications of their invention they are starting to see it from "outside the box" as they say in the computer business. So what could they be seeing that makes them want to control the flow of knowledge about this new invention?

While the focus now is on the "free energy" application of MEG technology, its ability to interact and deform the space time continuum offers an alarming new range of applications to include: Weapon of mass destruction, interstellar space drive and time machine engine. And that is only the beginning of the hypothetical possibilities that could emerge from this paradigm shifting invention.

However, before this genie is let out of the bottle, our elected representatives and all of us in the mainstream need to understand the MEG a little better. That is the goal of this superb article by Jacco van der Worp.

Marshall Masters, Publisher

A Hitchhiker's Guide to the "Free Energy" MEG

This fourth article in a YOWUSA series on the Motionless Electromagnetic Generator by Tom Bearden et al., now under patent, discusses this groundbreaking technology in non-technical layman's terms as opposed to delving deeply into the physical principles behind the MEG. Once you have finished reading the article, you will have a general idea of how the MEG works and why its inventors call it a "free energy" machine.

For those with bolder interests in the precise formulas and equations describing the MEG, those working on the project have already published several technical articles on the Internet. The best of these is a 69-page PDF file called The Motionless Electromagnetic Generator: Extracting Energy from a Permanent Magnet with Energy Replenishing from the Active Vacuum. This document lays out the most basic principles used for the MEG with some graphics added in.

Getting to know the MEG

The MEG represents a revolutionary approach to generating energy in our ever more demanding economy. However, it may also become a huge financial threat to big energy companies, as Marshall Masters outlined in his article Bearden's Free Energy MEG Destined For Chapter Eleven.

However, if the MEG grows into its destined role, it will conquer the market. It will do so by providing mankind with a durable and above all clean source of energy, which so far no other source of energy has achieved at an affordable price.

For the common person, the MEG is an obtuse technical wonder and understanding why it works requires one to dive headfirst into what seems to be a bottomless pool of technobabble. However, if we pare the issue down to five basic technological terms, we can create a basic understanding of the MEG.

In a MEG device there are five basic terms playing an important role in making it work. They are (energy) flux, efficiency, capacitance, magnetic field and shielding. This article will attempt to explain each MEG term...
simply, using everyday examples. After the basic explanation, we will explore a full analogy in the form of a rain barrel.

**Flux**

Flux, or energy flux to be more precise, is essentially a by-product of energy creation. For example, an automobile engine uses a mixture of gasoline and air to power the car. Older engines in particular were not extremely efficient in burning all of this mixture and the by-product is the smog that comes out the tailpipe of the car.

Modern car engines are more economical; less unburned gasoline goes out their tailpipes. However, even the most efficient cars on the road today still push unburned gasoline out the tailpipe. On top of that, part of the heat generated by the burning of the gasoline inside the engine also leaves that way. In a manner of speaking, the smog that comes out of your car’s exhaust is like flux. It is a by-product of the process of creating the energy needed to make your car travel down the road.

**Flux and Efficiency**

Before the oil embargo of 1973, American car designers largely ignored the issue of flux by building cars with larger engines to go faster. Consequently, this fuel economy suffered from the embargo. However, in 1973 the price of fuel did not make this an important issue. Once the fuel price rose after 1973, American auto manufacturers began losing sales to foreign manufacturers who were building more fuel-efficient engines.

**Efficiency**

We define efficiency as the useful application of energy flow. This means that if we build a more fuel-efficient engine, it will send less unburned fuel out the tailpipe and thereby increase the number of miles we can go on the same amount of gasoline.

The part we call useful here is the energy of the burned gasoline whose heat is used to move our car. That is what we aimed for, that part divided by the total energy that could be produced from the amount of gas we used, is called efficiency.

**Efficiency and Unity**

Since 1973, the goal of auto manufacturers is to use the available energy in gasoline as much as possible. The most they can hope for is what is called unity. Unity means that a system can use 100% of the energy input into it. In this case, that would be the energy stored in the gasoline to generate the desired output, the output in this case is the horsepower our engine delivers to move our car down the road.

No matter how efficient the designs are in pushing toward unity, the most a system can hope to achieve with present technologies is around 30% efficiency, which is some 70% short of unity.

**Unity and Closed Systems**

When we commonly think of unity (100% efficiency), we also tend to think in terms of closed systems. A closed system is a system that is completely isolated from the rest of the world. In a manner of speaking, an automobile engine is a closed system. The energy released from the burning of the gasoline to extract its energy is either captured to power the car or blown out the tailpipe as wasted flux. Likewise, you continually reduce the amount of gasoline in your tank as you drive down the road. The total amount of energy that is either still stored in unburned gasoline or is moving your car along or is leaving the tailpipe as waste flux is constant.

The essential point to keep in mind about a closed system is that it does not draw energy from the environment around it. On the other hand, an open system does draw energy from its surroundings.
Closed Systems and Open Systems

If we were to create automobiles with open systems, what would they look like? They would have the same engine, but an automobile with an open system would for example have a mast and a sail.

In this case, the driver would use the automobile engine to raise and lower the sail. The raised sail completes an open system by capturing motion energy from the wind and using it to propel the car down the road (provided the wind is with you.)

Once you have raised the sail, you can make the car go forward by angling the sail to the wind. To slow you can position the sail in line with the direction of the wind thereby neutralizing it as an active, open power system. Once you raise the sail, you do not need the car's engine for propulsion.

The essential point to keep in mind about an open system is that it draws energy from the environment around it like the sail on our modified car. In addition, it is controllable in that you can turn it on and off, just like a closed system.

Open Systems and the Coefficient of Performance (COP)

Because the auto sail is not limited to the energy of the fuel in the gas tank (which can never exceed unity or 100% efficiency), an open system (portrayed here by the auto sail) can in fact exceed unity. In other words, it can obtain more than 100% efficiency from the energy system it is interacting with, which in this case is the wind. So how do we measure systems than can achieve more than unity?

The term Coefficient of Performance (COP) compares the amount of energy input into a system versus the usable amount of energy output by the same system. For example, if using the engine in our auto to raise the sail requires one unit of energy and that when the sail is raised it generates or gathers 8 units of wind motion energy, the Coefficient of Performance is 800%. Another way of expressing this is 8:1, where 8 is the useful energy available and 1 is the amount of energy inserted into the system to trigger the generation of usable energy.

Coefficient of Performance and Capacitance

In our car example we used a sail to propel our car to achieve an 8:1 COP. Could this work with larger systems? For example, could it work with trucks as well? We already know that sails were used to propel huge wooden sailing ships centuries ago.

Let's go back in time to sailing ships for a moment. The builders of these great ships knew that the more and bigger sails they added to their ships, the faster they would go. However, great expanses of water surround that ship on the ocean. With this in mind, let's see how this applies to using sail power to propel cars and trucks.

Because cars and trucks travel in close proximity to each other and in the same direction on a highway, the amount of wind energy available in the open system must be divided amongst the various vehicles. Consequently, those in closest proximity to the wind direction will bleed off wind power from those ahead of them. In essence, they literally steal each other's wind.

In terms of capacitance, the essential concept here is that open systems may not be unlimited systems. In the case of our auto and truck sails, the proximity and number of sails accessing the same open wind system for energy will drain the open system. In other words, even if an open system is free, capacitance tells us that there is only so much of it to go around.

At this point, we've discussed some general terms used with the MEG. Now we're ready to discuss terms that are more specific to the MEG, beginning with fields.

Fields

In very simple terms, a field is any mechanism that serves as a means to an end. In the car example, we used a sail as our field, in that it gathered energy from the open wind system.

Unlike the sails we use as fields to capture the energy we need to propel our cars, in terms of the MEG, we must use something called a magnetic field.
**Magnetic Fields**

In the case of the auto sail, we used our sail as a field to pull energy from the open wind system around us so that we can propel out autos. The energy we needed was stored inside the wind.

With the MEG, the energy source we need to tap is not the wind, but electromagnetic forces of the universe that are just as omnipresent as the wind is on Earth, if not more so.

What the sail and the MEG have in common concerning the fields is that they must control their fields in order to prevent undesirable side effects.

Looking at our auto sail example, we attach lines to the sail and boom to control the trim of the sail so that it captures as much energy as possible without over stressing the sail and causing damage. Hence the popular sailing term, trimming the sails. Likewise, untrimmed sails can be dangerous, presenting a hazard to systems such as the boom and mast, or to the sailor if the wind moves the sail and boom violently across the ship, upsetting the balance of the ship.

In a manner of speaking, the MEG uses something called shielding to achieve the same thing as controlling the trimming of the sail if you will. Without it, violent effects may damage its surroundings.

**Magnetic Fields and Magnetic Shielding**

With the MEG, the magnetic fields are very powerful and must be controlled tightly at all times in order to prevent them from creating havoc in the space around them. This is why the MEG needs to use magnetic shielding.

The most important concept of magnetic shielding is that it serves as a safety control for magnetic fields by containing and minimizing their negative effects.

**The Rain Barrel Example**

At this point, we've covered all the bases with the exception of the magnetic vector potential, which forms the crux of the MEG theory. To help you to understand the complexity of this concept, let's first review what we have covered up this point within the context of a simple rain barrel system. The reason for this is that one may understand the MEG magnetic vector potential more easily from a systemic viewpoint.

**Flux**

Some of us may have tried the following as kids or even later in life. If we take a barrel filled with water (or a gas tank filled with petrol) and we want to take some of that out, we do not have to suck it all out ourselves.

We take a piece of hose; simple garden hose will do, and stick it into the reservoir from which we want to take the liquid. On the outside, we lower one end of the hose a little lower than the opposite end sitting inside the tank. Then we gently suck on the hose (let's keep to water from here if only for the sake of taste) and the fluid will start to flow. Once it does, it will continue to flow until the other end of the hose inside the tank is no longer submerged. Therefore, with only a little effort we move a lot of fluid out.

The mechanism that makes this work is called the capillary effect. In other words, the weight of the column of fluid in the hose with a height equal to the difference in height of the two ends of the hose is providing the force that is needed to keep the fluid moving. However, what we do know is that the water barrel will run empty if we just pour it all out.

On the other hand, the MEG draws energy from a 'barrel' that fills itself right back up! So it never runs empty! If you repeat the stimulated energy flow out of the MEG, energy flux will come out of it continually; it will not run dry like our rain barrel.

Therefore, a proper way to describe the MEG therefore in terms of this example would be a rain barrel into which more rain would fall the instant that that one draws water from it. Once you start the water flowing through the hose, the rain starts falling into the barrel and replaces the water you’re pulling out at a similar pace.

For this reason, a MEG-style water barrel will never run empty and the water will flow forever out through the hose once you have brought it in motion because the MEG is
an open system, which brings us to the next point of consideration, what efficiency vs. COP means for our rain barrel.

**Efficiency and the Coefficient of Performance**

For the purpose of our rain barrel example, the term "efficiency" can be defined by the amount of water we can pull from the barrel by drawing it into motion with the siphon hose.

With the closed system water barrel, we learned that a closed system is isolated from the rest of the world, so no rain comes falling in from above to replace what we're taking out. In this case the best we can do is position the hose at the very bottom of the barrel on the inside and while letting it hang even lower on the outside. By doing this, we can siphon all of the water out of the barrel, which gives us 100% of the water. This 100% of efficiency is called "unity."

Keeping the unity of our closed rain barrel system in mind, let's shift back to our open system variant.

The moment we begin to siphon water from the open system rain barrel, fresh rainwater falls in through the open top of the barrel. No matter how much water we siphon from our open system water barrel, enough new rain falls through the top to replace what we are taking about. Therefore, put in motion a never-ending stream of water with our open system rain barrel we can obtain results greater than that of unity. This is what the Coefficient of Performance (COP) is about. We use it to express the output result, which is greater than what we put in. Ergo, the COP for the open system rain barrel can exceed unity (100% efficiency) whereas the close system rain barrel can only hope to achieve unity. So then, what happens if we increase the size of our rain barrel?

**Capacitance**

Aside from the direct effect of having more water by increasing the size of our water barrel and siphon hose, there are indirect effects as well and they need to be carefully considered.

For starters, if we make our barrel bigger as well as our siphon hose what will that mean for us? Given that we'll be using a bigger hose to siphon out more fluid, we'll need a stronger suction force to begin with. We can do that simply (provided we have the lung power) without requiring a scaling-up of the entire system.

However, if we drain more water per second from a bigger barrel (e.g. the size of a lake) and we want it to keep running, it will have to rain harder to replenish the water that we take out and rainfall is bound to a natural limit.

At a certain barrel and hose size, not even a tropical storm will provide enough rain to keep the water level up and the system will start to collapse. On top of that, a normal barrel stands on a support structure. The bigger the barrel, the harder it will be to find a place for it to stand and remain standing. Otherwise it might fall over or break. So, how do we keep our bigger barrel from coming apart?

**Fields and Shielding**

If the barrel gets really big (let's assume for a moment it is the size of Lake Superior) and we start siphoning water out of it at the pace of four times the total water flux of the Sault Ste Marie Canals, then the water level will take time to readjust for the water poured out. The most important field in action here is the siphoning process, powered by gravity, which results in the water flow out of our bigger barrel lake. (Yes folks, now we're talking at a planetary scale.)
Normally, water level is horizontal (allowing of course for the curvature of Earth on a larger scale). However, if the pace of siphoning gets high enough, the normal water flow will become incapable of correcting the level quickly enough.

A permanent difference in height of the water level from one side of the lake to the other will arise. In that case stopping the siphoning action will not result in an immediate stop in water flowing towards the siphoning point. A sudden stop in pouring from a lake-sized barrel will cause at least a small tidal wave. The bigger the level difference across the lake, the worse the tidal wave will turn out. Although that looks like another field in action in the big barrel system, it isn't. It is a self-correcting mechanism for the lake surface after it has been disturbed.

In simplistic terms, what this all boils down to is that the flow energy like the flow water through our water barrel system represents a field. As a field increases in size it can likewise destabilize in greater amounts as well. Therefore, if we wish to increase the size of our fields we must find ways to shield them from those things, which could destabilize them.

**Fields and Shielding**

If our normal-sized rain barrel overfilled with water it could start to leak. In such a case, we would need measures to prevent a gushing flow of rainwater from damaging the immediate surroundings in a flood.

On the other hand, with our lake-sized version of water barrel we would need dikes to surround our lake to keep it from overflowing onto the land around it.

This flooding finds its cause in a pace difference between the raining in and pouring out of the water. These dikes must of course be able to withstand small tidal waves that emerge due to the starting and stopping of the siphoning action. In very simple terms, this is called shielding.

Up to this point, we've covered the most essential concepts we'll need before we tackle the big one -- vector potential. This is an important yet complex concept but it goes to the very heard of what a MEG is why it can do what it does.

**MEG Components and Layout**

The picture below, taken from the abstract by Magnetic Energy Limited as it published on the Internet. (We've added the colored placeholders to make it easier to view.) This illustration shows the basic layout of a lab prototype of the MEG used to successfully demonstrate the theory.

- **PERMANENT MAGNET (A):** The most important element is the permanent magnet sitting in the middle of the schematic picture. The magnetic field lines come out of that bar magnet at the top and bottom side (in this picture). This magnet is what helps drive the entire machine.

- **NANO-CRYSTALLINE FLUX PATH AND CORE MATERIAL (B):** Instead of freely 'circling' from the North Pole of the magnet to the South Pole they enter a 'nano-crystalline flux path and core material.' That material
captures all of the magnetic field of the permanent magnet, so that no magnetic field is present free in the air any more.

- COLLECTOR COIL (C): The collector coils are the points where energy can be tapped from the MEG.
- ACTUATOR (INPUT) COIL (D): The actuators are the points of input of energy to put the much larger amount into motion.

To compare it to the rain barrel, the actuators are your mouth drawing water through the hose. The collectors are the hose ends hanging out of the barrel that starts to pour once you've generated a capillary with your siphon hose. And finally, the magnet and the coil containing the magnetic field are the barrel reservoir containing the water.

**How the MEG Works**

Now we come to the crux of the whole system, the reason why it works in the first place. The driving force in our large, lake-sized rain barrel was the force of gravity. That made the water that falls at some distance away from our hose move towards the initial siphon point and in turn caused the water to run through the siphon. In this case, gravity is the restoring force of the water level of our lake-sized rain barrel as it makes the water level go horizontal again.

This force and the correction mechanism attached to it have an equivalent in the magnetic arena. That force is the magnetic vector potential. If we look at the MEG, we see that it converts an energy flux that was stored in such a vector potential outside a closed magnetic field path. (Whoa, wasn't that a mouthful. Let's break it down into more simpler terms.)

**OK, So What is a Vector Potential Anyway?**

To explain vector potential, we need to use something other than a rain barrel, but it must be familiar so why not the energy we use in our homes to run our computers, hairdryers, etc.

We all know about the electrical potential across the two wires of a wall outlet. This electrical potential is what makes a light bulb burn. If we're not careful with the outlet we could also find ourselves flat on our back as our family members frantically call for an ambulance. Thankfully though, the US, the electrical potential is 110 volts, which was chosen because it is not as lethal as the 220-240 volts standard found in most of the other countries in the world.

However, if we combine the numerical value of this electrical potential with a direction, we have a vector potential. In the case of our 110-volt outlet, if we change the direction from say the horizontal to the vertical, we can double our potential to 220 volts. Therefore, direction is important for the creation of any magnetic field; they all emerge from a magnetic vector potential where direction plays a critical role.

The following illustration compares the MEG with our rain barrel example for a very general layman's understanding of how the MEG works and why the magnetic vector potential is so important. (Please keep in mind a precise explanation would require an article several times the size of this one, so we'll just paint our picture with broad liberal brush strokes for now.)
• (A) An outside reservoir waits until the system is brought into motion and then starts to work to restore the balance that is broken by sucking the siphon hose. For the rain barrel it is the rain filling the barrel back up, for the MEG it is the vector potential converting its energy into magnetic field inside the closed path.

• (B) This adds an extra field to the magnet field inside the closed loop.

• (C) In essence the actuators work like the siphon hose in our rain barrel example and by changing the direction of the water it creates an outside vector potential.

• (D) Consequently, the closed path starts to interact with the magnetic field inside, to compensate for the change in the situation. It gives energy to the magnetic field inside the closed path.

• (E) We can then tap that energy from the collectors and we find that more electrical energy comes out the collectors than the amount we put in through the actuators. So energy from the vector potential field outside the closed path is ‘flowing towards the siphon’ to correct the ‘field level’ again. If we lead part of this energy back into the actuators again, the rest of it is free flux! Free flux?

With the MEG energy flux actually becomes the result product or output instead of a waste by-product as with fossil fuel powered systems like car engines. What used to be waste is now useful output, just like today’s electricity drawn from the net to light our houses.

In that respect, the MEG forms a new way of looking at energy flux and if you happen to install a MEG next to your home, it will require far less energy to provide you with far more electricity. Consequently, your energy costs will come down considerably.

Why the MEG is Commonly Misunderstood

The MEG uses an input energy flux to convert a far greater amount of thus far unusable energy flux into a controllable and more convenient form. This can leave some folks scratching their heads because this is a whole new twist on flux. For those who are familiar with the principles of conservation of energy this represents a paradigm shift in thinking that can defy years of heavily instructed thought about closed systems. And here is the rub. The rigid principles of conservation of energy apply only to closed systems such as automobile engines, whereas the MEG is an open system.
Because the MEG is an open system, it can turn flux into output because it is a system out of balance with the world around it and therefore constantly interacting with the environment around it! This way, it may result in a COP that is far greater than unity.

Another factor that makes it difficult for conventional thinkers to understand the MEG is that it does not use the Lorentz Gauge.

When Tom Bearden and his team of researchers discovered the principles behind the MEG when they chose to omit a commonly known calibration of an electromagnetic system, the so-called Lorentz Gauge.

The Lorentz Gauge is essentially a free choice of values for given parameters of an electrical system; this free choice makes mathematics simpler. At the same time however it discards a range of interesting (as it turns out now) solutions to a set of equations describing the same system. This range is the range of non-equilibrium states.

By keeping the MEG just off-equilibrium (out of balance) all the time, we can use it to pull a tremendous amount of energy out of a so far unusable reservoir into a convenient form. In essence, this is what the MEG is about.

**Potential Problems with the MEG**

We know that the MEG works, but it is also of interest to see just how much it can do. Most of you will likely be interested to know if a MEG can power a home. Can we scale it up without a limit, or could one such device even power a city?

The scale of many devices is only limited by practical design questions. The MEG needs a permanent magnet as well as a nano-crystalline material completely confining the magnetic field loops that leave this magnet. It also needs input and output coils. Electrical currents running through wires will produce heat, which will have to be dealt with at a high enough pace, but other than that, the potential size and productivity of the system is virtually unlimited. This type of generator should a priori be scalable to city-block level.

There are, however, possible side effects to its operation, which we want to take a closer look at before starting to operate a MEG for a city.

A few problems might exist for the MEG. Right now, it is uncharted territory, but we need to consider the possibility that above a certain level, the vector potential field cannot rearrange its energy fast enough for the working conditions to remain intact, thereby causing the MEG to fail. To fully illustrate this possibility, let's revisit some of the basic terms we discussed earlier in this article.

**Magnetic Fields**

The energy stored in the magnetic field and the vector potential field may interact with conducting materials outside the MEG as well, generating secondary magnetic fields and electric currents.

There's more. As energy leaves its surroundings, new energy comes flowing back in. We do not know if the pace of that is bound to a limit. It may have side effects that are currently unknown to us. Some pessimistic reactions have even spoken of an alteration of the space-time continuum surrounding the MEG. That would be a serious consequence indeed, but we have seen no proof of it so far.

Besides the argument presented above there is the coil material that is supposed to fully contain the permanent magnet's field and the additional field generated during interaction. A bigger MEG will also need a stronger magnetic field. Just how much can the coil material take before the field starts to break up the material itself? This bigger MEG may need superconducting materials to gain that stronger magnetic field. There will be additional conditions that are imposed by that material. We need to maintain that superconductivity to prevent damage to the material.

However, stronger magnetic fields do pose a health risk. For this reason, most people do not want to live under or very near high voltage power lines. They carry strong electromagnetic fields around them as well. It is however possible to shield magnetic fields.

**Shielding**
If someone were to switch off the input signal to a large MEG, the field may not die away instantly, which would result in a field spike as it follows suit to the signals. Then EM pulses may arise, which are (very) destructive to all electronic equipment. These EM pulses are so destructive in fact, that some nations have conducted extensive research into their possible application as a weapon.

A Faraday cage would form the "dike around the lake" for the MEG. This is a metal case enclosing the magnetic field plus the MEG completely. With the exception of strong EMP effects it will keep a semi-steady field contained so that no outside negative effects will occur. So in the course of normal operation, the MEG can be shielded quite easily. The worrisome moments occur when switching the MEG on or off. How will the shielding affect the ability of the vector potential field energy to replenish itself as energy leaves the unit?

We Need to Proceed With Caution

Concluding, we can say that the MEG is a means to pour energy from a tremendous reservoir with remarkable little effort. The result is almost limitless energy at practically no cost. The only drawback known in the current state of research is that on a large scale nasty, hard to control side effects may rear their ugly heads. Therefore while the MEG represents a ground breaking and innovative new technology it should not be rushed to market without exhaustive testing.

The Devices of Hans Coler

Hans Coler developed a device which he named the “Stromerzeuger” which consisted of an arrangement of magnets, flat coils and copper plates with a primary circuit powered by a small battery. The output from the secondary circuit was used to light a bank of lamps and it was claimed that the output power was many times the input power and could continue indefinitely.

The apparatus principally consists of two parallel connected spools which being bi-filar wound in a special way, are magnetically linked together. One of these spools is composed of copper sheets (the spool is called the ‘plate spool’). The other one is made of a number of thin parallel connected isolated wires (called ‘spool winding’), running parallel to the plates, at small intervals. Both spools can be fed by separate batteries (6 Volt, 6.5 AHr were used). At least two batteries are needed to get the apparatus operating, but subsequently, one battery can be removed.

The spools are arranged in two halves each by the bi-filar windings. The plate spool also contains iron rods with silver wire connections. These rods are magnetised by a special battery through exciter windings. Electrically, the exciter winding is completely isolated from the other windings. Hans said that the production of energy takes place principally in these iron rods and the winding of the spools plays an essential part in the process.

It should be mentioned that the spool circuit is powered up first. Initially, it took a current of 104 mA. The plates and exciter circuits are then switched on simultaneously. When this is done, the current in the spool circuit dropped from 104 mA to about 27 mA.

It is suggested that an electron be not only regarded as a negatively charged particle but also as a South magnetic pole. The basic Stromerzeuger element is that of an open secondary circuit, capacity loaded, inductively coupled to a primary circuit. The novel feature is that the capacities are connected to the secondary core through permanent magnets as shown here:

![Diagram of Stromerzeuger element](image)

It is claimed that on switching on the primary circuit, “separation of charges” takes place with M1 becoming positively charged and M2 becoming negatively charged and that these charges are “magnetically polarised” when they formed, owing to the presence of the magnets. When the primary circuit is switched off, a “reversing current” flows in the secondary but the magnets “do not exert a polarising effect on this reversal”.

Two of the basic elements shown above are placed together making a double stage arrangement with the copper plates close together.
Note that the M1 coil is reversed. The magnets carry current and so it would be reasonable to presume that they are iron magnets rather than ferrite, iron magnets being common sixty years ago, combined with the fact that ferrite magnets do not conduct current and neodymium types were not available in 1925. The secondary windings are both exactly equal and “wound in a direction such that, on switching the primary coil on”, the electrons flow from P1 to P2 and from F1 to F2. Again, this is a most peculiar statement as the direction of electron flow is not affected by the direction of winding of the coil, which suggests that the person making the report knew almost nothing about circuitry. It is highly likely therefore, that the brief report which has survived to today, is very vague and lacking in the essential details, the diagrams not indicating the bi-filar windings and straight wire lengths mentioned earlier.

One of the very unusual statements made is that the F1/F2 circuit only induces the effect and that the excess power is drawn from the P1/P2 circuit. This is the basic working arrangement. More of these double stages can be added to provide higher outputs, with their outputs connected in parallel for greater current.

The original document, with masterly ambiguity, states that to make this arrangement, two of the original circuits are placed one on top of the other and then promptly draws the arrangement, showing the M1 magnet poles reversed, which of course, contradicts what has just been stated. So, it is not clear if the diagram or the statement is correct, but the likelihood is that the diagram is right.

For there to be any kind of continuous output from a transformer, the input cannot be DC in spite of the fact that dry-cell batteries were used to power the circuits (even though the output could be as high as six kilowatts). Coler stated that his research indicates that permanent magnets actually oscillate at about 180 kHz. If that is correct, then that could account for the magnetic induction produced in the circuit. If that is not what is relied on in this circuit, then the batteries have to be connected and disconnected continuously, and the technology being simple at that time, is seems likely that a relay would have been wired to self-oscillate as in the early electric bells. While that arrangement could have been used just to connect and disconnect the batteries with a relay contact, the relay coil will have generated high-voltage sharp pulses, generating short magnetic pulses of the type which causes an inflow of cold electricity into the circuit from the local ambient background.

Alternatively, although it is not mentioned or suggested, the connection could have been made using a relay which had only one contact, in which case, the back-EMF of the relay coil may have fed high-voltage pulses directly into the circuit. This is, of course, just ill-informed speculation. The arrangement might have been:
In each case, the battery current flows the normally closed relay contact, powering the relay winding, which opens the switch contact, disconnecting the relay and so closing the switch contact again. This causes rapid pulsing of the battery voltage and the relay coil generates high voltages, typically of some hundreds of volts. If the circuit connection is as shown in the first arrangement, then when the relay switch opens, high back-EMF voltage pulses will be fed to the circuit. On the other hand, if a relay with two separate contacts is used, the second relay switch contact can be used to connect the battery to the circuit and disconnect it again in a very rapid sequence. There is a group of people at http://tech.groups.yahoo.com/group/testatika/ who are working towards making an operational version of this device. Information on the Coler devices is presented clearly at http://rimstar.org/sdenergy/coler/index.htm#STROMERZEUGER.

Chapter 14: Renewable Energy Devices

Note: If you are not at all familiar with basic electronics, you might find it easier to follow parts of this chapter if you read chapter 12 first.

Heaters.
The devices described here are not “free-energy” devices as such, but in spite of that, it is an area of considerable interest to many people, and the subject is included here because of that.

If you do not live in an urban area, then a solid fuel stove can be an economic solution, especially if the fuel can be collected free from wooded areas. Stove design has advanced considerably and it is now possible to make a simple stove with very high efficiency and very low emissions as shown here:

Although this stove is a very simple construction, it’s efficiency is very high indeed. The best fuel is made of smaller pieces which rest on a simple shelf. Branches work better than large pieces of wood as the consumption is more complete. As the fuel is consumed, it is pushed further into the stove, which gives the user an appreciation of the rate of consumption. Having the fuel resting on a shelf has the major advantage of allowing air to flow both above it and below it, which gives improved combustion. The operation is said to be so good that there is virtually no residue and no emissions.

Again, if land space is available, a solar oven (or Stirling motor) can be used, either to store energy for later use or generate heat for cooking or home heating, as can hot-water solar panels. However, it is only realistic to consider the application to be during the night in a built-up area with little or no spare space for equipment.

The Wood-Gas Stove.
There is another very effective type of wood-burning stove. There are several commercial versions of this stove on sale, but most of them use an electric fan to get the effect which is produced automatically by this design. This design has been replicated by Alberto Feliciano and found to be very effective in operation. It causes a load of wood which would normally burn up in fifteen minutes to burn for a whole hour, putting out a much greater amount of heat. The design is very straightforward. There is an outer drum which has a solid base, and the opposite end removed entirely as shown here:
A ring of ventilation holes is drilled around the whole of the bottom edge of the drum and threaded rods are run through the drum. These support a circle of wire mesh which forms a supporting shelf.

A smaller drum then has both ends removed, to form a cylinder. This cylinder is to fit inside the outer drum. It rests on the mesh shelf of the outer drum. This cylinder has a ring of ventilation holes drilled around the whole of its upper edge as shown here:

A third drum which is only slightly smaller than the outer drum is cut down to make a cap for the inner cylinder. This cap is not tight-fitting, but it effectively closes off the top of the gap between the sides of inner cylinder and the sides of the outer drum:

This cap has a circular hole cut in it, and this hole is only slightly smaller than the diameter of the inner cylinder. It is supported by the upper lip of the inner drum but the hole is large enough that it does not obstruct the flow of heat up through the top of the inner drum. These three pieces fit together like this:
Wood of any type, branches, sticks, firewood, etc. are placed inside the inner cylinder and set alight. Initially, the flames come out of the top of the stove as you would expect, but after a few minutes, the combustion alters completely. The burn now becomes that of wood-gas rather than of the wood itself. The wood is slowly converted to charcoal and the gas released by this process burns with greater heat than the wood would give as well as burning for a much greater length of time. This stove design can be made in any size. Small versions get a burn length of about three times that of the wood burning in the open air, while large versions can reach four times the burn length.

Flames no longer come out of the top of the stove, but instead, they come out of the ring of holes around the base of the outer drum. The process is like this:

A high-temperature gas burn takes place in the centre of the inner cylinder. This pushes heat out through the top and the bottom of the inner cylinder. The heat flowing out of the top is used for heating or cooking as before. The heat flowing out of the bottom gets diverted around the outside of the inner drum, flows upwards, is caught by the cap and fed back into the inner cylinder through the ring of holes at the top of the inner cylinder. This raises the temperature of the gas burn even further and it augments the heat coming out of the top of the stove. The result is a very hot burn which goes on far longer than would happen if the same wood was burnt on an open fire or in a single open drum. When the wood reaches the end of its burn cycle, it can be replaced by feeding new wood through the hole in the cap which rests on the inner cylinder. The stove will need to be emptied of ash from time to time.
Mr Teslonian’s Heating / Fuel-producing / Electricity and Refrigeration System

The Wood-gas stove shown above has been taken several steps further by “Mr Teslonian” as shown in his videos:  
[link](http://www.youtube.com/watch?v=arbXj9R6ZXw&list=PLw28_n7AgcmBtogfnxDV50M-VzPj3vtFt) 
and [link](http://www.youtube.com/watch?v=647R2R_VzG8) where he burns twigs in a home-made wood-gas furnace, heats his house, heats his water, produces engine fuel, runs an electricity generator off the gas and powers a refrigerator.  All that, from a few twigs!  This is very impressive and he is definitely to be congratulated for his development.  His basic wood-gas stove can produce flames up to eight feet (2.5m) tall when operating very effectively on just a few handfuls of short twigs and branches.  It looks like this:

This very effective wood burner produces enough heat to heat a house and produce hot water.  The wood-gas can also be used to produce both crude oil and fairly well-refined oil which can be used in an engine:

And as you can see from the picture above, the wood-gas can run an electricity generator.  There is a world of difference between burning wood like this and a typical camp fire or bonfire.

Wood-gas can also be used to run vehicles (as was done during World War 2).  Links to a great deal more information include:
Solid Fuel Producing Electricity

We then to think of small-scale solid-fuel burners as providing heat and perhaps a little light as well. The people in Siberia don’t think like that and they produce a range of (just) portable solid fuel stoves which provide heating, cooking and 12-volt electricity up to 50 watts. While 50 watts doesn’t sound like much, it is a major amount when there isn’t any at all available. A small inverter provides mains AC power for smaller appliances:

If it is still there, the video of this is at http://www.youtube.com/watch?v=2Za98e7-Mxg&feature=related and the manufacturers (http://www.termofor.ru/eng/products/for_heating/normal_pg/index.html) show a video of this stove design being used in a snow-covered wood at -32 Centigrade temperatures, giving about +35 degrees Centigrade inside the tent. Mind you, weighing in at 54 kilograms which is a whopping 120 pounds or so, this is not a back-packing solution for camping trips. Sales outlets are in Siberia, New York, Australia, Kyrgyzstan, Ukraine, Belarus, Kazakhstan and Latvia at the present time.

The HHO Gas Option.

One significant advantage of this design is that less wood is needed for any give heating or cooking application and there is very little smoke or soot produced which is a distinct advantage for a person using the stove for cooking and standing nearby during the cooking process. This can cause a major medical
improvement as smoke inhalation for women who need to undertake long periods of daily cooking using wood as a fuel, are liable to suffer serious breathing problems as a result.

Electrical heating, while very convenient, is usually expensive, and it often seems that the effectiveness of an electric heater is not directly related to its power consumption. In theory it definitely is, but in practice it just does not seem that way. There are other alternatives.

One of the other documents in this set, shows how to construct a Stanley Meyer style electrolyser which uses ordinary tap water and splits it into burnable fuel using just a low power electrical input:

The difficulty in creating a heating system which uses the gas produced by this unit, is in the very high temperature produced when the gas is burnt. Stan overcame this problem with by designing a special burner which mixes air and burnt gasses in with the gas before it is burnt. That lowers the flame temperature to a level which is suitable for heating and cooking:

While this looks a bit complicated, it’s construction is really quite simple. The combination of the Meyer electrolyser and Meyer burner form a system which has the potential of being operated from a solar panel and battery as shown here:
A system like this needs extreme care as the hydrogen / oxygen ("HHO") gas produced is explosive. So:

1. It is very important that the electrolyser has the ability to provide sufficient gas to keep the flame(s) sustained.

2. The electrolyser must be fitted with a pressure switch, typically operating at 5 pounds per square inch or so. This is included so that should the gas usage drop, then the drive from the electronics is cut off to stop further gas production, and incidentally, stopping the current draw from the battery.

3. It is absolutely essential that there be a flame-operated valve on the gas supply line to the burner, so that should the flame go out for any reason whatsoever, then the gas supply will be cut off. This type of valve is common on town-gas operated fires for use in homes.

**Henry Paine's Patent.**

There is an alternative method which it is claimed can convert the explosive HHO gas into a much more docile fuel, more suited to conventional burners and stoves. It must be stressed that this system is over 120 years old and it should not be used until you have carried out careful tests on it. David Quirey has been using this technique successfully for more than twenty years now. The method was patented by **Henry M. Paine** in US Letters Patent No. 308,276 dated 18th November 1884 and it is very simple:

The idea is to bubble the HHO gas produced by electrolysis of water, through a liquid hydrocarbon such as turpentine or acetone. The bubbler should have a large number of small holes in the incoming tube, so that a very large number of small bubbles of HHO gas pass through the hydrocarbon. This brings the majority of the HHO gas into intimate contact with the hydrocarbon and the process is claimed to convert the HHO gas into a new variety of gas which is not explosive, can be stored for later use, and which burns with the same characteristics as coal-gas ("town gas").

**The Heaters of Sang Nam Kim.**

Mr Kim of Korea also proposes methods of using hydroxy gas for heating and using Henry Paine's hydrocarbon bubbling method. He has four patents on the subject of heating:

- US 6,397,834 in June 2002 - Heating Furnace
- US 6,443,725 in September 2002 - Energy Generation
- US 6,761,558 in July 2004 - Heating Apparatus
US 7,014,740 in March 2006 - Electrolyser

The first of these shows his method of getting both beneficial radiant heat and convention heating from a stone construction like this:

This unit is intended as a seriously powerful heating source for a minimum of one room. Mr Kim quotes a hydroxy gas requirement of 30 litres per minute which is a very considerable amount, and if the gas is produced by electrolysis of water at Faraday efficiency, it would need a current draw of 4.2 kilowatts. There is every indication that Mr Kim’s method of electrolysis is low efficiency as his latest patent shows a radiator and fan:

It is virtually certain that there will be a high proportion of hot water vapour mixed in with the gas which is being burnt and that will reduce the explosive nature of the gas to near zero. It also means that the actual volume of hydroxy gas is likely to be well below the 30 lpm quoted by Mr Kim.
Mr Kim also shows a burner intended for use with an existing furnace. He remarks that the outer casing gets to be red hot, running at 1,000°C or more, and so any replication of his design should be treated with care when mounting fixtures are being constructed. In this design, Mr Kim uses the Paine technique and recommends bubbling his hydroxy gas through hexane liquid (C₆H₁₄) where 0.3 litres of hexane per hour gets burnt as well as the hydroxy gas. He rates the hydroxy gas requirement of this burner as being 20 lpm, which at Faraday efficiencies, represents 2.8 kilowatts of electricity, although as mentioned before, it is likely that the actual amount of hydroxy gas in his 20 lpm volume is much lower than he thinks, and so will have a lower electrical requirement when using a more electrically efficient electrolyser. His burner is like this:

Mr Kim believes that the hexane prevents flashback ignition. He does not appear to specify the heating material inside the burner but it is probably stainless steel wool. He speaks of gas pressures of 1 Kg per sq. cm., which, if my calculations are correct is 14.22 psi. which is not possible for 100% hydroxy gas as it will explode spontaneously at 12 psi. due to its high energy state and electrical charge.

He states that the secondary flames at the top of the unit "burn with a blue flame colour" and that is different to the flame colour lower down. Mr Kim believes that the hydroxy burnt at the bottom of the burner forms water vapour which is then split into hydroxy gas again by the very high temperature and that is the reason for the blue flames at the top. Personally, I don't believe that this will take place and that the effect may have a good deal to do with the hexane liquid being burnt. However, this burner design appears to be a good one for lower grades of hydroxy gas.

If a higher grade of hydroxy gas is being used, please be aware that a hypodermic-size tiny burner orifice will be needed to avoid flashbacks and no commercial flashback arrester will work reliably with good quality hydroxy gas on every occasion and so a bubbler is absolutely essential.

**The Hydrogen Garage**

In 2013, Andrew of the Hydrogen Garage in America stated:
We are heating up the shop with only 216 watts, 12 Volts at 18 amps using one “dual 7 plate” electrolyser cell with a water tank and bubbler and a 5-inch dryer, hose and torch which can be operated continuously 24/7 if desired. The flames produced are pointed into a central stainless steel tube 12-inches (300 mm) long and 1-inch (25 mm) in diameter. Wrapped all around the central pipe are 10 more stainless steel tubes held together as a group by 2 hose clamps. The set of pipes is placed on the concrete floor. In our work, we have to prepare HHO electrolyser cells and the HHO gas produced during that process is used to heat the shop. No more need for propane and no more headaches from 6 hours of heating the room. Now the HHO gas adds ozone to the air in the shop and there are no fumes and no smell. The burner used is shown at http://hydrogengarage.com/h2eat.html and it can be powered by one 14/7 HHO cell available at: http://stores.homestead.com/hydrogengarage/-strse-179/ICE-BLOCK-14-dsh-7-Cell/Detail.bok There is no need for a Pulse-Width Modulator unit as you can just use direct DC power from a DC power supply or battery charger. Solar panels can run HHO cells well.

Catalytic HHO Heating from Justin Church

On Sterling Allan’s website at http://peswiki.com/index.php/OS:Justin_Church%27s_H-Cat there is a description of an HHO heating process which has been under development since 2010. It is a particularly interesting system in that no flame is involved, but instead, a stream of HHO gas is fed into a standard vehicle catalytic converter along with air which can freely enter the converter. Justin has found that with a quite low flow of HHO, such as that produced by 13.8V at 5A (70 watts), the converter heats up to a level which can barely be touched and that is quite remarkable considering that the converter is has substantial weight of metal in its construction. Measurements of the temperature inside the converter show that it is running at more than five hundred degrees F. Justin calls his unit the “H-Cat”.

![ICE-BLOCK 14-7 COMPLETE HYDROGEN KIT](image)
Sterling’s web site is definitely worth a visit.

**Heating With Electric Power.**
Electric power is very popular for heaters. However, with most appliances, it is a very expensive form of heating. There is a technique which is reputed to improve the efficiency and lower the cost of electric heating. This method involves rotating a cylinder inside an outer cylinder and filling part of the narrow space between the cylinders with some variety of light oil.

**Eugene Frenette’s Patent.**
This method has been patented more than once. In 1979, Eugene Frenette was granted patent 4,143,639 where a single motor is used to rotate the drum and power a fan to boost the motion of the hot air:

It is not immediately obvious why this arrangement should work well, but it appears that it does. As the inner drum spins around, the oil rises up between the two inner cylinders. It lubricates the bearing under the rotating drum and the rotation causes the oil to heat up. This heats the middle cylinder and air being drawn...
up around it by the action of the fan blade, is also heated before being pushed out of the top of the heater. After a few minutes, the outer housing becomes so hot that the thermostat attached to it, cuts off the electrical supply.

The heater does not stop heating at this time as air continues to circulate through the heater by ordinary convection. In my opinion, it would be more effective if the fan motor were operated independently and did not cut off when the heater reaches its operating temperature.

**Eugene Perkins’ Patent.**

Very similar systems were patented by Eugene Perkins: January 1984 patent 4,424,797, November 1984 patent 4,483,277, March 1987 patent 4,651,681, October 1988 patent 4,779,575, and in January 1989 patent 4,798,176.

His first patent shows a horizontal drum which is completely immersed in the liquid:

![Diagram of a horizontal drum immersed in liquid.](image1)

This calls for a much greater accuracy of construction in that the liquid has to be contained even though it has a rotating shaft running through the housing. This device pumps the heated liquid through central-heating piping and radiators.

In his later patent of the same year, he shows a modified version with two drums and an impeller:

![Diagram of a modified system with two drums and an impeller.](image2)
The “heat exchanger” is a radiator or set of radiators.

He then progressed to a system where the shaft rotation forces the liquid to be expelled through the tips of arms radiating out from the centre of the impeller hub:

Here, the liquid is forced into a small space between the rotor and its drum housing. This system has been used very successfully for water heating and some measurements indicate that it is at least 100% efficient and some people believe that it is well over the 100% efficiency, though they don’t want to get drawn into long discussions on methods of measurement. It is sufficient to say here, that this method is very effective indeed.

**Frenette Variation:** The Frenette heater design shown above with it’s two vertical cylinders, is not the easiest for the home constructor unless one of the cylinders (presumably the inner one) is constructed from steel sheet, as it is difficult to find two commercially available steel cylinders of just the right relative size to produce the wanted gap between them. A much easier variation replaces the inner cylinder with a stack of circular steel discs. As these can be cut from 20 gauge steel sheet fairly readily by the home constructor, or alternatively, cut by any local metalworking or fabrication company, any available size of outer cylinder can be used and the disc diameter chosen accordingly.

The discs are mounted about 6 mm (1/4”) apart on a central steel rod which is rotated in order to drive the discs through the oil contained inside the body of the heater. While this looks like a Tesla Turbine, it is not because the spacing of the discs creates a different effect. The wider disc spacing creates shear as they spin through the surrounding oil, and this shearing creates a high degree of heating. It must be remembered that this is a heater, and the outer canister gets very hot during operation (which is the whole point of the exercise in the first place). For that reason, oil is used as a filling and not water, which boils at a much lower temperature. The larger the diameter of the canister and the greater the number of discs inside it, the greater the heat developed.

To ensure that the discs do not come loose during prolonged operation, a hole can be drilled through them just outside the area covered by the locking-spacing nuts, and a stiff wire run through the holes and the ends either welded to the central rod or pushed through a hole drilled in it and bent over to hold it in place. The heat of the cylinder can be circulated by attaching a simple fan blade to the spinning shaft. This blows air down the hot sides of the canister, moving it towards the floor which is the most effective place for it circulate and heat the entire room.
As the discs spin, the oil is pushed outwards and moves upwards, filling the top of the canister and building up some pressure there. This pressure can be relieved by running an external pipe from the top of the cylinder back to the bottom, allowing the oil to circulate freely. This has the decided advantage the circulating oil can be passed through a radiator as shown in the following diagram:

The central rod can be rotated by any convenient motor, conventional, Adams type, pulse-motor, permanent magnet motor, or whatever. An alternative to this style of operation, is to use the rotating motor to spin a ring of permanent magnets positioned close beside a thick aluminium plate. The eddy currents cause very strong heating of the aluminium plate which then can have air blown across it to provide space heating.
Peter Davey’s AC Heater.

During World War II, Peter Daysh Davey, of Christchurch, New Zealand, a fighter pilot and musician, designed and built an unusual water heater. This design is not particularly well known and information is fairly thin on the ground although the basic principle and design details are known.

The device is intended to operate on New Zealand’s mains supply of 220 volts 50 Hz and a requirement of the apparatus is that it resonates at that 50 Hz frequency. Resonance is a frequent requirement of free-energy systems, and the need for it is often overlooked by people who attempt to replicate free-energy devices. Properly built and tuned, this heater is said to have a COP of 20, which means that twenty times as much heat is produced as would normally be expected from that level of input power. This power gain is caused by additional energy being drawn in from the surrounding environment, and this is very important as a very large percentage of the energy used in cool climates is used for heating, so any reduction would be very welcome.

Peter was granted a New Zealand patent for his heater on 12th December 1944 but he found that opposition from the utility companies was so great that it prevented him from going into commercial production with it and although Peter kept trying for fifty years, he never succeeded.

The device is comprised of a hemispherical resonant cavity, formed by two metallic dome shapes, both of which resonate at 50 Hz. Initially, Peter used two bicycle bells and he found that when submerged in water, the device brought the water to the boil in a very short time indeed. The construction is like this:

If construction were to use two identical hemispheres, then the cavity between them would be anything but even width throughout, but the resonance would be the same. On the other hand, if you want the resonant cavity between the two hemispheres to be of constant width, then the outer hemisphere needs to be markedly larger than the inner hemisphere. The outside of both hemispheres needs to be insulated unless mounted in such a way that it is not possible to touch the hemispheres as both are attached to the mains.

In the diagram shown above, the mains live wire 6, is fed through the connecting pipe 8, and clamped to the inner hemisphere 1, by nut 3 which screws on to the threaded section of tube 8. It is important that it is the live wire which is connected to hemisphere 1. The mains neutral wire 7, is also fed through the connecting tube 8, then exits through a small hole and is then clamped on to the outside of the outer hemisphere 2, by nut 5, also on the threaded section of tube 8. The two hemispheres are held apart by a spacing washer 4, which is made from a high-temperature non-conducting plastic. As the tube 8 connects electrically and mechanically to both mains wires through the two locking nuts 3 and 5, it is essential that this tube is constructed from an electrically non-conducting material such as plastic. As the tube will be in boiling water...
on a regular basis, it is also necessary that the tube material is able to handle temperatures over 100°C and so possible materials include nylon and Teflon.

The washer is a key component of the heater and its thickness is key to the efficiency of the whole device. This thickness \( L \), is the tuning control for the cavity. The outer hemisphere is about 8 mm greater in diameter than the diameter of the inner hemisphere. Allowing for the thickness of the metal of the bowl, the resonant cavity will therefore be about 3 mm or one eighth of an inch.

The hemisphere 1 is also tuned to 50 Hz by grinding it carefully until it resonates freely at that frequency. Connecting a loudspeaker in series with a resistor of say, 100K ohms, will give a sound of the exact frequency with which this hemisphere needs to resonate. This tuning needs to be done with the unit fully assembled as the connections to the tube will alter the resonant frequency of the hemisphere. When this is being done, the resonance will be felt rather than heard, so hold the tube lightly so that it can resonate freely. The tuning is done by removing a small amount of metal from the face of hemisphere 1 and then testing for resonance again.

When hemisphere 1 resonates well at the mains frequency, (roughly G two octaves below middle C on a keyboard), the search for high-efficiency heating is carried out by very small adjustments of the gap \( L \). The adjustment of the gap \( L \) is carried out by very careful grinding down of the separating washer 4 and the result is best determined by measuring the length of time needed to boil a known volume of water and the current taken to do that. Repeated tests and recorded results, shows when the best gap has been reached and the highest efficiency achieved. The heater can, of course, be used to heat any liquid, not just water.

This heater is unlike a standard kettle heating element. In the standard method, the water is not a part of the main current-carrying circuit. Instead, the mains power is applied to the heater element and the current flowing through the heater element causes it to heat up, and the heat is then conveyed to the water by conduction. In Davey's heater, on the other hand, the current flow appears to be through the water between the two hemispheres. It seems likely that the actual heating is not produced by current flow at all, but from cavitation of the water caused by the resonating of the cavity between the two hemispheres. This technique is used in small jewellery cleaners where and audio frequency is applied to a cleaning fluid in a small container.

A small amount of electrolysis will take place with the Davey heater as it in effect also forms a single parallel-connected electrolyser. The amounts should be very small as only 1.24 volts out of the 220 volts applied will be used in the electrolysis process.

An early construction of the original heater is shown in the photograph below. The coin shown in the picture is 32 mm (1.25 inch) in diameter. The heater is submerged in water when it is being used, and it brings that water to the boil exceptionally quickly. The unit was tested by New Zealand scientists who were able to vouch for its performance, but who were unable to state exactly how its operation allowed it to output such a high level of heat for such a low level of electrical input. You will notice from the photograph, how carefully the electrical connections and outer bowl are insulated.

The original prototype which Peter made was constructed from the tops of two bicycle bells, only one of which was tuned to 50 Hz. This shows that the device will definitely work if the inner hemisphere is tuned correctly. You can find forum investigation at

Jean-Christophe Dumas

A Frenchman, Jean-Christophe Dumas, publicises his COP=1.17 heater design which appears to operate in a very similar way to that of Peter Davey. His website at http://leblogdejc.com/effetdumas/?page_id=165 gives an English translation of much of what he has to say.

In this design, steam is produced almost immediately after some 500 watts of input power is applied. He uses a metal sphere plus one metal hemisphere which has an adjustable spacing over half of the sphere’s surface. Jean-Christophe wishes to share his design freely with everybody and he sees it as being used for efficient space heating in houses, given a radiator system. His drawings are:

Dumas Effect Resonator

Construction sheet 1.0
7 April 2014

http://www.effetdumas.org
alternerg07@gmail.com

1) Take 3 half-spheres of the same size made of steel (galvanised if possible, otherwise any kind of metal, with the risk however of it deteriorating after a period of time). Solder two half-spheres together to make an airtight sphere.

2) Take a metal threaded rod and solder it to the centre of the sphere. Once soldered, insulate the base of the rod (e.g. with a plastic flange)
3) Drill a hole in the centre of the remaining half-sphere the size of the rod (possibly increased to fit the thickness of the insulation). Drill a maximum of 20 more holes with a diameter of 2 mm, so that the sphere looks like a sieve.

4) Place 2 x 2 mm plastic washers at the base of the soldered rod on the sphere, drill the half-sphere in the centre and adjust the gap to about 1.6-1.7 mm

(For perfect precision, it would be ideal to create the spheres using a 3D printer)
5) Screw a nut on the rod and adjust the gap between the upper half-sphere and lower part of the sphere to obtain an ideal gap of 1.61 mm (golden section). If the gap is much less (0.6 to 0.9 mm) there will be a short-circuit. If it is more than 1.8 to 1.9 mm, it will not produce any effect.

6) Connect an electrical live wire (16A) to the top of the rod soldered on the sphere.

7) As shown in the drawing, connect the 2\textsuperscript{nd} neutral wire (16A) to obtain direct contact on the upper half-sphere by means of a ring or spade connector.

8) Attach a switch to the wires and join the electrical wires to an ordinary electric switch made safe with a residual circuit breaker.
The Series-connected Heater.
While not a free-energy device, one simple arrangement which I use myself, is an adapted halogen heater. A standard, low-cost halogen heater consists of three separate 400-watt sections with a switching arrangement which allows one, two or three sections to be powered up:

WARNING: The assembly of this process is for scientific experiments and offers the possibility of numerous applications: water heater, domestic heating, production of drinking water, production of electricity by energy surplus, etc. It must be done by a professional or a handyman experienced in handling electrical appliances. This process shows several physical effects that are still largely unknown. The inventor declines all responsibility for misuse of this application. NEVER TOUCH THE APPLIANCE WHILE IT IS WORKING, OR THE WATER, OR THE JAR (risk of burns and/or electrocution). Never carry out the experiment alone. Make sure you have a secure environment in case of short circuits, as well as protective gear (masks, gloves). There is a risk being splashed by boiling water or steam, or possible release of flammable gases (oxygen, hydrogen). JC Dumas
I changed the connections inside my particular heater, so that all three halogen lamps are connected in a chain. This did not involve cutting any wires or making any new connections as the wires connecting to the lamps have push-on ‘spade’ connectors to allow for both simple manufacturing and easy replacement of a halogen lamp. The new arrangement is like this:

This arrangement ‘under-runs’ the lamps as each lamp only gets one third of the voltage which it was designed for. This has the effect of increasing the working life of the lamp enormously. You would expect the heat output to be very poor, and perhaps it is. But it gives the impression of being quite effective and with all of the three sections working, it provides a gentle heat and light which seems very effective in keeping a room warm.

The Home Power, Home-Build Wind-Powered Electrical Generator.
Here is an interesting article from the Home Power web site. If you are interested in renewable power, then I strongly recommend that you visit their web site http://www.homepower.com and consider subscribing to their magazine as they cover many practical topics using simple wording. Here is an example of the high quality material from Home Power – a 100 watt wind generator built from scratch in just one day:
William McDavid's Wind-Powered Generator.
William McDavid junior remarks that a horizontal axis windmill of that type creates an area of slow-moving air behind the blades and that restricts the flow of air past the blades. A way to overcome that is to project the outgoing air in a direction which does not impede the incoming air. He shows how this can be done in his patent US Patent 6,800,955 of 5th October 2004. In this design, the wind blows into the generator housing and is deflected upwards through the fan blades of a turbine which spins an electrical generator:

![Diagram of wind-powered generator](image)

One clever feature common to both of these designs is the use of a stationary circular housing with deflectors which uses the wind flow no matter what the wind direction happens to be at any given moment. Looking down from above, the housing looks like this:
This view shows two important features which enhance the performance of the device. The first is that hinged flaps allow the (horizontal) inflow of air but block the air from flowing straight out of the other side of the central section. This forces the wind to turn and flow upwards, and not only that, but this arrangement causes the air to spin, creating a miniature tornado vortex which amplifies the power of the wind as can be seen from the devastation caused by full-size tornadoes in the environment. As can be seen from the upper diagram, an upward-curving conical piece on the base of the housing assists the airflow to turn upwards as it spins. The spinning air helps to spin the generator blades faster, giving additional power.

A major additional feature is the fact that the dimension “A” is considerably less than the dimension “B” due to the reduced diameter of the housing nearer the centre. This means that the air flowing past the vanes of housing gets squeezed into a smaller space as it flows. This forces the air to speed up, causing the flow inside the central housing to be higher than the wind-speed outside and that boosts the performance of the device. This wind-powered generator looks like a straightforward project for home construction and with the air being deflected vertically, there does not appear to be any reason why several should not be located near each other. William’s full patent can be seen in the appendix of this eBook.

**Frank Herbert’s Wind-Powered Generator.**

As has been carefully explained by the above article, if a windmill of the blade variety is mounted low down then it is dangerous, and people on sailing boats have been killed by them. Also, if the blade arrangement is designed to operate well in low wind conditions, then it is not unusual for there to be a problem if the wind rises to gale force or higher, with some generator designs giving up and switching off entirely, even though the available free energy is at its highest level.

This design by Frank Herbert is perfectly capable of being home-built and yet it overcomes these problems as well as being a high-efficiency wind turbine. It has an outside cage which prevents human access to the moving parts inside and the ‘cage’ is not just for protection but is there to enhance the performance of the device. In passing, windmills can be used to compress air and compressed air cylinders can be used to power vehicles and/or power electrical generators during periods of heavy power requirements. The following information is from Frank Herbert’s US Patent 4,142,822 of 1979:
The vertical housing 22 shown dotted here, surrounds the vertical power take-off shaft 26. The wind is allowed to flow through this housing at any angle, so there is no need for the housing to move. In the diagram above small discs 44 are shown at each end of the vertical shaft. These discs have arms 42 extending outwards to support a series of vertical vanes or pressure surfaces 24. For clarity, just one vane is shown through there will actually be many of these (rather like the cutting blades on a cylinder lawnmower). In reality, there will be no arms on the discs 42 as it is much easier just to have a full-width solid disc supporting the vanes.

The outer housing has a series of vertical slats which are angled to direct the incoming wind on to the vanes at the best possible angle:

This top view of part of the device, shows the main mounting shaft 26 on which the top and bottom rotor discs are mounted. The red dots show the pivot points where the vanes 24 can turn to take the greatest advantage of the wind pressure. The incoming wind 36, is deflected by the slats of the housing 32, to give it
a good angle when flowing through the device as well as keeping humans away from the spinning mechanism. As the vanes and slats are located all the way around shaft 26, sudden changes in wind direction and/or wind strength have no particular effect on this design as it operates with wind coming from any direction and no physical movement of any part of the device is needed for a change in wind direction.

The vanes can have various different profiles and still work well. The shape shown above is the shape of an aircraft wing, where a force acting towards the curved surface is generated when air flows around the shape. This is not a particularly difficult shape to construct and it is very effective in an airflow (which is why it is used to lift aircraft off the ground). There can be any convenient number of vanes and a device built as shown above should be very effective..

As the overall efficiency is improved if there is no turbulence inside the device, Frank has found a method of minimising this. For this, he uses a mechanism which can alter the shape of the vanes when the wind speed gets high. The higher wind speed whirls the vanes around faster, causing higher ‘centrifugal’ forces on the vanes which Frank uses as follows. Weight 54 gets pushed across by the spin rate of the rotor.

This pushes against the spring 56, compressing it. The triangle link 59 moves upwards, pivoting at points 59a and 59c, and raising section 50 of the vane. This changes the shape of the vane as shown here:

The result of this changed shape is to reduce turbulence inside the device and raise the overall efficiency.

The Mead and Holmes Power System.
The US patent 4,229,661 dated 1980 from Claude Mead and William Holmes is entitled “Power Plant for Camping Trailer” proposes the use of a wind power generator to store compressed air for later use in providing household electrical current, and simultaneously charge batteries which can be used to drive the compressor in periods of very high electrical demand. There is also an option for a rapid system charge if AC mains power becomes available:
Solar Ovens.

The Solar Funnel Cooker

How to Make and Use The Brigham Young University Solar Cooker/Cooler
by Professor of Physics at Brigham Young University (BYU), with Colter Paulson, Jason Chesley, Jacob Fugal, Derek Hullinger, Jamie Winterton, Jeannette Lawler, and Seth, David, Nathan, and Danelle Jones.

Introduction
A few years ago, I woke up to the fact that half of the people in the world must burn wood or dried dung in order to cook their food. It came as quite a shock to me, especially as I learned of the illnesses caused by breathing smoke day in and day out, and the environmental impacts of deforestation - not to mention the time spent by people (mostly women) gathering sticks and dung to cook their food. And yet, many of these billions of people live near the equator, where sunshine is abundant and free. So.....

As a University Professor of Physics with a background in energy usage, I set out to develop a means of cooking food and sterilising water using the energy freely available from the sun. First, I looked at
existing methods.

The parabolic cooker involves a reflective dish which concentrates sunlight to a point where the food is cooked. This approach is very dangerous since the sun’s energy is focused to a point which is very hot, but which cannot be seen. (Brigham Young University students and I built one which will set paper on fire in about 3 seconds!). I learned that an altruistic group had offered reflecting parabolas to the people living at the Altiplano in Bolivia. But more than once these parabolas had been stored next to a shed – and the passing sun set the sheds on fire! The people did not want these dangerous, expensive devices, even though the Altiplano region has been stripped of fuel wood.

The box cooker: Is basically an insulated box with a glass or plastic lid, often with a reflecting lid to direct sunlight into the box. Light enters through the top glass (or plastic), to slowly heat up the box. The problems with this design are that energy enters only through the top, while heat is escaping through all of the other sides, which have a tendency to draw heat away from the food. When the box is opened to put food in or take it out, some of the heat escapes and is lost. Also, effective box cookers tend to be more complicated to build than the funnel cooker.

While studying this problem, I thought again and again of the great need for a safe, inexpensive yet effective solar cooker. It finally came to me at Christmastime a few years ago, a sort of hybrid between the parabola and the box cooker. It looks like a large, deep funnel, and incorporates what I believe are the best features of both the parabolic cooker and the box cooker.

The first reflector was made at my home out of aluminium foil glued on to cardboard, then this was curved to form a reflective funnel. My children and I figured out a way to make a large cardboard funnel easily. (I’ll tell you exactly how to do this later on.)

The Solar Funnel Cooker is safe and low cost, easy to make, yet very effective in capturing the sun’s energy for cooking and pasteurising water -> Eureka!

Later, I did extensive tests with students (including reflectivity tests) and found that aluminised Mylar was good too, but relatively expensive and rather hard to come by in large sheets. Besides, cardboard is found throughout the world and is inexpensive, and aluminium foil is also easy to come by. Also, individuals can make their own solar cookers easily, or start a cottage-industry to manufacture them for others.

Prototypes of the Solar Funnel Cooker were tested in Bolivia, and outperformed an expensive solar box cooker and a “Solar Coolkit” while costing much less then either. Brigham Young University submitted a patent application, mainly to insure that no company would prevent wide distribution of the Solar Funnel Cooker. Brigham Young University makes no profit from the invention. (I later learned that a few people had had a similar idea, but with methods differing from those developed and shown here). So now I'm trying to get the word out so that the invention can be used to capture the free energy coming from the sun - for camping and for emergencies, yes, but also for every day cooking where electricity is not available and where even fuel wood is getting scarce.

How it Works

The reflector is shaped like a giant funnel, and lined with aluminium foil. (Easy to follow instructions will be given soon). This funnel is rather like the parabolic cooker, except that the sunlight is concentrated along a line (not a point) at the bottom of the funnel. You can put your hand up the bottom of the funnel and feel the sun's heat, but it will not burn you.

Next, we paint a jar black on the outside, to collect heat, and place this at the bottom of the funnel. Or a black pot with a lid can be used. The black vessel gets hot, quickly, but not quite hot enough to cook with. We need some way to build up the heat without letting the outside air cool it. So, I put a cheap plastic bag around the jar -- and, the solar funnel cooker was born! The plastic bag, available in grocery stores as a "poultry bag", replaces the cumbersome and expensive box and glass lid of solar box ovens. You can use the plastic bags used in American stores to put groceries in, as long as they let a lot of sunlight pass. (Dark- coloured bags will not do).

I recently tested a bag used for fruits and vegetables, nearly transparent and available free at American grocery stores, that works great. This is stamped "HDPE" for high-density polyethylene on the bag (ordinary polyethylene melts too easily). A block of wood is placed under the jar to help hold the heat in. (Any insulator, such as a hot pad or rope or even sticks, will also work).
A friend of mine who is also a Physics Professor did not believe I could actually boil water with the thing. So I showed him that with this new "solar funnel cooker" I was able to boil water in Utah in the middle of winter! I laid the funnel on its side since it was winter and pointed a large funnel towards the sun to the south. I also had to suspend the black cooking vessel -- rather than placing it on a wooden block. This allows the weaker sun rays to strike the entire surface of the vessel.

Of course, the Solar Funnel works much better outside of winter days, that is, when the UV index is 7 or greater. Most other solar cookers will not cook in the winter in northern areas (or south of about 35 degrees, either).

I thought that a pressure cooker would be great. But the prices in stores were way too high for me. Wait, how about a canning jar? These little beauties are designed to relieve pressure through the lid -- a nice pressure cooker. And cooking time is cut in half for each 10ºC we raise the temperature (Professor Lee Hansen, private communication). I used one of my wife's wide-mouth canning jars, spray-painted (flat) black on the outside, and it worked great. Food cooks faster when you use a simple canning jar as a pressure cooker. However, you can also put a black pot in the plastic bag instead if you want. But don't use a sealed container with no pressure release like a mayonnaise jar -- it can break as the steam builds up (I've done it!)

How to Build Your Own Solar Funnel Cooker

What You will Need for the Funnel Cooker:

- A piece of flat cardboard, about 2 feet wide by 4 feet long. (The length should be just twice the width. The bigger, the better).
- Ordinary aluminium foil.
- A glue such as white glue (like Elmer's glue), and water to mix with it 50-50. Also, a brush to apply the glue to the cardboard (or a cloth or paper towel will do). Or, some may wish to use a cheap "spray adhesive" available in spray cans. You can also use flour paste.
- Three wire brads - or small nuts and bolts, or string to hold the funnel together.
- For a cooking vessel, I recommend a canning jar ("Ball" wide-mouth quart jars work fine for me; the rubber ring on the lid is less likely to melt than for other jars I've found. A two-quart canning jar is available and works fine for larger quantities of food, although the cooking is somewhat slower).
- The cooking jar (or vessel) should be spray-painted black on the outside. I find that a cheap flat-black spray paint works just fine. Scrape off a vertical stripe so that you have a clear glass "window" to look into the vessel, to check the food or water for boiling.
- A block of wood is used as an insulator under the jar. I use a piece of 2" x 4" board which is cut into a square nominally 4" x 4" by about 2" thick. (100 mm square x 50 mm thick). One square piece of wood makes a great insulator.
- A plastic bag is used to go around the cooking-jar and block of wood, to provide a green-house effect. Suggestions:
  - Reynolds™ Oven Bag, Regular Size works great: transparent and won't melt. (Cost about 25 cents each in U.S. grocery stores.)
  - Any nearly-transparent HDPE bag (High-density Polyethylene). Look for "HDPE" stamped on the bag. I've tested HDPE bags which I picked up for free at my grocery store, used for holding vegetables and fruits. These are thin, but very inexpensive. Tested side-by-side with an oven bag in two solar funnels, the HDPE bag worked just as well! Caution: we have found that some HDPE bags will melt should they contact the hot cooking vessel. For this reason, we recommend using the oven-safe plastic bag wherever possible.
  - An idea attributed to Roger Bernard and applied now to the BYU Funnel Cooker: place a pot (having a blackened bottom and sides) in a glass bowl, and cover with a lid. Try for a tight fit around the bottom to keep hot air trapped inside. The metal pot or bowl should be supported around the rim only, with an air space all around the bottom (where the sunlight strikes it). Put a blackened lid on top of the pot. Then simply place this pot-in-bowl down in the bottom of the funnel - no plastic bag is needed! This clever method also allows the cook to simply remove the lid to check the food and to stir. I like this idea - it makes the solar cooker a lot like cooking over a fire. See Photographs for further details.
Construction Steps

Cut a Half-circle out of the Cardboard

Cut a half circle out of the cardboard, along the bottom as shown below. When the funnel is formed, this becomes a full-circle and should be wide enough to go around your cooking pot. So for a 7" diameter cooking pot, the radius of the half-circle is 7". For a quart canning jar such as I use, I cut a 5" radius half-circle out of the cardboard.

Form the Funnel
To form the funnel, you will bring side A towards side B, as shown in the figure. The aluminium foil must go on the INSIDE of the funnel. Do this slowly, helping the cardboard to the shape of a funnel by using one hand to form creases that radiate out from the half-circle. Work your way around the funnel, bending it in stages to form the funnel shape, until the two sides overlap and the half-circle forms a complete circle. The aluminium foil will go on the INSIDE of funnel. Open the funnel and lay it flat, "inside up", in preparation for the next step.

**Glue Foil to Cardboard**

Apply glue or adhesive to the top (inner) surface of the cardboard, then quickly apply the aluminium foil on top of the glue, to affix the foil to the cardboard. Make sure the shiniest side of the foil is on top, since this becomes your reflective surface in the Funnel. I like to put just enough glue for one width of foil, so that the glue stays moist while the foil is applied. I also overlap strips of foil by about 1” (or 2 cm). Try to smooth out the aluminium foil as much as you reasonably can, but small wrinkles won’t make much difference. If cardboard is not available, one can simply dig a funnel-shaped hole in the ground and line it with a reflector, to make a fixed solar cooker for use at mid-day.

**Join side A to side B to keep the funnel together.**
The easiest way to do this is to punch three holes in the cardboard that line up on side A and side B (see figure). Then put a metal brad through each hole and fasten by pulling apart the metal tines. Or you can use a nut-and-bolt to secure the two sides (A & B) together.

Be creative here with what you have available. For example, by putting two holes about a thumb-width apart, you can put a string, twine, small rope, wire or twist-tie in one hole and out the other, and tie together.

When A and B are connected together, you will have a "funnel with two wings". The wings could be cut off, but these help to gather more sunlight, so I leave them on.

**Tape or glue a piece of aluminium foil across the hole at the bottom of the funnel, with shiny side in.**

This completes assembly of your solar funnel cooker.

For stability, place the funnel inside a cardboard or other box to provide support. For long-term applications, one may wish to dig a hole in the ground to hold the Funnel against strong winds.

**Final Steps**

At this stage, you are ready to put food items or water into the cooking vessel or jar, and put the lid on securely. (See instructions on food cooking times, to follow).

Place a wooden block in the INSIDE bottom of the cooking bag. I use a piece of 2" x 4" board which is cut into a square nominally 4" x 4" by 2" thick. Then place the cooking vessel containing the food or water on top of the wooden block, inside the bag.

Next, gather the top of the bag in your fingers and **blow air into the bag, to inflate it**. This will form a small "greenhouse" around the cooking vessel, to trap much of the heat inside. Close off the bag with a tight twist tie or wire. Important: the bag should not touch the sides or lid of the cooking vessel. The bag may be called a "convection shield," slowing convection-cooling due to air currents.

Place the entire bag and its contents inside the funnel near the bottom as shown in the Photographs.

Place the Solar Funnel Cooker so that it Faces the Sun
Remember: Sunlight can hurt the eyes: so please wear sunglasses when using a Solar Cooker! The Funnel Cooker is designed so that the hot region is deep down inside the funnel, out of harm's way.

Put the Solar Funnel Cooker in the sun pointing towards the sun, so that it captures as much sunlight as possible. The design of the funnel allows it to collect solar energy for about an hour without needing to be re-positioned. For longer cooking times, readjust the position of the funnel to follow the sun's path.

In the Northern Hemisphere, it helps to put the Solar Funnel Cooker in front of a south-facing wall or window as this reflects additional sunlight into the funnel. A reflective wall is most important in locations farther from the equator and in winter. In the Southern Hemisphere, put the Solar Funnel Cooker in front of a North-facing wall or window to reflect additional sunlight into your cooker.

After Cooking
Remember that the cooking vessel will be very hot: so use cooking pads or gloves when handling it! If you are heating water in a canning jar, you may notice that the water is boiling when the lid is first removed - it gets very hot!

Open the plastic cooking bag by removing the twist-tie. Using gloves or a thick cloth, lift the vessel out of the bag and place it on the ground or table. Carefully open the vessel and check the food, to make sure it has finished cooking. Let the hot food cool before eating.

Helpful Hints
Avoid leaving fingerprints and smudges on the inside surface of the cooker. Keep the inner surface clean and shiny by wiping occasionally with a wet towel. This will keep the Solar Funnel Cooker working at its best.

If your funnel gets out-of-round, it can be put back into a circular shape by attaching a rope or string between opposite sides which need to be brought closer together.

For long-term applications, a hole in the ground will hold the Funnel Cooker securely against winds. Bring the funnel inside or cover it during rain storms.

The lids can be used over and over. We have had some trouble with the rubber on some new canning-jar lids becoming soft and "sticky." "Ball canning lids" do not usually have this problem. Running new lids through very hot water before the first use seems to help. The lids can be used over and over if they are not bent too badly when opened (pry off lid carefully).

The jar can be suspended near the bottom of the funnel using fishing line or string (etc.), instead of placing the jar on a block of wood. A plastic bag is placed around the jar with air puffed inside, as
usual, to trap the heat. The suspension method allows sunlight to strike all surfaces of the jar, all around, so that heats faster and more evenly. This suspension method is crucial for use in winter months.

Adjust the funnel to put as much sunlight onto the cooking jar as possible. Look at the jar to check where the sunlight is hitting, and to be sure the bottom is not in the shadows. For long cooking times (over about an hour), readjust the position of the funnel to follow the sun’s path. During winter months, when the sun is low on the horizon (e.g., in North America), it is helpful to lay the funnel on its side, facing the sun.

Tests in Utah

I have personally used the Solar Funnel Cooker to cook lunches over many weeks. My favourite foods to cook are potatoes (cut into logs or slices) and carrot slices. Vegetables cook slowly in their own juices and taste delicious. I also make rice, melted cheese sandwiches, and even bread in the Solar Funnel Cooker. I usually put the food out around 11:30 and let it cook until 12:45 or 1 pm, just to be sure that it has time to cook. I’ve never had any food burn in this cooker.

I have also cooked food in the mountains, at an altitude of around 8,300 feet. If anything, the food cooked faster there - the sunlight passes through less atmosphere at high altitudes.

I find that people are surprised that the sun alone can actually cook food. And they are further pleasantly surprised at the rich flavours in the foods which cook slowly in the sun. This inexpensive device does it!

Students at Brigham Young University have performed numerous tests on the Solar Funnel Cooker along with other cookers. We have consistently found much faster cooking using the Solar Funnel Cooker. The efficiency/cost ratio is higher than any other solar cooking device we have found to date. Mr. Hullinger also performed studies of transmissivity, reflectivity and absorptivity of alternate materials which could be used in the Solar Funnel Cooker. While there are better materials, such as solar-selective absorbers, our goal has been to keep the cost of the Solar Cooker as low as possible, while maintaining safety as a first priority.

Tests in Bolivia

The BYU Benson Institute organised tests between the Solar Funnel Cooker and the "old-fashioned" solar box oven. The solar box oven cost about $70 and was made mostly of cardboard. It took nearly two hours just to reach water pasteurisation temperature. The Bolivian report notes that “food gets cold every time the pots are taken from and into the oven.” The solar box oven failed even to cook boiled eggs. (More expensive box cookers would hopefully work better.)
An aluminised-mylar Solar Funnel Cooker was also tested in Bolivia, during the Bolivian winter. Water pasteurisation temperature was reached in 50 minutes, boiled eggs cooked in 70 minutes, and rice cooked in 75 minutes. The Bolivian people were pleased by the performance. So were we! (La Paz, Bolivia, August, 1996).

I also donated two dozen solar funnel cookers for people in Guatemala. These were taken there by a group of doctors going there for humanitarian service. The people there also liked the idea of cooking with the sun's free energy. For an aluminised-Mylar Solar Funnel Cooker kit, please contact CRM (licensed manufacturer) at +1 (801) 292-9210.

**Water and Milk Pasteurisation**

Contaminated drinking water or milk kills thousands of people each day, especially children. The World Health Organisation reports that 80% of illnesses in the world are spread through contaminated water. Studies show that heating water to about 65º - 70º C (150º F) is sufficient to kill coliform bacteria, rotaviruses, enteroviruses and even Giardia. This is called pasteurisation.

Pasteurisation depends on how hot and how long water is heated. But how do you know if the water got hot enough? You could use a thermometer, but this would add to the cost, of course. When steam leaves the canning jar (with lid on tight) and forms "dew" on the inside of the cooking bag, then the water is probably pasteurised to drink. (The goal is to heat to 160º Fahrenheit for at least six minutes.) With a stripe of black paint scraped off the jar, one can look through the bag and into the jar and see when the water is boiling - then it is safe for sure.

Think of all the lives that can be saved simply by pasteurising water using a simple Solar Cooker!

**Safety**

Safety was my first concern in designing the Solar Funnel Cooker, then came low cost and effectiveness. But any time you have heat you need to take some precautions.

- The cooking vessel (jar) is going to get hot, otherwise the food inside it won't cook. Let the jar cool a bit before opening. Handle only with gloves or tongs.
- Always wear dark glasses to protect from the sun's rays. We naturally squint, but sunglasses are important.
- Keep the plastic bag away from children and away from nose and mouth to avoid any possibility of suffocation.

**Cooking with the Solar Funnel Cooker**

What do you cook in a crock pot or moderate-temperature oven? The same foods will cook about the same in the Solar Funnel Cooker - without burning. The charts below give approximate summer cooking times.

The solar cooker works best when the UV index is 7 or higher (Sun high overhead, few clouds).
Cooking times are approximate. Increase cooking times for partly-cloudy days, sun not overhead (e.g., wintertime) or for more than about 3 cups of food in the cooking jar.

Stirring is not necessary for most foods. Food generally will not burn in the solar cooker.

**Vegetables** (Potatoes, carrots, squash, beets, asparagus, etc.)

**Preparation:** No need to add water if fresh. Cut into slices or "logs" to ensure uniform cooking. Corn will cook fine with or without the cob.

**Cooking Time:** About 1.5 hours

**Cereals and Grains** (Rice, wheat, barley, oats, millet, etc.)

**Preparation:** Mix 2 parts water to every 1 part grain. Amount may vary according to individual taste. Let soak for a few hours for faster cooking. To ensure uniform cooking, shake jar after 50 minutes.

**CAUTION:** Jar will be hot. Use gloves or cooking pads.

**Cooking Time:** 1.5-2 hours

**Pasta and Dehydrated Soups**

**Preparation:** First heat water to near boiling (50-70 minutes). Then add the pasta or soup mix. Stir or shake, and cook 15 additional minutes.

**Cooking Time:** 65-85 minutes

**Beans**

**Preparation:** Let tough or dry beans soak overnight. Place in cooking jar with water.

**Cooking Time:** 2-3 hours

**Eggs**

**Preparation:** No need to add water. **Note:** If cooked too long, egg whites may darken, but taste remains the same.

**Cooking Time:** 1-1.5 hours, depending on desired yolk firmness.

**Meats** (Chicken, beef, and fish)

**Preparation:** No need to add water. Longer cooking makes the meat more tender.

**Cooking Time:** Chicken: 1.5 hours cut up or 2.5 hours whole; Beef: 1.5 hours cut up or 2.5-3 hours for larger cuts; Fish: 1-1.5 hours

**Baking**

**Preparation:** Times vary based on amount of dough.

**Cooking Times:** Breads: 1-1.5 hours; Biscuits: 1-1.5 hours; Cookies: 1 hour

**Roasted Nuts** (Peanuts, almonds, pumpkin seed, etc.)

**Preparation:** Place in jar. A little vegetable oil may be added if desired.

**Cooking Time:** About 1.5 hours

**MRE's and pre-packaged foods**

**Preparation:** For foods in dark containers, simply place the container in the cooking bag in place of the black cooking jar.

**Cooking Times:** Cooking time varies with the amount of food and darkness of package.

**How to Use the Solar Funnel as a Refrigerator/Cooler**

A university student (Jamie Winterton) and I were the first to demonstrate that the Brigham Young University Solar Funnel Cooker can be used - at night - as a refrigerator. Here is how this is done:

The Solar Funnel Cooker is set-up just as you would during sun-light hours, with two exceptions:

1. The funnel is directed at the dark night sky. It should not "see" any buildings or even trees. (The thermal radiation from walls, trees, or even clouds will diminish the cooling effect.).
2. It helps to place 2 (two) bags around the jar instead of just one, with air spaces between the bags and between the inner bag and the jar. HDPE and ordinary polyethylene bags work well, since polyethylene is nearly transparent to infrared radiation, allowing it to escape into the "heat sink" of the dark sky.
During the day, the sun's rays are reflected on to the cooking vessel which becomes hot quickly. At night, heat from the vessel is radiated outward, towards empty space, which is very cold indeed (a "heat sink"). As a result, the cooking vessel now becomes a small refrigerator. We routinely achieve cooling of about 20° F (10° C) below ambient air temperature using this remarkably simple scheme.

In September 1999, we placed two funnels out in the evening, with double-bagged jars inside. One jar was on a block of wood and the other was suspended in the funnel using fishing line. The temperature that evening (in Provo, Utah) was 78° F (25.5° C). Using a Radio Shack indoor/outdoor thermometer, a BYU student (Colter Paulson) measured the temperature inside the funnel and outside in the open air. He found that the temperature of the air inside the funnel dropped quickly by about 15° F (8° C), as its heat was radiated upwards in the clear sky. That night, the minimum outdoor air temperature measured was 47.5° F (8.6° C) - but the water in both jars had ICE. I invite others to try this, and please let me know if you get ice at 55 or even 60 degrees outside air temperature (minimum at night). A black PVC container may work even better than a black-painted jar, since PVC is a good infrared radiator - these matters are still being studied.

I would like to see the "Funnel Refrigerator" tried in desert climates, especially where freezing temperatures are rarely reached. It should be possible in this way to cheaply make ice for Hutus in Rwanda and for aborigines in Australia, without using any electricity or other modern "tricks." We are in effect bringing some of the cold of space to a little corner on earth. Please let me know how this works for you.

**Conclusion: Why We Need Solar Cookers**

The BYU Funnel Cooker/Cooler can:

- Cook food without the need for electricity or wood or petroleum or other fuels.
- Pasteurise water for safe drinking, preventing many diseases.
- Save trees and other resources.
- Avoid air pollution and breathing smoke while cooking.
- Use the sun's free energy. A renewable energy source.
- Cook food with little or no stirring, without burning.
- Kill insects in grains.
- Dehydrate fruits, etc.
- Serve as a refrigerator at night, to cool even freeze water.

(Try that without electricity or fuels!)

The burden for gathering the fuel wood and cooking falls mainly on women and children. Joseph Kiai reports:

From Dadaab, Kenya: "Women who can't afford to buy wood start at 4 am to go collecting and return about noon... They do this twice a week to get fuel for cooking... The rapes are averaging one per week."

From Belize: "Many times the women have to go into the forest dragging their small children when they go to look for wood. It is a special hardship for pregnant and nursing mothers to chop and drag trees back to the village... they are exposed to venomous snakes and clouds of mosquitoes."

And the forests are dwindling in many areas. Edwin Dobbs noted in *Audubon Magazine*, Nov. 1992, "The world can choose sunlight or further deforestation, solar cooking or widespread starvation."

Americans should be prepared for emergencies, incident to power failures. A Mormon pioneer noted in her journal: "We were now following in their trail travelling up the Platte River. Timber was sometimes very scarce and hard to get. We managed to do our cooking with what little we could gather up..." (Eliza R. Snow) Now there's someone who needed a light-weight Solar Cooker!

Here's another reason to use a solar cooker. Many people in developing countries look to see what's being done in America. I'm told that if Americans are using something, then they will want to try it, too. The more people there are cooking with the sun, the more others will want to join in. A good way to
spread this technology is to encourage small local industries or families to make these simple yet reliable solar cookers for others at low cost. I’ve used this cooker for three summers and I enjoy it. Cooking and making ice with the funnel cooker/cooler will permit a significant change in lifestyle. If you think about it, this could help a lot of people. The BYU Solar Funnel Cooker uses the glorious sunshine -- and the energy of the sun is a free gift from God for all to use!

Answers to commonly-asked questions

Will the cooker work in winter (in the United States)?

As the sun moves closer to the southern horizon in the winter, the solar cooker is naturally less effective. A good measure of the solar intensity is the “UV index” which is often reported with the weather. When the ultraviolet or UV index is 7 or above – common in summer months – the solar cooker works very well. In Salt Lake City in October, the UV index was reported to be 3.5 on a sunny day. We were able to boil water in the Solar Funnel Cooker during this time, but we had to suspend the black jar in the funnel so that sunlight struck all sides. (We ran a fishing line under the screw-on lid, and looped the fishing line over a rod above the funnel. As usual, a plastic bag was placed around the jar, and this was closed at the top to let the fishing line out for suspending the jar.)

The solar “minimum” for the northern hemisphere occurs on winter solstice, about December 21st each year. The solar “maximum” occurs six months later, June 21st. Solar cooking works best from about 20th March to 1st October in the north. If people try to cook with the sun for the first time outside of this time window, they should not be discouraged. Try again when the sun is more directly overhead. One may also suspend the jar in the funnel, which will make cooking faster any time of the year.

It is interesting to note that most developing countries are located near the equator where the sun is nearly directly overhead all the time. Solar Cookers will then serve year-round, as long as the sun is shining, for these fortunate people. They may be the first to apply fusion energy (of the sun) on a large scale. They may also accomplish this without the expensive infrastructure of electrical power grids that we take for granted in America.

How do you cook bread in a jar?

I have cooked bread by simply putting dough in the bottom of the jar and placing it in the funnel in the usual way. Rising and baking took place inside the jar in about an hour (during summer). One should put vegetable oil inside the jar before cooking to make removal of the bread easier. I would also suggest that using a 2-quart wide-mouth canning jar instead of a 1-quart jar would make baking a loaf of bread easier.

What is the optimum “opening angle” for the funnel cooker?

A graduate student at Brigham Young University did a calculus calculation to assess the best shape or opening angle for the Solar Funnel. Jeannette Lawler assumed that the best operation would occur when the sun’s rays bounced no more than once before hitting the cooking jar, while keeping the opening angle as large as possible to admit more sunlight. (Some sunlight is lost each time the light reflects from the shiny surface. If the sunlight misses on the first bounce, it can bounce again and again until being absorbed by the black bottle). She set up an approximate equation for this situation, took the calculus derivative with respect to the opening angle and set the derivative equal to zero. Optimising in this way, she found that the optimum opening angle is about 45 degrees, when the funnel is pointed directly towards the sun.

But we don’t want to have to “track the sun” by turning the funnel every few minutes. The sun moves (apparently) 360 degrees in 24 hours, or about 15 degrees per hour. So we finally chose a 60-degree opening angle so that the cooker is effective for about 1.2 hours. This turned out to be long enough to cook most vegetables, breads, boil water, etc. with the Solar Funnel Cooker. We also used a laser pointer to simulate sun rays entering the funnel at different angles, and found that the 60-degree cone was quite effective in concentrating the rays at the bottom of the funnel where the cooking jar sits.

For questions regarding the complete Solar Funnel Cooker kit using aluminised Mylar and a jar for the cooking vessel, please contact CRM at +1 (801) 292-9210.

Tests of the Solar Funnel and Bowl Cookers in 2001

14 - 37
Christopher McMillan and Steven E. Jones  
Brigham Young University  

Introduction  
With an increase in population and a decrease in available fuels such as wood and coal in developing countries, the need for alternative cooking methods has increased. Solar cookers are an alternative to conventional methods such as wood-fires and coal-fires. They provide usable heat for cooking and pasteurising water, without the harmful side effects such as smoke inhalation that non-renewable sources create. In many countries such as Haiti, Bolivia and Kenya, the need for cheap, effective, and safe cooking methods has increased due to poverty and deforestation. Solar cookers are ideal because they rely on the sun’s free energy which is abundant in many of the world’s poorest countries. Though there are good designs, more testing and improvement is desirable.

There are three areas of comparison that were focused on during the course of the study. The first area of comparison is in the reflective material used. The original material is a mirror-finished aluminium Mylar. Due to the mirror finish, the reflection light is very bright and can be difficult to work over when cooking. An alternative material is a matt-finish Mylar. This material diffuses the sunlight and is not as harsh on the eyes as is the mirrored finish.

The second area of concentration is on the method of containing the air that surrounds the cooker so that the cooker is kept from being cooled by convection currents. A common method is to use a clear plastic oven-safe bag around the cooking vessel. However, this method is rather tedious and awkward to use, and such bags are rarely available in developing countries. Another technique is to use a disk or window make out of a clear plastic or glass. This makes the cooker easier to use.

The third main area of focus is in the cooking containers used. The present cooking vessel for the Solar Funnel Cooker is a black-painted canning jar. This method is also tedious and awkward. The canning jars can be hard to clean, and they can break. Design changes are tested that would allow people to use their own cookware. This too would make the cooker more convenient to use.

The fourth area of testing pitted the wooden block support which we have been using for years against a rabbit-wire support. A rabbit-wire cylinder holds the cooking vessel up off the bottom of the cooker, and allows sunlight to strike essentially all surfaces of the cooking vessel, including the bottom.

The effectiveness of these methods is tested and compared both qualitatively and quantitatively. In addition to acquiring temperature-rise versus time data, we also cooked numerous meals in the solar cookers so as to get hands-on experience with cooking. Several students participated in these cooking tests.

Cooker Designs:  
Several solar cooker designs were used during these tests. The Solar Funnel Cooker was the main cooker tested. A Solar CooKit and a bowl-shaped variation of the Solar Funnel Cooker were also tested. Most experiments were comparative tests between the various designs, and the cooker set-up was varied from test to test. The basic design of the Solar Funnel Cooker is a funnel-shaped aluminium Mylar collector. A highly reflective material is necessary to collect and concentrate the sun's rays. The funnel walls are at a 60 degree angle (with respect to the horizontal) since this collects sunlight for a two hour time period without requiring re-orientation to follow the sun. Due to the way the Mylar sheets are cut and folded, a pair of wings
on opposite ends of the funnel is formed. The wings increase the collector size and create an elliptical shape at top. At the tips of the wings, the cooker stands about 20 inches high and has a diameter of about 28 inches. At the top, along the minor axis of the elliptical funnel, the cooker stands about 15 inches high, and has a diameter of about 20 inches. Since the Aluminium Mylar does not support itself well, a nine inch diameter by five inch high bucket is used to support the funnel.

The cooking container primarily tested is a glass canning jar that has been painted flat black. The black paint allows the jar to absorb the sun's rays. The canning jar works well due to the added pressure-cooker effect caused by the rubber ring on the inside of the lid. A black-enamel pot and a black-painted stainless steel canister were also used. We found immediately that raising the vessel off the bottom of the cooker using a rabbit-wire stand provided more rapid and even heating than the wooden block used previously. Placing the jar or pot on a wire stand allows as much reflected light onto the cooking vessel as possible. This allows even the bottom of the cooking container to absorb thermal energy that is reflected off the lower portion of the funnel.

Two methods of closing the cookers off from convection currents were used. It is important to keep the air that surrounds the container from circulating, thus keeping the cooking container from being cooled by convection currents or breezes. This first method used was to enclose the cooking vessel and wire stand in a clear plastic bag, such as a heat resistant Reynolds Oven Bag. It is important to make sure that the bag is not touching the cooking vessel, so once the vessel is placed into the clear bag, air is blown into the bag and the bag is tied off. This is the most common method used for solar panel cookers, such as the Solar CookIt, because of the bags' ability to withstand the temperatures attained in these types of cookers. But these bags tear rather easily and they are not readily available in developing countries and must be imported.

The second method of closing off the cooking vessel from convection currents, designed by Dr. Jones, is to place a clear plastic disk down into the funnel above the cooking vessel. The funnel used in the test was a conventional-shaped funnel that was constructed out of thin sheet metal and aluminium-foil lined for better reflectivity. The diameter of this funnel is about 30 inches at the top, and it stands about 16 inches high. The walls also form about a 60 degree angle with respect to the horizontal. This funnel was designed to hold a larger cooking container such as a pot. The diameter of the plastic disk is large enough that the disk does not touch the top of the container. For the experiments that tested this method, a one-sixteenth inch (1.6 mm) thick Lexan disk was used.

Data Collection
To collect the temperatures as a function of time, a Texas Instruments Calculator Based Laboratory (CBL) was used. This portable interface is capable of recording real-time data from multiple channels. The data were downloaded into a graphing calculator, where they can be analysed and graphed immediately. From the calculator, the data can be transferred to a computer spreadsheet such as Microsoft Excel for further analysis. Due to the nature of these experiments and the low cost to purchase the CBL, this is an ideal data collector to use. A graphing calculator was used to program the CBL and to tell it what data to collect, how many points to collect, and the time period between data points collected. Since the CBL does not have any internal programs for data collection, a program must be written into the graphing calculator. There are
ready-made programs that can be uploaded into the calculator, or a custom program can be made to fit the needs of the test. The program that the CBL used allowed multiple thermocouples to collect data simultaneously. To ensure that the thermocouples were calibrated against each other, both were run on the same constant temperature sample in very close proximity. Both temperature probes agreed to within 0.21°C of each other. For these experiments, this temperature difference was considered to be acceptable.

Procedure

Each experiment was conducted on the campus of Brigham Young University during mid-day, usually between 11:00 am and 2:00 pm to ensure that the sun was close to being directly over-head. This allowed as much sun light as possible to enter the solar collector. Each experiment included several steps, as listed below.

Before each experiment was set up, the volume of the water and the mass of the container were measured and recorded. The heat capacity of the water and the container were also found. The area of the cooker perpendicular to the sun's rays was also measured. To collect temperature data using thermocouple probes, small holes were drilled into the top of the canning jar and stainless steel canister lids. The jar and canister were both painted ultra-flat black to absorb as much of the sun's energy as possible.

On the morning of each test, the designated volume of water was measured out and poured into the cooking vessel. This volume ranged from 0.6 litre for one-quart jars, to 1.2 litters for half-gallon canning jars. For simultaneous testing, the same amount of water was poured into each container. The temperature probes were wired through the holes in the lids of the containers and secured about 13 mm into the water. For comparative tests, the probes were placed the same depth into the water to ensure that the probes did not read different measurements due to depth-related temperature differences within the containers. To enable later analysis; the time, ambient temperature, and solar irradiance were also noted and recorded. These numbers gave a reference point for each test. Each cooker that was to be tested was then completely set up. The temperature probes were secured through the lids, and the jar was placed into the clear oven bag – supported by a wire cage. Each bag was inflated so that no part of the bag touched the sides or top of the cooking container. The cord from the thermocouple to the CBL was passed through the top of the bag, and the bag was tied off with a twist-tie.

The test began once both cookers were completely ready and the CBL had been programmed. Care was taken to block the sun from radiating directly onto the cookers until both were ready to begin. This ensured that the water in both cookers started at very nearly the same temperature. Most tests were set up to collect one data point every four to five minutes, for up to two hours. This allowed the cooker temperatures to reach maxima and then remain at a nearly constant temperature. Once a test was complete, the cooker was disassembled and the data downloaded into the graphing calculator. Though the graphing calculator does allow analysis, a spread sheet such as Microsoft Excel is easier to use. Thus, the data from each test were downloaded from the calculator into Microsoft Excel. The elapsed time (in seconds) and the corresponding temperatures were listed next to each other. A graph of temperature versus time was made, with the Time being the horizontal axis for each test. For comparative tests, the Temperature versus Time data for both cookers was plotted on the same graph. As a reference, a trend-line was fitted to the linear portion of the graph, along with the linear regression and the coefficient of correlation (R2). It is important to have a coefficient of correlation close to one, as this is how close the linear regression fits the data. In a separate column, the temperatures were again listed, however only from 30°C to 70°C. The change in temperature for every ten or twelve minutes was found and logged next to the temperature column. The power output (in Watts) of each cooker could then be calculated.

To calculate the power output of the cookers for each specific test, the mass of the water and of the container were both measured. Though the thermal energy content of the container was relatively small compared to that of water (due to the large heat capacity of water), it was important to add it into the calculation. Also, since several different containers were compared, the energy content of the container was important. The power is found by:

\[
Q_{(out)} = Q_{(water)} + Q_{(container)}
\]

\[
Q_{(out)} = (m_w c_w + m_c c_c) \Delta T
\]

\[
Power_{(out)} = \frac{Q_{(out)}}{\Delta t}
\]
The power is found in Watts. A power output for each change in temperature for the time interval is calculated and logged next to the T column. Since there are uncertainties in all of the measurements, it is important to include the error in each power output. To do this, the error in the water’s and container’s measurements is taken into consideration. The error is found by:

\[ \pm \Delta P = \sqrt{\left( \frac{\partial P}{\partial m_w} \Delta m_w \right)^2 + \left( \frac{\partial P}{\partial m_c} \Delta m_c \right)^2 + \left( \frac{\partial P}{\partial t} \Delta t \right)_w^2 + \left( \frac{\partial P}{\partial t} \Delta t \right)_c^2 + 2\left( \frac{\partial P}{\partial T} \Delta T \right)_w^2 + 2\left( \frac{\partial P}{\partial T} \Delta T \right)_c^2} \]

Where ±dP is the total error in the calculated error, dmw and dmc are the error in the mass of the water and container respectively, delta-Tp is the error in the temperature difference, and delta-t is the error in the time interval.

This simplifies to:

\[ \pm \Delta P = \sqrt{\left( \frac{C_w \Delta T}{t} \Delta m_w \right)^2 + \left( \frac{C_c \Delta T}{t} \Delta m_c \right)^2 + \left( \frac{m_w c_w \Delta T}{t^2} \right)^2 + \left( \frac{m_c c_c \Delta T}{t^2} \right)^2 + 2\left( \frac{m_w c_w \Delta T}{t} \right)^2 + 2\left( \frac{m_c c_c \Delta T}{t} \right)^2} \]

The error was found only for the average change in temperature, rather than for each individual temperature measurement. Since the power output is dependant on the amount of energy coming in from the sun, the cooker efficiency is a good factor to calculate. To find the efficiency, the total amount of local solar radiation must be known. This should be given in watts per square metre, so that the input wattage can be found. To find the power coming in, the area of the cooker perpendicular to the sun’s rays was multiplied by the solar radiation to give the amount of power that was being collected by the cooker. Since the Solar Funnel is able to be kept on track with the sun, and since the tests were done during mid-day, it was not necessary to calculate any angles. The efficiency is simply the power output divided by the power input. The solar radiation for each test was supplied by the Department of Physics and Astronomy weather station at Brigham Young University in Provo, UT, where the tests took place.

Results:
Matt vs. Mirror: Several tests were conducted on the matt versus mirror finishes. In each test, the matt finish outperformed the mirror finish. On 27 July, 2001, a matt funnel and a mirror funnel were simultaneously tested with 650 cc of water. The average power output for the mirror finish was 46.4 W ± 1.7 W, while the matt funnel put out an average of 59.4 W ± 2.1 W. The efficiency of the mirror funnel was 15.8%, while the matt was 20.2% efficient.

The following graph shows the temperatures reached by the matt and mirror funnels.
Channel 1 (Ch1) was the mirror finish, and channel 2 (Ch2) was the matt finish. This shows that both funnels peaked at about the same temperature: 97°C (207°F). The matt funnel peaked in about 76 minutes, whereas the mirror funnel peaked in 96 minutes, twenty minutes later. Though this perhaps a tolerable time difference for actual cooking, it is substantial. Every matt vs. mirror test performed in a similar way. These results are due to the way the matt funnel reflects the sun’s rays. The mirror finish seems to focus a strip of light onto the cooking vessel more than the matt finish does. As a result, the matt finish diffuses the light more and the cooker is heated more uniformly. This is good, since the matt finish is easier to work with, delivering much less glare to the eyes.

The following graph shows the temperature rise with time for a Solar CoolKit:

![Solar Cookkit 1 (7/16/01)](image)

Comparing the two graphs above, we find that the Solar CoolKit performed very well, comparable to the Funnel Cooker. We should note that in both cases, we used a canning jar (pressurised) supported by a wire stand. We found that the wire stand improves the performance of the Solar CoolKit significantly and hope that this support stand will be used in countries where the Solar CoolKit is in use.

In tests where the use of the clear plastic disk was tested against the oven-bag, an aluminium pot was used in the disk-set-up. In these tests, the cooker with an oven bag outperformed the cooker using a plastic disk. On 10 August, 2001, a test was run which compared the disk/pot set-up against the oven-bag/jar set-up. Both cookers follow similar heating paths with time, but the oven-bag/jar did slightly better. Due to the higher mass of the jar compared to the mass of the aluminium pot, and the much higher heat capacity of the water, the average power output for the oven-bag/jar was 39.8 ± 1.4 W, while the disk/pot put out 30.3 W ± 1.2 W. The efficiency of the oven-bag/jar was 14.7% and the efficiency of the disk/pot set-up was 10.4% for this test. This is also partly due to the pressure-cooker effect that the canning jar produces. Though this is a considerable efficiency difference, the disk/pot set-up did very well in subjective tests where food was actually cooked and tasted. In all cases where the disk/pot set-up was used to cook food, the food cooked in about the same amount of time. The ease of the disk/pot set-up is also an important consideration. Overall, in tests where food was cooked, the disk/pot set-up was preferred over the oven-bag/jar set-up.

Conclusions:
As many countries are depleting their natural resources due to increased population and the resulting deforestation, methods other than burning wood are needed to cook food and pasteurise water. Solar
cookers provide a sustainable technology that relies on the sun’s free energy. We report several advances to make them better. The need for cheap and effective solar cookers is very great and growing.

The Solar Funnel Cooker has been designed to meet the growing need by being inexpensive and effective. We determined that the Solar CooKit was nearly as effective when a rabbit-wire stand was used to support the cooking vessel. By collecting time vs. temperature data, quantitative analysis has been done. This analysis approach is useful for further development of the cookers.

Several areas of research were explored in 2001. Two finishes were tested for the reflector, a matt finish and a mirror finish. The benefits of the matt over the mirror finish are:

1) The matt finish is easier to work over because the sun’s glaring reflection is diffused, and
2) the matt finish out-performs the mirror finish in temperature vs. time tests.

The method of closing off the cooker from convection current was tested and compared with an alternative method – a clear plastic disk. The use of a pot rather than a canning jar was also tested. Though the present oven-bag/jar method does outperform the disk/pot method, the disk/pot method is easier to use and seems to be nearly as efficient. Finally, we showed that a wire-mesh stand is a considerable improvement over the use of a wooden block or other opaque stand for the cooking vessel. We join with our fellow researchers around the world in pursuing further development of solar cookers, particularly to benefit people in developing countries.

Recent Advances in Solar Water Pasteurisation

Boiling isn't necessary to kill disease microbes

The main purpose of solar cookers is to change sunlight into heat which is then used to cook foods. We are all familiar with how successful solar cookers are at cooking and baking a wide variety of foods. In this article I want to consider using the heat in solar cookers for purposes other than cooking. My main focus will be solar water pasteurisation, which can complement solar cooking and address critical health problems in many developing countries.

The majority of diseases in developing countries today are infectious diseases caused by bacteria, viruses, and other microbes which are shed in human faeces and polluted water which people use for drinking or washing. When people drink the live microbes, they can multiply, cause disease, and be shed in faeces into water, continuing the cycle of disease transmission.

World-wide, unsafe water is a major problem. An estimated one billion people do not have access to safe water. It is estimated that diarrhoeal diseases that result from contaminated water kill about 2 million children and cause about 900 million episodes of illness each year.
Boiling contaminated water

How can infectious microbes in water be killed to make the water safe to drink? In the cities of developed countries this is often guaranteed by chlorination of water after it has been filtered. In developing countries, however, city water systems are less reliable, and water from streams, rivers and some wells may be contaminated with human faeces and pose a health threat. For the billion people who do not have safe water to drink, what recommendation do public health officials offer? The only major recommendation is to boil the water, sometimes for up to 10 minutes. It has been known since the time of Louis Pasteur 130 years ago that heat of boiling is very effective at killing all microbes which cause disease in milk and water.

If contaminated water could be made safe for drinking by boiling, why is boiling not uniformly practised? There seem to be five major reasons:

1) people do not believe in the germ theory of disease,
2) it takes too long,
3) boiled water tastes bad,
4) fuel is often limited or costly,
5) the heat and smoke are unpleasant.

Some examples of the cost of boiling water are worth mentioning. During the cholera outbreak in Peru, the Ministry of Health urged all residents to boil drinking water for 10 minutes. The cost of doing this would amount to 29% of the average poor household income. In Bangladesh, boiling drinking water would take 11% of the income of a family in the lowest quartile. In Jakarta, Indonesia, more than $50 million is spent each year by households for boiling water. It is estimated that in the city of Cebu in the Philippines, population about 900,000, about half the families boil their drinking water, and the proportion is actually higher for families that obtain their water from an unreliable chlorinated piped supply. Because the quantities of fuel consumed for boiling water are so large, approximately 1 kilogram of wood to boil 1 litre of water, and because firewood, coal, and coke are often used for this purpose, an inadequate water supply system significantly contributes to deforestation, urban air pollution, and other energy-related environmental effects.

If wood, charcoal, or dung is used as fuel for boiling water, the smoke creates a health hazard, as it does all the time with cooking. As a microbiologist, I have always been perplexed as to why boiling is recommended, when this is heat far in excess of that which is necessary to kill infectious microbes in water. I presume the reason boiling is recommended is to make sure that lethal temperatures have been reached, since unless one has a thermometer it is difficult to tell what temperature heated water has reached until a roaring boil is reached. Everyone is familiar with the process of milk pasteurisation. This is a heating process which is sufficient to kill the most heat resistant disease causing microbes in milk, such as the bacteria which cause tuberculosis, undulant fever, streptococcal infections and Salmonellosis. What temperatures are used to pasteurise milk? Most milk is pasteurised at 71.7°C (161°F) for only 15 seconds. Alternatively, 30 minutes at 62.8°C (145°F) can also pasteurise milk. Some bacteria are heat resistant and can survive pasteurisation, but these bacteria do not cause disease in people. They can, however, spoil the milk, so pasteurised milk is kept refrigerated.

There are some different disease microbes found in water, but they are not unusually heat resistant. The most common causes of water diseases, and their heat sensitivity, are presented in Table 1. The most common causes of acute diarrhoea among children in developing countries are the bacteria Escherichia coli and Shigelia SD. and the Rotavirus group of viruses. These are rapidly killed at temperatures of 60°C or greater.

Solar water pasteurisation

As water heats in a solar cooker, temperatures of 56°C and above start killing disease-causing microbes. A graduate student of mine, David Ciochetti, investigated this for his master's thesis in 1983, and concluded that heating water to 66°C in a solar cooker will provide enough heat to pasteurise the water and kill all disease causing microbes. The fact that water can be made safe to drink by heating it to this lower temperature - only 66°C - instead of 100°C (boiling) presents a real opportunity for addressing contaminated water in developing countries.

Testing water for faecal contamination
How can one readily determine if the water from a well, pump, stream, etc. is safe to drink? The common procedure is to test the water for bacterial indicators of faecal pollution. There are two groups of indicators which are used. The first is the coliform bacteria which are used as indicators in developed countries where water is chlorinated. Coliform bacteria may come from faeces or from plants. Among the coliform bacteria is the second indicator, Escherichia coli. This bacterium is present in large numbers in human faeces (approximately 100,000,000 per gram of faeces) and that of other mammals. This is the main indicator used if water is not chlorinated. A water source containing 100 E. coli per 100 ccs poses a substantial risk of disease.

The standard method of testing water for the presence of coliforms and E. coli requires trained personnel and a good laboratory facility or field unit which are usually not present in developing countries. Thus, water supplies are almost never tested.

A new approach to testing in developing countries

In 1987, the Colilert MPM Test (CLT) was introduced as the first method which used a defined substrate technology to simultaneously detect coliforms and E. coli. The CLT comes as dry chemicals in test tubes containing two indicator nutrients: one for coliforms and one for E. coli. The CLT involves adding 10 ml of water to a tube, shaking to dissolve the chemicals, and incubating at body temperature for 24 hours. I prefer incubating tubes under my belt against my body. At night I sleep on my back and use night clothes to hold the tubes against my body.

If no coliform bacteria are present, the water will remain clear. However, if one or more coliforms are present in the water, after 24 hours their growth will metabolise ONPG and the water will change in colour from clear to yellow (resembling urine). If E. coli is among the coliform bacteria present, it will metabolise MUG and the tube will fluoresce blue when a battery-operated, long-wave ultraviolet light shines on it, indicating a serious health hazard. I have invited participants at solar box cooker workshops in Sierra Leone, Mali, Mauritania, and Nepal to test their home water supplies with CLT. One hundred and twenty participants brought in samples. In all four countries, whether the water was from urban or rural areas, the majority of samples contained coliforms, and at least half of these had E. coli present. Bacteriological testing of the ONPG and MUG positive tubes brought back from Mali and Mauritania verified the presence of coliforms/E. coli in approximately 95% of the samples. It is likely that soon the Colilert MPN test will be modified so that the test for E. coli will not require an ultraviolet light, and the tube will turn a different colour than yellow if E. coli is present. This will make the test less expensive and easier to widely use in developing countries to assess water sources.

Effect of safe water on diarrhoea in children

What would be the effect if contaminated water could be made safe for drinking by pasteurisation or boiling? One estimate predicts that if in the Philippines, families at present using moderately contaminated wells (100 E. coli per 100 ml) were able to use a high-quality water source, diarrhoea among their children would be reduced by over 30%. Thus, if water which caused a MUG (+) test were solar pasteurised so it would be clear, this would help reduce the chance of diarrhoea, especially in children.

Water pasteurisation indicator

How can one determine if heated water has reached 65°C? In 1988, Dr. Fred Barrett (USDA, retired) developed the prototype for the Water Pasteurisation Indicator (WAPI). In 1992, Dale Andreatta, a graduate engineering student at the University of California, Berkeley, developed the current WAPI. The WAPI is a polycarbonate tube, sealed at both ends, partially filled with a soybean fat which melts at 69°C.
The WAPI is placed inside a water container with the fat at the top of the tube. A washer will keep the WAPI on the bottom of the container, which heats the slowest in a solar box cooker. If heat from the water melts the fat, the fat will move to the bottom of the WAPI, indicating water has been pasteurised. If the fat is still at the top of the tube, the water has not been pasteurised.

The WAPI is reusable. After the fat cools and becomes solid on the bottom, the fish line string is pulled to the other end and the washer slides to the bottom, which places the fat at the top of the tube. Another pasteurisation indicator has been developed by Roland Saye which is based on expansion of a bi-metal disc which is housed in a plastic container. This also shows promise and is in the early testing stages. The WAPI could be useful immediately for people who currently boil water to make it safe to drink. The WAPI will indicate clearly when a safe temperature has been reached, and will save much fuel which is currently is being wasted by excessive heating.

Different strategies for solar water pasteurisation

The solar box cooker was first used to pasteurise water. David Ciochetti built a deep-dish solar box cooker to hold several gallons of water. At this time of the year in Sacramento, three gallons could be pasteurised on our typical sunny days.

Dale Andreatta and Derek Yegian of the University of California, Berkeley, have developed creative ways to greatly increase the quantity of water which can be pasteurised, as we will hear about at this conference.

I am also excited about the possibility of pasteurising water using the simple solar panel cookers. By enclosing a dark water container in a polyester bag to create an insulating air space, and by using lots of reflectors to bounce light onto the jar, it is possible to pasteurise useful amounts of water with a simple system. It takes about four hours for me to pasteurise a gallon of water in the summer with the system I am using. Solar panel cookers open up enormous possibilities for heating water not only for pasteurisation, but also for making coffee and tea, which are quite popular in some developing countries. The heated water can also be kept hot for a long time by placing it in its bag inside an insulated box. In the insulated container I use, a gallon of 80°C water will be approximately 55°C after 14 hours. Water at a temperature of 55°C will be about 40°C after 14 hours, ideal for washing/shaving in the morning.

I will close with some advice from the most famous microbiologist, who pioneered the use of vaccinations in the 1890s: Louis Pasteur. When he was asked the secret of his success, he responded that above all else, it was persistence. I will add that you need good data to be persistent about, and we certainly have that with solar cookers; the work in Sacramento, Bolivia, Nepal, Mali, Guatemala, and wherever else the sun shines. Continued overuse of fuel-wood is non-sustainable. We need to persist until the knowledge we have spreads and becomes common knowledge world-wide.

Editor's Note: Testing Water in Developing Countries

The Colilert system makes it possible to test water without the need for a laboratory. IDEXX Laboratories, the manufacturer, recommends that you use five test tubes for each sample. Bob Metcalf explains that five tubes would comprise 50 ml, which is the minimum sample size permitted by US law. This is an unrealistically high standard by which to judge the water in developing countries where you are examining water that is already being drunk, in spite of the fact that it may be making people sick. By using a single test tube (10 ml) there is a very small chance that your sample missed the small number of bacteria that might have been present.

IDEXX Laboratories will also tell you that you need an incubator to achieve valid results. Again, Bob Metcalf tells us that all that is needed is to keep the tubes close to your body for 36 hours, since body temperature is the correct incubation temperature.

What you are actually measuring in the test is the presence of 1) coliform bacteria, and 2) E. coli, a type of coliform bacteria that is largely found in faecal matter. A positive test for coliform bacteria might be due to coliform bacteria that has washed off of plant leaves, and thus be fairly innocuous. A positive test for E. coli, however, would indicate that any bacteriological contamination was from a faecal source, which might also contain Giardia, cholera, or other serious infectious microbes.

The Solar Puddle

A new water pasteurisation technique for large amounts of water

The lack of clean drinking water is a major health problem in the developing world. To reduce this health risk ways of producing clean water at an affordable cost are needed, and people need to be educated about germs and sanitation, lest they accidentally re-contaminate their clean drinking water. Recently, several of us at the University of California at Berkeley have attacked the first of these requirements.

Previous issues of this newsletter have included stories about our water pasteurisation indicator and our flow-through water pasteurises based on a design by PAX World Service. In this article we describe a new low-cost device that pasteurises water.

For those not familiar with the pasteurisation process, if water is heated to 149°F (65°C) for about 6 minutes all the germs, viruses, and parasites that cause disease in humans are killed, including cholera and hepatitis A and B. [Ed. We have reports from the field that at 145°F (63°C) in a solar puddle, bacterial growth might actually be increased. Since this temperature is very close to the minimum pasteurisation temperature mentioned in this article, we suggest that you heat the water to a higher
temperature and perform tests before adopting a solar puddle as your method of pasteurisation]. This is similar to what is done with milk and other beverages. It is not necessary to boil the water as many people believe. Pasteurisation is not the only way to decontaminate drinking water, but pasteurisation is particularly easy to scale down so the initial cost is low.

The new device is called a solar puddle, and it is essentially a puddle in a greenhouse. One form of the solar puddle is sketched in the figure below, though many variations are possible.

![Double Plastic Layer (Top Layer Black) Clear Plastic Spacer Air Gap Water Trough Insulation](image)

One begins by digging a shallow pit about 4 inches deep. The test device was a "family-size" unit, about 3.5 feet by 3.5 feet, but the puddle could be made larger or smaller. If the puddle is made larger there is more water to pasteurise, but there is also proportionately more sunshine collected. The pit is filled with 2 to 4 inches of solid insulation. We used wadded paper, but straw, grass, leaves, or twigs could be used. This layer of insulation should be made flat, except for a low spot in one corner of the puddle.

Put a layer of clear plastic and then a layer of black plastic over the insulation with the edges of the plastic extending up and out of the pit. Two layers are used in case one develops a small leak. We used inexpensive polyethylene from a hardware store, though special UV stabilised plastic would last longer. Put in some water and flatten out the insulation so that the water depth is even to within about 0.5 inch throughout the puddle, except in the trough which should be about 1 inch deeper than the rest. Put in more water so that the average depth is 1 to 3 inches depending on how much sunshine is expected.

A pasteurisation indicator (available from Solar Cookers International at 916/455-4499) should go in this trough since this is where the coolest water will collect. Put a layer of clear plastic over the water, again with the edges extending beyond the edges extending beyond the edges of the pit. Form an insulating air gap by putting one or more spacers on top of the third layer of plastic (large wads of paper will do) and putting down a fourth layer of plastic, which must also be clear. The thickness of the air gap should be 2 inches or more. Pile dirt or rocks on the edges of the plastic sheets to hold them down. The puddle is drained by siphoning the water out, placing the siphon in the trough and holding it down by a rock or weight. If the bottom of the puddle is flat, well over 90% of the water can be siphoned out.

Once the puddle is built it would be used by adding water each day, either by folding back the top two layers of plastic in one corner and adding water by bucket, or by using a fill siphon. The fill siphon should NOT be the same siphon that is used to drain the puddle, as the fill siphon is re-contaminated each day, while the drain siphon MUST REMAIN CLEAN. Once in place the drain siphon should be left in place for the life of the puddle.

The only expensive materials used to make the puddle are a pasteurisation indicator (about $2 for the size tested). All of these items are easily transportable, so the solar puddle might be an excellent option for a refugee camp if the expertise were available for setting them up.

Many tests were done in the spring and summer of this year in Berkeley, California. On days with good sunshine the required temperature was achieved even with 17 gallons of water (2 1/2 inch depth). About 1 gallon is the minimum daily requirement per person, for drinking, brushing one's teeth, and dish washing. With thinner water layers higher temperatures can be reached. With 6 gallons (1 inch depth) 176°F was achieved on one day.

The device seems to work even under conditions that are not ideal. Condensation in the top layer of plastic doesn't seem to be a problem, though if one gets a lot of condensation the top layer should be
pulled back to let the condensation evaporate. Small holes in the top layers don’t make much difference. The device works in wind, or if the bottom insulation is damp. Water temperature is uniform throughout the puddle to within 2°F.

After some months the top plastic layers weaken under the combined effects of sun and heat and have to be replaced, but this can be minimised by avoiding hot spots. Another option would be to use a grade of plastic that is more resistant to sunlight. The two bottom layers of plastic tend to form tiny tears unless one is very careful in handling them, (that is why there are two layers on the bottom). A tiny hole may let a little water through and dampen the solid insulation, but this is not a big problem.

There are many variations of the solar puddle. We’ve been able to put the top layer of plastic into a tent-like arrangement that sheds rain. This would be good in a place that gets frequent brief showers. Adding a second insulating layer of air makes the device work even better, though this adds the cost of an extra layer of plastic. As mentioned the device can cover a larger or smaller area if more or less water is desired. One could make a water heater by roughly tripling the amount of water so that the maximum temperature was only 120°F or so, and this water would stay warm well into the evening hours. This water wouldn’t be pasteurised though. One could help solve the problem of dirty water vessels by putting drinking cups into the solar puddle and pasteurising them along with the water. The solar puddle could possibly cook foods like rice on an emergency basis, perhaps in a refugee camp.

The “Easy Lid” Solar Cooker.
Designed by Chao Tan and Tom Sponheim

Although designs for cardboard cookers have become more simple, fitting a lid can still be difficult and time consuming. In this version, a lid is formed automatically from the outer box.
**Making the Base**

Take a large box and cut it in half as shown in Figure 1. Set one half aside to be used for the lid. The other half becomes the base.

![Figure 1](image1.png)

Fold an extra cardboard piece so that it forms a liner around the inside of the base (see Figure 2).

![Figure 2](image2.png)

Use the lid piece as shown in Figure 3 to mark a line around the liner.

![Figure 3](image3.png)

Cut along this line, leaving the four tabs as shown in Figure 4.

![Figure 4](image4.png)

Glue aluminium foil to the inside of the liner and to the bottom of the outer box inside.

Set a smaller (inner) box into the opening formed by the liner until the flaps of the smaller box are horizontal and flush with the top of the liner (see Figure 5). Place some wads of newspaper between the two boxes for support.
Mark the underside of the flaps of the smaller box using the liner as a guide.

Fold these flaps down to fit down around the top of the liner and tuck them into the space between the base and the liner (see Figure 6).

Fold the tabs over and tuck them under the flaps of the inner box so that they obstruct the holes in the four corners (see Figure 6).

Now glue these pieces together in their present configuration.

As the glue is drying, line the inside of the inner box with aluminium foil.

**Finishing the Lid**

Measure the width of the walls of the base and use these measurements to calculate where to make the cuts that form the reflector in Figure 7. Only cut on three sides. The reflector is folded up using the fourth side as a hinge.

Glue plastic or glass in place on the underside of the lid. If you are using glass, sandwich the glass using extra strips of cardboard. Allow to dry.
Bend the ends of the wire as shown in Figure 7 and insert these into the corrugations on the lid and on the reflector to prop open the latter.

Paint the sheet metal (or cardboard) piece black and place it into the inside of the oven.

**Improving Efficiency**

Glue thin strips of cardboard underneath the sheet metal (or cardboard) piece to elevate it off of the bottom of the oven slightly.

Cut off the reflector and replace it with one that is as large as (or larger than) the entire lid. This reflects light into the oven more reliably.

Turn the oven over and open the bottom flaps. Place one foiled cardboard panel into each airspace to divide each into two spaces. The foiled side should face the centre of the oven.

**Drinking Water Collection Systems.**

Getting adequate drinking water can often be a problem as there are many places where the local water supply is heavily contaminated with poisons, deadly organisms or both. While it is definitely much better to drink purified water than seriously contaminated water, it should be understood that most of the systems mentioned here, produce either distilled water or something very close to distilled water. Drinking distilled water for more than a few weeks is not ideal as distilled water is able to dissolve almost anything and it can do that perfectly well inside your body, removing essential minerals and other important items. So, if possible, avoid drinking distilled water for lengthy periods of time unless there is no other option other than seriously contaminated water carrying diseases and poisons.

One solution introduced for an area where there is almost never any rainfall is particularly interesting. This region gets fogs in the early morning, so plastic devices were constructed to take advantage of this fact. The devices were like plastic clothes brushes with long, slender vertical projections. The fog encountering these condenses into freshwater droplets on the surface of these vertical fronds and run down the fronds into a plastic tank which forms the base of the device. No moving parts. No input power needed, but the result is large quantities of drinking water every morning. There is very little evaporation from the tanks, due to the small surface area of the stored water:
This effect is very noticeable on foggy days where trees drip water extensively due to the fog depositing moisture on the leaves and branches.

At [http://www.wired.com/2015/01/architecture-and-vision-warkawater/](http://www.wired.com/2015/01/architecture-and-vision-warkawater/) there is shown a very large (and comparatively expensive at £1000 each) and very elegantly designed version of this, designed in Italy and called the “warkawater” tower:

Supplied in kit form, using structural members made of bamboo, this unit is 4 metres wide and 9 metres tall with rotating mirrors to scare birds away. With passive water collection from fog, rain and dew, tested in Ethiopia it can produce between 50 and 100 litres per day. The condensation material is plastic netting.
An emergency measure where water is needed, is to fasten a clean plastic bag around a branch of a tree. Trees lift a large amount of water through their root systems and a good deal of that water exist from the leaves of the tree. The plastic bag intercepts that moisture loss and collects it as clean water:

Another emergency measure is to use a clean plastic sheet and a hole dug in the ground. A clean container is placed in the centre of the hole and the plastic sheet used to cover the hold. The sheet is held around the edges of the hole with stones or any other suitable heavy material – bricks, timber, etc. A weight is then placed in the centre of the plastic sheet, pulling it down into a slope in every direction and forming an inverted peak over the container:

The area under the plastic sheet is heated by the greenhouse effect. Moisture also comes from the earth inside the enclosed hole. The moisture in the air in the cavity condenses on the underside of the plastic sheet. But as the plastic sheet is shaped into an inverted pyramid due to the weight just above the container, the water runs down and drips into the container. Again, no input power required and no moving parts.

While these methods produce good quality water which is effectively distilled water, it should not be considered to be sterile and immediately ready for human consumption, even though any risk from drinking it ‘as-is’ is likely to be very low. There will always be air-borne pathogens, and the ‘clean’ components used to collect the water in the first place may not be as clean as was thought. The same applies to the excellent quality water produced by dehumidifiers, where the inner working surfaces cannot be considered sterile after the equipment has been used for any length of time. To raise the water quality, boiling briefly, microwaving the water or it to UV radiation should kill any remaining harmful organisms in the water and make it fit for consumption.
By applying these same methods on a more permanent basis, leads to the construction of devices of the type that can produce clean water at the rate of 4 litres for every 8 square feet (0.75 square meters) of glass area in only 5 hours of sunshine:

There can be many variations on this shape. These devices are generally built either with glass lids or the whole construction in acrylic sheet. Here, the greenhouse effect heats the inside of the box, causing evaporation of the water inside. This condenses on the walls and lid of the box, where it runs down and into the clean-water section. Please remember that after a long period of use, the device needs to be cleaned very carefully and to deal with air-borne bacteria, the water could be treated briefly with UV light.

This particular design can be further enhanced as shown on the [http://www.permapak.net/solarstill.htm](http://www.permapak.net/solarstill.htm) website, where the heating inside the box is upgraded by using black high-temperature silicone to coat the inside of the bottom of the case. The black material absorbs sunlight particularly well and so helps to heat the water. Another enhancement is to place a reflector, possibly made from aluminium foil, behind the unit in order to increase the amount of sunlight or UV radiation reaching the water inside the box:

The web site [http://www.gabrielediamanti.com/projects/eliodomestico---how-does-it-work/](http://www.gabrielediamanti.com/projects/eliodomestico---how-does-it-work/) shows details of what is considered to be a very effective, low-cost unit aimed at undeveloped countries. Please visit that site where there is a 'Donations' button which allows you to support this excellent work. The designer Gabriele Diamanti says “Eliodomestico is an open project, free to the people who need it. I would really appreciate if you would like to help me in the development of this project!”. It works like this:
This project is intended to bring good drinking water to the families in the developing countries at no operating cost, starting from the sea water.

It works like an upside down coffee maker: during the day, the heat of the sun raises up the steam pressure into the black watertight boiler. The steam is forced down through the expansion nozzle, thus condensing against the lid.
At the end of the day the *Elidomestico* delivers 5 liters of fresh drinking water. The lower basin is specifically designed for the transport over the head, supporting this common habit.

*Elidomestico* is entirely made from poor, widely available materials. The technologies involved in the production are very simple and popular. This also makes the maintenance much easier:
- No electricity
- No filters
- Very easy maintenance
- Good impact on the local economy
- No impact on the environment

---

attribution - non commercial - share alike
Very simple systems:

It is usually presumed that quite a bit of expenditure and construction is needed to make a solar still which will purify water. That is not necessarily the case. Here is a design which can cost nothing and which can work well in a sunny location:

This arrangement could hardly be more simple than it is. An inner container is used and it is made either from a dark material or is painted black, preferably, matt black as a shiny black reflects more of the light falling on it than a matt black surface does. In the diagram above, the black stops well short of the top of the inner container, but that is only to show the liquid inside the container and in fact, the inner container will be dark from top to bottom. Because of this dark colour, the liquid inside the inner container gets hotter than the air outside it (which is hotter than the air outside the outer container, due to the greenhouse effect). There is considerable evaporation from the inner container, but as it can’t escape, it forms droplets on the inside of the outer container and these droplets slide down and collect at the bottom of the container, forming a reservoir of distilled water which is safe to drink. The construction of this still can be from things which are already to hand. For example, the bottom can be cut off a transparent plastic drinks bottle and used to cover a dark glass drinks bottle standing in an ordinary bowl, as shown here:
It is, of course, essential for the outside of the glass bottle and the inside of the plastic bottle to be completely clean so that they do not contaminate the purified water.

Another variation on this is to use a dark glass jar inside a plastic storage jar, again, placed inside an ordinary bowl as shown here:

Alternatively, a plastic jar with a screw lid can be used upside down and the lid used to replace the bowl. The inner container in this case, happens to be plastic. The capacity of the lid limits the amount of clean water which can be produced at any one time, unless the lid is carefully removed and a larger bowl used to catch the clean water (which means that it would have been easier to use the bowl instead of the lid):
Water Purity and Quality

There are two main factors involved in pure drinking water:

1. Debris and other non-biological material.
2. Biological material.

It is necessary to deal with each of these problems.

1. Non-biological material is avoided if the water is gathered by any of the evaporation/distillation systems shown above as the solids, sea-salts, mud or whatever, gets left behind. The same applies to collecting the evapotranspiration water from a tree using a clean plastic bag as mentioned above.

If it is necessary to use stagnant, muddy water or water from a polluted river, then two things can be done. The first thing is to get the water as clean as possible before collecting it. If it is possible, dig a hole near the water supply, making the hole deeper than the bed of the river or pool. That causes the hole to fill partially with water coming from the source through the ground which acts as a filter and as a result, the water in the hole is likely to have a lower level of solids in it. Having extracted the water from the new hole, unless it is exceptionally good quality, it can be improved by filtering it through sand held in a cloth material, or even just through a fine-mesh cloth. Water can generally be found under the bed of a dried out river and the best point to dig is at the outside of a bend in the river bed.

2. Biological material is a serious hazard and it can make you very ill and/or kill you. The evaporation systems mentioned above, generally avoid this problem, but the safe method for producing safe drinking water is to boil it for at least ten minutes as that kills the organisms in the water, making it safe. Unfortunately, that requires a good deal of fuel and the water needs to cool afterwards. Mixing ozone into the water or shining ultraviolet light through the water are alternatives. Be very careful as even moistening your lips with contaminated water can make you severely ill.

Water in a fast-flowing or bubbling stream flowing over rocks and sand, should be safe to drink provided that there is a stretch of 10 metres (30 feet) upstream of the sampling point, which is free from contaminants (dead animals, effluent inflow, etc.) as the movement of the water mixes air into the water and the oxygen in the air kills the bacteria.

A very effective way of dealing with polluted water (and any illness caused by it) is to add some colloidal silver to it, as that deals with all serious pathogens and, for example, can totally clear a contaminated well. In case you are not familiar with how to make colloidal silver, details are given below.

Fresh water on a larger scale

US patent 2,996,897 (22 Aug 1961) from Elmer Grimes:

The fifty-year-old Grimes system is effectively an outdoor refrigerator. A series of cone-shaped metal panels are stacked together vertically to save space. Each cone has pipes inside it which pass the cooling fluid through the cones, ensuring that they are always at low temperature. In the same way that a cold drink gets water droplets on the outside of the glass, the cones get water droplets forming on them all the time. A wiper arm like a windscreen wiper on a car then brushes those droplets off, with the wiper arm rotating around the cones continuously, rather than backwards and forwards as a car wiper blade does. This produces a continuous stream of fresh water coming off the cones. Unless there is some good reason why not to, the cones are mounted in a raised position so that gravity can be used to direct the water flow to where it needs to end up. Cones are used as they have a greater surface area than a flat plate of the same diameter would have, and the downward slope of the cone helps the water droplets flow off the cone surfaces.
This invention relates to a method and apparatus for obtaining a fresh water supply from the atmosphere. In arid and semi-arid regions, the supply of fresh water is a considerable problem which has in the past, been met by the use of highly expensive apparatus, equipment and systems involving the transport of water over great distances, using equipment which is consequently very vulnerable to destruction and additionally expensive in upkeep and repair. Other types of apparatus for obtaining a fresh water supply in such regions, involves the processing of sea water which has proven to be slow and also extremely expensive for obtaining water in larger practical quantities. It is therefore a primary object of this invention to provide apparatus which is especially useful in such regions for providing a fresh water supply in a more efficient, rapid and less costly a manner.

Another object is to provide a source of fresh water obtained from the atmosphere in a manner similar to a portion of the natural water cycle and by a process which avoids the high cost of boiling, evaporating and pumping of sea water.

A further object is to provide an apparatus which removes water from the atmosphere by condensation and precipitation for use in home and commercial purposes having the advantage of providing a more local source of water which will be naturally soft, having no scale to clog plumbing, nor any disposal problem for salt and mineral matter as occurs with seawater.

An additional object is to provide apparatus for obtaining water directly from the atmosphere by condensing water vapour in the atmosphere on a number of conical condensing surfaces exposed to the air which may be cooled by the air if the air temperature is below the condensing temperature and automatically cooled by circulating refrigerant when necessary so as to provide means for continuously condensing on the condensing surfaces, the water vapour which is in the air. Continuously operating wipers on the condensing surfaces cause the condensation on them to be swept into the bottom funnel portion of the apparatus. The water so collected is then conducted to local storage or use while the kinetic energy of the water flowing from the apparatus may be converted by means of a turbine-driven generator into useful energy which may be used to operate the motor driving the precipitation wipers as well as the compressor by means of which, the refrigerant is circulated within the condensing surface members for maintaining them at a temperature lower than the water vapour’s condensing temperature.

It will therefore be apparent that the apparatus and method of this invention has the advantage of providing a continuous supply of water which may be so engineered to supply water at all times in sufficient quantities and at the same time, furnish the power for its own operation and even at times, excess power which may be used for other purposes. The apparatus and method take advantage of the potential energy acquired by water undergoing the natural waste cycle by prematurely condensing the water vapour in the atmosphere and mechanically precipitating it by a mechanism acting in concert with, and supplementing the natural phenomena.
Fig. 1 is a schematic illustration of the installation and operating principles of the method and apparatus.

Fig. 2 is a partial sectional view with parts shown in section of the apparatus.
**Fig. 3** is a sectional view taken substantially through a plane indicated by section line 3—3 of **Fig. 2**.

**Fig. 4** is a partial, enlarged sectional view of a portion of the conical condensing plate and wiper mechanism.

**Fig. 5** is a partial sectional view taken substantially through a plane indicated by section line 5—5 in **Fig. 2**.
Fig. 6 is a top plan view of an opening in the funnel portion of the apparatus as viewed from a plane indicated by section line 6—6 in Fig. 2.

Fig. 7 is a partial sectional view taken through a plane indicated by section line 7--7 in Fig. 3.

Referring to the drawings in detail:

Fig. 1 illustrates the installation set-up. The entire apparatus is indicated by reference number 10 and includes a tank structure 12, (preferably) mounted at a height greater than the area to be supplied with the water. The water supply originates in the tank structure and is fed to the water reservoir 14 by a conduit system 18 which has a turbine 20. A portion of the kinetic energy of the water flowing in the conduit 18 is absorbed by the turbine mechanism 20 which powers and electrical generator 22 from which electricity can be drawn via a voltage regulator 24, which is connected to an electric motor 26 which is associated with the tank mechanism 12 by power lines 28. The voltage regulator 24 is also connected to external power lines 30 which may be able to supply additional power to other equipment. On the other hand, the power line may be interrelated with the mains supply so that when the power output of the generator 22 is insufficient to energise motor 26, and external source of power through the power line 30 may be used.

It will also be noted from Fig. 1, that an additional electrical connection 32 is provided between the power lines 28 supplied either by the generator 22 or the external power source through line 30 and voltage regulator 24 so as to operate other parts of the equipment associated with the tank structure 12 as will be explained later.
Referring now to figures 2, 3, 4 and 5, it will be observed that the tank structure 12 includes a cylindrical portion 34 which is connected at the bottom to a funnel portion 36, to which the conduit 18 is connected. Water collects at the bottom of the funnel 46 and carried by conduit 18 for storage and use. On the funnel walls are a number of streamlined-shaped openings 37 with upward projecting rims enabling the circulation of moisture-laden air through the funnel portion for additional water collection, each opening being designed however to prevent flow of water from the funnel portion as seen from Fig.2 and Fig.6. It will also be observed that the motor 26 which is positioned above the open top of the cylindrical portion 34 of the tank structure 12, is mounted on the cylindrical section 34 by means of a suitable mounting structure 38 while a refrigerant circulating unit 40 is mounted within the funnel portion 36 in axial alignment with the motor 26 by any suitable supporting structure 42. In addition to the wiper of the unit 44 driven by the motor 26, the compressor mechanism 40 is also driven from the motor 26 and is connected by a thermostatically controlled disconnector mechanism 46 of any suitable design, using mains power for connecting and disconnecting using lines 32 which are there for that purpose. The specific designs for mechanism 46 are well known.
It will be observed for Fig.2 and Fig.4 in particular, that the motor 26 has an output shaft 48 to which there is connected an elongated extension shaft 50 which extends downwards through tank 12 for connection to the compressor 40 through the thermostatically-controlled electrically-operated clutch 46. Also connected to the motor shaft 48 are a number of interconnected wiper arms 52 of the wiper mechanism 44. It will be observed from Fig.2 and Fig.4 that there are provided several parallel downward-inclined wiper arms 52 which are connected by axial connecting members 54.

The wiper arms 52 are positioned around, and rotate with respect to, the cone-shaped parallel, vertically spaced apart, plates 56, each of which has an exposed upper condensing surface 58 and a lower condensing surface 50 which are connected at their outer edge, and at their inner edge, they are connected to the next plates vertically above and below by plate 62. As is more clearly seen in Fig.4, the plate members terminate at the top with an axial portion 64 with respect to which, the motor shaft 48 rotates, bearing 66 being positioned between motor shaft 48 and part 64 of the conical plate. Shown in Fig.3 and Fig.7, lined curved openings 63 are placed in the condensing portions 58 and 60 of the conical plate members 56 in order to accommodate the circulation of air through and between the plate members. The plate members may be held fixed with respect to the housing tank 12 while the wiper arms 52 of the wiper mechanism 44 may be rotated relative to it. Accordingly, the wiper arm 52 includes wiper material 68 which contacts the upper and lower surfaces 58 and 60 of each of the conical plate members 56 so as to wipe from them the condensation 70 formed there as more clearly seen in Fig.5. The water so precipitated falls down to collect at the bottom of the funnel portion 36 of the tank 12.

It will be understood that the water vapour in the air will condense on surfaces 58 and 60 if the temperature of the air is low enough, or below, the water condensing temperature. At certain times, such as at night, the air temperature will have the conducting surface at the proper temperature. However, at other times it will be necessary to cool the condensing surface artificially by use of a conventional circulating refrigerant system. Accordingly, circulating refrigerant coils 72 are placed inside each conical plate 56.

As seen more clearly in Fig.3, the coils 72 are arranged to provide cooling for the entire exposed surface of the conical condensing plate 56 between the upper and lower condensing surfaces 58 and 60 of each conical plate member as more clearly seen in Fig.4, with the lined openings 63 being located between the coils. Each cooling coil network 72 is connected by a radial connecting tube 74 (Fig.3) connected to an axial tube portion 76 (Fig.4) through which refrigerant may be pumped into the coil 72 of each of the conical plate members 56. The axial portion 76 of the cooling tube is connected at the bottom to the circulating unit 40. Refrigerant under pressure is applied to the supply tube 76 for circulation through each of the conical plate members 56 and returned through a parallel axial tube 78 as seen in Fig.2 and Fig.4.

It will also be understood that although the apparatus is described in the illustrated example with stationary conical plates and rotating wiper arms, it would be possible to have the wipers fixed and the cone rotating, and in that case the rotation of the cones may provide sufficient physical disturbance through inertia and centrifugal effect to cause precipitation, in which case the wipers will not be needed. Furthermore, the number of wiper arms may be varied to suit the conditions under which the apparatus operates and the quantity of water to be derived from the atmosphere. The wiper mechanism 44 which is operated by means of the electric motor 26 to which the compressor 40 is also connected, may for the most part receive its operating power from the generator 22 which in turn derives its power from the kinetic energy of the water flowing through the conduit 18.

Also, the unit 40, which in addition to the wiper mechanism 44 loads the motor 26 may have its load disconnected from the motor 26 for more efficient operation when the refrigerant is not needed, such as at night when the air temperature is low. Removing the compressor load may be done manually or automatically by the mechanism 46 shown schematically, and which may be electrically operated to disconnect the motor drive shaft extension 50 from the compressor of the unit 40 when the air temperature is low.

There is also patent 4,418,549 (1983) from Calice Courneya. In this method the cooling parts are buried underground as it is assumed that the ambient air will be at a higher temperature than that below ground. The passage of air through the apparatus is intended to be wind driven although the incoming air is filtered to remove particles before entering the apparatus. There is also the provision of an extractor fan on the outlet, presumably for when there is little or no wind.
Another system is using a large Fresnel lens to distil water which is not suitable for drinking. This is possible using the most simple equipment of two glass bottles and a piece of copper tubing. If it is still there, the video at http://www.youtube.com/watch?v=aXjMAItCMi0 shows the method, though I must admit that I would prefer to take the liquid which he drinks and pass it through the system again to improve it's quality further.

Making Colloidal Silver

Colloidal silver is minute charged particles of pure silver suspended in distilled water. It is completely harmless to humans and has no side effects of any kind. It should be stored in a cool, dark place away from direct sunlight.

It is made using a glass container, some 99.99% pure silver wire and a battery:

Two clip wires are used to connect to the battery which can be 6-volt, 9-volt, 18-Volt or 27-Volt (by plugging two or three 9V batteries together). The other end of the two wires are used to clip the silver wire to the sides of the glass container holding the distilled water, holding the silver wire in place as well as making the electrical connection to the silver. Be sure that the distilled water does not cover any part of the clips as that contaminates the water as the clips are steel and not pure silver.

When the battery is connected, the distilled water is stirred gently for about fifteen minutes. The stirrer needs to be non-metallic – glass, plastic or wood, to avoid the stirrer becoming part of the processing and preventing the production of pure colloidal silver. The stirring is a very important part of the processing. The current flowing from the battery is very small and it is influenced by the separation of the silver electrodes.
The space between the electrodes can be adjusted by choosing where they are placed on the rim of the glass container. The particles taken from the silver wire are so tiny that the silver wire never seems to need to be replaced.

After a few minutes, the silver wire which is connected to the minus terminal of the battery, will become coated with a black substance. This needs to be cleaned off. I use a clean tissue for this. As time goes by, the rate at which the black coating develops increases as the water becomes much more able to carry current from the battery. Do not use any kind of chemicals to clean the silver – the purity of the water and the silver is vital. The silver wire connected to the positive terminal of the battery develops a dull grey coating which needs to be cleaned off occasionally.

I generally continue the process until I have cleaned off the negative electrode four or five times using a clean tissue. In passing, “colloidal” just means that the silver particles are too small to drop out of the water under gravity and so, stay dispersed throughout the water indefinitely. The end product should be clear and look exactly like water (which it mainly is). If you shine a laser light such as a lecturer’s laser pointer, into the colloidal silver, it looks very pretty, lighting up with thousands of little sparkles as the light is reflected off the silver particles in the water.

The most popular concentration is 10 Parts Per Million as that is a very effective level and that is the level typically produced after fifteen minutes of production. If you want to take it orally, then a teaspoon of colloidal silver held under the tongue for a minute before swallowing is recommended perhaps five times per day. Some interesting facts:

1. When Czechoslovakia was under communist occupation, Soviet intelligence came across a domestic disinfectant which was capable of neutralising not only their existing biological weapons, but also those under development. The Soviets quickly dismantled the factory which was producing this product and moved the equipment, documentation and even the staff to the Soviet Union. Following this, no one heard of the disinfectant again. In a study of infected wells, it completely destroyed typhus, malaria, cholera, and amoebic dysentery. This domestic disinfectant is a variety of colloidal silver.

2. Colloidal silver does more than just kill disease-causing organisms, it also promotes major bone growth and accelerates the healing of injured tissues by over 50%. It promotes healing in skin and other soft tissues in a way which is unlike any other known natural process. An example of this is the case of Glen Roundtree, a 32 year old man, who was clearing brush and trees in his parent's yard when some petrol left on his hands after filling the chain saw ignited. He burned for over 30 seconds as he tried to get the fire out. Glen suffered third degree burns on his hands and face. His mother's friend brought him some colloidal silver. He drank it and sprayed it on his face often. He was able to stop taking morphine immediately. Within three and a half weeks his recovery was so advanced that his hospital attendant did not believe he was the same burns patient. In less than three months his face was completely healed with absolutely no scarring. The planned re-constructive surgery for his melted nose and ear was cancelled.

3. In the presence of colloidal silver, cancer cells change back to normal cells regardless of their location in the body. The presence of silver ions regenerates tissues and eliminates cancer cells and other abnormal cells. For many years, Dr Bjorn Nordstrom of Sweden's Karolinska Institute has used silver in his cancer treatment methods. He reports that he has successfully cured patients who had been diagnosed as "terminally ill" by other doctors. He also discovered that the silver was promoting the growth of a new kind of cell which looked like the cells only found in children. These cells grew fast, producing a diverse and surprising assortment of primitive cell forms able to multiply at great rate and then change into the specific cells of an organ or tissue which had been injured, even in patients over 50 years old. In no case were there any undesirable side effects. He also discovered that previously untreatable osteomyelitis and bones which refused to knit, could be healed quickly by applying a silver-impregnated nylon dressing attached to a small battery. This worked so well that it has become standard practice today when dealing with bones which refuse to knit.

4. Dr Paul Farber suffered a tick bite which overnight, gave him the crippling Lyme's Disease. There was no satisfactory treatment so he searched medical literature to see if he could find anything to help. He finally found the comments of Dr Crookes about colloidal silver killing a microbe in six minutes or less. He also found the research and development work done on colloidal silver by Dr Moyer, Dr Bretano and Dr Margraf. Dr Farber started taking colloidal silver with spectacular results, clearing the bacteria out of his body in a short time - colloidal silver kills the Lyme's Disease bacteria.
5. Antibiotics have no impact whatsoever on viruses. This means that taking any antibiotic will have no effect on a viral infection. Worse still, many forms of bacteria are now resistant to most antibiotics. Colloidal silver will kill both and boost your natural immune system at the same time, and it cures AIDS and Ebola.

**Agriculture**

The Elmer Grimes system for extracting water from the air is able to produce volumes of water capable of supporting agriculture, even in dry areas such as Texas. While agriculture or food production is not part of this publication, there are a few things which should be mentioned. I know nothing about agriculture but I do know that soil of very poor quality can be converted to rich, productive soil by burning vegetation and then working the resulting ash into the poor soil. That requires no chemicals and is very low cost and effective.

Also, the effectiveness of a growing area can be boosted substantially by using vertical stacking. The company Agricube at [http://www.agricube.co.uk](http://www.agricube.co.uk) has an effective, proven, low cost system for doing this with standard modules which stack on top of each other:

These stacking units can boost the effective growing area by a factor of five.

Trickier to operate but very neat in concept is the technique of hydroponics combined with fish farming. With that technique, the fish waste forms food for the plants and the plants draw the waste from the water, keeping it fresh for the fish. It is a very effective system and there is a free download manual on this at [http://www.fishplant.co.uk](http://www.fishplant.co.uk) where fish selection is explained as well as how to operate the system in family size or commercial scale. Useful video at [https://www.youtube.com/watch?v=HYR9s6chrI0](https://www.youtube.com/watch?v=HYR9s6chrI0).
Kimbal Musk’s “Urban Farming Accelerator”  
By Justin Gardner  29th August 2016

The demand for real, local food is growing as more people become aware that agribusiness corporations such as Monsanto, along with lobbying groups like the Grocery Manufacturers Association, have a frightening grip on America’s food system.

“Big Food” would rather have everyone continue to eat highly processed, mass-produced substances packed with genetically modified fillers and artificial ingredients.

The surge in organic and non-Genetically Modified sales is a heartening reminder that the power of the purse can make a difference. Farmer’s markets, where people congregate to buy real, nutritious food and meet the farmer who produces that food, have grown all over America but the availability of real, local food is limited in urban areas, where communities often experience “food deserts” where the only things available are the unhealthiest processed substances of the Big Food industry.

Kimbal Musk (brother of the innovating entrepreneur Elon Musk) and his colleague Tobias Peggs are looking to change that by bringing real food production into the heart of urban areas. This autumn they are launching Square Roots, an “urban farming accelerator” centered on the use of modular shipping containers to grow the equivalent of two acres of food year-round. It’s not just a box, though, but an initiative to join the energy of youth with healthy, sustainable solutions to food production.

“Square Roots builds campuses of climate-controlled, indoor, hydroponic vertical farms, right in the hearts of our biggest cities. We train young entrepreneurs to grow fresh, local food all year round. And we empower them to create forward-thinking, responsible businesses that strengthen their communities through real food. All this means year-round heaven for local foodies. From farmer’s market conversations to farm-campus parties, from speaker series’ to digital content, Square Roots creates opportunities for everyone to dig into local food – even if there’s two feet of snow on the ground.”

With technology and urbanisation, people have unfortunately been losing touch with the basic knowledge of where food comes from and how it is grown and made – which makes the system ripe for abuse by corporate interests and government lackeys. Square Roots is a brilliant counter to this trend. It not only puts power back in the hands of the people, but also creates opportunity for activities that contribute to the health of body and mind. Gardening is known to make you smarter and happier.

Last week, Kimbal Musk explained why he is “empowering thousands of young people to become #realfood entrepreneurs through Vertical Farming”. He says “strong communities are built around local, real food. Food we trust to nourish our bodies, the farmer and planet. This is #realfood. Sadly, many people in our biggest cities are at the mercy of industrial food. The industrial food system ships in high-calorie, low-nutrient, processed food from thousands of miles away. It leaves us disconnected from our food and the people who grow it. As Michael Pollan and others are have pointed out, the results are awful - from childhood obesity and diabetes to a total loss of community in our food".
For a decade, Musk’s startup called “The Kitchen” has served real, local food to millions of city residents, while getting kids interested in real food through 300 Learning Gardens across the country. Square Roots will naturally build on this success.

“Leveraging proven technologies like Freight Farms and ZipGrow, Square Roots’ vertical farms are literally built inside shipping containers. They essentially enable three-dimensional growing - giving farmers the annual yield equivalent of two acres of outdoor farmland inside a climate-controlled module with a footprint of barely 320 sq. ft. These systems also use 80% less water than outdoor farms. That’s the potential for a lot of real food grown in a very small space using very few resources. Best of all: vertical farms can be installed in the middle of cities. Our urban campuses will have anywhere from 10 to 100 farms. Using this platform, Square Roots entrepreneurs can avoid almost all the transport-impact of the industrial food system - by growing real food, at scale, right next to people who want to eat it”.

Their first campus will debut in Brooklyn, New York this autumn, and they admittedly “have a lot to prove” in the beginning stage. But all indications point to a huge demand for real food in urban areas, and plenty of young entrepreneurs ready to merge their business drive with sustainable solutions for the planet.

Toribio Bellocq’s Water Pump.
A serious problem for farmers and individuals is the cost of pumping water up from a borehole or well. While the combined Lever / Pendulum system of Veljko Milkovic described in Chapter 4 can reduce the amount of effort required by a substantial margin, there are other methods which could be useful.

It was originally thought that water could not readily be pumped to a greater height than 32 feet or so unless the pump was located at the bottom of the pipe. Toribio Bellocq demonstrated in 1924 that this is actually not the case and that water can be pumped to any height using a pump mounted at the top of a vertical pipe. He showed a working system to the Patent Office where an 80-foot vertical pipe was used to demonstrate the principle and having proved the point, he was granted US Patents 1,730,336, and 1,730,337, and later, US Patent 1,941,593 in which he describes chamber devices which can enhance the sonic wave operation.

Toribio’s system is very straightforward. He places a one-way ball valve at the bottom of the vertical pipe (item V in the diagram below). A crank rod is then used to vibrate piston C in its pumping cylinder. The pumping cylinder has no valves and the piston stroke is very short. Both the pipe and the pump cylinder are filled with water before the operation is begun.

The rapid movement of the piston creates a pressure wave in the water in the pipe. The pressure wave causes the water pressure inside the pipe to rise and fall rapidly. This altering water pressure at the one-way valve at the bottom of the pipe, causes water to be drawn into the pipe when the pressure is low and the valve prevents the water flowing out again when the pressure rises.

This repeating action causes water to be pumped up the vertical pipe and out through an adjustable valve R. When the pumping action is timed correctly, there is an almost continuous flow of water from the pipe.

Toribio quotes an example in his patent, where the vertical pipe has an internal diameter of one inch, placed in a well where the water is twenty metres below the ground level. The valve opening is 30 mm and the sealing ball of the valve has a diameter of about 38 mm and contained in an ordinary cage which allows some 20 mm of vertical movement of the valve.
With this arrangement, the piston at the surface has a diameter of 50 mm and a stroke of 38 mm and is driven by an electric motor at about 360 rpm. The outflow pipe has an internal diameter of half an inch and the valve R is used to control the rate of flow out of the system. When the valve is adjusted correctly, a continuous flow is achieved and the flow rate is about 1,000 litres per hour (265 US gallons per hour, or 220 Imperial gallons per hour). It is important that the initial filling of the pipe and fully-open piston avoids getting any air trapped along with the water. The compressor cylinder can be horizontal or vertical. The well can be of any depth and there is no need for the pipe to be straight or vertical. When the system is adjusted correctly, there is little or no wear on the valve at the bottom of the pipe. The liquid pumped does not have to be water.

Richard Dickinson's Water Pump.
US Patent 2,232,678 of 1937, show a very similar system with a piston being driven in a cylinder without valves, creating a pressure wave in the vertical pipe which has a similar one-way valve at the bottom of the pipe. Interestingly, no mention of Bellocq's patent is made. Dickinson's patent drawing of the system outline is shown here:
Arthur Bentley’s Water Pump.
The grandson of the car designer, Arthur Bentley has some 34 patents to his name, one of which (US 4,295,799) is very much like Toribio Bellocq’s pump system. Richard Bruner writing in the Calgary Herald newspaper in 1989, tells how a prototype of the Bentley design was tested on a Navajo reservation in Arizona. Driven by four solar panels, a flow rate of 120 US gallons per hour was achieved, (about half that of Bellocq’s rate at 20 metres depth), though the depth of the Navajo well was not mentioned. The manufacturers claim that the pump can operate at depths of up to 4,000 feet.

Neither this Bentley patent nor his earlier patent 3,804,557 makes any mention of Bellocq which seems somewhat strange, especially with the marked apparent similarity between the designs. Again, we see here, a piston being used to generate an acoustic wave in the vertical pipe and a series of one-way valves at the bottom of the tube being used to trap the rising column of water and prevent it from flowing out of the bottom of the pipe again. A variation in this patent is the addition of a spring loaded bottom section to the pipe which is alternately compressed and expanded by the sound waves as part of the pumping process as shown in the following diagrams:
The Ram Self-Powered Pump.
In hilly areas, it is frequently necessary to pump water up to locations where it is needed. These locations are usually considerably higher than the source of water. There is a simple device called a “Ram Pump” which is powered by water flow alone and needs no other form of power. In a way, it operates very much like the pumps just described, in that water flowing into a pressure chamber causes fluctuating pressure which with just two valves, and no other moving parts, pumps water to a considerable height.

A Ram Pump can be used if there is a fast-flowing stream of clean water, and more than 50% of the water flow into the pump can be lifted to a higher level. The remainder of the water flows back into the stream at a point lower down. These pumps are readily available commercially and interestingly, they have a COP of infinity as the user does not have to supply any input power and yet substantial pumping power is produced for an unlimited period. As this is a standard Engineering technique, nobody gets upset at the though of ‘perpetual motion’ or ‘free-energy’ even though the pump can go on pumping for years with absolutely no fuel being burnt. This is energy being drawn from the environment in the same way as a self-powered compressed air engine draws energy from the environment, and yet, the compressed air engine is considered to be “unbelievable” while the Ram Pump is accepted without question. Could there be a certain degree of bias being seen here? The power operating the pump comes from the water flowing down hill. The water arrives at this height by falling as rain. The rain gets up there by evaporation caused by water being heated by the sun. So, bottom line, the pumping power comes from the sun.

If a fast-flowing stream is not available but the terrain allows it, then a Ram Pump feeding system can be built. Ideally, there should be a drop of at least two metres (six feet) on the inlet pipe. This creates a fast flow into the pump by feeding it through a steeply sloping intake pipe, like this:
The performance of a Ram Pump is impressive even though it has only two moving parts. With an input fall of just four metres and a small flow rate of just three litres per minute, a Ram Pump can deliver 69 litres per day to a massive height of 100 metres vertically above the pump. Or, 159 lpd to 60 metres above the pump, or 258 lpd to a height of 40 metres above the pump. This is impressive for such a simple device.

It operates by the water rushing into the air chamber. This raises the pressure until the valve at the base of the chamber slams closed. The increased pressure in the chamber pushes water out of the delivery outlet, lowering the pressure again. While this is happening, the closed valve causes a ‘water-hammer’ wave of reverse pressure which pushes excess water out of the ‘waste’ pipe and pushes water back up the intake pipe. When the pressure wave in the intake pipe dissipates, the water rushes back down the pipe, pushing the valve at the base of the air chamber, open again, to repeat the cycle. This oscillating pressure wave causes the pumping action, very much in the same way as the previous pumps which use a mechanical oscillator pump as no free-flowing water is available to create the oscillation.

Commercial ram pumps have an efficiency of about 66%. The calculation of performance is:

\[ D = \frac{(S \times F \times E)}{L} \]

Where:
- \( D \) = The quantity of water in litres delivered in 24 hours.
- \( S \) = The quantity of water, in litters per minute, fed to the pump.
- \( F \) = The height in metres of the water source above the pump intake.
- \( E \) = The efficiency of the pump (assume 33% for home built units).
- \( L \) = The height in metres, of the supply outlet above the pump.

Reproduced here by kind permission of US AID 1982 from the web site shown in the diagram above, is a table of values, calculated from the formula above, and assuming the 66% efficiency of a commercial unit. The input flow for these numbers is a tiny 1 litre per minute trickle. This is less than the hydroxy gas rate produced by the Smack’s Booster shown in Chapter 10, so in practice, you will be multiplying the numbers in this table by a realistic number of inflow litres per minute.
Discouraging Mosquitoes and Small Flies

Maurice Cottrell (whose work is in chapter 11) presents what is a quite remarkable effect. He says:

What it is, is a church door in Ireland, surrounded with a white plastic pipe filled with water. When in Palenque in Mexico Maurice found that the local people discouraged flies, particularly mosquitoes and very
small flies, by hanging polythene bags filled with water, from the lintels of their open doors. They do not know why, but doing that discourages flies from entering the doorway.

Maurice considered the effect and his opinion is that small flies can be injured by raindrops and so they have learned to avoid them. A falling raindrop has an electrogravitic effect due to the hydrogen atoms in the water, and flies which can see in the ultraviolet spectrum, can detect that effect around water and their instinct makes them avoid water – whether falling as droplets or not. Large bluebottle flies do not seem to be affected, but there is a definite effect with smaller flies.

If a doorway is surrounded with a 1-inch (25 mm) diameter plastic pipe filled with water, as seen in the picture above, then Maurice believes that the resulting effect is like this:

Here, gravity waves spread out from the water and create an effective barrier all the way across the doorway, discouraging the smallest flies, including midges. Obviously, any opening can be surrounded with a water-filled pipe, and not just doorways. While this is not a renewable energy device as such, it is a method which could well be useful where serious diseases are carried by mosquitoes.

Wave Power.
Although not generally thought of as an option for personal use, wave power does have a high potential, although, like wind power and unlike tidal power, not always available. We tend to think of wave power systems as being large scale and very expensive, but that is not always the case. At it’s most basic level, most wave power system uses the varying distance between the surface of an ocean or sea and some fixed point on land or the sea bed.

Ideally, there should be a minimum of moving parts. One neat design uses a simple rectangular concrete housing with an electrical generator mounted above sea level. The generator being above sea level is easy to reach for maintenance or replacement and there are no moving parts underwater. It is a very simple design which can be built quite easily. In it’s most simple form, it is just a rectangular box with an underwater opening:
Here, a large opening allows the sea to flow into the structure which makes the water level inside the box move up and down with the wave motion outside. As a wave passes by, it compresses the air inside the box and the air is driven out through the generator opening, spinning the generator blades in the same way as a wind-powered generator has its blades spun by the wind.

Some generators operate well with the air flowing backwards and forwards through the blades, generating electricity no matter which way the blades are spun. With a generator which works better with just one direction of spin, then a large flap valve is installed and it allows air to flow into the structure when the water level is falling but closes immediately the water level starts rising again.

Even though this style of wave power generator is so simple, it works very well in practice, provided that the vertical dimensions are arranged so that the top of the underwater opening is below the lowest neap tide and the bottom of the generator opening is above the highest spring tide. A baffle arrangement can be used to protect the generator from spray and storm debris. There is no need to have the structure full width above the water level:
This has the very considerable advantage that the area of the water surface inside the structure is very much larger than the cross-sectional area of the generator housing column and so the air rushes out through the generator much faster than the wave rises. This amplification factor can be increased by increasing the length of the base of the unit, further enlarging the water surface area inside the structure. If wave action is frequently very strong, then it may be preferred to have the undersea opening facing inshore or sideways in order to reduce the amount of material driven into it by very strong surges.

Another fairly simple wave power generator system design which is based on simple principles, was suggested on Stefan Nystrom’s website which has been discontinued. It is called the “WaveReaper” system. It operates using a large number of separate buoys. Plastic barrels are suggested as suitable buoys but almost any non-dangerous containers which will not corrode in the sea and which have a considerable internal volume, can be used in this system.

Each basic unit consists of a float, a pulley, a cable and a ratchet drive connection to the shaft of an electrical generator. The power provided by the movement of the buoy can be very substantial as sea water weighs a considerable amount. The connecting cable is kept taught by a heavy weight, and the cable runs over a pulley which is mounted on a shaft which connects to the shaft of the generator. Bicycle parts are suggested for this section of the drive as they are cheap and readily available in most places and they come with a toothed sprocket wheel which already has a suitable ratchet built into it.

The reason for the shaft is that a whole series of buoys are used. These buoys are positioned progressively further and further from the shore so that an incoming wave raises the buoys one after the other in a regular sequence. This means that while one buoy is letting its cable run back inshore (pulled by it’s inshore weight), one or more of the other buoys will be rising and applying drive to the shaft linked to the generator. This arrangement allows the generator shaft to receive a continuous drive. Having a heavy flywheel on this shaft is an added advantage as it will smooth out the repeated drive strokes provided by the buoys:

![Diagram of WaveReaper system](image)

Having a sheaf of moving cables threaded through the sea near the shore is asking for a major tangle with seaweed and all kinds of other drifting material. Very sensibly then, Stefan suggests that the cables be housed in a protecting pipe. Considerable care needs to be taken to make sure that the cables do not rub against anything as the movement is constant and the forces involved are high. Each cable needs to have its own space keeping it clear of all the other cables and having a pulley mounted at any points where there is a change of direction.

To make maintenance easier, it is also suggested that these protecting pipes are not fixed in position but are themselves on a pulley system so that they can be hauled ashore:
The buoys are also linked together loosely on top with a securing cord so that they always stay in a compact group, though there is little chance of any great sideways movement as the tension in the buoy cables is high. Stefan requests that anyone who constructs his design makes a donation via http://www.o2gruppen.se/ though how that is done is by no means clear to me as there does not appear to be a “Donate” button on that website.

There are many other wave-power devices, some with excellent efficiencies, but most are not generally capable of construction by the average amateur. One example is the “Nodding Duck” design by Stephen Salter of Edinburgh in Scotland, and shown in the US patent 3,928,967 where the wave power is extracted by a raft-like construction with cam-shaped floats. These floats have a rippling movement on the surface of the water and the movement of each section relative to the other sections is used to generate power. This is not exactly a back-yard construction.

Other Systems.
Not included in this eBook, but on the website http://www.free-energy-info.tuks.nl/ there are articles from the highly recommended Home Power website http://www.homepower.com/home/ which are on this general topic. There is a system for producing blocks of ice using sun power alone and no other energy input at all:
Also, a two-part article on Solar cooling, which concentrates on heat absorption with different colours, the strategic positioning of buildings and vegetation, practical roof overhangs and the like, to lower the temperature inside buildings in very hot locations.

There are articles is on cooking with hydrogen, heating your house with hydrogen and using hydrogen with a barbecue. On the Home Power site there is information on how to use solar power to heat household water and you may find the Google video on how to make your own hot-water solar panel interesting and useful. It makes sense to reduce your essential costs by doing a few simple things which help.

**Cooling Using Heat.**
Most of our current refrigerators use electricity to drive a compressor to achieve cooling. Here is a patent from Albert Einstein (whom you may have heard of) and Leo Szilard which uses heat to power refrigeration instead of electricity. It is US Patent 1,781,541 titled “Refrigeration” and dated 11th November 1930.
Our invention relates to the art of refrigeration and particularly to an apparatus and method for producing refrigeration where the refrigerant evaporates in the presence an inert gas and more particularly, to the type disclosed in the Von Platen and Munters Patent No. 1,685,764 of 25th September 1928 and our British Patent No. 282,428.

The objects and advantages of our invention will be apparent from the following description considered in conjunction with the accompanying drawing which shows more or less diagrammatically, a preferred embodiment of our invention.

In the drawing, 1 is an evaporator which is normally placed inside the chamber which is to be cooled. A pipe 5 connects the upper part of evaporator 1 to the more intermediate portion of the condenser 6. Pipe 11 connects with the bottom of the evaporator 1 and extends into the condenser 6, at a level which is below the level of pipe 5. A cooling water jacket 12, surrounds the condenser and allows cooling water to flow through it.

Pipe 27 connects the bottom of the condenser 6, to the lower part of a heat-exchanger jacket 28. The upper part of jacket 28, is connected to the lower part of generator 29 which is heated by any suitable method. Pipe 30 connects the upper part of generator 29 to a point near the bottom of evaporator 1 where it
terminates in a distributor head 31. Pipe 30 runs inside pipe 5 so that there is a heat exchange between the fluids in those two pipes.

Pipe 32 runs upwards from the lower part of generator 29 to connect with a container 33 which is positioned at a level which is above that of condenser 6. A source of heat 36, is applied to pipe 32 at a point above generator 29. Pipe 37 runs down from container 33, passing through the heat-exchanger jacket 28 and then on up to the top of condenser 6 where it terminates in a distributor head 35. Pipe 37 runs inside the cooling water jacket 12 so that the fluid passing through it will be cooled as it flows. A venting pipe 34 connects the upper part of container 33 with the upper part of condenser 6.

The operation of the apparatus is as follows:

A suitable refrigerant, for example, butane in liquid form, is held inside the evaporator 1. An inert gas, such as ammonia, is introduced into evaporator 1 through pipe 30 and it’s distributor head 31. The refrigerant evaporates in the evaporator in the presence of the inert gas due to the fact that the partial pressure of the refrigerant is reduced thereby and the resulting gaseous mixture passes through pipe 5 and into condenser 6. Here, the mixture comes into intimate contact with an absorption liquid, for example, water, which is fed into the condenser through pipe 37 and it’s distributor head 35. The ammonia gas is very soluble in water but the butane is quite insoluble, so the ammonia is absorbed into the water freeing the butane from the gaseous mixture. Thus, the butane assumes substantially the entire pressure inside the condenser, and that pressure is sufficiently high to cause its liquefaction at the temperature maintained by the cooling water.

The specific gravity of liquid butane is less than that of the solution of ammonia in water and so stratification of the two liquids occurs with the liquid butane floating on top of the ammonia solution 26. The liquid butane passes from condenser 6, through pipe 11, and returns to evaporator 1, where it is again evaporated and the cycle repeated.

Gravity causes the ammonia solution to flow from condenser 6 through pipe 27 and heat-exchanger jacket 28, into generator 29. Here, the application of heat causes the ammonia to be expelled from the solution in the form of a gas, which then passes through pipe 30 and distributor head 31, into evaporator 1, where it reduces the partial pressure of the butane, causing it to evaporate as already described.

Water, containing very little ammonia in solution, passes from generator 29 through pipe 32 where it is further heated by the source of heat 36. This heating causes the formation of vapour in pipe 32 which lifts the liquid through this pipe and into container 33 and on from there under gravity through pipe 37 to condenser 6 and during its flow, this hot, low-concentration liquid is cooled by the heat-exchanger jacket 28. It is further cooled by the cooling water in jacket 12, and so reaches a condition where it can rapidly absorb ammonia in the condenser 6. Vapour entering container 33 through pipe 32, continues on its journey to the condenser 6 via the venting pipe 34.

During the operation of this piece of equipment, the pressure existing in the various components is uniform with the exception of slight differences caused by columns of liquid needed to cause the fluids to flow. The pressure existing in generator 29 must be sufficiently greater than the pressure in the upper part of evaporator 1, in order to make vapour flow through distributor head 31. In other words, the pressure difference must be sufficient to overcome the liquid head marked h2. This excess pressure in the generator is balanced by the pressure created by the column of liquid marked h1 in the drawing. This means that h2 must be less than h1, otherwise there would be no flow.

This patent of Einstein and Szilard seems to indicate that any source of heat such as a fire or a solar oven, should be able to produce cooling using a device which has no moving parts. It would probably be necessary to provide a trickle of water through the water cooling jacket, but apart from that, it looks like a device which could be used effectively by people who live “off the grid” and have little or no access to electricity. All in all, it is an interesting design.

Solar Panels.
A very well-know method of producing electricity from what appears to be a renewable resource is the use of solar panels. It hardly seems worth mentioning these as sales are so well promoted but it is possible that the problems with them are not understood. This used to be the most expensive way of producing electricity, but by 2015, electricity from free-energy and renewable energy sources have now exceeded the electricity produced by fuels such as oil, coal and nuclear energy. Much of this gain has been improvements in solar panels with a move away from the silicon wafer based technology to the newer thin film methods of
construction. That lowering in cost made the new solar panels viable as an investment for speculators and that drove up the installed volume enormously, with solar farms supplying the existing grid and getting paid for their input. Schemes in Germany produce 7% or 8% for investors. Details of this can be seen in the 2008 presentation https://www.youtube.com/watch?v=mLHBFyfvK8A which explains the details very well.

What is often not realised is that solar panels have a working life span and will need replacement at some later date. The life is quite good, typically ten to twenty years, but the price of replacement must be allowed for. Solar panels are not the only part of your electrical system which will need replacing. Generally speaking, solar panels are used to charge batteries which then power equipment, usually by using an "inverter" which changes a DC battery voltage to a mains voltage AC supply. The big snag is that the frequently used lead-acid batteries generally have a lifespan of about four years. They are expensive, heavy and as they contain lead, they are not easy to dispose of (legally). This is a major recurring cost and disposal problem. The Tesla Car company has a high power 'battery' design capable of storing solar power and then run an entire household. At the present time, the unit is about 4 feet x 2 feet x six inches which is about 1220 x 610 x 150 millimetres and the price is around US $3,500. Hopefully, the size and price will both reduce considerably as manufacturing volume increases.

Another point which may not be realised with the older systems is that the current which can be drawn from a lead-acid battery without reducing its working life is very limited, quite apart from the fact that any lead-acid battery is only 50% efficient, requiring it to be fed twice as much current as it can supply afterwards. The safe discharge rate for a lead-acid battery is called the "C20" rate which just means that the allowable current is one which discharges the battery in a period of 20 hours. For example, if a new battery is rated as being a 100 Amp-hour ("100 AHR") battery, then the safe discharge rate is about 100 amps divided by 20, which is 5 amps. At twelve volts, a current of five amps is a power output of sixty watts. A washing machine needs about 2,200 watts for at least some of the time, so to power it (and nothing else at the same time) would take 37 of those 100 AHR batteries. Could you conveniently house 37 large batteries? How much do you think it would cost to replace them every four years?

Please understand that I have nothing against solar panels and actually own some myself, but you need to be aware of the practical problems with using them and not imagine that buying them will give you free electricity for ever afterwards.

The next factor to be considered is the fact that the power "rating" of a panel such as "120 watts" is not the amount of power which will be provided by the panel. It will provide that amount of power IF it is positioned exactly square-on to very strong sunlight in a region near the Equator. If the panel is not aimed exactly at the sun, then the panel output will be considerably lower. The sun moves around at a rate of fifteen degrees per hour, so your panel will only be aimed directly at the sun for about four minutes unless you have it mounted on a rotating platform and you push the platform round slowly to face the sun at all times. While that sounds complicated, it is actually not a difficult or expensive thing to arrange although most people don't bother to do that.

Even though most solar panels operate on UV rather than visible light, any minor cloud cover drops the panel output quite noticeably. There is also the little detail that most solar panels only work in sunlight or with reduced output in very bright daylight. This means half the day does not contribute to electrical input and in winter, when the electrical need is greatest, the days are shortest, sunlight scarce and daylight quality very poor unless you live near the equator. The level of sunlight which you will receive drops off steadily the further you get from the equator as the light angle gets lower and lower. This also causes problems in winter with quite low obstacles casting a shadow on the panels and cutting the working time for the panel even further.

The effect of all this is that you will need a far greater claimed panel wattage than your needs seem to require and I would suggest that you probably need between two and three times as many panels as the stated panel wattage would suggest that you need. Considering that chapter 10 shows how to run a generator on water, it would be cheaper to buy and replace a generator on a regular basis than to buy batteries and panels and having to replace them. A generator also runs at night and through the winter.

However, if you are installing solar panels, please be aware that there are considerable differences between panels which have the same apparent rating. A key factor is the voltage produced by the cell under normal working conditions. This makes the difference between a good charging rate under poor conditions and a near-zero charging rate at those times. The good panels have a greater number of cells and the higher voltage produced can make a major difference, so check out the technical specification document on each panel you want to consider and pay attention to the voltage figures and not just the (maximum possible) "wattage" quoted by the manufacturer or sales person. The panels which I picked are made by Kyocera but
do your own checking as designs change from year to year. At the present time, solar panels are only about 17% efficient which means that 83% of the power reaching them does not go to make electricity.

Solar panels expand due to heat during the day and so need to be mounted in such a way that allows for this expansion and contraction during the day and night. As you don't want to over-charge a battery, it is generally considered essential to use a control circuit to prevent this happening. In real life, when you use the electricity generated on a daily basis, there is little or no chance of over-charging, but you can decide this for yourself.

One recent development is to use the solar panel(s) to drive a battery-pulsing charging system. This has the major advantage that battery charging does not stop when the light falling on the panel produces a voltage which is too low to charge the battery bank directly. With a pulsing unit, the charging pulse voltage is largely independent of the input voltage and so a good charging rate can be produced in poor lighting conditions, including twilight. This can extend the battery charging period very substantially, especially in winter when there is less light. At this time, one of John Bedini’s companies is offering these units for sale.

Assessing solar panels generally from the standpoint of knowing what the snags are, unless you live in a very good location on the planet and have a good deal of spare money to spend, then they are not a great solution, but this is something which you also need to decide for yourself.

However, having said that, a scheme has recently been introduced in the UK and it appears to be a realistic option. Under this scheme, the householder does not buy the solar panels but merely pays to cover the cost of installing them. For example, this house:

![Solar Panel Desk Lamp](image)

has twenty-one panels mounted on the roof and the total cost to the home owner was just £500. The home owner receives a very much reduced electricity cost and expects to recover the installation cost within two years. Even in November at latitude 52 degrees North, these panels are performing well. No batteries are involved and the panels tie in directly to the electricity grid.

Not having to pay for the purchase of the panels themselves makes an enormous difference to the viability of such an installation. I understand that the strategy behind this scheme is to increase the presently tiny percentage of electricity in the UK, which is produced from renewable sources, by offering people a scheme which actually makes it worthwhile to have an installation.

**A Solar Panel Desk Lamp**

Solar panels can be very useful items in spite of their very low efficiency and high cost. When thinking about solar panels people generally imagine a set of many large solar panels mounted on the roof of a house. The cost of doing that is far too great for most people to consider it. However, at this time, there are one billion people in the world who do not have any electricity at all. It appears that a useful electricity feature for them...
would be electric lighting at night. With the components which have become available recently, providing good lighting at realistic cost is now possible.

Small solar panels offered for sale as “10 watt, 12 volt” capacity can now be bought reasonably cheaply. Made in China, these panels can provide a current of just over half an amp. These panels which have an aluminium frame are typically 337 x 205 x 18 mm in size and look like this:

Tests which I have run show that a 1000 lux very realistic level of lighting can be provided with a total of just 1.5 watts of electrical power. The best lighting source that I have found is the “G4” style, LED arrays made in China using the “5050” chip technology. These are cheap and have a very heavily non-linear light output for current draw, which is a fact which we can use to our advantage. These LED arrays come in “white” or “warm white” versions (my preference is the warm white variety) and they look like this:

With a diameter of 30 mm and pins which are easy to connect to, these are very convenient devices which have an excellent lighting angle of 160 degrees and a light output of 165 lumens for a 1.2 watt electrical input.

One of the problems with such a unit is the selection of a suitable battery. Lithium batteries are excellent but the cost of a suitable lithium battery is ten times greater than the cost envisaged for the whole unit, effectively excluding lithium batteries. Lead-acid batteries are far too large, too heavy and too expensive for this application. Surprisingly, what appears to be the best choice is the very popular AA size Nickel-Manganese rechargeable battery which is 50 mm long and 14 mm in diameter:
Rated at up to 3 Amp-Hour capacity, they are very low cost, are lightweight and can be placed in a battery box like this:

The battery box can be adapted to hold seven batteries rather than the intended eight batteries, producing a nine volt battery pack with 1.2V batteries. If three of these battery packs are used with the solar panel, then there is no need for over-charging protection as NiMh batteries can deal with overcharging current if it does not exceed 10% of the battery’s milliamp-hour rating, and that simplifies the design very considerably.

However, some of these small NiMh batteries do not live up to the maker’s claims and so you need to run a load test on any particular make of battery which you may consider using. For example, here are six different types of these batteries tested in groups of four, with a load of about 50 milliamps at five volts. The same load was used to test each of these batteries:
The results were most revealing:

The BTY 3000 batteries do not actually claim on the battery to be 3000 mAHr (although the sellers do) and so, the "3000" could just be a trading name. The tests results for the BTY 3000 were so staggeringly poor that the test was repeated three times with longer recharging time for each test, and the one shown above is the 'best' result. You will notice how far short it falls when compared to the low-cost Fusiomax 800 mAHr batteries. The terrible performance of the BTY 3000 batteries is only exceeded by the incredible "SDNMY 3800 mAHr" batteries which show almost negligible capacity in spite of their amazing claims of 3800 mAHr.

NiMh batteries are 66% efficient. You should only ever charge a 3000 milliamp-hour NiMh battery at 300 milliamps or less and so with a 10-watt solar panel, overcharging is not a problem.

Light meter tests provide some very interesting results for the LED arrays. When using two LED arrays side by side in a light box, the figures for voltage / current draw / light produced using 1.2-volt NiMh batteries were:

9 batteries 11.7V 206 mA 1133 lux: 2.41 watts 470 lux per watt (the manufacturer's intended performance)
8 batteries 10.4V 124 mA 725 lux 1.29 watts 562 lux per watt
7 batteries 9.1V 66 mA 419 lux 0.60 watts 697 lux per watt (a very realistic performance level)
6 batteries 7.8V 6 mA 43 lux 0.0468 watts 918 lux per watt

This is very revealing information, showing that one of these LED arrays fed with just 33 milliamps can produce very impressive 210 lux lighting at a wide angle of illumination. To put that another way, feeding five LED arrays with 9 volts, generates a very acceptable 1000-lux lighting level for just 165 milliamps which is only 1.5 watts. That is spectacular performance.

Equally impressive is what happens when the battery voltage drops when the battery is nearly fully discharged. The LED performance rises to combat the loss of voltage and even at a ridiculously small 3 milliamps fed into each LED, there is a 21 lux light output from each LED array. The effect is that while the lighting does dim slightly, it does so very gradually in a barely noticeable way. With three sets of genuine high-capacity AA NiMh batteries, we can expect a minimum of eight hours of continuous 1000-lux lighting from our desk lamp. That is a total of twelve watt-hours, and the solar panel feeding 66% efficient batteries at nine volts, is capable of replacing one of those usable watt-hours in twenty minutes. In other words, just two hours forty minutes of good daytime lighting can provide eight hours of 1000-lux lighting every night.
The only moving component in this system is the On/Off switch and the circuit could not be any more simple than this:

All solar panels have a diode to prevent the panel drawing current from the batteries during the hours of darkness and it is not unusual for the panel to be supplied with a diode already connected in place. Personally, I would consider a fuse to be unnecessary but it is standard practice to fit one. The batteries are installed in a base box which supports the solar panel and gives sufficient weight to produce a very stable lamp. The five LED arrays are connected in parallel and fitted into a suitable lamp housing such as this one:

Only the flexible stem, 120 mm diameter lampshade and On/Off switch are used.

While this is an exceptionally simple and robust design, it is actually an affordable and very desirable unit which can provide years of cost-free lighting at a very satisfactory level. The prototype looks like this:
This is, of course, a perfectly ordinary and quite standard type of a solar-powered light. The difference here is that it is a very effective light suited to lighting a desk to a high level all night long. It is mobile and has a wide angle of lighting.

It is also possible to extend the design very slightly, to provide an even longer period of lighting or if preferred, a period of even brighter lighting. This can be done by using eight batteries in each battery holder – which has the advantage that standard battery holders can be used without any need to adapt them to hold just seven batteries.

This has the slight disadvantage that we do not want to supply the extra voltage to the LED arrays because doing that would cause a greater current draw than we want. We can overcome this by using an extra change-over switch and having two connections to each battery holder. The circuit could then become:

With this arrangement, the lighting unit is fed by either eight batteries or by seven batteries, depending on the position of the change-over switch. When the solar panel is charging the batteries, all eight batteries per holder get charged no matter what position the extra switch is in.

This has the advantage that when the battery voltage starts to drop after a few hours of powering the light, then the switch can be operated, raising the voltage reaching the lamp by the voltage of the extra battery, possibly producing a brightness exceeding the maximum when using just seven batteries in each battery holder. This arrangement has the slight disadvantage that the user could switch in all eight batteries from the beginning, producing a much higher current drain and while that would give a higher lighting level, the overall time is likely to be reduced. Mind you, it is possible that this might suit the user.

If this style of operation is chosen, then I suggest that the extra switch is located well away from the On/Off switch so that the user does not get confused as to which switch does which job. Perhaps the second switch might be located near the stem of the lamp support, like this:
Without knowing much electronics, it is possible to make a more versatile version of this desk lamp. This can be done by providing a fully adjustable lighting level. For this, we use three 10-battery holders, each containing a full set of ten batteries, producing a nominal 12-volts but in reality, about 13.8 volts when fully charged.

We would like the user to be able to adjust the voltage applied to the LED arrays in order to get the very high current-to-light output efficiency or a higher level for a shorter time, if that style of operation is preferred. This can be done quite easily, in a very simple and cheap way, using this arrangement where just one battery is shown to represent all three battery packs wired in parallel to produce a higher battery capacity:

Here, instead of feeding the battery voltage directly to the LED arrays, two cheap and widely available transistors are placed between the battery and the LEDs. These transistors control the voltage applied to the LEDs and that controls the current through the LEDs and the level of light produced. The chosen light level is set using the variable resistor “VR” and the light level can be turned down gradually, all the way to zero, so the unit could also be used as a night light if that was wanted.

The physical layout of the components could be like this:
Here, the weight of the solar panel and the three battery packs give the unit stability if the lamp is bent in any direction. With four LED arrays, an excellent level of lighting results, however, I would suggest using five LED arrays as that gives an even wider range of lighting. A big advantage of this arrangement is that if the variable resistor is fitted with a knob like this:

then each user will become familiar with the particular light-level setting which suits the recharging rate. It also allows for short periods of very high level lighting if that ever becomes necessary.

From a practical point of view, when the light is first switched on the battery voltage will almost certainly be over 13 volts. As we want about 9 volts applied to the LED arrays, some four volts need to be dropped off to stop the LEDs drawing excessive current and draining the batteries too quickly. In passing, it might be mentioned that the human eye is very bad at assessing light levels, and so, doubling the LED current (which would more than halve the length of lighting time) does not increase the visual effect by much, and so, controlling the current flow makes a major improvement in the length of time during which the light can be used each night. The lighting period each night is expected to be about eight hours.

The transistors controlling the light level drop off some 1.4 volts, no matter what the current is. This is not a problem during the normal lighting period. However, if the lighting period is unusually long and the battery voltage is starting to drop, then it is possible to gain that extra 1.4 volts by using another switch to bypass the transistor control. It is wired so that the battery is connected directly to the LEDs in order to extract every last milliamp of current from the batteries. That extra 1.4 volts makes a major difference to a falling light level but it should not be used for any length of time on a fully charged battery (quite apart from the excessive current draw) as it is feeding the LEDs a voltage higher than the LED designer was expecting and while it does produce exceptional lighting, it is being very unkind to the LEDs. The bypass switch would be arranged like this:
Here, the extra switch marked “BOOST” short-circuits across the transistors and so connects the LEDs directly to the battery. The fuse shown is optional but if your wiring is not the best, then it is worth having in case your wiring creates a direct short-circuit across the batteries. A ‘slow-blow’ fuse rated at 1-amp would be a good choice as the normal current flow, even on BOOST with a fully charged battery, will be less than one amp if five LED arrays are used. It is also possible to use a variable resistor which has the On/Off switch built into it:

Also shown in the diagram is the solar panel which is connected to the batteries at all times, even bypassing the fuse. It is connected through a diode such as a 1N4007 so that the panel will not draw current from the batteries during the hours of darkness. To make sure that the two switches are not mixed up by the user, I suggest that the extra switch “SW2” is positioned well away from the On/Off switch:
Of course, it is not essential to use a commercial, adjustable lamp such as this. Instead, the LED arrays could be mounted on a home-made strip attached to the back of the solar panel plate and possibly, angled slightly downwards if a desk or table is the main place to be lit. In either case, it is advisable to put a piece of frosted plastic across the LEDs as they can be lit so brightly that they can be difficult to look at. Also, just because this is intended primarily as a desk lamp, there is nothing to stop the user tipping the light upwards to light the whole room. Actually, the room will probably be fairly well lit even when the main lighting area is a desk or table even if that is located at one end of the room.

The construction sequence might be:

1. Lay the solar panel face up on the corner of a sheet of some suitable material such as 6 mm Medium Density Fibreboard (“MDF”). Run a pencil around the edge of the solar panel and cut the sheet along the pencil line to produce a sheet which can be attached to the back of the solar panel. Drill a 6 mm diameter hole about 30 mm in from one corner, that is 30 mm in and 30 mm up so that the hole will be clear of the sides and corner strips when they are attached later on. If it is your intention to paint the desk lamp, then painting this backing sheet before attaching it to the solar panel makes it much easier to do neatly.

2. Lay the solar panel face down on a soft surface and slide the cover off the electrical connection points. It should look like this:

Under the cover, there will be two connection terminals, one marked with a Plus symbol. Some of these panels come with wires already connected and a diode already soldered in place. If there is a diode already there and you are going to remove the cover permanently, it is advisable to embed the diode region in epoxy resin as the diode leads are unduly flexible and could break easily.
If there are not wires already attached, then you need to solder a wire to each of these two terminals. If you do not know how to solder, and don't have a friend who can, then you can learn quite easily. On the web there are several videos showing how to do it. The connecting wire used should not be solid core but should have several tiny strands of wire inside the insulation. The wire should be able to carry at least 1-amp and ideally two or three amps. The thicker the wire, the better electrically but the more difficult it is to solder. The convention is to have a red wire connected to the Plus and a black wire connected to the Minus of the panel, but so long as you know which wire is which, you can use any colour of wire that is convenient. Even if you forget which is which, a voltmeter will tell you which is the Plus when light shines on the panel. These wires need to be about 600 mm. (2 feet) long.

3. Pass the two wires through the hole drilled in the solar panel backing sheet and with the hole positioned at the bottom left. Attach the sheet securely to the back of the solar panel using a good quality adhesive. I prefer to use Impact Evostick or epoxy resin for this, but each constructor will have his own preferred adhesive.

You don’t need the plastic cover which can slide over the terminals and it can be discarded. It is far more important to make good electrical connections to the terminals rather than bothering about keeping under the plastic cover which usually has very, very little clearance and which can get in the way of the backing sheet. The result should look like this:

4. We now need to construct the housing for the batteries and other components. For convenience of description, I am going to assume that your sheet material is 6 mm thick. In America, that would be a thickness of one quarter of an inch. Cut a strip of the sheet material "L" long (‘L’ being the length of your particular solar panel). The width of the strip should be width of the battery box (typically 79 mm) plus one thickness of the material, which, with 6 mm thick material is likely to be 85 mm.

5. To make the ends of the box, cut two small strips with a length of that 85 mm (or whatever) and a width of 7 mm greater than the depth of your battery boxes, which are normally 30 mm deep, making the strip typically, 85 mm x 37 mm.

6. Epoxy these three strips to the bottom of the panel backing sheet to form an 85 mm wide, shallow channel like this:
7. Using the same sheet material (or thinner material if convenient), cut two 70 mm x 37 mm strips, and epoxy them one on each side of the three battery boxes. The battery boxes need to have the batteries inserted and the connectors attached to them to ensure that the spacing is right. These dividers connect to the solar panel backing sheet, leaving a gap on the near side as wires have to run from left to right past those dividers. The result should be like this:

![Diagram of battery boxes with strips]

It is important that the batteries are secured so they cannot move at all. As shown above, they can still swivel through an angle due to the gap created by the battery connecting clips. To prevent this, three strips of timber or other suitable material should be attached very firmly to the base to hold the batteries rigidly in place, as shown below.

8. Next, cut a strip of your 6 mm. thick sheet, 65 mm wide and slightly less than the gap between your two dividers. This strip is to hold the batteries securely in place and still allow room for wires to be run past the batteries. The strip will not be attached to the solar panel sheet although it will be positioned very close to it. Check that it fits in place. The gap will be on the near side to make the final wiring easier:

![Diagram of battery strip]

9. The next step is to cut the top strip which will hold the lamp, switches and variable resistor. While the lamp fitting is quite light, the length of the arm is so very much greater than the diameter of the screw thread which attaches it to the top plate that any load applied to the lamp arm when adjusting its position, generates many times that stress in the area of locking nut holding it in place. Because of that stress in such a small area, it is suggested that the top plate be particularly strong. A strip of laminate flooring material is very tough and being only 7 mm thick, it is not difficult to work with, so cut a strip to run across between the two end pieces like this:

![Diagram of top strip]

The objective here is to enclose the batteries so that they cannot move, nor can any individual AA cell move out of position. The laminate flooring strip will be used face down as the underside is normally a conservative and attractive matt finish which is particularly suited to this project.
10. It is much easier to work on the laminate strip before it is attached in place, so we will drill the holes for the lamp column and the variable resistor, and cut out the rectangular holes needed for mounting the two rocker switches. In the UK, the rocker switches and variable resistor look like this:

![Rocker Switches and Variable Resistor](image)

The switches need a rectangular hole of 13 x 19 mm, while the variable resistor needs a 10 mm diameter circular hole and the lamp shown also needs a 10 mm diameter hole. Hold the laminate strip in place and mark the locations carefully, making sure that each item will not foul anything underneath before cutting out the various apertures. Slide the knob on to the shaft of the variable resistor and note the length of shaft inside the knob. Cut the shaft, leaving that same length of shaft remaining. Attach the variable resistor and switches to the laminate strip and slide the knob on to the remaining variable resistor shaft. The skirt of the knob should now be close to the surface of the laminate strip and a V-shaped piece of material can be glued in place to give a reading point for the scale on the knob.

11. If a commercial lamp is being used, then it needs to be taken apart now and prepared for this project. The base is removed, the bulb holder is removed and two wires are fed through the remaining shaft so that the LED arrays can be fitted. A circular disc of any kind of rigid material is cut, the diameter being slightly less than the diameter of the mouth of the lamp. Four or five LED arrays (depending on your choice of numbers) are glued to the disc and wired up in parallel with all of the plus wires connected together and to one of the wires feeding through the shaft of the lamp, and all of the minus wires connected together and attached to the other wire passing through the column of the lamp:

![LED Array Diagram](image)

This disc is then eased through the mouth of the lamp shade where it sits about 10 mm below the rim of the shade due to the taper of the shade. Position the disc so that it is square on to the rim of the shade and glue it in position. If frosted plastic is to be used, then mark the sheet around the rim of the shade and cut out the resulting circle, drill some ventilation holes in it although the LED arrays always run cold, and glue the frosted plastic disc to the rim of the shade.

12. Connect the wires to the switches and variable resistor mounted on the laminate strip, and then position the lamp in its hole and fix it in place by tightening one nut. There are two nuts but I have found the locking nut to be less than adequate, so epoxy the tightened nut to the remainder of the screw thread as that keeps the nut securely in place and yet allows the lamp to be rotated quite easily.

To make construction easier, before placing this laminate strip in place, if a separate On/Off switch is being used, then make the connections shown here:
If a variable resistor with an integral On/Off switch is being used, the these connections become:

The 22K fixed resistor (colour bands red/red/orange) is connected to one of the outer tags of the 22K variable resistor and wire “5” is connected to the other end. I suggest that all wires coming off this panel are at least 200 mm (8-inches) long. A separate wire “4” is connected to the centre tag of the variable resistor, and the third tag is connected to the On/Off switch as shown, and when making the connection to the switch, also connect another wires to that same tag. The extra wire is run across and connected to the top tag of the “boost” switch along with another wire “3”. The wire connecting the switches is run close to the outer edge of the laminate strip so that it will clear the battery packs, as there is very little clearance past the batteries in order to hold them tightly and prevent them moving. The negative wire of the LED arrays is connected to the centre tag of the “boost” switch and another wire “1” is taken out from that central tag. When connected up as shown, there will be six wires coming out from the laminate strip and I will refer to these wires by the numbers shown above, so it might be worthwhile actually tagging those wires temporarily with those numbers.

13. If inclined, apply some glue to the variable resistor and switches (on the underside of the laminate strip) but do not epoxy the strip in place until the final connections have been made and the circuit confirmed to be working, including the solar panel charging the batteries.
14. The final connections which need to be made are:

a. The non-striped end of the diode is connected to the Plus wire “7” coming from the solar panel and the Plus wire of the three sets of batteries are connected together “9” along with the striped end of the diode and one end of the fuse (if no fuse is being used, then wire “6” is connected directly instead of to the other end of the fuse). A fuse rated at 1-amp would be suitable as the working current should only be one sixth of that:

b. Remove the insulation from the Minus wires coming from all three battery packs and twist them together (“10”). Connect wires “2”, “5” and “8” to this collection of Minus wires and solder them together make a solid joint, and insulate the joint with duct tape, epoxy, or any other robust form of insulation:
c. To complete the wiring, the three remaining wires are connected to the two transistors like this:

Please be aware that transistors are heat sensitive and so soldering transistor leads needs to be completed quickly and where possible, the transistor lead held in a pair of pliers while the solder joint is being made and when it remains hot, as the pliers diverts the heat away from the transistor.

The desk lamp is now ready to be tested.

15. If the light goes on and off when the On/Off switch is operated and the light intensity alters when the variable resistor knob is turned, and if the light level increases when the “boost” switch is closed, then all is well and the laminate strip can be epoxied into its final position. If the desk lamp does not operate as it should, then follow the test procedures below, until the desk lamp is fully functional and then continue with step 16.

16. Epoxy the laminate strip in position and glue four short lengths of timber in the corners. These lengths of timber should reinforce the joint between the four pieces which form the housing and the solar panel backing sheet, and they should stop off 6 mm short of the outside edge so that they both support the final piece as well as holding it in place.
17. Connect a voltmeter across the LEDs and rotate the knob of the variable resistor to get 9V across the LEDs and note or mark the reading on the scale attached to the knob. This is the initial setting for the knob when starting with a fully charged battery.

18. Finally, insulate the transistor circuitry with tape, plastic or whatever method suits you and secure it in place with a little adhesive to make sure that the wiring does not break if the unit is moved a lot. Then, a strip is cut to close the box and screwed at the corners using woodscrews or bolts:

The gap between the two rocker switches provides an easy gripping point for carrying the unit from place to place.

While this solar desk lamp can be built this way at quite reasonable cost even with one-off prices on individual prices, a really major improvement is achieved if they are being manufactured, especially if made in China. Firstly, all the effort of making the housing disappears as a cheap custom plastic case does away with all that time and effort as the solar panel has its wires connected, fed through the existing hole in the case and then the panel is just pushed into place. The battery packs are then assembled and pushed into place, the circuit connections made and the case clicked closed on its own or held in place by self-tapping screws. The component prices drop enormously with bulk purchasing, reducing the not unreasonable one-off price by a major factor, especially since wages in China are very low by our standards. The result is an attractive, useful product with a very large market and a unit price capable of taking full advantage of that large sales base.

Test procedures:
If the unit does not work straight off, then step-by-step tests are needed to locate and fix the problem. These are simple, common sense tests. If you do not have a voltmeter, then it is worth purchasing one as they are now very cheap.

1. We need to confirm that the battery has the electrical power to run the lamp, so open the “boost” switch “SW2” and connect a voltmeter as shown here:
This connects the meter directly across the battery and so the meter should show some realistic voltage around the 12V mark. If it doesn’t, then lift out one of the battery holders and check that the batteries are charged and confirm that the fuse has not blown. If the fuse has blown, then it will because of excessive current, probably caused by a direct short-circuit where the battery Plus is being connected directly to the battery Minus. Check the wiring from the battery to these two points until you do get a sensible voltage reading.

2. Next, connect the meter like this:

and confirm that the voltage appears and disappears when you operate the On/Off switch. If it does not, then it is highly likely that your connections to the two switch tags are touching and stopping the circuit being switched off. If that is the case, then adjust one of the connections to cure the problem and leave the On/Off switch switched On.

3. The next step is to connect the meter like this:
The same voltage reading should be seen. If it isn’t, then the wiring between the two switches is almost certainly defective and needs to be corrected.

4. Now close the boost switch, and the light should come on at full intensity because the transistors are being bypassed and the battery connected directly across the LEDs. The circuit is then:

If the light does not come on brightly, then check the wiring around this path – battery Plus – fuse – wire “6” - On/Off switch – boost switch – wire “1” – LEDs Positive – LEDs Negative – battery Minus (wire “2”).

5. When the boost switch circuit is working correctly, turn the boost switch off and check the operation of the transistors. First, use a screwdriver to short-circuit between the Collector and Emitter of the TIP3055 transistor:

This should have exactly the same effect as closing the boost switch but it is testing your wiring connections to the power transistor and simulating the TIP3055 being switched on fully. If this does not produce the full light output, then you need to check (visually) the wire “1” connection between the centre tag of the boost switch and the Emitter of the TIP3055 transistor. Also check the connection between the Collector of the TIP3055 transistor and the top tab of the boost switch as one or both of those connections has to be faulty if the boost switch works when you switch it On.
6. When you have corrected the wiring and short-circuiting between the TIP3055 Collector and Emitter turns the light on at full brightness and the light-level control variable resistor is still not controlling the light level, then short-circuit between the TIP3055 Collector and Base:

This bypasses the BC109C transistor and should produce the maximum light level. If it does not, then the TIP3055 transistor is defective. This is highly unlikely as the TIP3055 is enormously robust and can survive all sorts of mishandling. However, if this test definitely fails, replace the transistor without connecting its Base and confirm that the new one switches the light on fully when you short-circuit the Base to the Collector. Then connect the BC109C and repeat the TIP3055 Base to Collector short-circuit test to confirm that it is still working with the BC109C in place.

7. If the light-level control still does not work, then short-circuit the BC109C transistor’s Emitter to its Collector:

This checks the wiring between the Emitter of the BC109C and the Base of the TIP3055 (shown in blue in the diagram above). If the light comes on at full brightness, then the wiring is okay, otherwise, correct that connection.

8. Now we test the operation of the BC109C transistor. Turn the light-level control knob down to its minimum and short-circuit the BC109C Base to its Collector:

With the short-circuit in place, the light should be fully on and with the short-circuit removed (or if its base is short-circuited to its Emitter), the light should be fully off. If this does not happen, replace the BC109C transistor and repeat the test.

9. If the light-dimming control still does not control the light level, then the wiring of the variable resistor has to be suspect, so connect your voltmeter like this:
This is making a connection between the negative line and the slider of the variable resistor, and that should allow the slider to adjust the voltage fed to the BC109C transistor:

This is the test and unless there is a major problem with the resistor “R”, the variable resistor “VR” or the transistors short-circuiting the slider of the variable resistor, your voltmeter should show your full battery voltage when turned up as high as possible, and an evenly falling voltage to around half that voltage at the other end of the variable resistor shaft movement.

If this does not happen, then you need to check over the wiring connections for the variable resistor, fixed resistor and connection to the base of the BC109C transistor.

Components for home-build:
1. One 10-watt, 12-volt solar panel.
2. Thirty AA-size, 1.2V NiMh batteries with a capacity near 3000 mAHr if possible.
3. Three AA battery boxes each holding 10 batteries.
4. Three battery clip connectors to fit the battery boxes.
5. One 1-amp diode type 1N4007 or similar.
6. One 22K Linear variable resistor and graduated knob to fit the shaft diameter.
7. One 10% quarter watt (or higher rated) 22K resistor (colour bands red/red/orange)
8. One BC109C transistor.
9. One TIP3055 transistor.
10. Five G4 LED arrays.
11. One desk lamp (optional)
12. Two rocker switches.
13. One fuse holder (of any type) and a 1-amp fuse.
14. Ten metres of insulated, stranded wire rated for 1-amp or higher current.
15. Rigid sheet material 6 mm thick (possibly MDF).
16. One small off-cut of laminate flooring 85 x L (typically 337) mm
17. Adhesive.
18. Rubber feet or soft material for the underside of the desk lamp.

Notes:

Rocker switches are generally cheaper as the Change-over version with three switch tags, and so these have been shown. For this design, only On/Off action is needed. Press the “1” end of the rocker down, and the two contacts used are then the two farthest away from the “1”.

The TIP3055 transistor is the more recent version of the 2N3055 and is a particularly good transistor for this application being much easier to connect to. While the TIP3055 is strongly recommended, other power transistors may be used. No heat sink is needed if the transistor can handle 8 amps or more (the TIP3055 can handle 15 amps and 90 watts).

The BC109C transistor has a very high gain between 200 and 800, which is useful in this application, but a major advantage of it is that it switches off fully with pretty much zero leakage current, while I have some of the very popular 2N2222 transistors which don’t switch off properly at all and so are effectively rejects. Most alternative transistors are highly inferior to the BC109C and so, if it is not readily available, then it is worth ordering.

The 1N4007 diode is the cheapest readily available diode. It is rated for 1000-volt operation which is of course, of no interest here and so the lower voltage 1N4001 through 1N4006 diodes are perfectly suitable although slightly more expensive as they are less popular. While one diode is shown in this document, people who are expert in electronics are inclined to use three connected in parallel as that passes current more freely. That would cost an extra 6 pence at 1-off prices in the UK.

Some people are really put off by electronics of any kind, so here is a version of the solar desk lamp which effectively, has no electronics at all:

![Diagram of solar desk lamp with On/Off switch]

The only control on this version is the On/Off switch. As we no longer have any control over the voltage applied to the LED arrays installed in the lamp shade, and since that voltage controls dramatic changes in current draw, we need to reduce the number of 1.2V NiMh batteries from ten to seven. It is a matter of choice whether you use three or four sets of seven batteries. If 10-battery battery boxes are used, then a wire can be soldered across the gap left by the three omitted batteries.

The general construction is the same as before, with a rocker On/Off switch being installed instead of the variable resistor. As with all of these solar units, the important thing is to switch the light off when it is not in use, to avoid the next charging session being hindered by unwanted current draw through the light. The general layout of the unit can be the same:
There are other variations which can be low-cost and very versatile. For example, instead of connecting the three battery packs together, they can be kept separate from each other, individually housed with the same circuit, each driving one of the LED arrays:

---

Here, three identical units are charged from the solar panel, which can be any size or wattage, although a ten-watt panel would be considered to be the minimum for daily use. Each unit is in effect, just a wide-beam, high-intensity, high-capacity solar torch which can be dimmed and which will stand securely when unsupported. It has the advantage that the units can be constructed one at a time, and if necessary due to time constraints, or perhaps, very poor daylight, just two or even one unit can be charged from the entire solar panel output. If manufactured and sold, then the units could be sold separately, allowing a lighting...
system to be extended and improved when additional funds become available (or when the user has tried one unit and discovered how effective it is). Each unit is easy to understand and use:

A built unit of this type looks like this from the front:

and like this from the back:
While these particular units have just one of the LED arrays each, tests run since that construction show that with manual dimming control, two LED arrays per unit would be more satisfactory. Also, if the second LED array is mounted on the side of the box, then the lighting angle increases from 160 degrees to 250 degrees which should be helpful for indoor lighting of a room. The units could, of course, be used in different rooms simultaneously and there is the option of carrying one around for lighting anywhere. Again, the construction is very simple and the same circuit as for the desk lamp shown above, can be used in each box.

If good-quality NiMh AA-size batteries are used, each of the mobile units is capable of providing good light for eight hours, which means that if it gets dark at 4 pm (16:00), lighting is available until midnight as a minimum, at which point in time, the user should be going to sleep.

-------------

If a very powerful single source of lighting is needed, it is possible to use a larger solar panel, or for a more compact unit, two of the 12-volt 10-watt panels shown above. The arrangement can use the same simple manual control of lighting level and the same booster switch for even greater lighting for a few minutes. The arrangement can be like this:

When closed over, the face of solar panel P1 faces that of solar panel P2, protecting both when the unit is being carried.
An early prototype of this style of construction with the panels open, looks like this:

A magnetic catch is used to hold the hinged panel securely closed when the unit is being carried and a small flap is attached beside the magnetic catch to overcome the slightly excessive looseness of the hinges. The unit does not need to be as deep as this experimental model was made.

The front view of the unit, ready to receive the frosted plastic cover for the LED arrays, looks like this:

The underside of the unit is covered with a soft protective layer to ensure that it does not scratch any surface on which it is placed. In order to avoid the need for overcharging circuitry, this unit has six battery packs and so, having ten LED arrays, the duration of lighting is about the same as that of the desk lamp, although obviously, the light output can be much greater. With the greater lit area of ten LED arrays, a lower actual current can be used while still providing a good level of lighting.
With fully charged batteries switched to the ‘boost’ setting, this unit puts out more light than a 100-watt incandescent bulb powered by the mains. Tested in daylight, that looks like this:

Let me stress again, that these units are not difficult to build and they don’t call for any great knowledge of electronics.

Alternatives:
While the systems shown above are effective and reasonable cost, it is possible to make them more efficient. With battery packs of ten NiMh 1.2V AA cells, when fully charged, we get more than 13-volts, when we actually want 9-volts for effective lighting. We get this by using two transistors to drop the voltage down to 9-volts. The current flow is about 135 milliamps and so, the voltage drop of 4-volts at that current flow is a power loss of 540 milliwatts, which is a significant percentage of the power used to generate the lighting.

By arranging things in a different way, we can reduce that power loss very considerably, IF we don’t mind the user being involved in controlling the lighting level. We could do this by tapping into our 10-battery pack and using an extra 3-way switch which allows us to start off with 8 batteries and when the voltage starts to drop, switch to 9 batteries as the extra fully-charged battery would make a major difference to the lighting. Then when the voltage of the 9 batteries starts to get low, the tenth battery can be switched in:

Whether or not this is worth doing is a matter of opinion in spite of the longer and/or brighter lighting. With 8 batteries in use, the power saving is 350 milliwatts and with 9 batteries the power saving is 175 milliwatts. The lighting power is 1215 milliwatts, so these represent 29% and 14.5% of that power. If it is decided to use this arrangement, then the battery boxes can be tapped with additional output wires connected between batteries 8 and 9 and between 9 and 10.

The operational sequence would be:
1. Eight batteries switched in: variable light control.
2. Nine batteries switched in: variable light control.
3. Ten batteries switched in: variable light control.
4. Boost switch closed: fixed lighting level as batteries discharge to their minimum level.

Each of these switched levels gives a new lease of life to the lighting system, but it does require the intervention of the user, although that intervention is very minor.

It does not matter whether it is the Plus end of the battery chain, or the Minus end which is switched. The way that the battery boxes are constructed, actually make it more convenient to make the two extra connections at the Minus end of the stack:

Medical usage

The applications of the solar desk lamp shown above are intended for home or office use. There is one other serious lighting requirement and that is for doctors working in isolated rural areas, far from any electrical grid but also, very far from fuel supplies for running a conventional generator which is the only known option for most of them. For example, it can take a doctor two days of travelling to get some more generator fuel. If we apply a slight alteration to the desk lamp and sacrifice the long period of lighting, we could boost the light output from 1000 lux right up to 2,700 lux for an hour or two of very brightly lighting. I can see no reason why two or three of those would not give more than adequate light for night time emergency surgery when placed on stands or suspended from the ceiling. Being self-contained and mobile, an assistant could hold and aim one to illuminate exactly where the light is needed.

The basic solar desk lamp operates off seven 1.2V batteries in series. Eight batteries in series would boost the light level to 1730 lux at the cost of much higher current draw and reduced period of lighting. Increasing the batteries to nine would raise the light level to a massive 2,700 lux with a current draw so high that there might only be lighting for perhaps one hour, but that doesn’t matter in an emergency where a life could be saved. To achieve this emergency level of lighting all that is needed is an ordinary 4-way rotary switch which replaces the On/Off switch as it can do that job as well, otherwise the construction remains identical. The arrangement could be like this:
360 Degree Lighting for Africa

The desktop lighting unit described above is very effective for lighting in cold areas where houses have windows with glass in them and where the roof does not project much beyond the house wall. However, housing style is very different in places like Africa where strong sunlight is experienced all year round and so a house roof is likely to project well beyond the wall in order to give improved shade for outside seating.

Anna Brüderle’s “Solar Lamps – Africa” marketing research published by GIZ GmbH Uganda, has raised many previously unknown facts which should result in physical design changes. To date, I have produced three solar prototype lighting units, but these have been based on recharging using light coming through a glass window. That is not really possible in the African environment surveyed, as it shows:

1. Using a solar panel indoors is not possible due to lack of windows and major roof overhang.
2. Using a solar panel light being recharged outdoors is liable to have it stolen.
3. Using an outside solar panel connected by a wire is liable to damage and/or child injury when at play.

The survey-area lifestyle has the following characteristics:

1. Seven people living in one building is not unusual and so 360-degree lighting is preferred.
2. The kitchen is normally separate and has no windows and yet needs meal-preparation lighting.
3. Burning a fuel for lighting is liable to cause poor health from the fumes produced.
4. Child education is hindered by lack of lighting.
5. Light usage is usually 3 or 4 hours at night plus 2 hours in the morning.
6. Tests with 100 lumen lighting level have been considered to be satisfactory.
7. Lamps are normally placed on the dining table during meals and hung from the ceiling at other times.
8. When carried outside, a narrow forward lighting arc of say, 90-degrees is preferred for safety.
9. Units with variable lighting levels are preferred but why is not specified – probably light duration.

In these houses, there can be internal walls which do not reach the ceiling so that light in the central room spills over into the additional rooms.

These features call for a lighting unit which is:

1. Able to provide 360-degree illumination.
2. Able to give a restricted 90-degree lighting arc when used outside.
3. Stable when standing on a horizontal surface.
4. Able to be carried comfortably.
5. Able to be suspended from a ceiling.
6. Able to provide considerably more than 100 lumens for the lighting periods used.
7. Is cheap enough to be bought.
8. Is very robust.
9. Is free of any glass components as hurricane lamp accidents are mainly cuts from broken glass.
It is possible to design a lamp which meets all of these requirements although low cost is the most challenging requirement. To meet the user's needs, it might be possible to use a housing like this:

![Image of a lamp design](image)

The triangular shape makes for easy construction and is very robust from an engineering point of view. It also cuts down the number of faces needed for 360-degree lighting to just three. The versatility is increased greatly if two faces are hinged:

![Diagram showing hinged faces of the lamp](image)

This arrangement allows two faces to be aligned with the fixed front face, giving all horizontal lighting in one direction which is a very, very bright arrangement. The two faces can be moved further around to give the wanted narrow forward beam for walking outdoors. If desired, the lighting level can be controlled by making the On/Off switch a three-pole four-way rotary switch:

![Diagram showing rotary switch for lamp](image)

This arrangement gives Off, One panel, Two panels and Three panels of illumination, but it could also be that instead of switching off an entire panel that the switching illuminates one LED array per panel, two LED arrays per panel and three LED arrays per panel.
If ordinary 10-battery holders are used, then the lamp housing can be made more compact as the corners of the triangle are not needed. The battery packs fit in like this:

Giving a compact hexagonal shape which is strong and has the same lighting capability. The sides extend above the top and below the base so that the unit can stand on a flat surface either way up. The hinges need to be stiff so that they hold their position when set to the desired angle.

The addition of a simple hinged flap to the base allows a tilted option which imitates the downward lighting style of a desk lamp:
The Chinese LM2587 DC-DC converter from h-quality_electronic selling on eBay in October 2015 for £3.17 including postage, has COP>1 performance:

Ten LED arrays are brightly lit by it with just a 2.88 volt input. Measurements using three NiMh batteries connected in series, indicate an input of 800 mA at 3.33 volts (2.664W) driving the 10-LED array displays with 389 mA at 10.3 volts (4.01W) which is COP=1.5 and has the advantage of reducing the number of batteries needed for good LED array lighting. In practice, four batteries in series are used. This converter also charges ten NiMh batteries from 10.5V to 13V (falling eventually to 12.5V) in just 30 minutes at 50 mA current draw.

A very useful addition to this sort of lighting system is using a simple constant-current circuit to control the current draw and give a steady, unchanging lighting level throughout the entire period of illumination. I have found that zener diodes do not perform well when supplied by batteries with gradually falling voltage. A much better method of getting a reference voltage is to use ordinary diodes and use their normal voltage drop as a reference.

As the transistor TR1 has a voltage drop across it’s Base - Emitter junction equivalent to the voltage drop across one diode, we use two diodes to create a voltage reference level and so maintain a 0.7 volt voltage drop across resistor R2. R1 is chosen to give about 3 milliamps of current flowing through point “A” and the diodes can be any silicon type, perhaps 1N4148 diodes. The transistor needs to have a high gain and be able to handle the desired current flow through the load. A 2N2222 transistor appears to work well in this circuit. Resistor R2 is chosen to give the desired current flow, forcing that current flow through the load (provided that the battery can supply that current). The load can be the DC-DC converter shown above and the battery voltage can quite easily be 5 volts. If there is concern about the power handling ability of a 2N2222 transistor, then two or more can be used in parallel with the Bases connected together, the Collectors connected together and the Emitters connected together.

It may well be possible to charge a second battery pack when the lights are on and then, when the lights are switched off, to use that second battery to recharge the main battery pack. Alternatively, a 10 watt solar panel, as used with the desk light, can be used to recharge the battery pack through a length of low-resistance cable and a plug and socket. There is also the possibility of providing a USB socket for
recharging mobile phones. It should be able to supply 5 volts at 500 milliamps and draw no current when not in use. The user should be alerted to the fact that extensive use of the USB socket may reduce the power in the battery pack used for powering the lighting.

The prototype worked very well indeed when carried out of doors in a totally unlit and unfamiliar place. If the suspension cord is made longer and an additional hook is provided near the base, then the unit can be suspended indoors with all of the LED arrays facing downwards, which with their 160 degree angle of illumination would give excellent 360 degree lighting.

**Manoj Bhargava**

Throughout this ebook there are many designs for generating electricity, getting pure water and my websites also have some information on health issues. These things have all been approached from the point of view of you, as a single individual, doing something in spite of having very limited finance, workspace, tools and skills. There is a very interesting and inspiring video at [http://billionsinchange.com/film](http://billionsinchange.com/film) which describes some of the work of Manoj Bhargava and his colleagues. Manoj produced a drink called “Five-hour Energy” which became a major commercial product, leaving Manoj with four billion US dollars. That has given him the freedom to use his common sense and practical attitude to start to deal with the major issues of half the population of the world – free-energy, clean water and health improvement. With his finance, he works with much larger solutions to these problems and some of his designs are most interesting. He avoids any mention or use of unconventional systems.

For the provision of electricity, he proposes the use of an adapted bicycle which spins a generator and charges a battery which can slowly charge mobile phones and provide lighting. It is said that one hour of pedalling can produce 24 hours of (low-power) electricity. His design looks like this:

![Generator](Energy.png)

This is the generator which is spun by belt gearing from the pedals. The wheel with the large rim forms a flywheel and although he does not mention it, the flywheel causes an energy gain. The basic build looks like this:
the cyclist pedals in a reclining position and the belting drives the gearing which spins the generator shaft:

The design produces a good deal more electricity than I would have expected:
These metres show more than 100-watts being generated. However, production cost is always a major factor in these things, especially since the people who need them most are the people with least money. Perhaps a version which is driven by an existing bicycle might ease the situation – that method is already used for some exercise equipment. Another factor which might be missed by designers is the fact that the people needing this equipment are labourers and will be tired after a long, physical working day. Of course, the pedalling would be less effort for them due to their much higher muscle strength. The addition of two small motors like Chas Campbell does, would probably make the design self-powered and do away with most of the construction – pedals, belts, seat, etc.

In August 2016, Manoj found that his plans for shipping completed bicycles into India from his newly-built factory in Singapore, was effectively blocked off by import restrictions. So, He is building a factory in India and he expects production there to be implemented in 2017. He also found that a number of changes needed to be made because it is primarily women who are free to do the pedalling. The changes include a reduction in size to allow for smaller people, a chain guard to protect long clothing, a battery, low-voltage setting of 11.5 volts, a reduced gearing to allow easier pedalling, and finally, a detachable battery so that the power can be mobile. The main application is lighting, although I suspect that the lighting efficiency is not as high as the 1000-lux for just 1.5 watts of the LED designs shown in the previous section of this chapter.

**Low-cost Cooling Systems**

When most people think of air-conditioning systems they think of large pieces of equipment which are expensive to buy and expensive to run and which are mounted in one fixed location. While those systems are certainly effective (although, often noisy in operation), there are other ways of improving living, travelling and working conditions. Ways which are not very expensive to buy and which are not expensive to run. Many people have made effective air coolers and shared their designs using web videos, and I should like to thank them for showing what they have achieved.

Simple cooling systems can use two different methods of operation. One method is to use ice which has been produced using an ordinary refrigerator or freezer (those being very common in places where air-cooling would be considered an asset). Another method uses the well-known principle that when water evaporates, it draws heat from its surroundings as part of the process.

The general idea is to cool some air and then use a fan to blow that cooler air to where it is most effective for the user. Typically, cooling is most needed inside buildings and inside vehicles. Inside buildings, mains electricity is often available. Inside vehicles, twelve-volt or similar levels of DC power are generally available. In both locations, a solar panel (possibly aided by a car battery for night time operation) can operate a useful system.

What we are talking about here, is a small system which will not be as effective as a large commercial unit, but yet is something which can make a great improvement in a small area. Something which does not seem to occur to many people is that you can have more than one of these units operating in a room or vehicle.

While I am delighted that people have shared their simple designs on the web, they usually assume that the components which they have used are available to everybody, and that is very much not the case as the items which are readily available locally vary enormously at different places around the world. For that reason, I should like to discuss the basic principles used so that when any chosen design uses something which is just not available locally, you can choose a suitable alternative which is readily available locally at low cost.

Let us start with indoor cooling. The unwanted heating comes mainly from the sun shining in through windows, and from heat leaking in through the walls because the outside of the walls is being heated by sunlight falling directly on it or by hot air flowing along the outer surface of the wall. Of these two main sources of indoor heating, the sun coming through the windows is generally the greater source of heat.

If a room has one or more windows facing the sun and one or more windows which do not face the sun, then a first step might be to use shiny silver-faced insulation cut to exactly fit the windows through which the sun shines. Curtains can generally hold the insulation in place on their own, but if that is not convenient, then a few small pieces of adhesive tape work adequately and can be used again day after day. The outer shiny layer reflects most of the sunlight back out of the room. The outer surface of the insulation sheet heats up as not all of the light is reflected, but the insulation layer stops most of that heat actually entering the room, resulting in a major improvement in the room temperature, although the light level is reduced considerably as
well. This is suitable for people living in apartment blocks where there is no convenient access to the outside of windows.

In the case of people living in bungalows or other low buildings, the use of shade should not be overlooked as it is a very effective way of reducing temperature. This effect is even very noticeable in cooler countries on sunny days as there is a very marked effect driving down a road which has large trees on the same side as the sun. With the car windows open, there is a very considerable drop in temperature when the car enters the area shaded by the trees. I am not suggesting growing trees to give shade as that is not convenient for most people, but a simple overhang or a temporary or retractable awning may be possible to block direct sunlight from coming in through the windows. An awning or overhang has no running costs.

Let’s take a look at one of the systems shown on the web. This one is being used to lower the temperature in a house with a floor space of 1,700 square feet (158 square metres) and the video presentation is at https://www.youtube.com/watch?v=6ScZiMiva9M and deals with a house where the outside daytime temperatures exceed 100 degrees Fahrenheit (38 degrees Centigrade), making the indoor temperatures uncomfortable. With his cooler running and the outside air 90F (32C) the air entering the house is 69F (20.5C) which means that the warmest place in the house is around 75F (24C). As hot air rises, the hottest place in the house is the highest point and very sensibly, he has mounted an extraction fan which pulls the hottest air out of the house and pushes it into the attic (which is open to the outside and so vents to the outside air).

For the system to be effective, all of the windows and doors are kept closed except for the one which has the cooling system mounted on it. This blows the hottest air out of the house and at the same time, draws fresh air in through the cooling system. You can see the attic fan mounting here:

![Attic Fan Mounting](image)

The entering air comes in through a large window which has evaporative pads clamped to the window frame by a simple timber mounting system:
The pads are kept wet by droplets of water pumped to the top of the window by a small submersible pump submerged in a large plastic storage box filled with water:

Excess water is returned to the reservoir by two short lengths of plastic guttering as shown here:
The particular fan and pump used draw a total of 120 watts, and so as one “unit” of electricity is 1000 watts for one hour, running the system all day and night is a power usage of 120 /1000 x 24 = 2.88 Kilowatt-Hours per day. The construction costs in America in 2013 were about US $60.

If solar panel power is to be used with a lead-acid battery, please remember that the battery is only 50% efficient, which means that it will only return half of the current that you put into it. Also, please remember that solar panels are rated for bright sunlight shining directly on them at exactly 90-degrees to the panel and in normal operation, the panel output is far less than the retailer's claimed wattage, not to mention the fact that the panel will only be operational during daylight hours. As against that, many such installations do not need to be run day and night and so solar operation may be quite economical. Also, 120 watts is a large amount of input power and could almost certainly be reduced for smaller installations.

It is not unusual for the cooling of a single room to be satisfactory in many situations. For this, using a very small self-contained unit is often considered to be adequate. These units generally use a fan from an old computer, typically, running on 12-volts and drawing about 4-watts. For the cars which still do not have air conditioning, a fan of that type is very convenient as it can run directly off the ‘cigarette lighter’ socket or from a direct wire connection through a fuse, to the car battery. For indoor use, any tiny 12V mains power unit can power the unit for minimal cost.

These units have been made in all sorts of shapes and sizes and by all accounts, do very well when easing excessive heat. This very small unit uses a 12V 3.6-watt computer fan blowing air into a small insulated box containing ice and can be seen at https://www.youtube.com/watch?v=6pwXvXZr1A4. In spite of being rated as a 12-volt unit, the fan can actually run on a low-power USB socket. Cold air exits from the holes drilled beside the fan:

This one is at https://www.youtube.com/watch?v=Wf2Zhu4Fmzo uses a 21-inch (535 mm) square box fan with a simple evaporation system attached to it:
This one at https://www.youtube.com/watch?v=gawOWyhtthU also uses a computer fan:

This little radiator is called a Heater Core. All cars have one inside the dash. They’re around $20 (new) from car parts stores.

This one at https://www.youtube.com/watch?v=LiS0W5peFBk uses a Wal-Mart battery-powered fan which means that with a solar panel to recharge extra rechargeable batteries when the unit is in use, the unit could be very, very cheap to run. An ordinary ice-box is used, so perhaps cold drinks are a possible additional option:
Also using an ordinary ice-box the https://www.youtube.com/watch?v=N1NwXBpShQ unit has a wooden push-fit lid and uses a car fan:

The unit at https://www.youtube.com/watch?v=NUhs_1puHk0 is intended for use inside a car, although obviously, it could easily be operated inside a house using a small 12-volt mains unit. The preferred coolant is 2-litre plastic bottles filled with water which has been frozen solid in a freezer. The builder states that the bottles will cool a car down faster than ice does and the bottles also provide a longer period of cooling than ice can:

The fan is set to blow air into the container and the cold air exits through the four holes drilled around the fan. This design suggests that as a temporary measure, standing some frozen 2-litre bottles in front of an ordinary fan could well provide effective cooling in a room. Using ice or bottles of frozen water is energy efficient as refrigerators and freezers are generally about 300% efficient. That is, the cooling energy is three times greater than the electrical energy used to achieve that cooling.

These are only a few of the many ingenious and simple designs which could make life much more comfortable in conditions which are generally considered to be excessively warm. A little time spent examining these and similar units shown on in web videos should give you confidence to build your own, or if you prefer, to design and build your own simple cooler system.

**Sensible Building**

There is a famous American Architect called Michael Reynolds. He has a very low opinion of conventional housing which he considers to be a "compartment" which is wholly dependent on outside power sources. His opinion is justified. He produces buildings which have been named “EarthShips” by his wife and the name has caught on world-wide.
The objective is to make a home which has no utility bills at all. A building which collects its own water and uses that water several times. Generates its own electrical power. Provides its own heating and cooling. Grows some of its own food, and uses materials many of which have been disposed of by previous owners - vehicle tyres, aluminium drink cans and glass bottles. An EarthShip can be a stylish and comfortable home:

Although, obviously, the overall cost of the structure and furnishings depends on the quality chosen by the owner. This particular EarthShip is one shown in the film "Building Off The Grid" which can be found on the peer-to-peer network, took fifty volunteers four weeks to complete the basic structure and then another team of workers were paid to supply and install the fittings and fixtures.

The structure faces South and has twelve large solar panels mounted along the top of the greenhouse area. Although this picture does not show it, there is a drainage ditch along the back of the property to divert heavy rainwater coming off the protecting hillside behind the property:
The walls of the property are seven feet thick (2.13 metres) in order to allow the use of fairly simple materials and more importantly, to provide thermal mass which keeps the inside of the building warm in winter and cool in summer. There are no significant bills for heating or cooling and normal electrical equipment is run from the solar panels.

The design of the electrical system is elderly and as shown, it requires lead-acid batteries to be replaced about every four years. A smaller system driving DC battery pulse-chargers would provide fast battery charging and the batteries would never have to be replaced. However, this particular house was built using twelve large solar panels. Initially, three were used to provide electrical power during the building period. These were just propped up against the hillside near the battery box which contains control equipment, a battery bank and a mains inverter:

The battery box used during construction is very simple:
The overall design is set up for construction by unskilled workers under the supervision of a few experienced people, but let me point out that this is a Civil Engineering project and so a reasonable level of understanding is needed before you build one for yourself.

For example, the roof spans across the gap between the outside walls. The loading on any support beams increases with the cube of the distance between those walls. That means that if you were to double the width of the room, then the support needed to hold the roof up increases by a factor of eight times!! This can, of course, be achieved, but you really need to be aware of it. In this particular building, the roof is held up by numerous tree trunks which have been stripped and prepared for the job:

These beams are very heavy and are quite capable of causing serious injury if not handled carefully and sensibly. They form the joists which support the roof and there is a gap of about one foot between them, so many of them are needed. They are secured to the top of the wall by steel rods driven through them and on into the wall.
The main construction is with vehicle tyres and about a thousand are needed for the building. Each is filled with earth which is compacted carefully and then they are stacked in a staggered bank and grouted in place using mortar. In passing, most American get confused with concrete products, so to clarify:

1. Cement is a grey powder material.
2. Mortar is a mixture of cement and sand, wetted with water, which sets into a solid. It is normally used to fill the gap between concrete blocks or clay bricks.
3. Concrete is Mortar which has pebbles mixed into it.

Also used in these constructions is adobe which is mud and straw mixed together. Properly made adobe dries into a solid block and is used in hot dry countries as a main building material, but it needs to be waterproofed against future rain unless a temporary structure is sufficient.

The tyres are overlapped in successive rows, forming a stable structure and then grouting is applied between them. The outside is enclosed in an earth bank and the inside is later smoothed over.

This style can be seen at the back door alongside the greenhouse area:
The constructional details can be found in the books by Michael Reynolds “Garbage Warrior”, “EarthShip”, “Comfort in Any Climate”, etc. or full constructional plans can be bought direct from Michael.

Water is collected from the roof, filtered and then held in massive plastic tanks which have a total capacity of 6000 US-gallons (22,700 litres). There are no pumps as all water flows under gravity. Water used for washing is then used for toilets and then on to water plants which grow food.

The positioning of the tanks is important as they have to be just below the roof so that rainwater flows into them under gravity and yet they have to be higher than shower-heads for the same reason (unless a pump is used for showers). A simple filter is used to remove any blown material which finds its way into the water intake.

For all that unskilled people can do most of the work, there are a number of trade skills which are needed – plumber for the piping, electrician for the electrics, engineer for levelling and concrete work, glazier for the double glazing units, etc.
Steel bars called “rebar” are driven into the walls and positioned to the exact height, and a reinforced concrete ring is cast around the top of the walls to give overall strength to the structure, before the heavy tree trunks are put into place.

A nice feature of this style of construction is using coloured glass bottles in walls to allow light through and allow artistic designs to give the impression of stained glass.
When the wall is finished off and the bottles polished, the effect is really good, especially since the glass bottles are effectively free being recycle materials. However, choosing them as part of your living room is a matter of personal taste:

It is quite normal to have conventional styles of construction:
The important thing to remember about this house is that the walls are thick and so have a high thermal mass. The ‘greenhouse’ section all along the South side of the main building forms a heat buffer and water filtration. The roof is seriously effective with a one-inch thick layer of timber with tarred paper covering it, and then eight-inches of polystyrene on top of that and a ridged metal roof on top of that. That is a seriously effective thermal layer. This style of construction is definitely worth considering.

Chapter 15: You Are Being Deceived

Without your knowledge, you were stolen from your parents at birth and automatically became the judicial property of a commercial company pretending to be your government. What you think of as “your” birth certificate is proof of this action. The biggest secret is that your government is a collection of commercial companies whose only real purpose is to take as much money from ordinary people as they can, using unlawful actions. Their sole intention is to keep you poor, in fear and doing whatever they tell you to do.

The Situation in the UK
This is a large subject, so let’s take it step by step and start with people who were born in the UK. I will discuss the position of a typical native of what is called “The United Kingdom of Great Britain and Northern Ireland”. The average person living in this area believes that he is a free person living in a democracy which is governed by elected parliamentary representatives of the people, protected by legal statutes introduced by Parliament and enforced by police officers who are there to ensure your protection where physically possible. Those who are better informed, believe that the Magna Carta signed in 1215 affords them substantial rights and freedoms.

None of that is true. Not a single item.

The inhabitants of this region fall into two categories which are “landowners” and “everyone else”. The term “landowner” is, of course, ridiculous. No human can own land. The only way that you can own something is if you create it from materials which you own, if it is given to you as a gift by the rightful owner, or if you buy it from the rightful owner.

If I state “I own the whole of the planet Mars” it does not give me any genuine ownership of the planet. What has happened on planet Earth is that an individual stakes out an area and says “This is my land, I own it, and I will kill anyone who says that I don’t”. That can certainly frighten most people away from the area, but it does not give the squatter genuine ownership of the land. Consequently, no human owns any land whatsoever, and it is not possible for any land to be bought as there is no previous human owner of the land in question.

Killing a squatter on the land and claiming ownership of that land by right of conquest is farcical. It is true that violent bully-boys take control of areas of land through intimidation and peaceful people dare not oppose them. No human has any more rights than any other human, but violence and the threat of violence have been used to create a notional group of people called “landowners”. Is it right? Is it just? No, of course not, but it is what has happened.

This violent situation resulted in there being two groups of humans in the country. The violent “landowners” called “Knights”, “Lords”, “Barons” or some other irrelevant title, who join together to maintain what they have taken, and then there are the other people who have been intimidated by them, sometimes called “serfs”, whom the landowners feel free to rob on a regular basis through sheer intimidation.

Already, there was a certain degree of deception being practiced by the landowners as they said to the serfs “we will protect you, and in return, you can work for us and pay us to protect you. This, of course, was a complete con, because if it wasn’t for the landowners, there would be no need at all for “protection” from other landowners. And, oh yes, the protection required the serfs to put their lives on the line as part of the “protection” racket.
There was one group of landowners who operated more by trickery than by sheer force of arms. Going under the general title of the “Church” their influence came from telling people that when they die that they would not go to “heaven” if they were not servants of the Church. That technique worked very well and even influenced the head honcho of the landowners - the Monarch who was the ultimate “landowner”. Don’t get me wrong. I’m not saying that it is wrong to worship God, follow a moral code, live an upright and blameless life, but doing that has nothing whatsoever to do with being subject to any human or human organisation.

A point which you have probably missed is that the ‘landowners’ considered the serfs to be sub-human “things” and not people at all. Unfit to, and incapable of, owning land under any circumstances. Considered to be ‘goods and chattels’ owned by the landowners. At that time, “serf” was an alternative word for “slave”.

It is not possible for one human to genuinely “own” another human. Parents do not own the children born to them. They have a duty and a responsibility to nurture them and care for them and ideally, love them, but they do not own them. The weird notion which landowners have that they “own” humans is as false as anything can get. Slavery is another act of violence. Only a very ill-informed person believes that slavery has been ‘abolished’ as it is more widespread today than at any other time in all of recorded history, and it has nothing whatsoever to do with skin colour.

In the well-known year of 1066, another violent ‘landowner’ arrived in England and by force of arms, imposed Roman law on all of England. You will recall that Rome was very heavily into slaves and the slaves had no rights or privileges, no possessions and no protection, in spite of the fact that in reality, every one of them actually had equal entitlement to the rights claimed by their so-called “owners”, both slaves and masters being human beings. So, please understand clearly, that Roman law encompassed the notion of people being called slaves, and owned as “things”.

In 1213, King John was excommunicated and that frightened him so much that he signed a contract with the Pope. The contract is known as the “Treaty of Verona” and it undertook to introduce Rome’s canon law to England, which made Archbishop Stephan Langton, the effective ruler of all of the country. The contract was supposed to give the Pope ownership of all of the lands, people, animals, etc. of all of King John’s kingdom. According to this contract, the Vatican owns all of England and all of the British Commonwealth countries.

This is, of course, a rubbish document. Firstly, King John did not genuinely own any land of any description and never could have. Secondly, King John did not and never could have owned any of the people living on that land. Thirdly, a contract cannot be signed on behalf of a third party, so his signature could never, ever have any genuine effect on the people of the land. If that were not the case, then I could sign a contract on your behalf, guaranteeing that you would pay me a million pounds. It couldn’t happen and if it did, it would be meaningless. The Treaty of Verona contract only applies to the signing parties, to have any effect on the people of the land would require them to be fully informed of the consequences and give their consent to the contract, and that never happened.

In an attempt to be cunning, the treaty was worded so as to make it appear to apply to the direct descendants of both the English monarch and the direct descendents of the Pope, namely, his successors. Personally, that seems highly doubtful to me as that would make it, in effect, a contract between people who have not agreed to it or signed it, and it is by no means obvious how a contract could be binding on people who are not party to it and who have not signed it.

However, just two years later in 1215 the landowners forced King John to sign a contract called the “Magna Carta”. It is highly doubtful that a contract where one of the parties is intimidated into signing, has any actual validity, but that aside, the contract was made under the conditions
prevailing at that time. The landowners, called “Barons” or “Free men” in the document, were insisting on a continuing agreement between them and the monarch. The contract has nothing to do with the serfs who were considered “things” with no rights at all. Today, members of the general public, who are actually the descendants of those serfs, read the Magna Carta and not understanding the situation when it was written, mistakenly think that it speaks of them. It doesn’t. The objective was actually an attempt to strengthen the Treaty of Verona.

This power-play continued in 1600 when a private company was set up. It is still in place today and it is called “The Ministry of Justice” D-U-N-S Number 22-549-8526, Directors: Lord Falconer of Thoroton. Today, all Magistrate Courts are private for-profit companies subsidiaries of this main commercial company and not, as most believe, part of the government of the UK.

The next step came in 1689 with the “Bill of Rights” whose purpose was to make the monarch subject to Parliament. Again, this was introduced with the intention of ensuring that no monarch could set aside the Treaty of Verona and deny the Pope (supposed) ownership of the British empire and all the people in it. The Bill of Rights settled the succession of the crown, creating a Dynasty which has been maintained right up to now. The only powers of a Constitutional Sovereign created by this “Bill of Rights” is to warn, to guide and to be informed, just that and nothing else. In 1701 there was the Act of Settlement to confirm the line of royal succession.

In 1694 a privately owned company called “The Bank of England” was formed. The name gives the impression that it is a government organisation, but that is not the case. Actually, the UK has no government but instead there is a set of interlocking, privately owned, for-profit commercial companies designed to give the false impression of a government. For example, the House of Commons is a commercial for-profit company (number UC2279443). The Labour Party is a commercial company which trades under the name of “Allister Darling MP”. The House of Lords which is the highest court in the land is a private company.

Then there is the United Kingdom Corporation Ltd., formerly known as the “United Kingdom plc”. In passing, anyone who has a National Insurance Number, is automatically deemed to be an employee of the United Kingdom Corporation Ltd. The Company policy of that corporation requires each employee, to pay tax and follow all the legislative rules (“statutes”) of that corporation. Anyone who breaks the rules of the corporation will be disciplined under the legislation of that corporation.

The police forces of the United Kingdom Corporation are all companies which can be seen from their company registrations, and their job is to enforce the rules of the Corporation. Every court in the land is a company. There is a commercial company called the Secretary of State for Trade and Industry, which ceased trading on 4th November 2002 and yet it still operates TV licensing, taking £3 billion per year through it’s subsidiary commercial private limited company called “Consignia (Customer Management) Ltd.”, which is part of it’s group of 35 subsidiary companies.

This continues to a ridiculous level where the company called “The Devon and Cornwall Police” has been taken over by a company called SouthWestOne which is one of a group of companies whose Ultimate Parent Company is IBM, but this Police Constabulary is a public service paid for by the taxpayer and given an annual budget of £256,800,000 taken from members of the public. Isn’t IBM a lucky company to be given £256,800,000 per year to help it run it’s business at a profit!

Equally ridiculous is the Lancashire County Council which was incorporated as a company (IP00666C) in 2002. It’s registered office was 3rd Floor, Christ Church Precinct, County Hall, Preston. It was completely dissolved on 25th January 2008 and all of it’s Assets and Liabilities were transferred on 12th November 2007 to another company - “The Blues and Twos Credit Union Ltd.” whose registered address is Lancashire Police Headquarters, PO Box 77, Hutton, Preston.
If you feel that these things are all straightforward and aboveboard, then I would like you to change a bundle of £3 notes for me, and as well, perhaps you would be interested in buying the Eiffel Tower.

The ordinary people resident in the UK are descended from the slaves called “serfs” and the only protection which they have is the “Common Law”, upheld by a policeman or a policewoman, each of whom receive authority through, and only through, their personal oath of allegiance to the monarch and the monarch’s oath to uphold Common Law. The Police Authority for whom the policeman or policewoman work, actually has no authority itself as, being a company, it cannot swear an oath. Policemen and policewomen have a duty to uphold Common Law and to protect and serve members of the public.

UK Common Law deals with a human causing death or injury to another human, damage to property or acting fraudulently in dealings with others. It is based mainly on the earlier findings of courts and is modified from time to time if it is found to be unjust. Surprisingly, the main corrections are supposed to come, not from judges, but from juries. A jury is the most powerful element in any court of law for they have the power to dismiss a case and even to go against the law. A jury has “discretion” and they can order the judge to find against the law if they believe that in the particular case which they are trying, the law would be unfair, so they adjudicate on both the individual case and on the underlying law. Judges do not always bring this to the attention of jurors.

A system has been set up by the Law Society with the express intention of enslaving members of the general public. They have taken words from the English language and redefined them to create another language called “Legalese”.

The translation for this language back into English is given in the publication “Black’s Law Dictionary”. The average member of the UK public is generally unaware that Legalese is being spoken and that what sounds like a simple, innocuous question in English, is actually a highly-loaded and underhand attempt to cause him both distress and unwarranted financial loss.
The objective of a lawyer is to make money for his commercial company and particularly for himself. To help them, lawyers have set up a system of “statutes” which are supposed to have the force of law, but which, being crafted by their sister parliamentary commercial companies, are not the law. These things are “statutes” and they don’t actually apply to humans. Being wholly invented “legal” devices, they only apply to other “legal” things, which are essentially, just pieces of paper. Since a piece of paper does not own any money or goods, to get any real financial gain from their actions, they need to trick a human into taking on responsibility for a piece of paper. If they succeed in this, then they can demand money from that piece of paper and get the unfortunate human to actually provide the money even though the fictitious legal charges do not apply to that human.

Meet Your Strawman
In order to do this, they have to persuade the human to enter into a contract with them, agreeing to pay them money, essentially, for nothing in return. Their main trick is creating a fictitious legal identity using the name of the human. This is done by creating a “Birth Certificate” in the same name. Most parents mistakenly believe that they have to register the birth of their child, which is actually not a requirement under the law (which does apply to humans, as opposed to “statutes” which don’t apply to humans).

In spite of their mistake, the fictitious legal “person” produced by creating the Birth Certificate document, the human who has the same first and last names as those recorded on the birth certificate, has no actual link to that document unless he can be tricked into agreeing to be linked to it.

All of the company statutes such as Income tax, Council tax, television licence, parking tickets, and the like are not being charged against a human but instead are being charged against the legal fiction with nearly the same name, sometimes called a “strawman”. If the human refuses to agree that there is a link, then the invented charges collapse and the human is left alone until the next attempt to fool him. At this time there is a very nicely produced video http://www.youtube.com/watch?v=ME7K6P7hiko which explains the fiction of the strawman legal document.

The people who work for one of the commercial companies called Police Forces have two entirely different roles. As a policeman or policewoman they have a duty under common law to protect members of the public, and serve them by upholding common law. They have an entirely different role as a police officer dedicated to making money for their employer by imposing all kinds of fines, charges and penalties under a series of statutes invented by their sister companies. These financial penalties do not actually apply to humans, and so trickery must be employed in order to con the human into undertaking to pay when there is no requirement for the human to do so.

A Police Officer is a corporate employee who acts as a Revenue Collector for the Corporation and enforces Acts of Parliament.

A Police Community Support Officer is a Corporate employee who has no powers whatsoever, and holds no Oath of Office. They are given a Warrant Card and told to keep it because while they don’t need it now, they will need it at some point in the future. Without an oath to the monarch, they have no authority at all.

The British people live in a “common law jurisdiction”. This means that no Civil Law Statute applies to them at any point unless the individual consents to it. If asked to give your name, do not do so as that is a trick which places you into the realm of civil law which does not apply to
you at all unless you consent to be placed under it. You are not obliged under common law to answer the question which asks your name and/or address. The police officer will be following training and may well not be aware that trickery is involved, never having been trained in common law and their duties under it, to each member of the public.

The Comments of John Harris

John Harris of the [http://www.tpuc.org/](http://www.tpuc.org/) web site makes the following points:

**The deception of “Joiner”** or more aptly named “pretensive joinder”: The human is asked for his full name, address and date of birth in order to establish the LEGAL PERSONALITY, the address of the LEGAL PERSONALITY and the date on which the LEGAL PERSONALITY was created. Once Joinder has been established, they can then offer that LEGAL PERSONALITY a contract. But, they need the consent of the human to act on behalf of the fictitious LEGAL PERSONALITY and so the human is asked “do you UNDERSTAND?” The human is then required to sign at least one piece of paper saying that he is the LEGAL PERSONALITY and that as the LEGAL PERSONALITY, he UNDERSTANDS.

This is deception as “UNDERSTAND” is taken to mean “STAND UNDER” and has nothing to do with the human comprehending anything. During any process where a human has any dealing with Corporation Officers, he is asked “do you understand?” and that is simply about consent. He is being asked to represent the LEGAL PERSONALITY and give the Corporate Officer authority over him.

**The deception of “Notice”**: In Legalese, a “notice” is not a bill or a demand, instead, it is an offer of contract. When the offer has been made, the LEGAL PERSONALITY must be established through Joinder because the LEGAL PERSONALITY is only a piece of paper. Consequently, the human has to agree to represent that piece of paper by saying “I understand”. Fixed penalty notices are the same as all, and any, statements made: they are simply, self-perpetuating Contracts. Making a statement to police is exactly the same - a self-perpetuating contract.

**The deception of “Includes”**: The Inclusion of one is the Exclusion of another – this is a maxim (an established, unchallengeable fact). A summons (invitation) for watching TV without a licence has “We will present any evidence found of your watching TV without a licence, which may include a statement taken under caution by one of our Enforcement Officers”. But the legalese “may” translates into “must”, but if you make a statement with your name, address and confirmation of watching TV, then the court issues summary judgement as you have already incriminated yourself and the court has nothing to decide.

**The deception of “Summons”**: Summons is synonymous with “invitation” which is a choice. They are inviting a LEGAL PERSONALITY to a Corporate place of business. The LEGAL PERSONALITY is just a piece of paper, a BIRTH CERTIFICATE created by the United Kingdom Corporation and it is not the human. You can’t be forced into a contract, so they have to deceive you into entering into one without realising what you are doing. They are using deception as every Magistrates Court is a trading name of the commercial company called “The Ministry of Justice” D-U-N-S Number 22-549-8526 which does not have a Parent Company listed meaning that it is a Parent Company. Directors: Lord Falconer of Thoroton, date of incorporation 1600. Legal people on being shown this registration, responded by saying that if this information is genuine (which it is), then the UK has been lawless for more than 400 years because the whole Justice System is being dealt with by a company.

**Deception of the Name**: If you go to a Court (which is a Corporate place of Business) as the Accused, you will be asked to confirm your Name, quoting the full name shown on your birth certificate, which is the LEGAL PERSONALITY. Titles such as Mr, Dr, Lord, PC, QC, or whatever are not asked for as they are not required. The “Accused” is actually the LEGAL PERSONALITY which is the name on the birth certificate, so when they ask for the person’s NAME, they are
talking to the LEGAL PERSONALITY and not the human. This is because a human cannot exist in the legal world - only pieces of paper can, and that is something which they are very careful not to tell you.

This is a really key issue. Natural Law and Common Law are the only laws which apply to humans and they deal only with harming other people or causing them loss, and outside of those restrictions, a human has free and unlimited entitlement to do anything he chooses which complies with these principles. As opposed to this, Acts of Parliament, "Statutes" and Statutory Instruments "Contracts" do not apply to the human but only to the piece of paper which is the LEGAL PERSONALITY and which has no reality. As the legal fiction of the LEGAL PERSONALITY was created by the company called "the United Kingdom Corporation", it is that company which gets to say what the rights and duties are for that piece of paper.

The deception of the Birth Certificate: When a person is born in Britain, the mother and father submit a Birth Certificate Registration Form, which is a piece of paper. There is no requirement under common law to do this. When any limited company or corporation is set up, there is always a Certificate of Registration in order to create it's LEGAL PERSONALITY and that is a piece of paper. Please note that a British Birth Certificate states quite clearly that it is not evidence of identity, that is, it has nothing to do with a human. Marked on it is "Crown Copyright" showing clearly that it does not belong to an individual and was created by "the crown" which is not the monarch but is the independent 'City of London' represented by the Law Society and acting on behalf of the private owners. This act of Registering a child, makes that child a "ward of the court" which means that the child can be taken away from the parents at any time.

The deception of Registration: If I lawfully own a vehicle, then it cannot be taken away from me and crushed as that would constitute a criminal act and considered theft, no matter who takes it. However, if I Register my vehicle, then, without realising it, I hand ownership of the vehicle over to the registering company as a free gift. They acknowledge the gift by issuing me with a piece of paper stating that I am "the Registered Keeper" of their vehicle, to which they assign a number in their registration records of the vehicles which they own (although they will not pay for the upkeep of their vehicles).

John also asks:

Do you believe Parliament is elected to Represent the people and their wishes? It isn't, they are Directors of a commercial ‘for-profit' corporation and so, nothing will ever change.

Do you believe in Politics? There is no such thing.

Do you believe that the only way to sort the UK out is to elect a different Political Party? It makes no difference as all you are doing is choosing employees of a commercial company, and the owners dictate what the company does, no matter who the corporate serving officers may be.

Do you believe that Acts of Parliament ("Statutes") are Law? They aren't.

Do you believe that Statutory Instruments are Law? They aren't.

What The UK Police Can, and Can’t Do
Posted September 26th, 2008 by Guy_Euden

Do you feel intimidated when pulled over? Do you feel intimidated when stopped in the street?
Do you feel that you are obliged to give them information or answer their questions? If your answer is “yes” to any of these questions, then you don’t know your rights. A police officer is not what he was many moons ago. In bygone days they cared for their employers (yes you), they actually wanted to help you, they wanted to solve crimes, they had compassion, a sense of fair play and in response to this they earned our respect and admiration.

ALL of that has changed! Police officers are now Revenue Agents plain and simple and if any police officer is silly enough to think that’s not true, or just wish to profess it isn’t, then let him try not giving out fixed penalties for a month and see if a talking to is not the result! The truth is that they are now your adversary and that is not meant in a violent way, more like a game of who can get who to do as they’re told, and they are trained to get from you what they need in order to actually fine or arrest you by actually getting you to consent to it. Let’s quickly look at all laws that don’t include Death or Injury to others, Damage to another’s property or using fraud in your contracts.

OK, these three very heavy crimes are all you can truly be guilty of - YES it’s all you can truly be guilty of!!! Anything else is just STATUTE LAW and the simple to remember definition of this law is “laws that only apply if you consent to them”!! Here, look at the definition of a Statute: "Legislative rule of society given the force of law by the consent of the governed". Yes look at the last four words, "CONSENT OF THE GOVERNED" that is you!! So, if you don't consent, then they can’t do anything. Yes, I know what you’re thinking, but it really is that simple. Ok, an officer walks up to you and says "can I ask you some questions?" Don't consent. Ask him "what is the nature of the intended detention?". Record the conversation and let him see that you are doing this. Use your mobile, as 99% of mobile phones available today have recorders so go for it! If he says that you cannot record this conversation, then what he is in fact saying is, “yep you guessed it - I don't consent to be recorded!!”. So, you simply say “Ok, am I free to go?”

The simple fact is that they need your consent, and they have some very cool tools to use to get it, one is intimidation, and another is acting. They act like they are your friend. They act like they care. They just ACT! This is to put you off guard and most people sing like canaries!! Their other weapon of choice is Inconvenience. You don't have time to waste playing their game, so you talk in order to get away quicker, and wham! - they have their result! If you are pulled over for an offence under an act, for example, speeding, seatbelt or some other infraction, it is all part of the “Road Traffic Act of 1988 keyword is “ACT” and believe you me what a merry old act it is, it is pure stage play.

When issuing a ticket they need your name so SHUT UP! Don’t argue with them as that is “adversarial” so just SHUT UP! They need your name and date of birth to confirm which corporation they are going to give the bill of exchange to (bills of exchange defences are simple but we are not doing those right now). So don’t provide a name, or date of birth, or address. Don't give them anything to work with, don’t say a single word no matter what coercion they try, hell they might even go for some "good cop bad cop" stuff this is great to watch when you are fully aware of their lack of power, it’s like watching "EastEnders". If they read you your rights you have to say that you understand in order for handcuffs to be put on you. Again, your consent is necessary (get it?) don’t say a word!!

Now these Officers of Revenue don't like the grim realisation that they have no power. You could get arrested, yes I am afraid that they can still arrest you, but the worst that they can do is keep you for a few hours, so get some sleep, oh and if you have a “notarised claim of right, with a schedule of charges for arrest and detention”, then sleep even sweeter because these fools are paying you to learn that they have no power! I know that getting arrested isn't nice, they know this, that's why its one of their tools to get you to consent to their unnecessary and unlawful penalties.

But if you don't stay quiet, then they will always have power over you. Now if they are going to arrest you, one nice way of them playing into your hands is if you say these few of words:
"Officer, I am a peaceful man, there will be no violence, but you are obliged to note that if you are going to arrest me it will be under protest and duress at all times and I reserve all of my rights at all times, and I waive none of those rights at any time for any cause or reason". If they take you to the station remember DON'T SAY A SINGLE WORD. Hell you might get a new name! "JOHN DOE". If they try to fingerprint you, tell them that you do not consent to this. If they try to get your DNA then tell them that you do not consent to this. If they touch you, tell them, "Officer I do not consent to be touched at all".

If you make it known that you know your rights then they will leave you alone. Trust me, they will only act illegally if you continue to let them do so. Remember that any "legal" acts that they choose to quote are powerless, a clawless, toothless tiger.... they have no power if you don’t consent.

Summary:
The present UK (and world) situation is designed to confuse you. The UK is a "Common Law jurisdiction" which has had a spurious and fake "legal" system added on to it in order to rob you blind. The average inhabitant of the UK is bound to keep the common law or suffer the consequences. The common law requires a human not to kill or injure another human, not to damage or steal his property and not to swindle him.

The spurious "legal" system introduced by the Law Society (who consider all other humans as inferiors), is designed to steal from those humans by deception and fraud. It operates by tricking humans into inadvertently and unknowingly entering into a contract to pay money to someone who will not provide anything of worth in exchange.

This is done by using the legalese language which has taken words from the English language and changed their meanings without making the changes of meaning made clear to the public. This covert and surreptitious method is used to get a human to represent a legal fiction which is a piece of paper and undertake to pay invented debts attached to that piece of paper.

The average UK resident believes that there is a UK government, when in fact, there is no actual government, just a commercial company pretending to be a government, namely, the company called "The United Kingdom Corporation Limited". People are fooled into "voting" for the election of corporate officers in this company in order to make them believe that there actually is a government where no government exists.

This hateful “legal” system is there solely to enslave and rob ordinary people living in the UK and there appears to be no way to circumvent it. I have seen a calculation which estimates that on average, ordinary people in the UK have 80% of their income taken from them in taxes. So, for every £100 they earn, they only receive £20.

A self-employed person may be able to avoid paying Income Tax, Council Tax, TV licence and some other minor taxes. An employed person is tied to a "legal entity" employer which cannot escape the legal snare and so is forced to take Income Tax, National Insurance and Child Support amounts off a person’s earned payment before the remainder is given to the employee.

Unfortunately, even self-employed people can’t escape the thieves because they add their massive charge on to essential items which are not sold to people by name. For example, I have been told that 85% of the cost of a gallon of fuel for a vehicle is tax. That means that if I buy £100 of fuel, it really should have only cost me £15 as that is the cost of finding it, extracting it, refining it, transporting it and making a profit on selling it. My £85 has been taken against my will, by people who are not entitled to it.

If I buy almost anything in a shop, then 17.5% of the selling price is taken from me and given to someone who doesn’t deserve it. In reality, it is much more than that because the item
purchased was transported to the shop using fuel which was heavily taxed, and I have to pay that tax indirectly in the raised cost of the item. Also, the shop has to have heating and lighting, both of which are powered by heavily taxed fuel, which raises the price which I have to pay on the item. Then, there is the tax on the company and the tax on the company for having employees, both of which have to be covered in the price which I am charged. You can see why the person who worked out how much is really paid in tax, came up with an overall figure of 80% of a person’s earned income. Even a self-employed person can’t escape paying a major amount of indirect tax. The often-quoted phrase “we live in a free country” does not seem to have any basis in fact. So, how about “the land of the brave and the land of the free” across the Atlantic ocean, do they fare any better?

The Situation in America

In 1606, King James I the King of England set up a commercial enterprise called “The Virginia Company” with himself as the main stockholder. The Virginia Company was formed in anticipation of the imminent influx of white Europeans, mostly British at first, into the North American continent. The Virginia Company of London (also called the “London Company”) was chartered by King James with the object of colonising the eastern coast of North America between latitudes 34° N and 41° N. It’s shareholders were Londoners. The Virginia Company claimed ownership of most of the land that we now call America. The Virginia Company (the British Crown and the bloodline families) claimed rights to 50% of all gold and silver mined, plus percentages of other minerals and raw materials, and 5% of all profits from other ventures.

As has been already remarked, no human can own land as there is no way that genuine title to the land can be bestowed on any human, short of God giving him a written deed of ownership as a gift. No human can buy land from another human or organisation as they didn’t genuinely own the land in the first place. King James was essentially, no different from any other man and he had no justification for blithely claiming ownership of another country. Even being the first squatter on the land (which he wasn’t) does not give any man ownership of that land. Consequently, his was, and is, a spurious claim with no basis in fact or any form of justification.

At this time, America does not have a government because “The UNITED STATES” is a commercial company. The term “United States” means a Federal corporation. The US President is the President of a commercial corporation and American citizens are, in effect, the employees of that Corporation. This present situation was sneaked in by the covert actions of the Americans who organised and ran the civil war with the intention of taking lands and assets from people who lived in the South. Most people imagine that, say, Virginia, is a part of the American nation under the American government. However, this is not true as every one of the “States” is actually set up as a commercial, for-profit, company, under the parent company “The United States of America”. So the reality is that instead of being a State of the Nation, the “State of Virginia” is the name of a commercial for-profit company.

The Vatican claims that it owns Britain and all of the commonwealth countries. Britain claims that it owns America as a British colony. The King of England provided financial backing to both sides of the Revolutionary war and believed that the lands of the Virginia Company were granted (on lease) to the colonies under a Deed of Trust and therefore they could not claim ownership of the land. They could pass on the perpetual use of the land to their heirs or sell the perpetual use, but they could never own the land itself as ownership was supposedly retained by the British Crown.

You may be interested to know that the Vatican’s system of law is based on the ancient Roman system and in Rome, the seat of power for Caesar was called “Capitol Hill” where Caesar would meet with ‘the Senate’. The Pope believes that he can abolish any law in the United States (Elements of Ecclesiastical Law Vol. 1, 53-54). The Pope’s laws are supposed to be obligatory on everyone.
The conglomeration of privately owned commercial corporations know as “the United Sates of America” go along with the same old ridiculous scam of considering American human beings to be “slaves” under Roman law. Consequently, no American can own property because slaves can’t own property. If an American reads the Deed to a property which he thinks that he owns, he will discover that he is listed as a “Tenant” (Senate Document 43, 73rd Congress, 1st Session).

After the first 21 years from the formation of the Virginia Company, all ‘duties, imposts and excises’ paid on trading activities in the colonies were paid directly to the British Crown through the Crown treasurer. Queen Elizabeth II of Britain, controls and has amended U.S. Social Security: Statutory Instrument 1997 No. 1778 The Social Security (United States of America) Order 1997.

The American Inland Revenue Service Publication 6209 is form 1040 which is to be used for tribute paid to Britain. Americans are considered to be slaves to the Queen and own absolutely nothing (Senate Document 43). America’s Social Security is not insurance or a contract, nor is there a Trust Fund. The criminal courts on the lands of the Virginia Company were to be operated under Admiralty Law, the law of the sea, and the civil courts under common law, the law of the land. This is a crucial point. The United States of America is not a country, it is a corporation owned by the same Brotherhood bloodlines who owned the Virginia Company, because the USA is considered to be the property of the Virginia Company.

There is a “USA” which is the 68 square miles of land west of the Potomac River on which is built the federal capital, Washington DC and the District of Columbia, also the US protectorates of Guam and Puerto Rico. And then there is a “usA” the “united states of America” which are the lands of the various states. These lands are still supposedly owned by the British Crown as the head of the Virginia Company.

The Act of 1871 created a new, altered Constitution. The title was changed to capital letters and the word “for” was changed to the word “of”. That is, “The Constitution for the united states of America” was altered to “THE CONSTITUTION OF THE UNITED STATES OF AMERICA”.

An American cannot use the Constitution to defend himself because he is not a party to it. “The People” does not include ordinary U.S. Citizens. The Act of 1871 also created a separate form of government for the District of Columbia, which is a ten mile square parcel of land which is governed with British Admiralty law, U.C.C. (Acts of the Forty-First Congress, Section 34, Session III, chapters 61 and 62).

When Americans agree to have a Social Security Number, they surrender their sovereignty and agree to become franchisees of the United States (which is supposedly the Virginia Company of the British Crown). Americans are led to believe that there is only one United States and that the Federal government is the rightful government. The use of lower/upper-case characters is making a legal statement. If you are American, then you should notice that when you receive any correspondence relating to government, law or anything to do with finance or taxation that your name is always spelt entirely in block capitals.

Your name in block capitals is not you. It is a corporation set up by the ‘government’ Corporation through the treasury department at the time of your birth. Any time that a child is born, a corporation/trust is created using his or her name in block capitals. One definition of “a human being” is “a corporation treated as having the rights and obligations of a person” while the definition of a “natural person” is ‘a real human being’, as distinguished from a corporation, which is often treated at law as being a fictitious person.

Everything in the “United States” is “For Sale”: roads, bridges, schools, hospitals, water, prisons, airports, etc. (Executive Order 12803). Americans are Human capital (Executive Order 13037).

The Emergency Banking Relief Act of 9th March 1933, defined the American people as legally,
the **enemy** of the United States Government and the private, international Federal Reserve System became the Government of the United States.

The national flag of the United States always has a gold fringe when displayed in court or federal buildings, federally-funded schools and the uniforms of US troops. Under the International Law of the Flags, a gold fringe indicates the jurisdiction of commercial law, also known as British Maritime Law, and in the US as the uniform Commercial Code or "UCC".

George Bush launched a 'war on terrorism' on behalf of a private Corporation, to further the goals of that Corporation. It had nothing to do with 'America' or 'Americans', because those are very different legal entities. The United States Corporation owns the United States military and everything else that comes under the term 'federal'. It is not the duty of the US police to protect Americans. Their job is to protect the Corporation and arrest code breakers (Sapp v. Tallahassee, 348 So. 2nd. 363, etc.). There are no Judicial courts in America and there have not been since 1789. Judges do not enforce Statutes and Codes but instead, Executive Administrators enforce Statutes and Codes. The most powerful court in America is not the United States Supreme Court but instead, it is the Supreme Court of Pennsylvania (42 Pa.C.S.A. 502). Pennsylvania is the keystone state.

The FCC, CIA, FBI, NASA and all similar organisations were never part of the United States government, even though the "US Government" held shares of stock in the various Agencies. (U.S. v Strang, 254 US 451, Lewis v US, 680 F.2d, 1239).

Americans may think that their government and legal system is pegged in some way to the Constitution, but it is not. The United States, like Britain and elsewhere, is ruled by commercial law to overcome the checks and balances of common law. It is a monumental fraud.

The web site [http://www.youtube.com/watch?v=klwWcp9eiPw&feature=player_embedded](http://www.youtube.com/watch?v=klwWcp9eiPw&feature=player_embedded) lists what it considers to be a series of little-known facts about America. It says:

"The IRS is not a U.S. government agency. It is an agency of the IMF which in turn is an agency of the United Nations. The United States has **not** had a Treasury since 1921 as the U.S. Treasury is now the IMF. The United States does not have any employees because there no longer is a United States. The FCC, CIA, FBI, NASA, etc. were never part of the U.S. government but are privately owned companies. US Social Security numbers are issued by the UN through the IMF, (the SS5 form does not state who issues it). There have been no Judicial Courts in America since 1789. There have been no Judges in America since 1789. According to GATT, Americans must have a Social Security Number. New York City is defined in the Federal regulations as the United Nations. Social Security is not insurance or a contract and Social Security cheques come directly from the IMF which is an agency of the UN.

All Americans are slaves and so can own absolutely nothing, not even what they think of as being their own children. The most powerful court in America is the Supreme Court of Pennsylvania. The King of England financially backed both sides of the Revolutionary War. Americans can’t use the US Constitution to defend themselves because they are not a party to it. Britain is owned by the Vatican and the Pope claims to own the entire planet through the laws of conquest and discovery (Papal Bulls of 1495 and 1493). The Pope has ordered the genocide and enslavement of millions of people (Papal Bulls of 1455 and 1493). The Pope’s laws are obligatory on all Americans. “The People" does not include ordinary Americans. (Barron v City Council of Baltimore 32 US 243)."

When you become aware of these things, it becomes easier to understand why voting in a Presidential election can never make any difference - after all, he is only the President of a commercial company whose corporate policy is set by the owners of the company and not by the President. It also explains what these commercial companies have done and are still doing through their agencies such as the CIA.

15 - 12
The fractional reserve policy perpetrated by the Federal Reserve, which has spread in practice to the great majority of banks in the world, is, in fact, a system of modern slavery. Think about it: money is created out of debt. What do people do when they earn debt? They submit to employment to pay it off. But if money can only be created out of loans, how can society ever be debt-free? It can’t, and that’s the point. And it is the fear of losing assets coupled with the struggle to keep up with the perpetual debt and inflation in the system, compounded by the inescapable scarcity in the money supply itself, created by the interest which can never be repaid, that keeps the wage-slave in line, powering the pyramid which benefits only the elite at the top of the pyramid. At the end of the day, for whom are you really working? The banks. Money is created in a bank and inevitably ends up in a bank. They are the true masters along with the corporations and governments which they support. Physical slavery requires people to be housed and fed, economic slavery requires people to house and feed themselves.

Michael Rivero has put together a concise statement on the situation in America, and his statement is at http://whatreallyhappened.com/WRHARTICLES/allwarsarebankerwars.php where he says:

I know that many people have a great deal of difficulty with understanding just how many wars are started for no other purpose than to force private central banks on to nations, so let me share a few examples, in order that that you can understand why the US Government is engaged in so many wars against so many foreign nations. There is ample precedent for this.

The United States fought the war of the American Revolution primarily over King George III's Currency Act, which forced the colonists to conduct their business only using printed bank notes borrowed from the Bank of England at interest. After the revolution, the new United States adopted a radically different economic system in which the government issued its own value-based money, so that private banks like the Bank of England were not siphoning off the wealth of the people through interest-bearing bank notes.

"The refusal of King George 3rd to allow the colonies to operate an honest money system, which freed the ordinary man from the clutches of the money manipulators, was probably the prime cause of the revolution". -- Benjamin Franklin, Founding Father

But bankers are nothing if not dedicated to their schemes to acquire your wealth, and they know how easy it is to corrupt the leaders of a nation. Just one year after Mayer Amschel Rothschild had uttered his infamous statement: "Let me issue and control a nation's money and I care not who makes the laws", the bankers succeeded in setting up a new Private Central Bank called the First Bank of the United States, largely through the efforts of the Rothschild's chief US supporter, Alexander Hamilton.

Founded in 1791, by the end of its twenty year charter the First Bank of the United States had almost ruined the nation's economy, while enriching the bankers. Congress refused to renew the charter and signalled their intention to go back to a state-issued value-based currency on which the people paid no interest at all to any banker. This resulted in a threat from Nathan Mayer Rothschild against the US Government: "Either the application for renewal of the charter is granted, or the United States will find itself involved in a most disastrous war". Congress still refused to renew the charter for the First Bank of the United States, whereupon Nathan Mayer Rothschild railed, "Teach those impudent Americans a lesson! Bring them back to colonial status!"

Financed by the Rothschild-controlled Bank of England, Britain then launched the war of 1812 to re-colonise the United States and force them back into the slavery of the Bank of England, or to plunge the United States into so much debt they would be forced to accept a new private central bank. The plan worked. Even though the War of 1812 was won by the United States, Congress was forced to grant a new charter for yet another private bank issuing the public currency as
loans at interest, and that was the Second Bank of the United States. Once again, private bankers were in control of the nation's money supply and cared not who made the laws or how many British and American soldiers had to die for it.

Once again the nation was plunged into debt, unemployment, and poverty through the plundering of the private central bank, and in 1832 Andrew Jackson successfully campaigned for his second term as President under the slogan, "Jackson And No Bank!" True to his word, Jackson succeeds in blocking the renewal of the charter for the Second Bank of the United States.

"Gentlemen! I too have been a close observer of the doings of the Bank of the United States. I have had men watching you for a long time, and am convinced that you have used the funds of the bank to speculate in the breadstuffs of the country. When you won, you divided the profits amongst you, and when you lost, you charged it to the bank. You tell me that if I take the deposits from the bank and annul its charter I shall ruin ten thousand families. That may be true, gentlemen, but that is your sin! If I let you go on, you will ruin fifty thousand families, and that would be my sin! You are a den of vipers and thieves. I have determined to rout you out, and by the Eternal, (bringing his fist down on the table) I will rout you out!" -- Andrew Jackson, shortly before ending the charter of the Second Bank of the United States. From the original minutes of the Philadelphia committee of citizens sent to meet with President Jackson (February 1834), according to Andrew Jackson and the Bank of the United States (1928) by Stan V. Henkels

Shortly after President Jackson (the only American President to actually pay off the National Debt) ended the Second Bank of the United States, there was an attempted assassination which failed when both pistols used by the assassin, Richard Lawrence, failed to fire. Lawrence later said that with Jackson dead, "Money would be more plenty".

Of course, the present day American public school system is as subservient to the bankers' wishes to keep certain items of history from you, just as the corporate media is subservient to Monsanto's wishes to keep the dangers of Genetically Modified foodstuffs from you, and the Global Warming cult's wishes to conceal from you the fact that the Earth has actually been cooling for the last 16 years. Thus is should come as little surprise, that much of the real reasons for the events of the Civil War are not well known to the average American.

When the Confederacy seceded from the United States, the bankers once again saw the opportunity for a rich harvest of debt, and offered to fund Lincoln's efforts to bring the south back into the union, but at 30% interest. Lincoln remarked that he would not free the black man by enslaving the white man to the bankers and using his authority as President, he issued a new government currency, the "greenback". This was a direct threat to the wealth and power of the central bankers, who responded quickly.

"If this mischievous financial policy, which has its origin in North America, becomes entrenched, then that Government will issue its own money without cost. It will pay off debts and be without debt. It will have all the money necessary to carry on its commerce. It will become prosperous to a degree which is without precedent in the history of the world. The brains, and wealth of all countries will migrate to North America. That country must be destroyed or it will destroy every monarchy on the globe". -- The London Times responding to Lincoln's decision to issue government Greenbacks to finance the Civil War, rather than agree to private banker's loans at 30% interest.

In 1872 New York bankers sent a letter to every bank in the United States, urging them to fund any newspapers which opposed government-issued money (Lincoln's greenbacks): "Dear Sir: It is advisable to do all in your power to sustain such prominent daily and weekly newspapers... as will oppose the issuing of greenback paper money, and that you also withhold patronage or favours from all applicants who are not willing to oppose the Government issue of money. Let the Government issue the coin and the banks issue the paper money of the country...To restore to circulation the Government issue of money, will be to provide the people with money, and will
therefore seriously affect your individual profit as bankers and lenders". -- Triumphant plutocracy; the story of American public life from 1870 to 1920, by Lynn Wheeler

"It will not do to allow the greenback, as it is called, to circulate as money any length of time, as we cannot control that". -- Triumphant plutocracy; the story of American public life from 1870 to 1920, by Lynn Wheeler

"Slavery is likely to be abolished by the war, power, and chattel slavery destroyed. This, I and my European friends are in favour of, for slavery is but the owning of labour and carries with it the care for the labourer, while the European plan, led on by England, is for capital to control labour by controlling the wages. THIS CAN BE DONE BY CONTROLLING THE MONEY". -- Triumphant plutocracy; the story of American public life from 1870 to 1920, by Lynn Wheeler

Goaded by the private bankers, much of Europe supported the Confederacy against the Union, with the expectation that victory over Lincoln would mean the end of the Greenback. France and Britain considered an outright attack on the United States to aid the confederacy, but were held at bay by Russia, which had just ended the serfdom system and had a state central bank similar to the system the United States had been founded on. Left free of European intervention, the Union won the war, and Lincoln announced his intention to go on issuing greenbacks. Following Lincoln's assassination, the Greenbacks were pulled from circulation and the American people forced to go back to an economy based on bank notes borrowed at interest from the private bankers.

Finally, in 1913, the Private Central Bankers of Europe, in particular the Rothschilds of Great Britain and the Warburgs of Germany, met with their American financial collaborators on Jekyll Island, Georgia to form a new banking cartel with the express purpose of forming the Third Bank of the United States, with the aim of placing complete control of the United States money supply once again under the control of private bankers. Owing to hostility over the previous banks, the name was changed to "The Federal Reserve" system in order to grant the new bank a quasi-governmental image, but in fact it is a privately owned bank, no more "Federal" than Federal Express. Indeed, in 2012, the Federal Reserve successfully rebuffed a Freedom of Information Lawsuit by Bloomberg News on the grounds that as a private banking corporation and not actually a part of the government, the Freedom of Information Act did not apply to the operations of the Federal Reserve. The year 1913 proved to be a transformative year for the nation's economy, first with the passage of the 16th "income tax" Amendment and the false claim that it had been ratified.

"I think that if you were to go back and try to find and review the ratification of the 16th Amendment, which was the internal revenue, the income tax, I think that if you went back and examined that carefully, you would find that a sufficient number of States never ratified that Amendment". – U.S. District Court Judge James C. Fox (Sullivan vs United States, 2003).

Later in 1913, apparently unwilling to risk another questionable amendment, Congress passed the Federal Reserve Act over the Christmas holiday, while members of Congress who were opposed to the measure were at home. This was a very underhanded deal, as the Constitution which explicitly grants Congress the authority to issue the public currency, does not authorise it to delegate that authority, and so it should have required a new Amendment to allow Congress to transfer that authority to a private bank. But Congress did pass it, and President Woodrow Wilson signed it (as he had promised the bankers that he would, in exchange for generous campaign contributions). Wilson later regretted that decision, stating: "I am a most unhappy man. I have unwittingly ruined my country. A great industrial nation is now controlled by its system of credit. We are no longer a government by free opinion, no longer a government by conviction and vote of the majority, but a government by the opinion and duress of a small group of dominant men". – Woodrow Wilson 1919.

The next year, World War One started, and it is important to remember that prior to the creation
of the Federal Reserve, there was no such thing as a world war.

The First World War started between Austria-Hungary and Serbia, but quickly shifted to focus to Germany, whose industrial capacity was seen as an economic threat to Great Britain, who saw the decline of the British Pound as a result of too much emphasis on financial activity to the neglect of agriculture, industrial development, and infrastructure (not unlike the present day United States).

Although pre-war Germany had a private central bank, that bank was heavily restricted, and inflation kept to reasonable levels. Under government control, investment was guaranteed to internal economic development, and Germany was seen as a major power. So, in the media of the day, Germany was portrayed as the prime instigator of World War One, and subsequently, not just defeated, but had its industrial base flattened.

Following the Treaty of Versailles, Germany was ordered to pay the war costs of all of the participating nations, even though Germany had not actually started the war. This amounted to three times the value of all of Germany itself. Germany's private central bank, to whom Germany had gone deeply into debt to pay the costs of the war, broke free of government control, and massive inflation followed (mostly triggered by currency speculators), permanently trapping the German people in endless debt.

When the Weimar Republic collapsed economically, it opened the door for the National Socialists to take power. Their first financial move was to issue their own state currency which was not borrowed from private central bankers. Freed from having to pay interest on the money in circulation, Germany blossomed and quickly began to rebuild its industry. The media called it "The German Miracle". TIME magazine lionized Hitler for the amazing improvement in life for the German people and the explosion of German industry, and even named him TIME Magazine's "Man Of The Year" in 1938.

Once again, Germany's industrial output became a threat to Great Britain, resulting in these comments:
"Should Germany merchandise (do business) again in the next 50 years, we have led this war (WW1) in vain". - Winston Churchill in The Times (1919)

"We will force this war upon Hitler, if he wants it or not". - Winston Churchill (1936 broadcast)

"Germany becomes too powerful. We have to crush it". - Winston Churchill (November 1936 speaking to US - General Robert E. Wood).

"This war is an English war and its goal is the destruction of Germany". - Winston Churchill (Autumn 1939 broadcast).

Germany's state-issued value-based currency was also a direct threat to the wealth and power of the private central banks, and as early as 1933 they started to organise a global boycott against Germany to strangle this upstart ruler who thought he could break free of private central bankers!

As had been the case in World War One, Great Britain and other nations threatened by Germany's economic power looked for an excuse to go to war, and as public anger in Germany grew over the boycott, Hitler foolishly gave them that excuse. Years later, in a spirit of candour, the real reasons for that war were made clear:

"The war wasn't only about abolishing fascism, but to conquer sales markets. We could have, if we had intended to, prevented this war from breaking out without firing one shot, but we didn't want to". - Winston Churchill to Truman (Fultun, USA March 1946).

"Germany's unforgivable crime before WW2 was its attempt to loosen its economy out of the
world trade system and to build up an independent exchange system from which the world-
finance couldn't profit any more. ...We butchered the wrong pig". - Winston Churchill (The

As a side note, we need to step back before WW2 and recall Marine Major General Smedley
Butler. In 1933, Wall Street bankers and financiers had bankrolled the successful coups by both
Hitler and Mussolini. Brown Brothers Harriman in New York was financing Hitler right up to the
day war was declared with Germany. And they decided that a fascist dictatorship in the United
States based on the one on Italy would be far better for their business interests than Roosevelt's
"New Deal" which threatened massive wealth re-distribution to recapitalise the working and
middle class of America. So the Wall Street tycoons recruited General Butler to lead the
overthrow of the US Government and install a "Secretary of General Affairs" who would be
answerable to Wall Street and not the people, would crush social unrest and shut down all labour
unions.

General Butler pretended to go along with the scheme but then exposed the plot to Congress.
Congress, then as now in the pocket of the Wall Street bankers, refused to act. When Roosevelt
learned of the planned coup he demanded the arrest of the plotters, but the plotters simply
reminded Roosevelt that if any one of them were sent to prison, their friends on Wall Street would
deliberately collapse the still-fragile economy and blame Roosevelt for it. Roosevelt was thus
unable to act until the start of WW2, at which time he prosecuted many of the plotters under the
Trading With The Enemy Act. The Congressional minutes into the coup were finally released in
1967 and became the inspiration for the movie, "Seven Days in May" but with the true financial
villains erased from the script.

"I spent 33 years and four months in active military service as a member of our country's most
agile military force -- the Marine Corps. I served in all commissioned ranks from second lieutenant
to Major General. During that period I spent more of my time being a high-class muscle man for
Big Business, for Wall Street and for the bankers. In short, I was a racketeer, a gangster for
capitalism. I suspected that I was just a part of a racket at the time. Now I am sure of it. Like all
members of the military profession I never had an original thought until I left the service. My
mental faculties remained in suspended animation while I obeyed the orders of the higher-ups.
This is typical with everyone in the military service. Thus I helped make Mexico and especially
Tampico safe for American oil interests in 1914. I helped make Haiti and Cuba a decent place for
the National City Bank boys to collect revenues in. I helped in the raping of half a dozen Central
American republics for the benefit of Wall Street. The record of racketeering is long. I helped
purify Nicaragua for the international banking house of Brown Brothers in 1909-12. I brought light
to the Dominican Republic for American sugar interests in 1916. In China in 1927 I helped see to
it that Standard Oil went on its way unmolested. During those years, I had, as the boys in the
back room would say, a swell racket. I was rewarded with honours, medals and promotion.
Looking back on it, I feel I might have given Al Capone a few hints. The best he could do was to
operate his racket in three city districts. I operated on three continents". -- General Smedley
Butler, former US Marine Corps Commandant, 1935

As President, John F. Kennedy understood the predatory nature of private central banking, he
understood why Andrew Jackson fought so hard to end the Second Bank of the United States.
So Kennedy wrote and signed Executive Order 11110 which ordered the US Treasury to issue a
new public currency, the United States Note.
Kennedy’s United States Notes were not borrowed from the Federal Reserve but created by the US Government and backed by the silver stockpiles held by the US Government. It represented a return to the system of economics on which the United States had been founded, and this was perfectly legal for Kennedy to do. All told, some four and a half billion dollars went into public circulation, eroding interest payments to the Federal Reserve and loosening their control over the nation. Five months later John F. Kennedy was assassinated in Dallas Texas, and the United States Notes pulled from circulation and destroyed (except for samples held by collectors). John J. McCloy, President of the Chase Manhattan Bank, and President of the World Bank, was named as part of the Warren Commission, presumably to make certain that the banking dimensions behind the assassination were concealed from the public.

As we enter the eleventh year of what future history will most certainly describe as World War Three, we need to examine the financial dimensions behind the wars. Towards the end of World War Two, when it became obvious that the allies were going to win and dictate the post war environment, the major world economic powers met at Bretton Woods, a luxury resort in New Hampshire in July 1944, and hammered out the Bretton Woods agreement for international finance. The British Pound lost its position as the global trade and reserve currency and its place was taken by the US dollar (part of the price demanded by Roosevelt in exchange for the US entry into the war). Without the economic advantages of being the world’s central currency, Britain was forced to nationalise the Bank of England in 1946. The Bretton Woods agreement, was ratified in 1945, and in addition to making the US dollar the global reserve and trade currency, obliged the signatory nations to tie their currencies to the dollar. The nations which ratified Bretton Woods did so on two conditions. The first was that the Federal Reserve would refrain from over-printing the dollar as a means to loot real products and produce from other nations in exchange for ink and paper; basically an imperial tax. That assurance was backed up by the second requirement, which was that the US dollar would always be convertible to gold at $35 per ounce.

Of course, the Federal Reserve, being a private bank and not answerable to the US Government, did start overprinting paper dollars, and much of the perceived prosperity of the 1950s and 1960s was the result of foreign nations’ obligations to accept the paper notes as being worth gold at the rate of $35 an ounce. Then in 1970, France looked at the huge pile of paper notes sitting in their vaults, for which real French products like wine and cheese had been traded, and notified the United States government that they would exercise their option under Bretton Woods to return the paper notes for gold at the $35 per ounce exchange rate. Of course, the United States had nowhere near the gold to redeem the paper notes, so on August 15th, 1971, Richard Nixon “temporarily” suspended the gold convertibility of the US Federal Reserve Notes.

This "Nixon shock" effectively ended Bretton Woods and many global currencies started to disengage from the US dollar. Worse still, since the United States had collateralised their loans with the nation's gold reserves, it quickly became apparent that the US Government did not in fact
have enough gold to cover the outstanding debts. Foreign nations began to get very nervous about their loans to the US and understandably were reluctant to lend any additional money to the United States without some form of collateral. So Richard Nixon started the environmental movement, with the EPA and its various programs such as "wilderness zones", "Road-less areas", "Heritage rivers", "Wetlands", all of which took vast areas of public lands and made them off limits to the American people who were technically the owners of those lands. But Nixon had little concern for the environment and the real purpose of this land grab under the guise of the environment was to pledge those pristine lands and their vast mineral resources as collateral on the national debt. The plethora of different programs was simply to conceal the true scale of how much American land was being pledged to foreign lenders as collateral on the government's debts; eventually almost 25% of the nation itself.

With open lands for collateral already in short supply, the US Government embarked on a new program to shore up sagging international demand for the dollar. The United States approached the world's oil producing nations, mostly in the Middle East, and offered them a deal. In exchange for only selling their oil for dollars, the United States would guarantee the military safety of those oil-rich nations. The oil rich nations would agree to spend and invest their US paper dollars inside the United States, in particular in US Treasury Bonds, redeemable through future generations of US taxpayers. The concept was labelled the "petrodollar". In effect, the US, no longer able to back the dollar with gold, was now backing it with oil. Other peoples' oil, and the necessity to keep control over those oil nations in order to prop up the dollar has shaped America's foreign policy in the region ever since.

But as America's manufacturing and agriculture has declined, the oil producing nations faced a dilemma. Those piles of US Federal Reserve notes were not able to purchase much from the United States because the United States had little (other than real estate) which anyone wanted to buy. Europe's cars and aircraft were superior and less costly, while experiments with GMO food crops led to nations refusing to buy US food exports. Israel's constant belligerence against its neighbours caused them to wonder if the US could actually keep their end of the petrodollar arrangement. Oil-producing nations started to talk of selling their oil for whatever currency the purchasers chose to use. Iraq, already hostile to the United States following Desert Storm, demanded the right to sell their oil for Euros in 2000 and in 2002, the United Nations agreed to allow it under the "Oil for food" program instituted following Desert Storm. One year later the United States re-invaded Iraq, lynched Saddam Hussein, and placed Iraq's oil back on the world market only for US dollars.

Following 9-11, the clear US policy shift away from being an impartial broker of peace in the Middle East to one of unquestioned support for Israel's aggressions, only further eroded confidence in the Petrodollar deal and even more oil-producing nations started openly talking of oil trade for other global currencies.

Over in Libya, Muammar Gaddafi had instituted a state-owned central bank and a value-based trade currency, the Gold Dinar. Gaddafi announced that Libya's oil was for sale, but only for the Gold Dinar. Other African nations, seeing the rise of the Gold Dinar and the Euro, even as the US dollar continued its inflation-driven decline, flocked to the new Libyan currency for trade. This move had the potential to seriously undermine the global hegemony of the dollar. French
President Nicolas Sarkozy reportedly went so far as to call Libya a “threat” to the financial security of the world.

So, the United States invaded Libya, brutally murdered Gaddafi (the object lesson of Saddam's lynching not being enough of a message, apparently), imposed a private central bank, and returned Libya's oil output to dollars only. The gold that was to have been made into the Gold Dinars is, as of last report, unaccounted for.

According to General Wesley Clark, the master plan for the “dollarification” of the world's oil nations included seven targets, Iraq, Syria, Lebanon, Libya, Somalia, Sudan, and Iran (Venezuela, which dared to sell their oil to China for the Yuan, is a late addition). What is notable about the original seven nations originally targeted by the US is that none of them are members of the Bank for International Settlements, the private central bankers private central bank, located in Switzerland. This meant that these nations were deciding for themselves how to run their nations’ economies, rather than submit to the international private banks.

Now the gun sights of the bankers are on Iran, which dares to have a government central bank and sell their oil for whatever currency they choose. The war agenda is, as always, to force Iran's oil to be sold only for dollars and to force them to accept a privately owned central bank.

The German government recently asked for the return of some of their gold bullion from the Bank of France and the New York Federal Reserve. France has said it will take 5 years to return Germany's gold. The United States has said they will need 8 years to return Germany's gold. This suggests strongly that the Bank of France and the NY Federal Reserve have used the deposited gold for other purposes, and they are scrambling to find new gold to cover the shortfall and prevent a gold run. So it is inevitable that suddenly France invades Mali, ostensibly to combat Al Qaeda, with the US joining in. Mali just happens to be one of the world's largest gold producers with gold accounting for 80% of Mali exports. War for the bankers does not get more obvious than that!

Americans have been raised by a public school system and media that constantly assures them that the reasons for all these wars and assassinations are many and varied. The US claims to bring democracy to the conquered lands (they haven't; the usual result of a US overthrow is the imposition of a dictatorship, such as the 1953 CIA overthrow of Iran's democratically elected government of Mohammad Mosaddegh and the imposition of the Shah, or the 1973 CIA overthrow of Chile’s democratically elected government of President Salvador Allende, and the imposition of Agusto Pinochet), or to save a people from a cruel oppressor, revenge for 9-11, or that tired worn-out catch all excuse for invasion: “weapons of mass destruction”. Assassinations are always passed off as "crazed lone nuts" to obscure the real agenda.

The real agenda is simple. It is enslavement of the people by the creation of a false sense of obligation. That obligation is false because the Private Central Banking system, by design, always creates more debt than money with which to pay that debt. Private Central Banking is not science, it is a religion; a set of arbitrary rules created to benefit the priesthood, meaning the owners of the Private Central Bank. The fraud persists, with often lethal results, because the people are tricked into believing that this is the way life is supposed to be and no alternative exists or should be dreamt of. The same was true of two earlier systems of enslavement, ‘Rule by Divine Right' and ‘Slavery', both of which are systems designed to trick people into obedience, and both of which are now recognised by modern civilization as illegitimate. Now we are entering a time in human history where we will recognise that ‘rule by debt', or rule by Private Central Bankers issuing the public currency as a loan at interest, is equally illegitimate. It only works as long as people allow themselves to believe that this is the way life is supposed to be.
But understand this above all else, Private Central Banks do not exist to serve the people, the community, or the nation. Private Central Banks exist to serve their owners, to make them rich beyond the dreams of Midas and all for the cost of ink, paper, and the right bribe to the right official.

Behind all these wars, all these assassinations, the hundred million horrible deaths from all the wars lies a single policy of dictatorship. The private central bankers allow rulers to rule only on the condition that the people of a nation remain enslaved to the private central banks. Failing that, any ruler will be killed, and their nation invaded by those other nations which are already enslaved to private central banks.

The so-called "clash of civilizations" we read about on the corporate media is really a war between banking systems, with the private central bankers forcing themselves on to the rest of the world, no matter how many millions must die for it. Indeed the constant hatemongering against Muslims lies in a simple fact. Like the ancient Christians (prior to the Knights Templar's private banking system), Muslims forbid usury (the lending of money at interest), and that is the reason why the American government and media insist that Muslims must be killed or converted. They refuse to submit to currencies issued at interest. They refuse to be debt slaves. So off to war American children must go, to spill their blood for the gold of the money-junkies. We barely survived the last two world wars. In the nuclear/bio weapon age, are the private central bankers willing to risk incinerating the whole planet just to feed their greed? Apparently so.

Flag waving and propaganda aside, all modern wars are wars by and for the private bankers, fought and bled for by third parties unaware of the true reason why they are expected to be killed and crippled. The process is quite simple. As soon as the Private Central Bank issues its currency as a loan at interest, the public is forced deeper and deeper into debt. When the people are reluctant to borrow any more, that is when the Keynesian economists demand the government borrow more to keep the pyramid scheme working. When both the people and government refuse to borrow any more, that is when wars are started, to plunge everyone even deeper into debt to pay for the war, then after the war to borrow more to rebuild. When the war is over, the people have about the same as they did before the war, except the graveyards are far larger and everyone is in debt to the private bankers for the next century. This is why Brown Brothers Harriman in New York was funding the rise of Adolf Hitler.

As long as Private Central Banks are allowed to exist, inevitably, as night follows day, there will be poverty, hopelessness, and millions of deaths in endless World Wars, until the Earth itself is sacrificed in flames to Mammon. The path to true peace on Earth lies in the abolishment of all private central banking everywhere, and a return to the state-issued value-based currencies that allow nations and people to become prosperous.

*Michael Rivero*
The Economic Hit-Men

It is one of the most ingenious scams for social manipulation ever invented, and at its core, it is an invisible war waged against the population, and you will remember that the Emergency Banking Relief Act of 9th March 1933, defined the American people as “the enemy” of the United States Government. Debt is the weapon used to conquer and enslave societies and interest is its prime ammunition. While the majority of people are not aware of this reality, banks in collusion with governments and corporations continue to expand and perfect their tactics of economic warfare, spawning new bases such as the World Bank and the International Monetary Fund and introducing a new kind of soldier - the economic hit-man.

Here is the testimony of one of those American economic hit-men, John Perkins:

We, the economic hit men, are the ones really responsible for creating the first really global empire, and we work many different ways. Perhaps the most common is that we will identify a country which has resources which our corporations covet, such as oil, and then arrange a huge loan to that country from the World Bank or one of it’s sister organisations. But the money never actually goes to the country, instead, it goes to our big construction corporations to build infrastructure projects in that country, like industrial power plants, things which benefit a few rich people in that country (in addition to our corporations), but really don’t help the people involved, however those people and the whole country are left holding a huge debt so big that they can’t repay it, which is the whole plan - that they can’t repay it. So we economic hit men go back to them and say “listen, you owe us a lot of money, you can’t repay it, so sell your oil real cheap to our oil companies, allow us to build a military base in your country or send troops to some place in the world to support our troops in somewhere like Iraq, or vote with us in the UN to have their electric utility company privatised, or their sewage system privatised and sold to US corporations or other multinational corporations, so there is a whole mushrooming thing and it’s the way that the World Bank and the International Monetary Fund operate to put a whole country in debt with such a big debt that it can’t pay it, so you then offer to refinance that debt and get them to pay even more interest and you demand this ‘quid pro quo’ or ‘conditionality’ or ‘good governance’ which means basically that they have to sell off their resources, including their social services and utility companies, their school systems sometimes, their penal systems, their insurance systems to foreign corporations. So, it’s a double, triple, quadruple whammy.

Examples:
Iran 1953: The precedent for economic hit men began back in the early 1950s when the democratically elected Prime Minister of Iran, Dr Mohammed Mossadegh, was considered to be a hope for democracy - Time Magazine’s Man of the Year. One of the policies which he ran on was the idea that the oil companies needed to pay the Iranian people a lot more for the oil which they were taking out of Iran. We didn’t like that, of course, but we were afraid to do what we would normally do, which is to send in the military. Instead, we sent in one CIA agent, a relative of President Roosevelt. He went in with a few million dollars and was very efficient and effective and in a short amount of time he managed to get Mossadegh overthrown and brought in the Shah of Iran to replace him. It was extremely effective. So back here in the United States, people in Washington looked around and said “wow - that was easy and cheap!” So this established the whole new way of manipulating countries and creating empire. The only problem with Roosevelt was that he was a card-carrying CIA agent and if he had been caught, the ramifications would have been pretty serious. So, very quickly at that point a decision was made to use private ‘consultants’, to channel the money through the World Bank, the IMF or one of the other such agencies, bring in people like me who worked for private companies, so that if we got caught, there would be no government ramifications.

Guatemala 1954: When Arbenz (Jacob Arbenz Guzman) became President of Guatemala, the country was very much under the thumb of the United Fruit Company, the big international corporation and Guzman ran under the strategy of giving the land back to the people. When he was elected he started implementing those policies of giving the land back to the people. United
Fruit didn’t like that so much, so they hired a Public Relations company in the United States mounted a huge campaign to convince the people of the US, the press of the US and the Congress of the US that Arbenz was a Soviet puppet and if we allowed him to stay in power the Soviets would have a foothold in this hemisphere, which, at that time, was a huge fear on everybody’s minds, so to make a long story short, out of this public relations campaign came a commitment on the part of the CIA and the military to take this man out, and in fact, we did. We sent in planes, we sent in soldiers, we sent in jackals, we sent in everything to take him out, and we did take him out. And as soon as he was removed, his successor reinstated the links to the big corporations including United Fruit.

Ecuador 1981: Ecuador for many, many years was ruled by pro-US dictators, often relatively brutal. Then it was decided that they were going to have a truly democratic election Jaime Roldos (Aguilera) ran for office and his main goal, he said, as President was to make sure that Ecuador’s resources were used to help the people. And he won, overwhelmingly, by more votes than anyone has ever won anything in Ecuador and he began to implement these policies to make sure that the profits from oil went to help the people. Well, we didn’t like that in the United States. I was sent down as one of several economic hit men to change Roldos, to corrupt him, to bring him around, to let him know “you know, you and your family can get very rich if you play our game but if you but if you continue to try and keep these policies you promised, then you are going to go”. He wouldn’t listen. He was assassinated “Ecuadorean Leader Dies in Plane Crash”. As soon as the plane crashed, the whole area was cordoned off. The only people allowed in were the US military from a nearby base and some of the Ecuadorian military. When an investigation was launched, two of the key witnesses died in car accidents before they had a chance to testify. A lot of very, very strange things went on around the assassination of Roldos. I, like most of the people who really looked at this case had absolutely no doubt that it was an assassination and of course, in my position of an economic hit man, I was expecting something to happen to Jaime, whether a coup or an assassination I was sure that he would be taken down as he was not being corrupted, he would not allow himself to be corrupted the way we wanted to corrupt him.
Panama 1981: Omar Tarrijas President of Panama was one of my favourite people. I really, really liked him, he was very charismatic and he really wanted to help his country. When I tried to bribe him, to corrupt him, he said "look, John, he called me Juanita, look Juanita, you know, I don't need the money, what I really need is for my country to be treated fairly. I need the United States to replay the debts which you owe my people for all the destruction you have done here. I need to be in a position to help other Latin American countries with their independence and be free of this terrible presence from the North. You people are exploiting us so badly. I need to have the Panama Canal back in the hands of the Panamanian people. That's what I want. So leave me alone, don't try to bribe me". It was in 1981 and in May Jaime Roldos was assassinated and Omar was very aware of this. He got his family together and said "I'm probably next, but it is ok because I've done what I came here to do, I've renegotiated the Canal, the Canal will now be in our hands". He had been renegotiating the treaty with Jimmy Carter:

In June of that same year, just a couple of months later, he also went down in an aeroplane crash which there is no question was executed by CIA jackals. There is a tremendous amount of evidence, one of Tarrijas' security guards handed him, at the last moment as he was getting on the plane, a small tape recorder which contained a bomb.
Venezuela 2002: It is interesting to me how this system has continued pretty much the same way for years and years and years except the economic hit men get better and better and better. Then we come up with, very recently, what happened in Venezuela in 1998 when (Hugo Rafael) Chavez gets elected, following a long line of Presidents who were very corrupt and who basically destroyed the economy of the country, and Chavez was elected following all of that. Chavez stood up to the United States demanding that Venezuela oil be used to help the Venezuelan people. Well we didn't like that in the United States, so in 2002, a coup was staged, and there is no question in my mind or in most other people’s minds, that the CIA was behind that coup. The way that coup was fermented was very effective, like Colonel Roosevelt had done in Iran - paying people to go out into the streets to riot, to protest and say that Chavez is very unpopular. You know, if you can get a few thousand people to do that, television can make it look like the whole country and things start to mushroom, except in the case of Chavez, he was smart enough and the people were so strongly behind him that they overcame it, which was a phenomenal moment in the life of Latin America.

Iraq 2003: Iraq, actually, is a perfect example of the way the whole system works. We economic hit men are the first line of defence. We go in and try to corrupt governments and get them to accept these huge loans which we then use as leverage to basically own them. If we fail, as I failed in Panama with Omar Tarrijas, and in Ecuador with Jaime Roldos, men who refused to be corrupted, then the second line of defence is we send in the jackals and the jackals either overthrow governments or they assassinate and when that happens and a new government comes in, boy, it's going to toe the line as the new President knows what will happen if he
doesn’t. And in the case of Iraq, both of those things failed and the economic hit men were not able to get through to Saddam Hussein although they tried very hard. We tried very hard to get him to accept a deal but he wouldn’t accept it and so the jackals went in to take him out but they couldn’t do it as his security was very good. After all, he had at one time worked for the CIA and been hired to assassinate a former President of Iraq and failed, but he knew the system. So, in 1991 we send in the troops and we take out the Iraqi military, assuming that at that point that Saddam is going to come around. We could, of course, have taken him out at that time, but we didn’t want to as he is the kind of strong man that we like, able to control his people and keep pumping oil for us. But when we took out his military he didn’t come around so the economic hit men go back in the 90s without success. If they had had success, he’d still be running the country - we’d be selling him all the fighter jets he’d want, but they didn’t have success. The jackals couldn’t take him out again, so we sent the military in once again and took him out, and created for ourselves very lucrative reconstruction deals to rebuild a country which we had essentially destroyed - which is a very good deal if you own a construction company - a really big one. So, Iraq shows the three stages: the economic hit men - failed there, the jackals failed there, so as the final measure, the military goes in.

And in that way, we have really created an empire, but we have done it very, very subtly, it’s clandestine. All the empires in the past were built by the military and everybody knew they were building them. The British knew they were building it, the French, the Germans, the Romans, the Greeks - they were all proud of it and they always had some excuse like “spreading civilisation”, or spreading some religion, something like that, but they knew they were doing it. We don’t. The majority of the people in the United States have no idea that we are living off the benefits of a clandestine empire, that today there is more slavery in the world than ever before.

You may have to ask yourself if it’s an empire, then who’s the Emperor? Obviously, our Presidents in the United States are not Emperors. An Emperor is someone who is not elected, does not serve a limited term, and who doesn’t report to anyone. So you can’t classify Presidents that way. But we do have what I consider to be the equivalent of the Emperor in what I call the “Corporatocracy”. The Corporatocracy is this group of individuals who run our biggest corporations and they really act as the Emperor of this empire. They control our media (either by direct ownership or by advertising), they control most of our politicians because they finance their campaigns, either through corporations or through personal donations. They are not elected, they don’t serve a limited term, they don’t report to anybody, and at the very top of the Corporatocracy, we can’t tell if the person is working for a corporation or for the government as they are always moving back and forth, so you get a guy who is one moment the president of a big company like Halliburton and the next moment he’s the Vice President of the United States, or the President who is in the oil business and this is true whether you get Democrats or Republicans in the office, you have them moving back and forth through the revolving door, and in a way, our government is invisible a lot of the time as it’s policies are carried out by a corporation on one level or another, and then again, the policies of the government are basically forged by the Corporatocracy and then presented to the government and become government policies. So, it is an incredibly cosy relationship. This isn’t a “conspiracy theory” kind of thing, these people don’t have to get together and plot to do things, they all basically work under one primary assumption, and that is that they must maximise profits regardless of the social and environmental costs.

This process of manipulation by the Corporatocracy, through the use of debt, bribery and political overthrow, is called “Globalisation”. Just as the Federal Reserve keeps the American people in a position of indentured servitude, through perpetual debt, inflation and interest, the World Bank and International Monetary Fund fulfil this role on a global scale.

Oh, and by the way, the lame excuse for going to war with Iraq which was never believable beforehand, is laid out in fair detail here by a high-ranking US Major General expert in gathering and interpreting military and terrorist intelligence:

http://www.youtube.com/watch?v=W0xzsbSbVUE&feature=player_embedded.
Libya 2011: If the ruler of a country refuses to become the servant of the New World Order people, he is subjected to character assassination and physically attacked with troops. I don’t for a moment suggest that Col. Gaddafi was a saint, but as the Bible so aptly remarks, you can tell a man’s character by the things which he does, so what did Col. Gaddafi do? Well, here is some information passed to me and I leave you to decide for yourself:

1. In Libya, electricity is free for all of its citizens.

2. There is no interest on loans, banks in Libya are state-owned and loans are given to all its citizens at 0% interest which is requirement of Libyan law.

3. Owning a home is considered a human right in Libya – Gaddafi vowed that his parents would not get a house until everyone else in Libya had a home. Gaddafi’s father has died while he, his wife and his mother were still living in a tent.

4. Education and medical treatments are free in Libya. Before Gaddafi only 25% of Libyans were literate. Today the figure is 83%.

5. If any Libyan wants to take up farming, he receives farming land, a farm house, equipment, seeds and livestock to kick-start their farms – all for free.

6. If Libyans cannot find the education or medical facilities they need in Libya, the government funds them to go abroad for it – not just free, but they get US $2,300 per month for accommodation and running a car.

7. If a Libyan buys a car, the government pays 50% of the price.

8. The price of petrol in Libya is US $0.14 per litre (in the UK, it is $2.17 per litre at this time, which is more than 15 times as much).

9. Libya has no external debt and its reserves amount to US $150 billion – now frozen globally.

10. If a Libyan is unable to get employment after graduation, the state pays the average salary of the profession as if he or she is employed, until employment is found.

11. A portion of Libyan oil sale revenues is credited directly to the bank accounts of all Libyan citizens.

12. 40 loaves of bread in Libya costs just US $0.15 (in the UK, it is 200 times more expensive).

13. 25% of Libyans have a university degree, while in the UK, Sir Clive Woodhead, former Chief
Inspector of Schools, has recently recommended that children should leave school at age 14 and become apprentices.

14. Col. Gaddafi carried out the world’s largest irrigation project, known as the Great Man-Made River project, to make water readily available throughout his desert country.

So, I will leave it up to you to decide if the attacks on Libya and the killing of Col. Gaddafi was an honest action designed to make the world a safer and better place, or if those actions were motivated by some other agenda.

The Technique:
The lawyers and bankers have the objective of taking all of your money and keeping you permanently in debt to them. In the UK, the currency was “the pound sterling” and a £1 note was a promise certifying that there was literally a one pound weight of sterling silver held in storage to back the value of that note and save the person carrying around the actual pound weight of silver.

That link was broken, and nowadays, the £1 note (or in the US, the $1 note) has no actual value as it is no longer a promise that an amount of valuable metal is being held in storage in order to give that piece of paper it’s value. In reality, these paper currency notes have no more value than the paper notes in the board game “Monopoly” and that value is only the value of the paper on which the notes are physically printed, which is, almost nothing at all.

Take the process in America as an example: The “government” decides that it needs some money, so it calls up the (privately owned) Federal Reserve Bank and requests, say, $10,000,000,000. The Federal Reserve Bank replies saying “Sure, we will buy $10 billion in government Bonds from you”. So the “government” takes some pieces of paper, paints some official-looking designs on them and calls them “Treasury Bonds”. Then it puts a value on them of $10 billion and sends them over to the Federal Reserve Bank. In turn, the people in the Federal Reserve Bank draw up a series of impressive looking pieces of paper themselves, only, this time, calling them Federal Reserve notes, also designated with a value of $10 billion. The Federal Reserve Bank then takes these notes and trades them for the Treasury Bonds. Once this trade is complete, the government then takes the $10 billion in Federal Reserve notes and deposits them in a bank account, and on doing this, the $10 billion becomes legal tender money, adding $10 billion to the US money supply. And there it is: $10 billion in new money has been created out of nothing and with no intrinsic value whatsoever. Of course, this example is a generalisation because in reality, this transaction would occur electronically, with no paper used at all. In fact, only 3% of the US money supply exists in physical currency and the other 97% exists in computers alone.

The same style of operation happens in the UK as well with the (privately owned) Bank of England, producing valueless ‘currency’. The banks deliberately compound the problem by lending this valueless money to individual people as a loan or mortgage, knowing full well that there is not enough money in circulation to pay off the loan and the interest. If, for example, the loan is £1000 on a credit card, then the credit card company will want about £1200 back as they charge interest. But as they do that with all of the “money” fraudulently created (actually ten times the amount in America), there is physically not enough to allow the interest to be paid unless the economy of the country keeps on expanding rapidly. The objective here is to take physical goods and possessions away from the borrower when he finds himself unable to pay the amount asked for.

The total lack of value of present day currency was demonstrated when a mortgage loan repossession was challenged in court in America. For any commercial contract anywhere in the world to be valid, something of worth has to be put forward by both parties to that contract. When a bank “lends” it’s worthless money as a mortgage, it has put forward nothing of value and so the
mortgage contract is not valid in law.

In 1969, there was a Minnesota court case involving a man named Jerome Daly who was challenging the foreclosure of his home by the bank which provided the loan to purchase it. His argument was that the mortgage contract required both parties (himself and the bank) to put up a legitimate form of property for the exchange. In legal language, this is called a "consideration" from both parties. Mr Daly explained that the money was, in fact, not the property of the bank as it was created out of nothing as soon as the loan agreement was signed. In other words, the money didn't come out of the bank's existing assets as the bank simply invented it, consequently, the bank put up nothing of value of it's own, except for a theoretical liability on paper. As the court case progressed, the bank's President, Mr Morgan, took the stand and the judges memorandum records that the "Plaintiff admitted that it, in combination with the Federal Reserve Bank ... did create the entire $14,000 in money in credit upon it's own books by bookkeeping entry ... the money and credit first came into existence when they created it. Mr Morgan admitted that no United States Law or Statute existed which gave him the right to do this. A lawful consideration must exist and must be tendered to support the Note" ... The jury found that there was no lawful consideration, and on this finding, the court rejected the bank's application for foreclosure and Mr Daly kept his home.

The Consequences:
The does not seem to be much point in commenting on the situation in other countries around the world as you will find the same style of underhand operation in most of them. However, when you understand what is going on, it explains why it has been so difficult to get any free-energy device on to the market for sale to members of the public.

A really major strand of both income and control comes from access to energy. The average person wants energy for heating and cooling a home, running household equipment such as refrigeration, lighting, computing, etc. and for powering a vehicle, operating power tools, and so on. Under the present deceptive regime, we are told from an early age that we need to burn a fuel in order to get this power, and instead of doing it individually, it appears to be cheaper to buy the power from the local energy company.

The reality is that we live in a sea of energy which can supply our every need for ever and ever without the slightest need for burning any kind of fuel. Devices for tapping this energy have been produced by literally thousands of inventive people and yet, they are not for sale. Why do you think that is?

Well, one of the reasons is that inventors of these devices often feel that they should “protect” their invention by patenting it and so they make an application to a Patent Office. Unfortunately, the Patent Office is a commercial business owned by the same people who make massive amounts of money from selling you oil to burn and electricity to use. Because of that, they steal the best of these inventions, often by telling the inventor that his invention is “Of National Security Importance” and so he can’t use it, sell it or even speak to other people about it, and if he did, he would be put in prison. That is, of course, an unlawful deception as the people telling him that have nothing whatsoever to do with anything National, except the use of the word in their company name. There certainly is no government around to make any kind of statement like that.

The wonderful people then use your money in unlimited amounts to develop these inventions as secret “black” projects and they have been doing this for at least a hundred years. People who have been employed in some of these projects report that they now have technology anything from 100 to 1,000 years in advance of what the public is told about. Almost everything shown in the fictional “Star Trek” series has already been produced covertly in real life. The internet has made it difficult to keep on hiding these advances, but they fight back by posting false information, contradicting people who present the real deal, and generally disrupting and flooding
every useful forum with a combination of rubbish and inflammatory attacks on forum members.

A major strand of the attempt to suppress the truth is through universities and respected Engineering bodies and publications. This is done through financial pressure. To have a successful career, a university professor needs to have regular publication of research papers. For this, he needs researchers who are paid to do the research. This is done through grants from rich people and organisations. Those are the very people who will under no circumstances allow the publication of any research which demonstrates that free-energy exists and they make sure that no funding will ever be available for any such research.

If a scientist steps out of line and goes public with the facts, he is immediately attacked by all of his former colleagues who promptly say that what he says is “impossible” and “breaks the laws of physics”, neither of which are actually true. For example, in 2010, Rosemary Ainslie and her colleagues demonstrated under strict laboratory conditions that a pulsed heating element produces 17 times more heat output than could be produced by the tiny electrical input driving the element. This was written up in standard scientific paper format and passed to the Institute of Electrical Engineers for examination and publication. As was expected, the paper was refused in spite of the fact (or perhaps because of the fact) that the laboratory results were conclusive. None of the present scientific institutions will publish any form of free-energy paper as that would not be good for the business of their owners.

If an inventor skips the Patent Office, avoids the scientific journals, and tries to get his invention manufactured, he needs substantial funding and that is usually blocked by the concerted efforts of the groups of companies whose businesses would be harmed by the invention becoming freely available to the public. Some times, the inventor is threatened and intimidated. I personally know several people who have had this done to them, but the most common block is financial. For example, Cal-Tech in America spent a million dollars developing, testing, proving and perfecting a carburettor which gave vastly improved mpg results and which cut pollution to near zero. They teamed up with the very large auto-parts supplier Arvin Meritor to put the carburettor into production vehicles. Then “One Equity Partners” bought out the Arvin Meritor division which did all the final work, and then they created a new company, “EMCON Technologies”, which dropped the carburettor from their product line, not because it did not work but because it did work. Oil sales were the only interest and cutting pollution was seen as irrelevant.

The Practical Situation
Some of this is quite difficult to absorb and understand, so perhaps a little extra detail may be helpful. Just to recap; there are two separate and totally different systems: the law and the legal system.

The law boils down to “don’t harm anyone or his property, steal his property or swindle him”. That is pretty straightforward and it is binding on everyone. You will notice that it does not say
anything about keeping to a speed limit, paying taxes, getting married, serving in an army, voting in an election, or any one of thousands of other things. Those things are not required by the law. The requirements of the law are “don’t harm anyone, damage or steal his property or defraud him”, nothing else.

The legal system is an invention intended to do exactly the opposite, namely, harm you, steal your property, subject you to the will of someone else and to defraud you generally. The operating method is lies and deception and a prolonged attempt to prevent you finding out the facts. Thankfully, being subject to the legal system is optional – completely your own choice. So, by refusing to consent to being subject to it, you can shrug it off and live a life free from it.

One of the really difficult things to understand is finance. For example: Al Baker, decides to set up a finance company, lending money and charging interest on the loans. He registers “The Swindle Finance Company Limited”, which is a paper invention of the legal system and is not actually a real thing at all – just some pieces of paper and a name written into a list of paper companies.

His friend Charles Daly who lives across the street, decides to deposit £10,000 (or dollars, or Euros, or whatever the local currency is called) with Al because Al is offering 10% annual interest on all deposits as a special advertising promotion. Al puts the money in the bank account of Swindle Finance Company Limited and enters the amount as a credit in the company accounts ledger. Big smile – the business is starting to roll in.

Gary Hughes then decides that he could do with a round-the-world holiday cruise and so he asks Al for a loan of £10,000. Al is delighted and is about to lend him the £10,000 which Charles lodged when his financial director, Ed Foyle, says “hey, you can’t do that, there is a (statute) law against it - if Charles suddenly need money for something and wants to withdraw his money, you have to be able to repay him in full, so you are not allowed to lend his money to anyone else”.

Al is a bit stumped by that and asks “how can we lend money then – it seems impossible?”. It’s quite ok says Ed, we just invent the money. Here, get Gary Hughes to sign this form, but make quite sure that the form says “Mr Gary Hughes” or “MR GARY HUGHES” as that is very important. When the form is signed, we can enter it in our company accounts as a credit because his signature makes it a promissory note which has a value of £10,000 for us. Then, we start making real money by writing him a cheque instead of handing him money. He will sign that cheque in order to cash it and that is worth another £10,000 to us. This is great business as we can enter his signed cheque into our ledger as another £10,000 asset, and write £10,000 which goes into his account as a debit. We have now got £20,000 coming in and only £10,000 going out, so we are already ahead by £10,000 and it isn’t even time for lunch on our first day. Also, if Gary pays back the loan and our 20% interest, then this transaction will have made us a net profit of £22,000. If he didn’t pay us back anything, we would still be £10,000 ahead, so let’s celebrate.

Poor Al is a bit confused, so he asks “but where does the £10,000 that we lend Patrick come from?”. Ed laughs and says, it doesn’t come from anywhere, we just write numbers into our ledger against the name of Mr Gary Hughes – it doesn’t cost us anything – do you think he would hold still long enough for us to stamp “sucker” on his forehead? After all, he is about to pay us more than twice, which means that we will make millions in profit each year. Poor Al is still confused, which is a pity, as Gary is the only person which Ed wants to keep confused about the transaction.

Ed knows all of the legal angles and when he is driving home he exceeds the speed limit. It is not dangerous in any way as there is no other traffic, and the road conditions are perfect. A police car pulls alongside him and indicates that they want him to stop, so he pulls over and stops. A police officer approaches and asks Ed if he is aware that he was driving at 40 mph in a 30 mph zone. Ed says that he was indeed aware of that.
The police officer then asks Ed for his name and address. But, Ed is aware of the fact that this is a fraudulent attempt to get him to agree to “Joinder”, that is, agreeing that he is subject to all legal statutes, giving the police officer authority over him. So, he promptly states that the law does not require him to provide any such information, he also mentions the fact that the law does not require him to drive at, or below, 30 mph in a 30 mph zone. The police officer tries this again several times, getting the same answer each time.

Being a bit stumped by this unexpected response, the police officer switches tactics and says that he may have to take Ed down to the police station for further questioning and asks if Ed understands. Being well up on legal tactics and realising that asking “do you understand” is a fraudulent attempt to establish Joinder, he calmly states that under the law, he is not required to go to a police station and he does NOT “stand under” the police officer or his statement. He also remarks that if he is taken to a police station unlawfully and against his will and without his consent, then he will take action against the police officer personally as a man and not as a police officer, for his unlawful actions. He also asks the police officer if he is aware that the Police Authority which employs him is not a government agency but is a commercial for-profit company with no powers whatsoever to uphold the law, that the police officer is only empowered to uphold the law through the oath which he personally took when he became a policeman and it has nothing whatsoever to do with any form of authority coming from his employers. In other words, he is on his own on this one.

Ed further points out that under the law, there has to be a victim (who has been injured, has his goods damaged or stolen, or who has been defrauded) and he asks the police officer to identify the victim in this case. He also remarks that legal statutes only have the force of law for those people who consent to be bound by them, and he does NOT consent to be bound by them, and so, driving at 40 mph in a 30 mph zone where nobody was endangered and no harm or damage occurred, is not an offence for him.

I’ll leave you to work out the likely outcome of the conversation between Ed and the police officer.

Six months later, Ivan Johnson, a friend of Gary Hughes, remarks that Gary is looking worried and asks him if anything is wrong. Gary, who is self-employed, says that business has been very poor for some time and he is having financial problems. His main difficulty is this loan that he has with the Swindle Finance Company Limited. He has not been able to keep up the payments and he has just has a letter from them saying that he has to pay £2,231.47 by Friday, or they will take him to court. Fortunately, Ivan is familiar with both finance and legal matters, so he tells Gary what to do. His advice is simple, he says; for your contract with the Swindle Finance Company Limited to be valid, it has to meet these requirements:

1. Full disclosure, which didn’t happen as they did not tell you that your signature created the credit.
2. Equal Consideration, which didn’t happen as they have nothing to lose as they didn’t bring anything to the table.
3. Lawful terms and conditions
4. Signatures of the Parties, which didn’t happen as companies can’t produce a “wet ink” signature.

So, you send them a letter agreeing to pay any financial obligation which you might lawfully owe, as soon as they:
1. Provide validation of the debt, that is, the actual accounting.
2. Verification of their claim against you, that is, a sworn affidavit or a signed Invoice.
3. A copy of the Contract binding both parties.

Sign the Letter “Gary Hughes” (not “Mr Gary Hughes”) and write “All Rights Reserved” after your signature. Send the letter by registered delivery so that there is a third-party record of it being
delivered to them.

The financial institution can't validate the debt as they never sustained a loss. They can't verify any claim against you as their billing is to “Mr Gary Hughes” or “MR GARY HUGHES” or “Mr G. Hughes” or “Hughes, Mr G” or some such wording, and none of those is you, since you are the man Gary Hughes. They can't produce a copy of the contract, because one doesn't exist – what exists is an unenforceable unilateral contract with no standing in law.

If they send you a statement of account, then tell them that a statement is not an Invoice and that you need an Invoice. If they send you a photocopy of your loan application form, then tell them that it is not a contract, being signed by only one of the parties.

If they delay and delay, then write and tell them that if they do not provide the requested documentation within fourteen days, that you will consider any debt as being fully discharged.

If they are ill-advised enough to attempt to take you to court, send a copy of your letter agreeing to pay provided they produce the evidence that there is something outstanding to pay, to the court. They may well be penalised by the court for wasting court time as courts only adjudicate between parties who disagree and there is no disagreement in your case as you have agreed to pay if the Swindle Finance Company Limited shows you that you are liable to pay them some amount of other.

Having had this explained to him, I will leave it up to you to decide if Gary felt any better about his situation.

The legal system is very large and very complex. This is quite deliberate and it is intended to make sure that no ordinary person knows all of it. Fortunately, the law is much less complicated and if you are very careful not to walk into any of the traps set for you, you can effectively ignore the legal system. If required to sign anything and you decide to do so, then Gary Hughes should sign it “By: Gary Hughes, agent” or “By: Gary Hughes, principal” as that you are not taking on any responsibilities in the strawman's name.

John Harris of the TPUC organisation, has found a very effective technique for dealing with the attempts of the legal people to extract money from you, is to never go to court (remember that a 'Summons' is only an invitation and you can decline it) and returning all correspondence marking it “No Contract – Return to Sender”. This avoid you ever walking into a “Joinder” trap and becoming liable for the fraudulent claims being made against your strawman. I suggest that you research this subject further and become completely familiar with your rights under common law, and the fraudulent “Joinder” traps being set for you. What you decide to do after that, is entirely up to you.

The Situation in Australia

It appears that both the government and the legal system of Australia are null and void as the basis on which they were created no longer exists. Sir Harry Gibb has this to say about the situation:

I am a former member of the High Court and I wish to take this unusual method of informing you about a matter that is going to deeply affect us all. Unfortunately, a document such as this is too easily "lost" in the bureaucratic jungle in which we operate.

A group of Australian Citizens have taken it upon themselves to test the validity of our current political and judicial system. Like you, I have lived my entire legal career with the assumption that the basis for our legal and political system, state and federal, was written in stone. This group has undertaken to present this paper where they test the legal system.
The group is articulate, well educated and has some of our best legal minds amongst its members. One of Australia’s best known barristers is one of the group’s leading lights. It is far better informed with regard to international law than most members of the judiciary or for that matter, the legal academe. It has better international contacts than I would have thought possible.

After spending some time with the group leader, I was able to elicit it’s primary intentions. It is the introduction of a totally democratic system of government devoid of party politics operated by the will of the people incorporating a system of debit taxation which should go a long way to eliminating the current unemployment problem and addressing other pressing social issues. An A.B.S. financial model supports the proposal.

The group has so far concentrated on matters relating to taxation, state and federal, minor industrial and motor traffic while undertaking not to present a criminal defence using their current presentation. I challenged the leader of this group to present any evidence which he had with regard to the above defence so that I could use my legal expertise to play the part of devil’s advocate. It should be brought to your attention that the group has access to documentation of which we members of the judiciary have little knowledge. I refer to the British Parliamentary Papers for the Colony of Australia for the years 1860 through to 1922.

These are photocopies of all documents correspondence etc., between the states and later the Commonwealth of Australia, the British Crown and the British Government. They are very revealing documents and indicate the degree of chicanery in which the politicians of all shades were involved and as I can now see, at the expense of the legal academe and the judiciary. I present for your perusal the details of the group’s presentation along with my comment on each major item. The group relies solely upon historical fact and rejects political rhetoric and legal opinion unless based upon historical fact.

1. "The Commonwealth of Australia Constitution Act 1900 (UK) is an act of the parliament of the United Kingdom. It did not contain any substance of sovereignty and was a colonial act centralising self-government of the six Australian Colonies. Australia remained a colony of the United Kingdom."

1a. Although the late Lionel Murphy attempted to show that there was an element of sovereignty in this act, he failed to do so. The international definition of sovereignty has been espoused at length and the above act although important in the development of Australia, did not have the authority of sovereignty. The historical evidence that Australia remained a British Colony post 1901 is overwhelming.

2. “Australia made an international declaration of its intention to become a sovereign nation when Prime Minister Hughes and his deputy; Sir Joseph Cook signed the Treaty of Versailles on June 28, 1919. On its cognisance of signing this treaty, Australia was granted a “C” class League of Nations mandate over former German territories in the Pacific. In effect, Papua New Guinea became a colony of Australia achieving its own independence on 16 September 1975. The League of Nations became part of International Law on 10 January 1920 with Article X of the Covenant of League of Nations guaranteeing the sovereignty of each member."

2A. The Significance of Australia joining the League of Nations as a foundation member has never been addressed in Australia before. Strangely, only one book has ever examined the question of Australian independence. Written by W. J. Hudson and M. P. Sharp in 1988 “Australian Independence” printed by Melbourne University Press. As both were members of the Department of Foreign Affairs and Trade at the time of authorship and had access to the, British Parliamentary Papers, I find it most interesting they have avoided any mention of these papers in their book. Their conclusion that Australia became an independent nation via. the Statute of Westminster in 1931 flies in the face of contradictory evidence within the
above mentioned papers and readily available historical fact.

Prime Minister Hughes address to the Commonwealth Parliament on 10 September 1919, “Australia has now entered into a family of nations on a footing of equality. Australia has been born in a blood sacrifice" demonstrates that the politicians of the day were only too well aware of the change of status from a colony to that of a sovereign nation, while attempting to remain within the Empire.

Prime Minister Bruce made this reply to the British Government in 1922 after a request for troops against Kernel Ataturk in the Chanak crisis. Bruce’s reply is contained in the British Parliamentary Papers: "We have to try to ensure there shall be an Empire foreign policy which if we are to be in anyway responsible for it, must be one to which we agree and to which we have assented. If we are to take any responsibility for the Empire’s foreign policy, then there must be a better system, so that we may be consulted and have a better opportunity to express the views of the people of this country. We cannot blindly submit to any policy which may involve us in war." This is a far cry from the declaration of war against Germany made on behalf of the British Colony of Australia by George V of the United Kingdom in 1914.

I have reproduced Bruce’s reply in full as I believe this reply contains clear historical evidence of a Prime Minister who was well aware of the change of status from a colony to a sovereign nation. The later Statute of Westminster 1931 was an acknowledgment of that status.

3A Paragraph 4 of the Statute of Westminster reads "No Act of Parliament of the United Kingdom, passed after the commencement of this Act, shall extend, or be deemed to extend, to a Dominion as part of the law of that Dominion, unless it is expressly declared in that Act, that the Dominion, has requested, and consented to the enactment thereof." Paragraph 1 of the Australia Act is very similar: "No Act of the Parliament of the United Kingdom passed after the commencement of this Act shall extend, or be deemed to extend, to the Commonwealth, or a State or Territory as part of the law of the Commonwealth, of the State or of the Territory."

I passed this one to the Federal Attorney General and asked him what was the source of this quite incredible authority that sought to overturn the authority legislated within the Covenant of the League of Nations in Article X and the Charter of the United Nations in Article 2 paragraphs 1 and 4. He is unable to provide any documentation to support these clauses, Article X of the Covenant of the League of Nations states: “The members of the League undertake to respect and preserve against external aggression the territorial integrity and existing political independence of all Members of the League. In case of any such aggression or in case of any threat or danger of such aggression, the Council shall advise upon the means by which this obligation shall be fulfilled."

It is appropriate that I now introduce a statement by Sir Geoffrey Butler KBE, MA and Fellow, Librarian and Lecturer in International Law and Diplomacy of Corpus Christi College, Cambridge author of “A Handbook to-the League of Nations" used as a reference to the League by virtually all nations at that time. He refers to Article 1 of the Covenant of the League of Nations:

"It is arguable that this article is the Covenant's most significant single measure. By it the British Dominions, namely New Zealand, Australia, South Africa, and Canada, have their independent nationhood established for the first time. There may be friction over small matters in giving effect to this internationally acknowledged fact but the Dominions will always look to the League of Nations Covenant as their Declaration of Independence."
Article 2 paragraph 1 of the United Nation’s Charter states "The Organisation is based on the principle of the sovereign equality of all of its Members."

Article 2 paragraph 4 of the Charter states ‘All members shall refrain in their international relations, from the threat or use of force against the territorial integrity or political independence of any state, or in any other manner inconsistent with the Purposes of the United Nations."

In view of the above, the historical evidence for Australian Independence by 10 January 1920 when the League of Nations became part of International Law is overwhelming. When this evidence is reinforced with the contents of the Charter of the United Nations, the continued usage of any legislation that owes its very legitimacy to the parliament of an acknowledged foreign power cannot be supported by either legal opinion or indeed historical evidence.

I therefore have come to the conclusion that the current legal and political system in use in Australia and its States and Territories has no basis in law.

Following discussions with members of the British Government relating to the Letters Patent for the Governor General and State Governors I find that these documents no longer have any authority. Indeed, the Queen of the United Kingdom is excluded from any position of power in Australia by the United Nations Charter and is excluded under UK law from the issue of a Letters Patent to other than a British Subject. A Letters Patent must refer to an action to be taken with regard to British Citizens. In the Immigration Act 1972, the UK defines Australian Citizens as “aliens”.

The Governor General’s Letters Patent is a comedy of errors. We are greeted in the name of the Queen of Australia who suddenly becomes the Queen of the United Kingdom in the next paragraph of the Letters Patent. This Queen then gives instructions to the Governor General with reference to the Commonwealth of Australia Constitution Act 1900 UK. Here we have a clear breach of Article 2 paragraph 1 of the United Nation Charter. Under both UK and international law, the Queen is a British Citizen.

State Governors are in a worse position since their authority comes from the late Queen Victoria of the United Kingdom. Regardless of the validity of the Commonwealth of Australia Constitution Act 1900 UK, if the authority of Governor General and the State Governors is invalid then so is the entire political and legal system of government.

When advised that the War Crimes Commission was taking an interest, I called them in Geneva. Under the 1947 Geneva Convention, they are empowered to look into cases here in Australia where it is alleged that the law of a foreign country was enforced against a citizen of a member state of the United Nations. As they perceive that only the judiciary can actually enforce the law, the judiciary becomes their target. The group has already placed cases before them which they are currently investigating. If found guilty, the penalties are horrific and include the death penalty!

I could go on with more relevant information however I think now is the time for a summary. The group leader, a QC, states the obvious when he asked me how could a colony now acknowledged by all world nations to be a sovereign Nation, retain exactly the same legal and political system which it enjoyed as a colony, without any change whatsoever to the basis for law. This point alone requires an answer.

The High Court has already answered with regard to the position held by treaties signed by the Commonwealth Government in the Teoh case of 1994. "Ordinary people have the right to expect government officials to consider Australia's international obligations even if those obligations are not reflected in specific Acts of Parliament: the rights recognised in international treaties are an implied limit on executive processes."

My advice is to adjourn any case "sine die" that challenges the authority of the Letters
Patent. Under no circumstances hear a case that challenges the validity of a State or the Federal Constitution. It is the politicians who are using us as pawns without them having to face the music. If these matters are of concern to politicians, then let them sort out these problems and accept any inherent risks themselves! Article 36 of the Statute of the International Court of Justice is the correct reference for you to refuse to hear a matter when an international treaty is cited as a defence.

The Comments of Brian Collins
The following is some of what the very knowledgeable Brian Collins has to say on his web site. I merely quote what he says here and I have not verified any of this material, and so I recommend that you check out these things for yourself.

The Greatest Lie Ever Told

The government and legal system of the United States, Canada, Australia, New Zealand and of course, Britain, is totally controlled by the Crown. The Crown is not the British Monarch. The Crown is the Inner City of London, which is an independent State in London belonging to the Vatican system. It is a banking cartel which has a massive system around and beneath it, which hides its true power. The City is in fact, the Knights Templar Church, also known as the 'Crown Temple' or 'Crown Templar', and is located between Fleet Street and Victoria Embankment. The Temple grounds are also home to the Crown Offices at Crown Office Row.

The Crown Temple controls the Global 'Legal' system, including those in the United States, Canada, Australia, and much more; this is because all Bar Associations are franchises of the International Bar Association at the Inns of Court at Crown Temple based at Chancery Lane in London. All Bar Associations are franchises of the Crown and all Bar Attorneys/ Barristers throughout the world pledge a solemn oath to the Temple, even though many may not be aware that this is what they are doing. Bar Association 'licensed' Solicitors / Barristers must keep to their Oath, Pledge and terms of allegiance to the Crown Temple if they are to be "called to the Bar" and work in the legal profession. The ruling Monarch is also subordinate to the Crown Temple, this as been so since the reign of King John in the 13th century when Royal Sovereignty was transferred to the Crown Temple and, through this, to the Roman Church. King John 1167-1216 is the key to this deception.

It was at the Chancel, or Chancery, of the Crown Inner Temple Court in January 1215 that King John was faced with the demands of the French/English Barons in England (mainly French), to confirm the rights enshrined in the Magna Carta. When he signed the Magna Carta in 1215 history records this as an event that extended human freedom, but the real affect was very different as we shall see. The governments of the USA, Canada, Australia and more, are subsidiaries of the Crown Temple and so is the US Central Bank the Federal Reserve, as are all Central Banks on the planet, including the IMF World Bank.

Bar Associations are awarded their franchises by the Four Inns of Court at Temple Bar. These are the Inner Temple, Middle Temple, Lincolns Inn and Greys Inn and they are nothing less than elite secret societies without charters or statutes. They are the law unto themselves. The Inner Temple controls the legal system franchise for Canada and Britain while the Middle Temple does the same for the United States. Queen Elizabeth II is a member of both Temples. At least five signatories to the American Declaration of Independence were Temple Bar Attorneys who had pledged allegiance to the Crown! Another Middle Temple operative during the formation of the USA was Alexander Hamilton who structured the American Banking system to fulfil the Crown
Temples agenda for total control of the United States. So in truth, a State wherever it is on this planet, is a legal entity of the Temple Crown, or a Crown Colony. A man named Michael Edwards wrote:

"Americans were fooled into believing that the legal Crown Colonies comprising New England, were independent nation states, but they never were, nor are they today. They were, and still are, Colonies of the Crown Temple, through letters patent and charters, who have no legal authority to be independent from the rule and order of the Crown Temple. A legal state is a Crown Temple Colony".

"Neither the American people nor the monarch of Britain own America. The Crown Temple owns America through the deception of those who have sworn their allegiance by oath to the Middle Temple Bar. The Crown Bankers and their Middle Templar Attorneys rule America through unlawful contracts, unlawful Taxes, and contract documents of false equity through debt deceit, all strictly enforced by their completely unlawful, but 'legal', orders, rules and codes of the Crown Temple Courts, or the so called, 'Judiciary', in America. This is because the Crown Temple holds the land titles and estate deeds to all of North America".

Seven Middle Inn Templars who had pledged an oath of allegiance to the Crown Temple (including Alexander Hamilton) were among the members of the Constitutional Convention who signed the completed 'American Constitution'. How symbolic it is that copies of the American Constitution and the Declaration of Independence hang on the wall of the Middle Temple in London. It's not that surprising when you consider that this Temple controlled both sides in these shenanigans.

So while the Middle Bar Templars were orchestrating the illusion of freedom from the perceived rule by King George III, the King too, was a sworn member of the same Temple. Michael Edwards continues:

"1776 is the year that will truly live in infamy for all Americans. It is the year that the Crown Colonies became legal Crown States. The Declaration of Independence was a legal, not lawful, document. It was signed on both sides by representatives of the Crown Temple. Legally, it announced the status quo of the Crown Colonies to that of the new legal name called 'States' as directly possessed estates of the Crown.

"The American people were hoodwinked into thinking that they were declaring lawful independence from the Crown. The proof that the colonies are still a Crown possession is the use of the word 'State' to signify a 'legal estate of possession'. Had this been a document "of and by the people", then both the Declaration of Independence and the US Constitution would have been written using the word 'States'. By the use of 'State', the significance of government of estate possessions was legally established. All of the North American States are Crown Templar possessions through their legal document, signed by their representation of both parties to the contract, known as the Constitution of the United States of America.

Who controls the Crown? On 15th May 1213, King John, being a puppet of the Knights Templar, effectively signed away the Kingdom of England and Ireland to Pope Innocent III and the Roman Church, witnessed by the Crown Templars. As King John said at the time: "I myself bearing witness in the house of the Knights Templars".

The King John Charter said:

" We wish it to be known to all of you, through this our charter, furnished with our seal... not induced by force or compelled by fear, but of our own good and spontaneous will and by common counsel of our Barons, do offer and freely concede to God and his Holy Apostles Peter and Paul and to our mother the holy Roman Church, and to our lord Pope Innocent and to his Catholic successors, the whole kingdom of England and the whole kingdom of Ireland, with all their rights..."
and appurtenances... we perform and swear fealty for them to him are aforesaid lord pope Innocent, and his Catholic successors and the Roman Church... binding our successors and our heirs by our wife forever, in a similar manner to perform fealty and show homage to him who shall be chief pontiff at the time, and to the Roman church without demur. As a sign... we will and establish perpetual obligation and concession... from the proper and especial revenues of our aforesaid kingdoms... the Roman church shall receive yearly a thousand marks sterling... saving to us and to our heirs our rights, liberties and regalia; all of which things, as they have been described above, we wish to have perpetually valid and firm; and we bind ourselves and our successors not to act counter to them. And if we or any of our successors shall presume to attempt this, whoever he be, unless being duly warned he come to his kingdom, and his senses, he shall lose his right to the kingdom, and this charter of our obligation and concession shall always remain firm."

Now it gets interesting. Historical accounts concentrate on the fact that this charter obliged the Crown to pay money to the Roman Church, but it also states that if the terms of the charter are broken, the 'right to the kingdom' shall be lost. When King John signed the Magna Carter on 15th June 1215, he broke the terms of the charter with the Pope and therefore lost the right to his Kingdom. Pope Innocent III then declared the Magna Carter to be null and void. From that time, the 'Crown' passed from the Monarch to the Knights Templar who to this day, govern Britain on behalf of the Roman Illuminati Church.

The St Clair's now Sinclair are the initial directors of this link of Templar and Rome in the British Isles as they took hold in Scotland at the time of the 1066 Norsemen-Norman invasion. This means that ultimately, through the Crown Temple, the Roman system also owns the United States, Canada and all countries and Bar associations controlled both overtly and covertly by the Crown. This is why the Peace Treaty between the American Colonies and the British Crown in 1783, stated:

"It having pleased the Divine Providence to dispose the hearts of the most serene and most potent Prince George the third, by the grace of God, King of Great Britain, France and Ireland, defender of the faith, Duke of Brunswick and Luneburg, arch treasurer and prince elector of the Holy Roman Empire etc... and of the United States of America..."

And ironically, a Roman Catholic is barred from being the British Monarch while all along the Monarch and the Kingdom have been owned by the system that is Rome.

The Queen is the Grand Patroness of Freemasonry. She is served by the 390 members of the Privy Council which connects with it's equivalent in all other Commonwealth Countries. The Privy Council is 'LEGALLY' above Parliament because of its prerogative powers. It's members, are appointed for life and they include Prince Philip, Prince Charles, the Archbishop of Canterbury, the Prime Minister and many others. They hold nine official meetings each year and the government (Crown) minister's stand to attention while the Queen is told of the government measures they are asking the Queen to approve, which are nothing other than what the Crown dictates via the elected leader and via the Whips of whichever political party has power... After taking their bow to the Queen and shaking her hand they are sworn to conduct their business in the utmost secrecy.

Another network of this structure is the CROWN AGENTS. Formed in 1833 as 'Crown Agents for the Colonies', to run the day to day administration of the empire and to serve as private bankers to government officials, colonial authorities, and heads of state. It is also an older version of Brown & Root supplying a vast range of goods throughout the empire. Goods that included arms, drugs, viruses, especially to Africa to create the genocidal wars we are now witnessing and have witnessed in the past. The 'Crown Agents' is the network which links the Crown Temple to the organised crime operations throughout the empire, the Golden Dawn being one of the most powerful occult operations to be used in Britain amongst the crime syndicates to ensure that the right crime waves are in full swing when required.
We can see this in the current agenda for guns. The Golden Dawn also operates within legal organisations, but is the interconnecting network across all secret societies and religion. Remember that the Crown Agents work directly for the Monarch who works for the Knights Templar Church, which operates for the Vatican, and to add insult to injury, the entire debt of the Crown Agents is guaranteed by the British Government, and that means you!

In the 1970's it was bailed out by the Bank of England costing hundreds of millions of pounds. For many years the Crown Agents managed the personal wealth of the Sultan of Brunei who just happens to be a great friend of the Queen, and who has funded many of Prince Philips', Prince Charles', and George Bush senior's private projects. The Sultan is also the financier of both the British and the American unofficial intelligence operations as he has backed many of Mohammed Al Fayed's operations, in fact the Sultan could be said to be Mohammed Al Fayed!

After the murder of Princess Diana, the role of Al Fayed was for him to hijack the conspiracy and thus lead investigators down the Al Fayed rap of misinformation as was done with Nick Brown over the top-up fees debate, and is currently being played by David Davis. Fortunately no one needed to go to him for information because we all in our hearts already know that she was murdered.

In 1996 the ‘Crown Agents’ operation was privatised and given the name ‘Crown Agents for Overseas Government and Administration Ltd’. Of course, privatisation is nothing but transfer of Power from Crown Temple through Government agency to Crown Temple via direct ownership: they own everything in this nation!

Just to give an idea of What the Crown Agencies controls, here are a few little companies which it controls. It acts as a holding company for:

- Barclays bank
- Standard and Chartered bank
- Unilever
- Tate and Lyle
- Securicor
- British Telecom
- The Prince of Wales Business Leaders Forum, and
- Aga Khan Foundation

I think you get the picture; it's big to say the least.

It manages the customs services of Mozambique, and through a company called Europe SA, it is in charge of all of the economic construction procurement for Bosnia. It is also in a joint venture with the Monaco-based company ES-KO, to provide all the food for United Nations peace keeping forces in Angola and Bosnia. So, the more war the more profit for the Crown Agents, and if it were to fail financially, then the British Taxpayer will have to foot the bill !!!!

The queen of England owns the 40,000 acre Duchy of Lancaster, and the 44,000 acre Duchy of Cornwall which gives Charles his income. In truth, it is the Crown that owns these assets, which are assigned to the ruling monarch, so long as they do as they are told. The Crown, it transpires, owns land in the UK to the tune of 40 million acres. The Queen owns over 300 residences around the country, and invests heavily in corporations like Rio Tinto Zinc, Royal Dutch Shell, ICI, and General Electric. This is no surprise as these companies are 100% Illuminati operations.

Rio Tinto is the largest mining company in the world and was established in 1873 by Hugh Matheson of the Global drug running operation Jardine Matheson. Rio Tinto was in at the start of the North Sea Oil, along with Texaco. They used the refineries of BP in which the Queen also has massive investments, so now you know where all the revenues from the North Sea oil reserves
went - to the Crown Temple. This shows insider dealing on an individual basis enabling the Queen to make massive profits.

Another blatant conflict of interest to have been identified, was Rio Tinto's involvement in a cartel formed in 1971 to fix the price of uranium. A Federal grand jury and the 1976 US Senate Foreign Relations Committee, chaired by Frank Church, exposed the sting. It also included a company called Mary Kathleen Uranium of Australia. This company had been secretly encouraging the Aborigines to occupy uranium-rich lands in Australia to take these lands out of production in order to raise the price of uranium on the world market. The manipulated shortage of uranium had a serious effect on the American Westinghouse company who sought to take legal action against Rio Tinto for price rigging.

This strategy has been used in the USA against the Native Americans and throughout Africa. An American court ordered that Rio Tinto officials answer questions, but this was quashed by the British Law Lords. The Australian government passed legislation to the same effect. This was after the Australian Prime Minister, Gough Whitlam, had been dismissed from office by the Queen's Governor General of Australia, Sir John Kerr. Whitlam was pursuing a policy of buying out the mining and raw material cartels, like Rio Tinto and Anglo American, to stop them raping Australia's resource base, while giving nothing in return.

The Queen having enormous investments in both companies, removed Whitlam by using some of her wide range of prerogative powers, which by the way, she has in all commonwealth countries including Britain, which she can instigate when the Crown deem necessary, but of course in the minds of the masses the Queen has no powers today! Well I suppose she doesn't in that she is a puppet of the Crown Temple and ultimately, of the Roman system. Sir John Kerr, a former high level operative of British Intelligence, was made a member of the Privy Council and the Royal Victorian Order for his loyal and most profitable service to the Queen's portfolio.

He was later murdered however, when the truth about the removal of Gough Whitlam was in danger of coming out - how they look after their own! He was obviously outer circle, and a good man and would have exposed the lies of the inner circle. The Crown Cartels continue through a House of Windsor extremely secretive society called the Club of the Isles. It was named after King Edward VII, Queen Victoria's son.

The title is held today by Prince Charles. King Edward VII was heavily involved with the Black Nobility barons of 'the square mile of London' Financial District and helped them to engineer the Crimean War, the Russia - Japan War, the preparations for the First World War, and the Opium Wars against China. Through the central organisation of the Club of the Isles comes the fantastic web of interlocking directorships which holds apparently 'independent' companies in a network of common control and common agenda. Part of that web includes:

- The Bank of England
- Anglo American Corporation of South Africa
- Rio Tinto
- Minorco Minerals and Resources Corp
- De Beers Consolidated Mines
- De Beers Centenary AG
- N.M Rothschild’s Bank
- Barclays Bank
- Lloyds Bank
- Lloyds Insurance Market
- HSBC Bank
- National Westminster Bank
- Barings Bank
- Schroders bank
- Standard Chartered Bank

15 - 44
This is just a few of them. In 1999, Lonrho had 640 subsidiary companies itself; today, it has many more, and all of these companies have themselves, staggering numbers of subsidiaries. In studying the subsidiaries of the multi-nationals, you arrive at the fact that everything is controlled by the Crown, and that all of them lead back to operatives of the Roman Illuminati Church via the Knights Templar Church.

A fact worth noting is that just because a company like Pilkington Glass is now perceived to be owned by a non-British company, it has only moved from the British economy, not from the control or economy of the Illuminati who own everything, this type of movement is only a movement within the global conglomerate that is the New World Order and still earning for, and controlled by, the bloodline elite, albeit via a different branch of the elite tree.

Just look at some of the TV companies owned and thus controlled by General Electric:

- NBC network
- CNBC
- MSNBC
- Bravo
- MUN2 TV
- Sci-Fi channel
- Trio
- WNBC - New York
- KNBC - Los Angeles
WMAQ - Chicago
WCAU - Philadelphia
KNTV - San Jose - San Francisco
KXAS - Dallas - Fort Worth
WRAC Washington
WTJV - Miami
KNSDF - San Diego
WVIT - Hartford
WNKN - Raleigh
WCMH - Columbus
WVTM - Birmingham (USA)
WJAR - Providence
KVEA / KWHY - Los Angeles
WNJU - New York
WSCV - Miami
KTMD - Houston
WSNS - Chicago
KXTX - Dallas
KVDA - San Antonio
KSTS - San Francisco
KDRX - Phoenix
KNSO - Fresno
KMAS - Denver
WNEU - Boston / Merrimack
KHRR - Tucson
WKAQ - Puerto Rico
Universal Studios
NBC Universal Television Studio
NBC Universal Television Distribution.

This is one company controlling a major chunk of the TV dream state given out to the whole of America. Is it any wonder that Americans are completely under the control of the American elite?

Another important part of the Windsor network which is part of the Crown Temple, are the City Livery Companies. These purport to represent the various groups of merchants like the gun makers, stationers, newspaper makers, goldsmiths and the like. They are in fact, very secret societies, fundamental to the control of the City institutions and much further afield. In the 1350's, in the wake of the plague known to history as the Black Death, the government of the City passed from the ward councils to the City Livery Companies. In 1979, the year when Margaret Thatcher took power, the Honourable Company of Freemen of the City of London and of North America, began to hold meetings in New York and Toronto, and on 21st October 1991, the Association of Liverymen of the City of London in Hong Kong was founded and all their members were Architects (Freemasons). The late author Peter Jones, researched some of the Livery Companies in the 1990's for his book,' The Obedience of Australia', which exposed the manipulation which led to the removal by the Queen, of Australian Prime Minister, Gough Whitlam. These are some of the names which he found within these companies:

Engineers: The Duke of Edinburgh.

Airline Pilots and Navigators: The Duke of Edinburgh Prince Andrew

Butchers: Queen Mother, Lord Vesty (of the meat family and Lord Prior of the Order of St John of Jerusalem)

Merchant Tailors: Queen Mother, Lord Whitelaw
Glovers: Margaret Thatcher, Sir John Fieldhouse (Admiral of the Fleet during the Falklands conflict)

Poulterers: Margaret Thatcher, Duchess of Devonshire.

Fishmongers: Duke and Duchess of Devonshire, C.E.A

Hambro (Hambros Bank, Taylor Woodrow, and P&O), Lord Inchcape (Her Majesty's Lieutenant of London)

Goldsmiths: J.H Hambro.

Grocers: Edward Heath.

Salter's: Duke of Kent (Grand Master of English Freemasonry) Lord Armstrong.

Cloth workers: Sir Peter Gadson (a Grand Master of the United Grand Lodge), Lord Carrington (Thatcher's handler).

Another name prominent within these companies is McAlpine of the construction family.

You will of course have noted that Prince Philip heads the Pilots and Navigators, which gives indication as to whom is in control of the current attack on our right to travel by plane and the whole swath of legislation about to come out relative to air traffic, using the environment scam to force it through. Just as a matter of interest, the cheap-flight operator 'Easy Jet' is financed by the Warburg Bank which is part of the Rothschild empire which has been proved beyond doubt, to have funded the rise of Hitler's war machine on behalf of the Rothschilds.

The fact that they are now blaming these cheap flight operators for the rise in carbon emissions shows you why the Warburg bank has funded this airline, it is the catalyst for the introduction of the carbon emissions scam. Basically they will determine how much you, as a household, can travel. You have to look at this whole carbon emissions agenda as an attempt to instil a massive suppressing layer of control upon families and business via the introduction of quotas per household.

This will stifle people's movements to unimaginable levels. Don't forget that the House of Rothschild operates directly under the current British chief, Prince Philip. Prince Philip's whole family were supporters of the Nazi's as was he himself. In 1935, Prince Christoph, the husband of Philip's sister Sophie, was a colonel in the SS of Himmler's personal staff and head of the Forschungsamt, an elite intelligence operation controlled by Hermann Goering.

It was they who carried out the famous 'Night of the Long Knives' when Hitler removed his key opponents. Christoph and Sophie named their eldest child, Karl Adolf, after Hitler and Prince Philip was involved in his education. Christoph's brother, Philip of Hess, was related to the King of Italy and was the official liaison between the fascists of Italy and Germany. Also at the same time the British King Edward VIII, who was forced to abdicate in order the Queen Mother could be placed in the position of Chief Toad which meant she had to marry the lesser of the brothers, Bertie, the one she could obviously control.

King Edward VIII was well known to be a Nazi supporter. Prince Philip kept up very serious connections with Edward even after his abdication in 1936. Another of Edward's supporters, and mentor to Prince Philip, was the known paedophile and Satanist Lord Louis Mountbatten (Battenberg). Mountbatten was Philip's route into the House of Windsor. Mountbatten was the grandson of Queen Victoria and Prince Albert and was born at Windsor Castle in 1900. While Mountbatten was supposedly fighting on the British side during the war, he maintained serious communications with the Windsor's German Clan via his sister Louise, the Crown Princess of
Sweden and wife of King Gustav. Louise was Prince Philip’s aunt.

At the end of the war, in June 1945, the British King, George VI, the father of Queen Elizabeth and puppet of the Queen Mother, sent the former MI5 officer, Anthony Blunt, to the Kronberg Castle of Prince Philip’s sister Sophie, and her Nazi husband Prince Christoph of Hess, to recover correspondence between the British Royal Family and their Nazi relatives, for propaganda aimed at convincing the aristocrats of Britain they had not been in contact all along. Blunt was the ‘surveyor of the Queens Pictures’ and a world expert in the paintings of Poussin, the initiate who painted pictures called ‘The Shepherds of Arcadia’ which related to the Rennes-le-Chateau mysteries. Blunt was named as a member of a KGB unit inside British Intelligence along with Burgess, MacLean, and Philby, the fifth man was never named, but was in fact, Lord Victor Rothschild.

If you have seen the latest Bond movies, you hear the Character ‘M’ played by Dame Judy Dench state, ‘ in the cold war days intelligence operatives that made a big mistake had the common decency to defect’, of course they would the intelligence services of the world are one and the same. When Blunt was finally caught in the 1980’s, Queen Elizabeth II demanded he was not questioned on his clandestine mission to Kronberg Castle… So who controls the law?

Another important secret society within the Crown Temple is the Knights Grand Cross of the Order of the Bath, sounds pretty strange until you understand its symbolism. Both George Bush snr. and Ronald Reagan were given this title. The resurrection bath of alchemy, symbolises rebirth and purification or absolution. Baths are given to Masonic Knights of the Bath before they perform horrendous deeds, hence the term ‘Blood Baths’.

The information in the last few paragraphs only hints at the true power of the Crown Temple. One has also to include all that the Vatican openly controls, to see the true extent of the power of the Roman Illuminati Church to which the Knights Templar Church is subordinate. Through all these networks and more, thirteen Royal Nefilim families control the world, and it is they who are carrying out all of the atrocities in the world at this present time, to carry out the agenda of the Elohim.

The Crown also owns massive parts of our coastline around this nation and 12 miles out to sea, in total about half of the coastline. Some of this is under the control of the Ministry of Defence which is itself controlled by the Crown. The current legislation, under which the National Trust will purchase some of this land from the MOD and coast not belonging to the MOD, changes nothing. The National Trust is 100% controlled by the Crown. We have the British Waterways agency, and the railways again controlling massive amounts of land, and we are effectively almost back to the middle ages now.

One of the greatest means to the Windsor land-grab is the:

CLUB OF THE ISLES

Controlling the World Wildlife Fund, WWF, this is one hell of a heinous operation and given the fact that Prince Philip inherited the position as the Queen’s husband, becoming Commander of the Club of the Isles…then he is at the helm of genocide the likes of which the Holocaust could never imagine.

I see that the Royals are playing the good guys relative to the Sunni Muslims with the release of the Manchester man after 18 years in prison in Pakistan, this in itself shows you who operates President Musharaff of Pakistan, via such orders as the Order of the Mystic Shrine. This is important, given that Pakistan is now under attack from NATO forces, again controlled by the Inner City banking cartel which includes the Dutch and the Swiss.

So how does the Crown control all the MPs? Answer; via the whip system. All of the MPs which
you vote in to represent you, are told how to vote each day by each party’s leadership via the whips. So when any politician that has ever been and will be while this system exists, tells lies to the whole population the minute he or she opens his mouth and speaks. No matter what he speaks about, it is saying what he has been told to say, how to speak and when to speak. If it does not obey the whips, then his career is over. Thus the Crown need only control the people at leadership level or the cabinet of each political party and the Whips office, then through that clique of puppets, they demand obedience from all MPs down to the MPs sitting in each constituency, claiming to be acting on behalf of their constituents. The majority of MPs don't even get to see each bill before it goes to the vote, and indeed they don't need to as they are told how to vote on every Bill.

On Sunday 11th February 2007 on the political show 'Sunday AM', Giles Brandreth, a Conservative Party whip stated:

"As a whip, we understand each MP's marital problems, their drinking problems their financial problems, we know a lot about them. We then advise and guide them to making the right decisions".

Do you still feel that MPs act according to their own understanding and emotions? Of course they do not. This is the best I have witnessed from a politician handing you on a plate how the game of politics actually operates. They are all, through fear of their personal information being leaked; totally afraid of the whips, and so do the whips’ bidding, which, of course, is the Crown's bidding. All MPs who speak at the box in the Commons do so under oath to the Bible positioned under the box. What does that tell you about those who operate as very religious people (Blair) when they spew the bullshit? Blair is a high member of the Illuminati and that is why he can lie with ease as he speaks to the House and the people.

The Economic Techniques

The following is an excerpt from a document, dated May 1979, and which appears to be a statement of the methods and techniques used in the economic warfare which is being waged against all ordinary people at this time. Let me emphasise that these are not my words but that I am quoting the contents of an old and unverified document of unknown origin. Anonymous documents are a standard method of spreading disinformation, however, the statements quoted below are included because they have every appearance of being a factual New World Order strategy already being implemented.

**Top Secret**

Silent Weapons for Quiet Wars, An introductory programming manual, Operations Research Technical Manual TM-SW7905.1 This publication marks the 25th anniversary of the Third World War, called the "Quiet War", being conducted using subjective biological warfare, fought with "silent weapons." May 1979

Security

It is patently impossible to discuss social engineering or the automation of a society, i.e., the engineering of social automation systems (silent weapons) on a national or worldwide scale without implying extensive objectives of social control and destruction of human life, i.e., slavery and genocide. Whenever any person or group of persons in a position of great power and without full knowledge and consent of the public, uses such knowledge and methodologies for economic conquest - it must be understood that a state of domestic warfare exists between that person, or group of persons, and the public. The solution of today's problems requires an approach which is ruthlessly candid, with no agonizing over religious, moral or cultural values.

Historical Introduction
Silent weapon technology has evolved from Operations Research ("OR"), a strategic and tactical methodology developed under the Military Management in England during the Second World War. The original purpose of Operations Research was to study the strategic and tactical problems of air and land defence with the objective of effective use of limited military resources against foreign enemies (i.e., logistics). It was soon recognised by those in positions of power that the same methods might be useful for totally controlling a society, but better tools were needed.

Social engineering (the analysis and automation of a society) requires the correlation of great amounts of constantly changing economic information (data), so a high-speed computerised data-processing system was necessary which could predict when society would arrive at the point of capitulation. Mechanical computers were too slow, but the electronic computer fills the bill. The next breakthrough was the development of the simplex method of linear programming in 1947 by the mathematician George B. Dantzig. Then in 1948, the transistor, promised great expansion of the computer field by reducing space and power requirements.

With these three inventions, those in positions of power strongly suspected that it was possible for them to control the whole world. Immediately, the Rockefeller Foundation got in on the ground floor by making a four-year grant to Harvard College, funding the Harvard Economic Research Project for the study of the structure of the American Economy. One year later, in 1949, The United States Air Force joined in. In 1952 the grant period terminated, and a high-level meeting of the Elite was held to determine the next phase of social Operations Research. The Harvard project had been very fruitful, as is borne out by the publication of some of its results in 1953 suggesting the feasibility of economic (social) engineering. (Studies in the Structure of the American Economy - copyright 1953 by Wassily Leontief, International Science Press Inc., White Plains, New York).

Engineered during the last half of the 1940's, by 1954 the new Quiet-War machine was ready. With the creation of the maser in 1954, the promise of unlocking unlimited sources of fusion atomic energy from the heavy hydrogen in sea water and the consequent availability of unlimited social power was a possibility only decades away. The combination was irresistible. The Quiet War was quietly declared by the International Elite at a meeting held in 1954. Although the silent weapons system was nearly exposed 13 years later, the evolution of the new weapon-system has never suffered any major setbacks. This year of 1979 marks the 25th anniversary of the beginning of the Quiet War. Already this domestic war has had many victories on many fronts throughout the world.

**Political Introduction**

In 1954 it was well recognised by those in positions of authority, that it would be only a few decades, before the general public would be able to grasp and upset the cradle of power, for the elements of the new silent-weapon technology were as accessible for use in providing a public utopia as they were for providing a private utopia. So, the issue of primary concern, namely that of dominance, revolved around the subject of the energy sciences.

**Energy**

Energy is recognised as the key to all activity on earth. Natural science is the study of the sources and control of natural energy, and social science (theoretically expressed as economics) is the study of the sources and control of social energy. Both are bookkeeping systems based on mathematics. Therefore, mathematics is the primary energy science and the bookkeeper can be king if the public can be kept ignorant of the methodology of the bookkeeping.

All science is merely a means to an end. The means is knowledge. The end is control. Beyond this remains only one issue: Who will be the beneficiary? In 1954 this was the issue of primary concern. Although the so-called "moral issues" were raised, in view of the law of natural selection
it was agreed that a nation or world of people who will not use their intelligence are no better than animals who do not have intelligence. Such people are beasts of burden and steaks on the table by choice and consent.

Consequently, in the interest of future world order, peace, and tranquillity, it was decided to wage a private quiet war against the American public with an ultimate objective of permanently shifting the natural and social energy (wealth) of the undisciplined and irresponsible many into the hands of the self-disciplined, responsible, and "worthy" few.

In order to implement this objective, it was necessary to create, secure, and apply new weapons which, as it turned out, were a class of weapons so subtle and sophisticated in their principle of operation and public appearance as to earn for themselves the name of "silent weapons." In conclusion, the objective of economic research, as conducted by the magnates of capital (banking) and the industries of commodities (goods and services), is the establishment of an economy which is totally predictable and which can be manipulated.

In order to achieve this totally predictable economy, the low-class elements of society must be brought under total control, i.e., They must be housebroken, trained, and assigned a yoke and long-term social duties from a very early age, before they have an opportunity to question the propriety of the matter. In order to achieve such conformity, the lower-class family unit must be disintegrated by a process of increasing preoccupation of the parents and the establishment of government-operated day-care centres for the occupationally orphaned children.

The quality of education given to the lower class must be of the poorest sort, so that the moat of ignorance isolating the inferior class from the superior class is and always remains, incomprehensible to the inferior class. With such an initial handicap, even bright lower class individuals have little if any hope of extricating themselves from their assigned lot in life. This form of slavery is essential to maintain some measure of social order, peace, and tranquillity for the ruling upper class.

**Descriptive Introduction to the Silent Weapon**

Everything which can be expected from an ordinary weapon is also expected from a silent weapon by its creators, but only in its own manner of functioning. It shoots situations, instead of bullets; it's propellant is data processing, instead of the conventional chemical explosion. The power originates from bits of data in a computer, instead of grains of gunpowder inside a gun. The operator is a computer programmer, instead of a military marksman, and the orders are issued by a banking magnate, instead of a military general. It makes no obvious explosive noises, causes no obvious physical or mental injuries, and does not interfere in an obvious way with anyone's daily social life.

However, it makes an unmistakable "noise," causes unmistakable physical and mental damage, and interferes unmistakably with daily social life, that is, in ways which are unmistakable to a trained observer who knows what to look for. The public cannot comprehend this weapon, and therefore cannot believe that they are being attacked and subdued by a weapon. The public might instinctively feel that something is wrong, but because of the technical nature of the silent weapon, they cannot express their feeling in any rational way, or handle the problem with intelligence. Therefore, they do not know how to call for help, nor do they know how to associate with others to defend themselves against it.

When a silent weapon is applied gradually, the public adjusts and adapts to its presence and learns to tolerate its encroachment on their lives until the psychological pressure (applied via economic methods) becomes too great and they crack up. Therefore, in a way, the silent weapon can be considered to be a type of biological weapon. It attacks the vitality, options, and mobility of the individuals of a society by knowing, understanding, manipulating, and attacking their
sources of natural and social energy, and their physical, mental, and emotional strengths and weaknesses.

**Theoretical Introduction**

"Give me control over a nation's currency, and I care not who makes its laws." - Mayer Amschel Rothschild (1743 - 1812). Today's silent weapons technology is an outgrowth of a simple idea discovered, succinctly expressed, and effectively applied by Mr. Mayer Amschel Rothschild. Mr. Rothschild discovered the missing passive component of economic theory known as economic inductance. He, of course, did not think of his discovery in these twentieth century terms, and, to be sure, mathematical analysis had to wait for the Second Industrial Revolution, the rise of the theory of mechanics and electronics, and finally, the invention of the electronic computer before it could be effectively applied in the control of the world economy.

**General Energy Concepts**

In the study of energy systems, there always appears three elementary concepts. These are:

- **Potential Energy**
- **Kinetic Energy**
- **Energy Dissipation**

Corresponding to these concepts, there are three idealised, essentially pure physical counterparts called passive components.

In the science of physical mechanics, the phenomenon of Potential Energy is associated with a physical property called Elasticity or stiffness, and can be represented by a stretched spring. In electronic science, Potential energy is stored in a capacitor instead of a spring. This property is called Capacitance instead of Elasticity.

In the science of physical mechanics, the phenomenon of Kinetic Energy is associated with a physical property called Inertia or Mass, and can be represented by a mass or a flywheel in motion. In electronic science, Kinetic Energy is stored in an inductor (in a magnetic field) instead of a mass. This property is called Inductance instead of Inertia.

In the science of physical mechanics, the phenomenon of Energy Dissipation is associated with a physical property called Friction or Resistance, and can be represented by a dashpot or other device which converts energy into heat. In electronic science, Energy Dissipation is performed by an element called either a Resistor.

In economics the equivalents of these three energy concepts are:

- **Economic Capacitance** - **Capital** (money, stock/inventory, investments in buildings etc.)
- **Economic Conductance** - **Goods** (production flow coefficients)
- **Economic Inductance** - **Services** (the influence of the industrial population on output)

All of the mathematical theory developed in the study of one energy system (e.g., mechanics, electronics, etc.) can be immediately applied in the study of any other energy system (e.g., economics).

**Mr Rothschild's Energy Discovery**

What Mr. Rothschild discovered was the basic principle of power, influence, and control over people as applied to economics. That principle is "when you assume the appearance of power, people soon give it to you." Mr. Rothschild had discovered that currency or deposit loan accounts had the required appearance of power that could be used to induce people (inductance, with people corresponding to a magnetic field) into surrendering their real wealth in exchange for a promise of greater wealth (instead of real compensation). They would put up real collateral in exchange for a loan of promissory notes. Mr. Rothschild found that he could issue more notes than he had backing for, provided he had someone's stock of gold to show his customers as a
persuader.

Mr. Rothschild loaned his promissory notes to individual and to governments. These would create overconfidence. Then he would make money scarce, tighten control of the system, and collect the collateral through the obligation of contracts. The cycle was then repeated. These pressures could be used to ignite a war. Then he would control the availability of currency to determine who would win the war. Any government which agreed to give him control of its economic system got his support. Collection of debts was guaranteed by economic aid to the enemy of the debtor. The profit derived from this economic methodology made Mr. Rothschild all the more able to expand his wealth. He found that the public greed would allow currency to be printed by government order beyond the limits (inflation) of backing in precious metal or the production of goods and services.

**Apparent Capital as "Paper" Inductor**

In this structure, credit, presented as a pure element called "currency," has the appearance of capital, but is in effect, negative capital. Hence, it has the appearance of service, but it is, in fact, indebtedness or debt. It is therefore an economic inductance instead of an economic capacitance, and if balanced in no other way, will be balanced by the negation of population (war, genocide). The total sum of goods and services represents real capital and it is called the Gross National Product, and currency may be printed up to this level and still represent economic capacitance; but currency printed beyond this level is subtractive, represents the introduction of economic inductance, and so becomes notes of indebtedness.

War is therefore the balancing of the system by killing the true creditors (the public which has been taught to exchange true value for inflated currency) and falling back on whatever is left of the resources of nature and regeneration of those resources. Mr. Rothschild had discovered that currency gave him the power to rearrange the economic structure to his own advantage, to shift economic inductance to those economic positions which would encourage the greatest economic instability and oscillation.

The final key to economic control had to wait until there was sufficient data and high-speed computing equipment to keep close watch on the economic oscillations created by price shocking and excess paper energy credits - paper inductance/inflation.

**Breakthrough**

The aviation field provided the greatest evolution in economic engineering by way of the mathematical theory of shock testing. In this process, a projectile is fired from an airframe on the ground and the impulse of the recoil is monitored by vibration transducers connected to the airframe and wired to chart recorders. By studying the echoes or reflections of the recoil impulse in the airframe, it is possible to discover critical vibrations in the structure of the airframe which either vibrations of the engine or aeolian vibrations of the wings, or a combination of the two, might reinforce resulting in a resonant self-destruction of the airframe in flight. From the standpoint of engineering, this means that the strengths and weaknesses of the structure of the airframe in terms of vibrational energy can be discovered and manipulated.

**Application in Economics**

To use this method of airframe shock testing in economic engineering, the prices of commodities are shocked, and the public consumer reaction is monitored. The resulting echoes of the economic shock are interpreted theoretically by computers and the psycho-economic structure of the economy is thus discovered. It is by this process that partial differential and difference matrices are discovered that define the family household and make possible its evaluation as an economic industry (dissipative consumer structure). Then the response of the household to future shocks can be predicted and manipulated, and society becomes a well-regulated animal with its reins under the control of a sophisticated computer-regulated social energy bookkeeping system. Eventually every individual element of the structure comes under computer control through a knowledge of personal preferences, such knowledge guaranteed by computer
association of consumer preferences (universal product code - the striped bar codes on packages) with identified consumers (initially identified through the use of a credit card and later through a permanent "tattooed" body number invisible under normal ambient illumination).

**The Economic Model**

The Harvard Economic Research Project (1948-1952) was an extension of World War II Operations Research. Its purpose was to discover the science of controlling an economy: at first the American economy, and then the world economy. It was felt that with sufficient mathematical foundation and data, it would be nearly as easy to predict and control the trend of an economy as to predict and control the trajectory of a projectile. Such has proven to be the case. Moreover, the economy has been transformed into an accurately targeted guided missile.

The immediate aim of the Harvard project was to discover the economic structure, what forces can change that structure, how the behaviour of the structure can be predicted, and how it can be manipulated. What was needed was a well-organised knowledge of the mathematical structures and interrelationships of investment, production, distribution, and consumption. Briefly, it was discovered that an economy obeyed the same laws as electricity and that all of the mathematical theory and practical and computer know-how developed for the electronic field could be directly applied in the study of economics. This discovery was not openly declared, and its more subtle implications were, and are, kept as a closely guarded secret, for example, in an economic model, human life is measured in dollars, and that the electric spark generated when opening a switch connected to an active inductor is mathematically the same as starting a war.

The greatest hurdle which theoretical economists faced was the accurate description of the household as an industry. This is a challenge because consumer purchases are a matter of choice which in turn is influenced by family income, purchase price, and other economic factors. This hurdle was cleared in an indirect and statistically approximate way by an application of shock testing to determine the current characteristics, called current technical coefficients, of a household industry. Finally, because problems in theoretical electronics can be translated very easily into problems of theoretical economics, and the solution translated back again, it follows that only a book of language translation and concept definition needed to be written for economics. The remainder could be got from standard works on mathematics and electronics. This makes the publication of books on advanced economics unnecessary, and greatly simplifies the silent war project security.

**Industrial Diagrams**

An ideal industry is defined as a device which receives value from other industries in several forms and converts them into one specific product for sales and distribution to other industries. It has several inputs and one output. What the public normally thinks of as one industry is really an industrial complex, where several industries under one roof produce one or more products.

**Three Industrial Classes**

Industries fall into three categories or classes by type of output:
- Class 1 - **Capital** (resources)
- Class 2 - **Goods** (commodities or use - dissipative)
- Class 3 - **Services** (action of population).

Class 1 industries exist at three levels:
- (a) **Nature** - sources of energy and raw materials.
- (b) **Government** - printing of currency equal to the gross national product (GNP), and extension of currency in excess of GNP.
- (c) **Banking** - loaning of money for interest, and extension (inflation/counterfeiting) of economic value through deposit loan accounts.

Class 2 industries exist as producers of tangible or consumer (dissipated) products. This sort of activity is usually recognised and labelled by the public as "industry."
Class 3 industries are those which have service rather than a tangible product as their output. These industries are called
(a) Households, and
(b) Governments. Their output is human activity of a mechanical sort, and their basis is population.

**Aggregation**
The whole economic system can be represented by a three-industry model if one allows the names of the outputs to be:
(1) Capital,
(2) Goods, and
(3) Services.

The problem with this representation is that it would not show the influence of, say, the textile industry on the steel industry. This is because both the textile industry and the steel industry would be contained within a single classification called the "goods industry" and by this process of combining or aggregating these two industries under one system block they would lose their economic individuality.

**The E- Model**
A national economy consists of simultaneous flows of production, distribution, consumption, and investment. If all of these elements including labour and human functions are assigned a numerical value using common units of measure, say, US dollars at their 1939 value, then this flow can be further represented by a current flow in an electronic circuit, and its behaviour can be predicted and manipulated with useful precision.

The three ideal passive energy components of electronics, the capacitor, the resistor, and the inductor correspond to the three ideal passive energy components of economics called the pure industries of capital, goods, and services.

**Economic Capacitance** represents the storage of capital in one form or another.

**Economic Conductance** represents the level of conductance of materials for the production of goods.

**Economic Inductance** represents the inertia of economic value in motion. This is a population phenomenon known as services.

**Economic Inductance**
An electrical inductor (e.g., a coil or wire) has an electric current as its primary phenomenon and a magnetic field as its secondary phenomenon (inertia). Corresponding to this, an economic inductor has a flow of economic value as its primary phenomenon and a population field as its secondary field phenomenon of inertia. When the flow of economic value (e.g., money) diminishes, the human population field collapses in order to keep the economic value (money) flowing (extreme case - war). This public inertia is a result of consumer buying habits, expected standard of living, etc., and is generally a phenomenon of self-preservation.

**Inductive Factors to Consider**
(1) Population
(2) Magnitude of the economic activities of the government
(3) The method of financing these government activities
    (See Peter-Paul Principle - inflation of the currency.)

**Translation**
(a few examples will be given.)
**Charge** - coulombs - dollars (1939).
**Current Flow** - amperes (coulombs per second) - dollars of flow per year.
**Motivating Force** - volts - dollars (output) demand.
**Conductance** - amperes per volt - dollars of flow per year per dollar demand.
**Capacitance** - coulombs per volt - dollars of production inventory/stock per dollar demand.

**Time-Flow Relationships and Self-Destructive Oscillations**
An ideal industry may be symbolised electronically in various ways. The simplest way is to represent a demand by a voltage and a supply by a current. When this is done, the relationship between the two becomes what is called an admittance, which can result from three economic factors:

1. **Hindsight flow**, 
2. **Present flow**, and 
3. **Foresight flow**.

**Foresight flow** is the result of that property of living entities to cause energy (food) to be stored for a period of low energy (e.g., a winter season). It consists of demands made upon an economic system for that period of low energy (winter season). In a production industry it takes several forms, one of which is known as production stock or inventory. In electronic symbology this specific industry demand (a pure capital industry) is represented by capacitance and the stock or resource is represented by a stored charge. Satisfaction of an industry demand suffers a lag because of the loading effect of inventory priorities.

**Present flow** ideally involves no delays. It is, so to speak, input today for output today, a "hand to mouth" flow. In electronic symbology, this specific industry demand is represented by a conductance which is then a simple economic valve (a dissipative element).

**Hindsight flow** is known as habit or inertia. In electronics this phenomenon is the characteristic of an inductor (economic analogue = a pure service industry) in which a current flow (economic analogue = flow of money) creates a magnetic field (economic analogue = active human population) which, if the current (money flow) begins to diminish, will collapse (war) to maintain the current (flow of money - energy).

Other large alternatives to war as economic inductors or economic flywheels are an open-ended social welfare program, or an enormous (but fruitful) open-ended space program. The problem with stabilising the economic system is that there is too much demand on account of:

1. Too much greed and
2. Too much population.

This creates excessive economic inductance which can only be balanced with economic capacitance (true resources or value - e.g., in goods or services).

The social welfare program is nothing more than an open-ended credit balance system which creates a false capital industry to give non-productive people a roof over their heads and food in their stomachs. This can be useful, however, because the recipients become state property in return for the "gift," and form a standing army for the Elite - as he who pays the piper picks the tune. Those who get hooked on the economic drug, must go to the Elite for a fix. In this, the method of introducing large amounts of stabilising capacitance is by borrowing on the future "credit" of the world. This is a fourth law of motion - **onset**, and consists of performing an action and leaving the system before the reflected reaction returns to the point of action - a delayed reaction.

The means of surviving the reaction is by changing the system before the reaction can return. By this means, politicians become more popular in their own time and the public pays later. In fact, the measure of such a politician is the delay time. The same thing is achieved by a government
by printing money beyond the limit of the gross national product, and economic process called inflation. This puts a large quantity of money into the hands of the public and maintains a balance against their greed, creates a false self-confidence in them and, for a while, stays the wolf from the door.

They must eventually resort to war to balance the account, because war ultimately is merely the act of destroying the creditor, and the politicians are the publicly hired hit men that justify the act to keep the responsibility and blood off the public conscience. If the people really cared about their fellow man, they would control their appetites (greed, procreation, etc.) so that they would not have to operate on a credit or welfare social system which steals from the worker to satisfy the bum. Since most of the general public will not exercise restraint, there are only two alternatives to reduce the economic inductance of the system.

(1) Let the populace bludgeon each other to death in war, which will only result in a total destruction of the living earth.

(2) Take control of the world by the use of economic "silent weapons" in a form of "quiet warfare" and reduce the economic inductance of the world to a safe level by a process of benevolent slavery and genocide.
