This eBook has more than 400 bookmarks to speed up your access to any section of interest. The contents of this eBook is only about 5% of the information on the http://www.free-energy-info.tuks.nl web site
Preface

Here is a small amount of background information in order that you can understand the nature of this “Practical Guide to Free-Energy Devices”.

I am just an ordinary person who became interested in “free-energy” as a result of a television programme entitled ‘It Runs on Water’ shown in the 1980s by a UK television company called ‘Channel 4’. At the present time that programme can be seen at https://www.youtube.com/watch?v=xHISTsIR9qc. From my point of view, the content of this documentary seemed to be rather unsatisfactory as it suggested quite a number of very interesting things but gave no real hard and fast specifics for the viewer to follow up on to investigate the subject further. However, it had the enormous benefit of making me aware that there was such a thing as “free-energy”.

My attempts to find out more were not very successful. I bought paper copies of several of Stan Meyer’s HHO gas patents from the Patent Office in 1986 but while they were interesting, they did not provide much in the way of additional information. Searching on the internet at that time did not produce much more in the way of practical information. Things have changed dramatically since then and there has been an enormous increase in available information. But, even today, it is relatively difficult to find much in the way of direct, useful and practical information on free-energy systems and techniques. Much of the information consists of chatty, lightweight articles describing people, events and inventions in vague, broad outline terms which are almost completely lacking in specifics.

These articles have the style of saying “There is a new invention called a ‘bus’ which is used to carry passengers from place to place. We saw one the other day, it was painted green and blue and looked most attractive. It is driven by Joe Bloggs who wears an engaging smile and a hand-knitted sweater. Joe says that even his children could drive a bus as it is so easy to do. Joe expects to retire in six months time as he is going to take up gold prospecting.” While I’m sure that an article like that is interesting, the sort of description which I would want would be: “There is a new invention called a ‘bus’ which is used to carry passengers from place to place. We saw one the other day, and were very impressed as it has seats for some forty-five people. It has bodywork made of pressed aluminium, a wheel at each corner of its considerable 40’ x 10’ structure, a five litre diesel engine made by the Bosworth Engineering Company of Newtown, and has power-assisted steering, hydraulic brakes and ……”

There are also many articles, scientific papers and books, some of which, quite frankly, I am not able to understand as the authors think mathematically and express themselves in equations (where they frequently do not define the terms which they use in their equations, making them effectively meaningless). I do not think in mathematical equations, so I do not share in this much higher level of thinking and analysis, though I do have some of these papers on my web site for the benefit of visitors who do have the ability to understand them easily.

After a long period of searching and investigating I was beginning to gather enough information to be fairly confident of what was being done, what had already been achieved, and some of the possible background reasons for the effects which were being observed. Early in 2005 I decided that as I had encountered so much difficulty and had to put in so much effort to find out the basics of “free-energy” that it could be helpful to others if I shared what I had found out. So I wrote the first edition of this presentation and created a simple web site to make it available to others. Of course, this body of information is not static – on the contrary, it is very fast-moving. Consequently, this information digest is updated and refined typically many times each year. The present form of presentation is the third style of layout which has been used as the volume of material has increased.

It should be stressed that this information is what I have discovered as part of my interest in the subject and is mainly a reporting on what is being said by other people. I have not built and proved every device described – to do that would take many lifetimes, so please understand that this is just an attempt to aid your own investigation. While it can be proved that some device works as described, through independent replication and verification, the reverse is not true. If someone were to build a device and fail to get it to work as described, then the most that can honestly be said is that an unsuccessful attempt was made to replicate it. It does not, of course, show that the original device did not operate exactly as described, just that the (possibly inept) attempt at replication, was not successful. In some instances, you will see that I have expressed the opinion that the device is not viable, or, as in the case of the ‘Nitro Cell’ that I do think that it does work, but as many people have tried to build it and failed
to get the results described, that it can’t be recommended as an investigation project. However, as soon as I said that, a local man announced that he had made two Nitro Cells and attached them to his two Ford Transit trucks and that resulted in saving him an estimated £500 over the course of two years.

I do not suggest that this set of information covers every possible device, nor that my description is by any means the complete and definitive statement of everything to be known on the subject. The old saying applies here: “If you think you know all the answers, then you just haven’t heard all the questions!” So, this material is just an introduction to the subject and not an encyclopaedia of every known device.

I should like to thank the very large number of people who have most kindly given me their permission to reproduce details of some of their work, providing photographs, checking what I have written, suggesting additions, etc. Also those kind people who have given me permission to reproduce their own works directly on my web sites or in my documents. There seems to be a common thread of concern among many people that shows as a desire to share this information freely rather than to try to make money from selling it, and I thank these people for their generosity.

Many people hold “conspiracy theory” views and believe that there is a concerted effort to suppress this information, and more especially, to prevent free-energy devices reaching the market. Personally, I think that while that is certainly true, much of this opposition may be just the normal reaction of vested commercial interests. If you were making a profit of literally millions per hour, would you welcome the introduction of a system which would eventually cut your income to zero? If not, then how much would you be willing to pay someone to make sure that the present system is never changed – a million? A billion? While this opposition is definitely there and people who stand to lose money and/or power through change will continue to oppose this knowledge, and to a much greater extent, the introduction of any commercial free-energy device, almost the entire focus of the information is on devices – what they do, how they are made and how they may operate when they draw additional energy from the local environment.

Let me stress again, that this set of information is not by any means the final word on the subject, but just an introduction to the subject by a single person who makes no claims to knowing all the answers. Enjoy your research – I hope you are successful in every respect.

**Patrick Kelly**

April 2008
**Contents**

Index .......................................................................................................................... 1

Introduction ............................................................................................................. 1 - 1

**Chapter 1: Magnet Power**
The ShenHe Wang permanent magnet motor-generator .............................................. 1 - 1
The Ecklin-Brown generator ....................................................................................... 1 - 4
The Howard Johnson magnet motor ......................................................................... 1 - 8
The 'Carousel' permanent magnet motor .................................................................. 1 - 10
The Robert Tracy permanent magnet motor .............................................................. 1 - 11
The Ben Teal electromagnet motor .......................................................................... 1 - 11
The Jines permanent magnet motor ......................................................................... 1 - 13
The Stephen Kundel permanent magnet motor ....................................................... 1 - 14
Charles Flynn's permanent magnet motor .............................................................. 1 - 17
Steom's Magnet Motor ............................................................................................. 1 - 26
George Soukup's Magnet Motor .............................................................................. 1 - 29
Dietmar Hohl's V-Magnet Motor and Jes Ascanius' implementation of it ............... 1 - 31
Constructing a simple permanent magnet motor ..................................................... 1 - 33
Muammer Yildiz's Magnet Motor ............................................................................ 1 - 37
Donald Kelly's Magnet Motor ................................................................................. 1 - 56
Mike Brady's Perendev Magnet Motor .................................................................... 1 - 57
Magnetic shielding from Pasi Mäkilä ....................................................................... 1 - 57
The Twin Rotor suggestion ....................................................................................... 1 - 58
The Permanent Magnet Motor of Victor Diduck ...................................................... 1 - 60
The Permanent Magnet Motor of Harold Miller and Andrew Colson ................. 1 - 67

**Chapter 2: Moving Pulsed Systems**
The Adams Motor/Generator .................................................................................... 2 - 1
Tewari Paramahamsa's 2-kilowatt motor-generator .................................................. 2 - 51
Lidmotor's Low-voltage Rotor .................................................................................. 2 - 62
The Phemax Self-Powered motor/generator ............................................................ 2 - 63
The Kromrey No-Drag Electrical Generator ............................................................ 2 - 66
The Teruo Kawai Motor ........................................................................................... 2 - 75
James Hardy's Water-jet Generator ....................................................................... 2 - 77
Georges Mourier's COP=10,000 Motor/Generator Patent ....................................... 2 - 79
The RotoVerter ........................................................................................................ 2 - 89
Coil-shorting techniques ......................................................................................... 2 - 94
Raoul Hatem's Energy System ............................................................................... 2 - 99
Lawrence Tseung's COP = 3.3 Pulsed Rotor ............................................................ 2 - 101
Art Porter's Electromagnetic Motor System ............................................................. 2 - 107
Raising DC Motor Efficiency .................................................................................. 2 - 108
Direct Coupled Motors ............................................................................................ 2 - 118

**Chapter 3: Motionless Pulsed Systems**
Charles Flynn's devices ............................................................................................. 3 - 1
Lawrence Tseung's magnetic frame .......................................................................... 3 - 2
Thane Heins' dual toroidal magnetic frame .............................................................. 3 - 3
Professor Markov's Transformers .......................................................................... 3 - 6
A Lenz-Law-Free Transformer .................................................................................. 3 - 18
David Klingelhofer's dual toroid transformer .......................................................... 3 - 23
The High-power Motionless Generator of Clemente Figuera ............................... 3 - 24
The Zero back-EMF Coils of Alexkor .................................................................... 3 - 28
The Self-Powered Generators of Barbosa and Leal ................................................. 3 - 33
The First Barbosa and Leal Replication .................................................................. 3 - 52
The Ultra-simple Device of Lorrie Matchett ............................................................ 3 - 58
The Motionless Generator of Theodore Annis and Patrick Eberly ...................... 3 - 65
Chapter 4: Gravity-Powered Systems

Lawrence Tseung’s Gravity Impact wheel .......................................................... 4 - 1
The Chas Campbell System .................................................................................. 4 - 4
Jacob Bitsadze’s Pulley Ratio Information ............................................................. 4 - 6
The self-powered generator of José Luis Garcia del Castillo ................................. 4 - 7
The Wilson self-powered DC generator ................................................................. 4 - 11
The Bedini Pulsed Flywheel .................................................................................. 4 - 12
James Hardy’s Water-jet Generator .................................................................... 4 - 13
The Donnie Watts self-powered generator ............................................................ 4 - 14
The Two-year magnetic Pendulum ...................................................................... 4 - 21
Jerzy Zbikowski’s Chain Drive system .................................................................. 4 - 24
Gravitational Effects ............................................................................................. 4 - 25
Mikhail Dmitriev’s nudged weights gravity wheel ............................................... 4 - 27
The Dale Simpson Gravity Wheel ......................................................................... 4 - 29
The Veljko Milkovic Pendulum / Lever system ..................................................... 4 - 32
Amr Al-Hossary’s Hinged-Plate Design ................................................................ 4 - 33
The Munilo Luciano Gravity Chain ..................................................................... 4 - 34
Other Gravity Designs .......................................................................................... 4 - 42
James Kwok’s “Hidro” Self-Powered Generator .................................................. 4 - 42
The Ribero Buoyancy Patent ................................................................................ 4 - 55
The 30-kilowatt Gravity-Powered Motor ............................................................... 4 - 57
Bhaskara’s Gravity Wheel .................................................................................... 4 - 58
William Skinners’ torque multiplier ..................................................................... 4 - 60

Chapter 5: Energy-Tapping Pulsed Systems

Frank Prentice’s horizontal wire system ............................................................... 5 - 1
Dave Lawton’s Water Fuel Cell ............................................................................. 5 - 3
John Bedini’s Battery Pulse-Charger ..................................................................... 5 - 4
The Tesla Switch ................................................................................................... 5 - 5
A 3-Battery Switching Circuit ............................................................................... 5 - 11
The Self-powered Free-Energy Generators of Carlos Benitez .............................. 5 - 20
Bozidar Lisac’s 1-battery charger patent ............................................................... 5 - 37
Don Smith’s devices ............................................................................................... 5 - 47
Tariel Kapanadze’s system ................................................................................... 5 - 48
Walter Ford’s high-powered crystal set .................................................................. 5 - 49
Lawrence Tseung’s “FLEET” toroid .................................................................... 5 - 51
Advanced Joule Thief circuits ............................................................................. 5 - 61
LaserSaber’s Joule Thief lighting circuits ............................................................. 5 - 75
The Ed Gray / Marvin Cole Power System .......................................................... 5 - 78
Chapter 6: Battery-Charging Pulsed Systems
Bedini Pulsing .................................................. 6 - 2
Roger Andrews’ switching system ............................ 6 - 2
Ron Knight’s professional battery advice .................. 6 - 5
Ron Pugh’s Charger ............................................. 6 - 5
Ossie Callanan’s charging system ............................ 6 - 18
The Self-charging system ...................................... 6 - 24
The Relay Coil Battery Charger ............................... 6 - 25
The Re-wired Fan Charger ..................................... 6 - 26
The Automotive Coil Charger ................................. 6 - 28
The Self-charging Motor ........................................ 6 - 30
The Alexkor multiple battery charger ....................... 6 - 34
Sucayho’s pulse battery charger ............................... 6 - 40
Howard Halay’s cold electricity conditioning ............. 6 - 41
The Tesla Switch .................................................. 6 - 43
The self-charging motor ...................................... 6 - 44
The ‘UFopolitics’ motor ......................................... 6 - 48
Some battery charging suggestions ......................... 6 - 48
Michael Emme’s 3 Kilowatt Earth Battery ................ 6 - 54
A Battery Charger for just One Battery .................... 6 - 57
A Fast-Charge Joule Thief Arrangement from Rene ...... 6 - 65
Charles Seiler charging circuits ............................... 6 - 65

Chapter 7: Aerial Systems and Electrostatic Generators
Nikola Tesla’s Aerial Plate Power System .................. 7 - 1
The Jes Ascanius replication of Tesla’s Aerial Plate System 7 - 8
The printed circuit board of Dragan Kljajic .................. 7 - 12
Thomas Henry Moray’s System ................................ 7 - 14
Herman Plauson’s System ...................................... 7 - 31
Roy Meyer’s System ............................................. 7 - 33
Raymond Phillips’ RF System ................................ 7 - 34
The ‘Alexkor’ Aerial System .................................. 7 - 38
The ‘TREC’ Aerial System of Lawrence Rayburn ...... 7 - 39
The Patent Application of Harold Deyo ..................... 7 - 41
The Electrostatic Generator of Charles Goldie ............ 7 - 51
The Electrostatic Generator of D. Le May ................. 7 - 55
The Electrostatic Generator of Onezime Breaux ........ 7 - 68

Chapter 8: Fuel-less Motors
The Bob Neal Motor ........................................... 8 - 1
The Scott Robertson air compressor ........................ 8 - 4
The Leroy Rogers Motor ...................................... 8 - 6
The Vortex Tube ................................................. 8 - 21
The Eber Van Valkinburg Motor ............................... 8 - 23
The Clem Motor .................................................. 8 - 23
The Papp Motor .................................................. 8 - 25
The Robert Britt Motor ......................................... 8 - 28
Heinrich Klostermann’s Air Plasma Motor .................. 8 - 29
The Michael Eskeli Turbine .................................. 8 - 39
James Hardy’s Water-Jet Generator ......................... 8 - 57
The Cahill & Scott Generator ................................ 8 - 58
### Chapter 9: Passive Systems

- Hans Cohler's device .............................................. 9 - 1
- Thomas Trawoeger's pyramid ................................... 9 - 3
- Peter Grandics' pyramid ....................................... 9 - 20
- Les Brown's pyramid ........................................... 9 - 22
- Joseph H. Cater's explanation of how a pyramid actually works ........................................... 9 - 29
- Pier Luigi Ighina’s "ERIM" and "Elios" passive devices .................................................. 9 - 31
- The Joe Cell ......................................................... 9 - 35
- The Italian B.A.C. Coil ........................................... 9 - 67
- Co-axial Cable Electrets ........................................ 9 - 69
- The Orgone devices of Mehran Keshe ......................... 9 - 70
- Dan Davidson's Research ........................................ 9 - 95

### Chapter 10: Vehicle Systems

- Booster design ..................................................... 10 - 1
- Simple DC boosters ............................................... 10 - 2
- The “Smack's” booster .......................................... 10 - 17
- The “Hotsabi” booster ........................................... 10 - 18
- The Zach West booster ........................................... 10 - 18
- Bill Williams’ “DuPlex” booster .............................. 10 - 28
- The ‘Hogg’ Electrolyser .......................................... 10 – 28
- AVA Magnetic Levitation’s Spiral booster .................. 10 - 34
- Advanced Boosters .................................................. 10 - 41
- The Bob Boyce DC electrolyser ................................ 10 - 41
- Pulsed Water-Splitters ........................................... 10 - 82
- Dave Lawton’s Meyer Replication ............................. 10 - 83
- Dr Cramton’s water-splitter .................................... 10 - 102
- Bob Boyce's Toroidal water-splitter .......................... 10 - 108
- John Bedini Water-Splitting ................................... 10 - 109
- Dave Lawton’s Auto-Tune Circuit ............................. 10 - 110
- Running an Electrical Generator on Water Alone ......... 10 - 111
- Running an Unmodified Generator on Water Alone ...... 10 - 136
- Stan Meyer's Water Injection System ......................... 10 - 140
- Peter Lindemann running a lawnmower on water alone .................................................. 10 - 145
- Peter Lowrie’s High-Current Electrolyser System ....... 10 - 146
- Water use in engines ............................................... 10 - 147
- Ted Ewert’s Vortex Tube ........................................ 10 - 150
- Cam timing Issues .................................................. 10 - 155
- Robert Krupa’s ‘FireStorm’ Spark Plug ..................... 10 - 156
- Plasma Ignition ...................................................... 10 - 157
- Roger Maynard’s Water Vapour Injection System ....... 10 - 158
- “Fuel savers” streamlining ...................................... 10 - 160
- The Ram Implosion Wing ........................................ 10 - 160
- High mpg Carburettors ......................................... 10 - 160
- Allen Caggiano’s High-mpg carburettor ..................... 10 - 162
- A Fuel Vapourisation System .................................. 10 - 166
- Vortex Fuel Reforming (GEET) ............................... 10 - 167
- Electric Power ....................................................... 10 - 169
- The Weird Nature of Water and Advanced Electrolysis .................................................. 10 - 171
- The Production of SG Water ..................................... 10 - 177
- The Electrolyser of Charles Garrett ......................... 10 - 190
- The Electrolyser of Archie Blue ............................... 10 - 191
- The HHO cell of Paul Zigouras ................................ 10 - 193
- The Petro Dollar ..................................................... 10 - 195

### Chapter 11: Other Devices and Theories

- The Tesla Generators ............................................. 11 - 1
- The Aspden Device ................................................ 11 - 3
- Paulo & Alexandra Correa ....................................... 11 - 15
- Professor Konstantin Meyl ..................................... 11 - 16
- Tesla’s MHD unit ..................................................... 11 - 16
- The Unified Field Theory ........................................ 11 - 18
- Maurice Cotterell’s Explanation of Gravity ................ 11 - 22
- John R. R. Searle .................................................. 11 - 32
Chapter 12: Electronics Tutorial

Voltage .......................................................... 12 - 1
Resistance ...................................................... 12 - 2
Ohm's Law (resistive circuits only) ......................... 12 - 10
The Potentiometer .............................................. 12 - 12
Understanding what circuit diagrams mean ............... 12 - 13
Semiconductors – Transistors .............................. 12 - 15
Transistor Testers ............................................. 12 - 18
Emitter-followers ............................................ 12 - 21
Constant Current circuits .................................. 12 - 20
Substitute Transistors ...................................... 12 - 22
Diodes ........................................................ 12 - 25
Alternating Current.......................................... 12 - 28
Coils (Inductors) ............................................ 12 - 28
Transformers .................................................. 12 - 32
Rectification and Power Supplies ......................... 12 - 33
The Voltage Doubler ........................................ 12 - 36
Multivibrators ................................................ 12 - 37
The Bistable .................................................. 12 - 37
The Monostable .............................................. 12 - 38
The Astable ................................................... 12 - 39
Inverters ....................................................... 12 - 39
Digital Logic and Truth Tables ............................ 12 - 39
The NAND gate and Gating ............................... 12 - 45
The NE555 Timer Chip .................................... 12 - 49
The 741 Op-amp Chip ..................................... 12 - 64
The SCR (Thyristor) ....................................... 12 - 67
The Triac ..................................................... 12 - 67
A simple, versatile, Schmitt inverter signal generator ..... 12 - 70
The CD4022BC Divide-By-Eight Chip ..................... 12 - 70
The cascaded CD4017B Divide-By-N circuitry ......... 12 - 73
The PIC chip ................................................ 12 - 74
Capacitors ..................................................... 12 - 79
AC Circuitry, inductors and resonance ................. 12 - 81
Resonance .................................................... 12 - 85
Choosing unspecified component values ............... 12 - 86
Prototype Construction .................................. 12 - 89
Test Equipment .............................................. 12 - 94
Power Supply Unit ......................................... 12 - 97
The Oscilloscope .......................................... 12 - 997
Measuring magnetic field strength ...................... 12 - 100
The Weird Stuff ............................................. 12 - 101

Chapter 13: Doubtful Devices

Paul Baumann's "Thestakia" ................................ 13 - 1
The Homopolar or "N-Machine" ......................... 13 - 4
The Borderland Science Homopolar AC Generator .... 13 - 5
Tesla's Homopolar Generator ............................ 13 - 7
The "Romag" and "Mini-Romag" Generators .......... 13 - 8
Cold Fusion ................................................. 13 - 11
Moller's Atomic Hydrogen Generator .................... 13 - 11
Chapter 19: Building a Simple Generator
Suggestions for building a flywheel generator

Chapter 20: Building an Advanced Flywheel Generator
Suggestions for building an advanced flywheel generator

Chapter 21: Building a Small Self-Powered Generator
Suggestions for building an advanced flywheel generator

Chapter 22: Health
Methods of home treatment which have proved effective

Chapter 23: Reversing Genetic Modification
A method of returning seed to its original healthy state

Chapter 24: Dealing With Chemtrails
A method of dispersing and negating Chemtrails

Chapter 25: The Mandela Effect
The changes being made to our present reality

Chapter 26: The Sabourin Generator
Self-powered generator which charges a mobile phone overnight

Appendix
US and UK Wire sizes and capacities
Frank Facera’s permanent magnet motor patent
Howard Johnson’s permanent magnet motor patent
Harold Ewing’s Carousel permanent magnet-generator patent.
The Pavel Imris minimal power lighting system patent
The Colman/Seddon-Gillespie 70-year battery patent
The Jon Sok An Lenz-less electrical generator patent
The Molina Martinez self-powered electrical generator patent
Michael Oglyanov’s solid-state electrical generator patent
Edwin Gray’s electric motor patent
Edwin Gray’s electric power supply patent
The Adams-Aspden electrical motor-generator patent
William Barbat’s self-powered electrical generator patent
John Reardon’s AC generator patent
Geoffrey Spence’s self-powered electrical generator patent
Robert Alexander’s COP = 2.93 electrical generator patent.
Shigeaki Hayasaka’s electrical generator patent
Larry Jamison’s electrical generator patent application
Teruo Kawai’s COP>1 electric motor patent
Joseph Newman’s Energy Generator patent
Philip Brody’s very high output ceramic solar devices patent
Charles Flynn’s controlled magnetic devices patent
The Motionless Electromagnetic Generator patent
Dan Davidson’s acoustic-magnetic electrical generator patent
John Bedini’s battery-charging patent
John Bedini’s motor-generator patent
John Bedini’s pulse-charging system patent
Richard Weir and Carl Nelson’s battery replacement patent
Hermann Plauson’s aerial power systems patent
Roy Meyers’ Electricity-producing device patent
Paulo and Alexandra Correa’s free-electricity patent
Paulo and Alexandra Correa’s energy conversion patent
The Mead-Nachamkin ZPE to electricity conversion patent
Stanley Meyer’s Water Fuel patent 4,936,961
Stanley Meyer’s hydrogen injection system for vehicles patent 4,389,981
Stanley Meyer’s hydrogen gas burner patent 4,421,474
Stanley Meyer’s hydrogen generation and enhancement patent 5,149,407
Stanley Meyer’s water fuel generator patent CA 2,067,735 .................................................. A - 659
Stanley Meyer’s WFC control circuitry patent WO 92/07861 .................................................. A - 670
Stephen Meyer’s water-splitting patent application 2005/0246059 ........................................ A - 680
Henry Puharich’s water-splitting patent 4,392,230 ................................................................. A - 689
Shigeta Hasebe’s spiral electrolyser patent ............................................................................. A - 719
Stephen Chambers’hydroxy generator patent (Xogen Power Inc.) ........................................... A - 725
Charles Garrett’s water carburettor patent ............................................................................. A - 740
Archie Blue’s electrolyser patent ............................................................................................ A - 748
Ruggiero Santilli’s plasma arc electrolysis patent ..................................................................... A - 754
Chak Chang’s low-voltage low-temperature plasma patent application ................................. A - 764
Juan Aguero’s water engine patent application ......................................................................... A - 823
Stephen Horvath’s water-powered car patent ......................................................................... A - 830
Christopher Eccles’ water-splitting cell patent ....................................................................... A - 857
Spiro Spiros’ COP>1 electrolyser patent .................................................................................. A - 864
Henry Paine’s hydroxy gas conversion patent .......................................................................... A - 901
Boris Volfsen’s gravity drive patent. ......................................................................................... A - 904
Charles Pogue’s first high-mpg carburettor patent ................................................................. A - 919
Charles Pogue’s second high-mpg carburettor patent ............................................................ A - 927
Charles Pogue’s third high-mpg carburettor patent ............................................................... A - 932
Ivor Newberry’s high-mpg carburettor patent ......................................................................... A - 940
Robert Shelton’s high-mpg carburettor patent ......................................................................... A - 945
Harold Schwartz’s high-mpg carburettor patent ..................................................................... A - 949
Oliver Tucker’s high-mpg carburettor patent .......................................................................... A - 952
Thomas Ogle’s high-mpg carburettor patent .......................................................................... A - 955
Stephen Kundel’s permanent magnet motor ........................................................................... A - 968
Charles Flynn’s permanent magnet motor ................................................................................ A - 992
Claude Mead and William Holmes’ wind power storage system ............................................. A - 1021
The Richard Willis COP>>1 electrical generator .................................................................... A - 1028
Graham Gunderson’s pulsed toroid generator ......................................................................... A - 1038
Mark McKay’s investigation into Edwin Gray’s technology ..................................................... A - 1046
Mike Brady’s “Perendev” magnet motor patent ...................................................................... A - 1107
Donald Kelly’s magnet motor patent ....................................................................................... A - 1117
Bob Neal’s compressor patent ................................................................................................... A - 1125
Leroy Rogers’ compressed air engine patent ........................................................................... A - 1132
Eber Van Valkinburg’s compressed air/foil engine patent ......................................................... A - 1148
Josef Papp’s inert-gas engine patent ........................................................................................ A - 1153
Robert Britt’s inert-gas engine patent ....................................................................................... A - 1186
Floyd Sweet’s “VTA” Electrical Generator .............................................................................. A - 1196
Meguer Kalfayan’s Electrical Generator .................................................................................. A - 1210
Theodore Annis and Patrick Eberly’s Motionless Generator ..................................................... A - 1220

A Practical Guide to ‘Free-Energy’ Devices

Overview

This eBook contains most of what I have learned about this subject after researching it for a number of years. I am not trying to sell you anything, nor am I trying to convince you of anything. When I started looking into this subject, there was very little useful information and any that was around was buried deep in incomprehensible patents and documents. My purpose here is to make it easier for you to locate and understand some of the relevant material now available. What you believe is up to yourself and is none of my business. Let me stress that almost all of the devices discussed in the following pages, are devices which I have not personally built and tested. It would take several lifetimes to do that and it would not be in any way a practical option. Consequently, although I believe everything said is fully accurate and correct, you should treat everything as being “hearsay” or opinion.

Some time ago, it was commonly believed that the world was flat and rested on the backs of four elephants and that when earthquakes shook the ground, it was the elephants getting restless. If you want to believe that, you are fully at liberty to do so, however, you can count me out as I don’t believe that.

The Wright brothers were told that it was impossible for aeroplanes to fly because they were heavier than air. That was a commonly believed view. The Wright brothers watched birds flying and since, without question, birds are considerably heavier than air, it was clear that the commonly held view was plain wrong. Working from that realisation, they developed aeroplanes which flew perfectly well.

The years passed, and the technology started by the Wright brothers and their careful scientific measurements and well-reasoned theory, advanced to become the “science” of aeronautics. This science was used extensively to design and build very successful aircraft and “aeronautics” gained the aura of being a “law”.

Unfortunately, somebody applied aeronautic calculations to the flight of bumblebees and discovered that according to aeronautics, bumblebees couldn’t possibly fly as their wings could not generate enough lift to get them off the ground. This was a problem, as it was perfectly possible to watch bees flying in a very competent manner. So, the “laws” of aeronautics said that bees can’t fly, but bees actually do fly.

Does that mean that the laws of aeronautics were no use? Certainly not - those “laws” had been used for years and proved their worth by producing excellent aircraft. What it did show was that the “laws” of aeronautics did not yet cover every case and needed to be extended to cover the way that bees fly, which is through lift generated by turbulent airflow.

It is very important to realise that what are described as scientific “laws” are just the best working theories at the present time and it is virtually certain that those “laws” will have to be upgraded and extended as further scientific observations are made and further facts discovered. Let’s hope those four elephants don’t get restless before we have a chance to learn a bit more!

Introduction

It should be stressed at this point, that this material is intended to provide you with information and only that. If you should decide, on the basis of what you read here, to build some device or other, you do so solely and entirely at your own risk and on your own responsibility. For example, if you build something in a heavy box and then drop it on your toe, then that is completely your own responsibility (you should learn to be more careful) and nobody other than yourself is in any way liable for your injury, or any loss of income caused while your toe is recovering. Let me amplify that by stating that I do not warrant that any device or system described in this document works as described, or in any other way, nor do I claim that any of the following information is useful in any way or that any device described is useful in any way or for any purpose whatsoever. Also, let me stress that I am not encouraging you to actually construct any device described here, and the fact that very detailed construction details are provided, must not be interpreted as my encouraging you to physically construct any device described in this document. You are welcome to consider this a work of fiction if you choose to do so.

I apologise if this presentation seems very elementary, but the intention is to make each description as simple as possible so that everybody can understand it, including people whose native language is not English. If you are not familiar with the basic principles of electronics, then please read the simple step-by-step electronics tutorial in Chapter 12 which is intended to help complete beginners in the subject.
At this point in time - the early years of the twenty-first century - we have reached the point where we need to realise that some of the “laws" of science do not cover every case, and while they have been very useful in the past, they do need to be extended to cover some cases which have been left out until now.

For example, suppose a bank robber broke into a bank and stole all of the cash there. How much could he take? Answer: “every coin and every note”. The limit is the sum total of all cash in the building. This is what the “Law” of Conservation of Energy is all about. What it says is very simple – you can’t take out any more than there is there in the beginning. That seems pretty straightforward, doesn’t it?

As another example, consider a glass tumbler filled completely with water. Using common sense, tell me, how much water can be poured out of the glass? For the purposes of this illustration, please take it that temperature, pressure, gravity, etc. all remain constant for the duration of the experiment.

The answer is: “the exact volume contained inside the tumbler”. Agreed. This is what present day science says. To be strictly accurate, you will never be able to pour all of the water out as a small amount will remain, wetting the inside of the glass. Another way of putting this is to say that the “efficiency” of the pouring operation is not 100%. This is typical of life in general, where very few, if any, actions are 100% efficient.

So, are we agreed with current scientific thinking then – the maximum amount of water which can pour out of the tumbler is the total volume inside the tumbler? This seems simple and straightforward, doesn’t it? Science thinks so, and insists that this is the end of the story, and nothing else is possible. This arrangement is called a “closed system” as the only things being considered are the glass, the water and gravity.

Well, unfortunately for current scientific thinking, this is not the only possible situation and “closed systems” are almost unknown in the real world. Mostly, assumptions are made that the effects of anything else around will cancel out and add up to a net zero effect. This is a very convenient theory, but unfortunately it has no basis in reality.

Let’s fill our glass with water again and begin to pour it out again, but this time we position it underneath a source of flowing water:
So, now, how much water can be poured out of the tumbler? Answer: “millions of times the volume of the tumbler”. But hang on a moment, haven’t we just said that the absolute limit of water poured from the tumbler has to be the volume inside the tumbler? Yes, that’s exactly what we said, and that is what current science teaching says. The bottom line here is that what current science says does in fact hold true for most of the time, but there are cases where the basic assumption of it being a “closed system” is just not true.

One popular misconception is that you can’t get more energy out of a system than you put into it. That is wrong, because the sentence was worded carefully. Let me say it again and this time, emphasise the key words: “you can’t get more energy out of a system than you put into it”. If that were true, then it would be impossible to sail a yacht all the way around the world without burning any fuel, and that has been done many times and none of the driving energy came from the crews. If it were true, then a grain mill driven by a waterwheel would not be able to produce flour as the miller certainly does not push the millstones around himself. If that were true, then nobody would build windmills, or construct solar panels, or tidal power stations.

What the statement should say is “more energy can’t be taken out of a system than is put into it or is already in it” and that is a very different statement. When sailing a yacht, the wind provides the driving force which makes the trip possible. Notice that, it is the environment providing the power and not the sailors. The wind arrived without them having to do anything about it, and a lot less than 100% of the wind energy reaching the yacht actually becomes forward thrust, contributing to the voyage. A good deal of the energy arriving at the yacht ends up stretching the rigging, creating a wake, producing noise, pushing the helmsman, etc. etc. This idea of no more energy coming out of a system than goes into it, is called “The Law of Conservation of Energy” and it is perfectly right, in spite of the fact that it gets people confused.

“Free-Energy Devices” or “Zero-Point Energy Devices” are the names applied to systems which appear to produce a higher output power than their input power. There is a strong tendency for people to state that such a system is not possible since it contravenes the Law of Conservation of Energy. It doesn’t. If it did, and any such system was shown to work, then the “Law” would have to be modified to include the newly observed fact. No such change is necessary, it merely depends on your point of view.
For example, consider a crystal set radio receiver:

![Crystal Set Diagram]

Looking at this in isolation, we appear to have a free-energy system which contradicts the Law of Conservation of Energy. It doesn’t, of course, but if you do not view the whole picture, you see a device which has only passive components and yet which (when the coil is of the correct size) causes the headphones to generate vibrations which reproduce recognisable speech and music. This looks like a system which has no energy input and yet which produces an energy output. Considered in isolation, this would be a serious problem for the Law of Conservation of Energy, but when examined from a common sense point of view, it is no problem at all.

The whole picture is:

![Whole Picture Diagram]

Power is supplied to a nearby transmitter which generates radio waves which in turn, induce a small voltage in the aerial of the crystal set, which in turn, powers the headphones. The power in the headphones is far, far less than the power taken to drive the transmitter. There is most definitely, no conflict with the Law of Conservation of Energy. However, there is a quantity called the “Coefficient Of Performance” or “COP” for short. This is defined as the amount of power coming out of a system, divided by the amount of power that the operator has to put into that system to make it work. In the example above, while the efficiency of the crystal set radio is well below 100%, the COP is greater than 1. This is because the owner of the crystal radio set does not have to supply any power at all to make it work, and yet it outputs power in the form of sound. As the input power from the user, needed to make it work is zero, and the COP value is calculated by dividing the output power by this zero input power, the COP is actually infinity. Efficiency and COP are two different things. Efficiency can never exceed 100% and almost never gets anywhere near 100% due to the losses suffered by any practical system.
As another example, consider an electrical solar panel:

The energy which powers the solar panel comes from the sun. Only some 17% of the energy reaching the solar panel is converted to electrical current. This is most definitely not a contravention of the Law of Conservation of Energy. This needs to be explained in greater detail. The Law of Conservation of Energy applies to closed systems, and only to closed systems. If there is energy coming in from the environment, then the Law of Conservation of Energy just does not apply, unless you take into account the energy entering the system from outside.

People sometimes speak of “over-unity” when talking about the efficiency of a system. From the point of efficiency, there is no such thing as “over-unity” as that would mean that more power was coming out of the system than the amount of power entering the system. Our trusty bank robber mentioned above would have to take out of the bank vault, more money than was actually in it, and that is a physical impossibility. There are always some losses in all practical systems, so the efficiency is always less than 100% of the power entering the system. In other words, the efficiency of any practical system is always under unity.

However, it is perfectly possible to have a system which has a greater power output than the power input which we have to put into it to make it work. Take the solar panel mentioned above. It has a terribly low efficiency of about 17%, but, we don’t have to supply it with any power to make it work. Consequently, when it is in sunlight, it’s Coefficient Of Performance (“COP”) is its output power (say, 50 watts) divided by the input power needed to make it work (zero watts) which is infinity. So, our humble, well-known solar panel has terrible efficiency of 17% but at the same time it has a COP of infinity.

It is now generally accepted that “Dark Matter” and “Dark Energy” form more than 80% of our universe. There is nothing sinister about the adjective “Dark” as in this context, it merely means that we cannot see it. There are many useful things which we utilise, which we can’t see, for example, radio waves, TV signals, magnetism, gravity, x-rays, etc. etc.
The actual situation is, that we are sitting in a vast field of energy which we can’t see. This is the equivalent of the situation for the crystal set shown above, except that the energy field we are in is very, very much more powerful than the radio waves from a radio transmitter. The problem is, how to tap the energy which is freely available all around us, and get it to do useful work for us. It can definitely be done, but it is not easy to do.

Some people think that we will never be able to access this energy. Not very long ago, it was widely believed that nobody could ride a bicycle faster than 15 miles per hour because the wind pressure on the face of the rider would suffocate him. Today, many people cycle much faster than this without suffocating - why? - because the original negative opinion was wrong.

Not very long ago, it was thought that metal aircraft would never be able to fly because metal is so much heavier than air. Today, aircraft weighing hundreds of tons fly on a daily basis. Why? - because the original negative opinion was not correct.

It is probably worth while, at this point, to explain the basics of Zero-Point Energy. The experts in Quantum Mechanics refer to how the universe operates as “Quantum Foam”. Every cubic centimetre of “empty” space is seething with energy, so much in fact, that if it were converted using Oliver Heaviside’s equation (made famous by Albert Einstein) $E = mC^2$ (that is Energy = Mass multiplied by a very big number), then it would produce as much matter as can be seen by the most powerful telescope. There is actually nothing “empty” about space. So why can’t we see anything there? Well, you can’t actually see energy. All right then, why can’t you measure the energy there? Well, two reasons actually, firstly, we have never managed to design an instrument which can measure this energy, and secondly, the energy is changing direction incredibly rapidly, billions and billions of times each second.

So, how do you alter the natural state of the energy in our environment? Actually, quite easily. All that is needed is a positive charge and a negative charge, reasonably near each other. A battery will do the trick, as will a generator, as will an aerial and earth, as will an electrostatic device like a Wimshurst machine. When you generate a Plus and a Minus, the quantum foam is affected. Now, instead of entirely random plus and minus charged particles appearing everywhere, the Plus which you created gets surrounded by a sphere of minus charge particles popping into existence all around it. Also, the Minus which you created, gets surrounded by a spherical-shaped cloud of plus-charge particles popping into existence all around it. The technical term for this situation is “broken symmetry” which is just a fancy way of saying that the charge distribution of the quantum foam is no longer evenly distributed or “symmetrical”. In passing, the fancy technical name for your Plus and Minus near each other, is a “dipole” which is just a techno-babble way of saying “two poles: a plus and a minus” - isn’t jargon wonderful?

So, just to get it straight in your mind, when you make a battery, the chemical action inside the battery creates a Plus terminal and a Minus terminal. Those poles actually distort the universe around your battery, and causes vast streams of energy to radiate out in every direction from each pole of the battery. Why doesn’t the battery run down? Because the energy is flowing from the environment and not from the battery. If you were taught basic physics or electrical theory, you will probably have been told that the battery used to power any circuit, supplies a vast streams of energy to radiate out in every direction from each pole of the battery. Why? - because physics or electrical theory, you will probably have been told that the battery used to power any circuit, supplies a vast streams of energy to radiate out in every direction from each pole of the battery. Why? - because the original negative opinion was wrong.

But, do not despair, our trusty battery immediately creates the Plus and Minus terminals again and the process starts all over again. This happens so rapidly that we don’t see the breaks in the operation of the circuit and it is the continual recreation of the dipole which causes the battery to run down and lose it’s power. Let me say it again, the battery
does not supply the current that powers the circuit, it never has and it never will - the current flows into the circuit from the surrounding environment.

What we really need, is a method of pulling off the power flowing in from the environment, without continually destroying the dipole which pushes the environment into supplying the power. That is the tricky bit, but it has been done. If you can do that, then you tap into an unlimited stream of inexhaustible energy, with no need to provide any input energy to keep the flow of energy going. In passing, if you want to check out the details of all of this, Lee and Yang were awarded the Nobel Prize for Physics in 1957 for this theory which was proved by experiment in that same year. This eBook includes circuits and devices which manage to tap this energy successfully.

Today, many people have managed to tap this energy but very few commercial devices are readily available for home use. The reason for this is human rather than technical. More than 10,000 Americans have produced devices or ideas for devices but none have reached commercial production due to opposition from influential people who do not want such devices freely available. One technique is to classify a device as “essential to US National Security”. If that is done, then the developer is prevented from speaking to anyone about the device, even if he has a patent. He cannot produce or sell the device even though he invented it. Consequently, you will find many patents for perfectly workable devices if you were to put in the time and effort to locate them, though most of these patents never see the light of day, having been taken for their own use, by the people issuing these bogus “National Security” classifications.

If you feel that this opposition to free-energy and related technology is a figment of my imagination and that the people who state that more than 40,000 free-energy device patents have already been suppressed, then please consider this extract from a 2006 reminder to Patent Office staff in America to single out all patents which have to do with free-energy and any related subjects and take those patent applications to their supervisor to be dealt with differently to all other patent applications:

B. Subject matter of special interest in TC 2800

1. Perpetual motion machines; classes 310 and 290
2. Anti-gravity devices
3. Room temperature superconductivity; class 310
4. Free energy – Tachyons, etc.
5. Gain-Assisted Superluminal Light Propagation (faster than the speed of light); class 702, 359
6. Other matters that violate the general laws of physics; classes 73, 290.
7. Applications containing claims to subject matter which, if issued, would generate unfavorable publicity for the USPTO, class 84, 702.
8. Reexamination proceedings involving patents in litigation and:
   The court decision/verdict is subject to review by the Supreme Court
   The court decision includes high monetary awards
   The technology and companies involved would likely generate high publicity

Here “USPTO” is the United States Patent and Trademark Office, which is a privately owned commercial company run to make money for its owners.

The purpose of this eBook is to present the facts about some of these devices and more importantly, where possible, explain the background details of why and how systems of that type function. As has been said before, it is not the aim of this book to convince you of anything, just to present you with some of the facts which are not that easy to find, so that you can make up your own mind on the subject.
The science taught in schools, colleges and universities at this time, is well out of date and in serious need of being brought up to date. This has not happened for some time now as people who make massive financial profits have made it their business to prevent any significant advance for many years now. However, the internet and free sharing of information through it, is making things very difficult for them. What is it that they don't want you to know? Well, how about the fact that you don't have to burn a fuel to get power? Shocking, isn't it!! Does it sound a bit mad to you? Well, stick around and start doing some thinking.

Suppose you were to cover a boat with lots of solar panels which were used to charge a large bank of batteries inside the boat. And if those batteries were used to operate electric motors turning propellers which drive the boat along. If it is sunny weather, how far could you go? As far as the boat can travel while the sun is up and if the battery bank is large, probably most of the night as well. At sun-up on the next day, you can continue your journey. Oceans have been crossed doing this. How much fuel is burned to power the boat? None!! Absolutely none at all. And yet, it is a fixed idea that you have to burn a fuel to get power.

Yes, certainly, you can get power from the chemical reaction of burning a fuel - after all, we pour fuel into the tanks of vehicles “to make them go” and we burn oil in the central heating systems of buildings. But the big question is: “Do we have to?” and the answer is “No”. So why do we do it? Because there is no alternative at present. Why is there no alternative at present? Because the people making incredibly large financial profits from selling this fuel, have seen to it that no alternative is available. We have been the suckers in this con trick for decades now, and it is time for us to snap out of it. Let’s have a look at some of the basic facts:

Let me start by presenting some of the facts about electrolysis. The electrolysis of water is performed by passing an electric current through the water, causing it to break up into hydrogen gas and oxygen gas. This process was examined in minute detail by Michael Faraday who determined the most energy efficient possible conditions for electrolysis of water. Faraday determined the amount of electric current needed to break the water apart, and his findings are accepted as a scientific standard for the process.

We now bump into a problem which scientists are desperate to ignore or deny, as they have the mistaken idea that it contradicts the Law of Conservation of Energy – which, of course, it doesn’t. The problem is an electrolyser design by Bob Boyce of America which appears to have an efficiency twelve times greater than Faraday’s maximum possible gas production. This is a terrible heresy in the scientific arena and it gets the average “by the book” scientist very up-tight and flustered. There is no need for this worry. The Law of Conservation of Energy remains intact and Faraday’s results are not challenged. However, an explanation is called for.

To start with, let me show the arrangement for a standard electrolyser system:

![Standard Electrolyser System Diagram]

Here, current is supplied to the electrolyser by the electrical supply. The current flow causes breakdown of the water contained in the electrolyser, resulting in the amount of gas predicted by Faraday (or less if the electrolyser is not well designed and accurately built).

Bob Boyce, who is an exceptionally intelligent, perceptive and able man, has developed a system which performs the electrolysis of water using power drawn from the environment. To a quick glance, Bob’s design looks pretty much like a high-grade electrolyser (which it is) but it is a good deal more than that. The practical construction and operational details of Bob’s design are shown in [http://www.free-energy-info.tuks.nl/D9.pdf](http://www.free-energy-info.tuks.nl/D9.pdf), but for here, let us just consider the operation of his system in very broad outline:

![Bob Boyce's Electrolyser System Diagram]
The very important distinction here is that the power flowing into the electrolyser and causing the water to break down and produce the gas output, is coming almost exclusively from the environment and not from the electrical supply. The main function of Bob’s electrical supply is to power the device which draws energy in from the environment. Consequently, if you assume that the current supplied by the electrical supply is the whole of the power driving the electrolyser, then you have a real problem, because, when properly built and finely tuned, Bob’s electrolyser produces up to 1,200% of Faraday’s maximum efficiency production rate.

This is an illusion. Yes, the electrical input is exactly as measured. Yes, the gas output is exactly as measured. Yes, the gas output is twelve times the Faraday maximum. But Faraday’s work and the Law of Conservation of Energy are not challenged in any way because the electrical current measured is used primarily to power the interface to the environment and nearly all of the energy used in the electrolysis process flows in from the local environment and is not measured. What we can reasonably deduce is that the energy inflow from the environment is probably about twelve times the amount of power drawn from the electrical supply.

At this point in time, we do not have any equipment which can measure this environmental energy. We are in the same position as people were with electrical current five hundred years ago – there was just no equipment around which could be used to make the measurement. That, of course, does not mean that electrical current did not exist at that time, just that we had not developed any equipment capable of performing measurement of that current. Today, we know that this environmental energy exists because we can see the effects it causes such as running Bob’s electrolyser, charging batteries, etc. but we can’t measure it directly because it vibrates at right-angles to the direction that electrical current vibrates in. Electrical current is said to vibrate “transversely” while this zero-point energy vibrates “longitudinally”, and so has no effect on instruments which respond transversely such as ammeters, voltmeters, etc.

Bob Boyce’s 101-plate electrolyser produces anything up to 100 litres of gas per minute, and that rate of production is able to power internal combustion engines of low capacity. The vehicle alternator is perfectly capable of powering Bob’s system, so the result is a vehicle which appears to run with water as the only fuel. This is not the case, nor is it correct to say that the engine is powered by the gas produced. Yes, it does utilise that gas when running, but the power running the vehicle is coming directly from the environment as an inexhaustible supply. In the same way, a steam engine does not run on water. Yes, it does utilise water in the process, but the power that runs a steam engine comes from burning the coal and not from the water.

**The Basics of "Free-Energy":**

This beginner’s introduction presumes that you have never heard of free-energy before and would like an outline sketch of what it is all about, so let’s begin at the beginning.

We tend to have the impression that people who lived a long time ago were not as clever as we are - after all, we have television, computers, mobile phones, games consoles, aeroplanes, …. But, and it is a big “but”, the reason why they did not have those things is because science had not advanced far enough for those things to become possible. That did not mean that the people who lived before us were any less clever than we are.

For example, could you, personally, come up with an accurate calculation of the circumference of the Earth? This has to be without prior knowledge, no satellites, no astronomical information, no calculators, no computers and no experts to guide you. Eratosthenes did by observing the shadows in two wells some 800 kilometres apart. When was that? More than two thousand years ago.

You have probably heard of the geometry of Pythagoras who lived hundreds of years before Eratosthenes, and that geometry is still used in remote areas to lay out the foundations for new buildings. You have probably heard of Archimedes who worked out why things float. He lived more than two thousand years ago. So, how do those people stack up against you and me? Were they stupid people?

This is quite an important point because it demonstrates that the body of scientific information enables many things which were not thought possible in earlier times. This effect is not restricted to centuries ago. Take the year 1900. My father was a youngster then, so it is not all that long ago. It would be another three years before Orville and Wilbur Wright made their first ‘heavier-than-air’ flight, so there no aircraft around in 1900. There were no radio stations and most definitely, no television stations, nor would you have found a telephone inside a house. The only serious forms of information were books and periodicals or teaching establishments which relied on the knowledge of the teachers. There were no cars and the fastest form of transport for the average person was on a galloping horse.

Today, it is difficult to grasp what things were like not all that long ago, but come closer in time and look back just fifty years. Then, people researching in scientific fields had to design and build their own instruments before they ever got to experimenting in their chosen fields of knowledge. They were instrument makers, glass-blowers, metal workers, etc. as well as being scientific researchers. Nowadays there are measuring instruments of all
kinds for sale ready-made. We have silicon semiconductors which they didn't have, integrated circuits, computers, etc. etc.

The important point here is the fact that advances in scientific theory have made possible many things which would have been considered quite ridiculous notions in my father's time. However, we need to stop thinking as if we already know everything there is to know and that nothing which we think of as "impossible!!" could ever happen. Let me try to illustrate this by remarking on just a few things which as recently as the year 1900 would have marked you out as a "lunatic crank", things which we take for granted today because, and only because, we are now familiar with the science behind each of these things.

**Certainties in the year 1900**

*A metal aeroplane weighing 350 tons couldn't possibly fly - everyone knows that!!*

*You couldn't possibly watch someone who is a thousand miles away - talk sense!!*
No! Of course you can't speak to somebody who lives in a different country unless you visit them!

The fastest way to travel is on a galloping horse.

A machine could never beat a man at chess - be realistic!
Today, we know that these things are not just possible, but we take them for granted. We have a mobile phone in our pocket and could easily use it to talk to friends in other countries almost anywhere in the world. It would seem very strange if we could not do that any more.

We each have a television and can watch, say, a golf tournament taking place at the other side of the world. We watch in real time, seeing the result of each stroke almost as soon as the golfer does himself. Even suggesting that such a thing was possible might have got you burnt at the stake for witchcraft, not all that long ago, but not having television would seem a very strange situation for us today.

If we see a 350 ton metal Boeing 747 aircraft flying past, we would not think it to be strange in any way, let alone think it was "impossible". It is routine, casual travel at 500 mph, a speed which would have been considered to be a fantasy when my father was young. The fact that the aircraft is so heavy, is of no concern to us as we know that it will fly, and does so, routinely, every day of the year.

We take for granted, a computer which can do a million things in one second. Today, we have lost the understanding of how big "a million" is, and we know that most people are likely to lose a game of chess if they play against a computer, even a cheap chess computer.

What we need to understand is that our present scientific knowledge is far from being comprehensive and there is still a very large amount to be learned, and that things which the average person today would consider "impossible" are quite liable to be casually routine day-to-day devices in just a few years time. This is not because we are stupid but instead it is because our current science still has a long way to go.

The objective of this website ([http://www.free-energy-info.tuks.nl](http://www.free-energy-info.tuks.nl)) is to explain some of the things which current science is not teaching at the present time. Ideally, we want a device which will power our homes and cars without the need to burn a fuel of any kind. Before you get the idea that this is some new and wild idea, please remember that windmills have been pumping water, milling grain, lifting heavy loads and generating electricity for a very long time now. Water wheels have been doing similar work for a very long time and both of these devices are fuel-less.

The energy which powers windmills and water wheels comes to us via our Sun which heats air and water, causing wind and rain, feeding power to our devices. The energy flows in from our local environment, costs us nothing and will keep on coming whether we make use of it or not.

Most of the pictures of wind generators and water wheels which you will see, show devices which would take a large amount of money to set up. The title of this eBook is "The Practical Guide to Free-Energy Devices" and the word "practical" is intended to indicate that most of the things spoken about are things which you, personally, have a reasonable chance of constructing for yourself if you decide to do so. However, while in chapter 14 there are instructions for building your own wind-powered electrical generator from scratch, pumping water uphill without using a fuel and utilising wave power at low cost, these things are subject to the weather. So, because of this, the main subject is the next generation of commercial devices, devices which do not need a fuel in order to function and power our homes and vehicles, devices which operate no matter what the weather is doing.

Perhaps I should remark at this point, that the commercial introduction of this new wave of hi-tech devices is being actively opposed by people who will lose a very large stream of revenue when it does eventually happen, as it most certainly will. For example, Shell BP which is a typical oil company, makes about US $3,000,000 profit per hour, every hour of every day of every year, and there are dozens of oil companies. The government makes even more than that out of the operation, with 85% of the sale price of oil in the UK being government tax. No matter what they say, (and they both do like to talk "green" in order to gain popularity), neither would ever for a single moment, consider allowing the introduction of fuel-less power devices, and they have the financial muscle to oppose this new technology at every possible level.

For example, some years ago Cal-Tech in the USA spent millions proving that on board fuel reformers for vehicles would give us all better fuel economy and cleaner air. They did long-term testing on buses and cars to provide proof. They teamed up with the very large auto-parts supplier Arvin Meritor to put these new devices in production vehicles. Then "One Equity Partners" bought out Arvin Meritor's division that did all the final work to get fuel reformers put into all new vehicles. They created a new company, EMCON Technologies, and that company dropped the fuel reformer from their product line, not because it did not work, but because it did work. This is not "conspiracy theory" but a matter of public record.

Some years ago, Stanley Meyer, a very talented man living in America, found a very energy-efficient way of breaking water into a mixture of hydrogen gas and oxygen gas. He pushed on further and found that a vehicle engine could be run on quite a small amount of this "HHO" gas if it was mixed with air, water droplets and some of the exhaust gas coming from the engine. He got funding to allow him to start manufacturing retro-fit kits which would allow any car to run on water alone and not use any fossil fuel at all. You can imagine how popular that
would have been with the oil companies and the government. Just after getting his funding, Stan was eating a meal at a restaurant when he jumped up, said "I've been poisoned!", rushed out into the car park and died on the spot. If Stan was mistaken, and he died of 'natural causes', then it was remarkably convenient timing for the oil companies and the government, and his retro-fit kits were never manufactured.

Even though Stan left behind many patents on the subject, until recently nobody managed to replicate his very low-power electrolyser, then Dave Lawton in Wales achieved the feat and many people have since replicated it by following Dave's instructions. More difficult still is getting an engine to run on no fossil fuel as Stan did, but recently, three men in the UK achieved just that by getting a standard petrol-engined electrical generator to run with water as the only fuel. Interestingly, this is not something which they want to pursue as they have other areas which appeal more to them. Consequently, they have no objections to sharing the practical information on what they did and the details are in chapter 10.

In very brief outline, they took a standard 5.5 kilowatt generator and delayed the spark timing, suppressed the 'waste' spark and fed the engine a mix of air, water droplets and just a small amount of HHO gas (which they measured at a flow rate of just three litres per minute). They test-loaded the generator with four kilowatts of electrical equipment to confirm that it worked well under load, and then moved on to a larger engine. This is the general style of generator which they used:

And their arrangement for running it without petrol, is shown in outline here, the full details being in chapter 10, including how to make your own high-performance electrolyser:
Conventional science says that it can prove mathematically that it is quite impossible to do this. However, the calculation is massively flawed in that it is not based on what is actually happening and worse still, it makes initial assumptions which are just plain wrong. Even if we were not aware of these calculations, the fact that it has been done is quite enough to show that the current engineering theory is out of date and needs to be upgraded.

In passing, it might be remarked that an isolated, almost self-sufficient commune in Australia has been supplying their electrical needs by running ordinary electrical generators on water as the only (apparent) fuel for many years now.

However, let us now consider a device built by John Bedini, another talented man in America. He built a battery-powered motor with a flywheel on the shaft of the motor. This, of course, does not sound like startling stuff, but the crunch is that this motor ran in his workshop for more than three years, keeping it's battery fully charged during that time - now that is startling. The arrangement is like this:
What makes this arrangement different from a standard set-up is that the battery powered motor is not connected directly to the battery but instead is fed with a rapid series of DC pulses. This has two effects. Firstly, that method of driving a motor is very efficient electrically speaking and secondly, when a flywheel is driven with a series of pulses, it picks up additional energy from the local environment.

One other unusual feature is the way that the motor shaft spins a disc with permanent magnets mounted on it. These sweep past a matching set of coils attached to a stationary board, forming an ordinary electrical generator and the resulting electrical power which is generated is converted to DC current and fed back to the driving battery, charging it and maintaining its voltage.

Standard theory says that a system like this has to be less than 100% efficient because the DC motor is less than 100% efficient (true) and the battery is only about 50% efficient (true). Therefore, the conclusion is that the system cannot possibly work (false). What is not understood by conventional science is that the pulsed flywheel draws in additional energy from the local environment, showing that conventional science theory is inadequate and out of date and needs to be upgraded, after all, this is not a ‘closed system’.

An American called Jim Watson built a much larger version of John's system, a version which was twenty feet (6 meters) long. Jim's version not only powered itself, but generated 12 kilowatts of excess electrical power. That extra 12 kilowatts of power must be a considerable embarrassment for conventional science and so they will either ignore it, or deny that it ever existed, in spite of the fact that it was demonstrated at a public seminar. This is what Jim's device looked like:

![Image of Jim Watson's device](image1.jpg)

Working quite independently, an Australian called Chas Campbell, discovered the same effect. He found that if he used an AC motor plugged into the mains to drive a flywheel which in turn drove an ordinary generator, that it was possible to get a greater power output from the generator than the amount needed to drive the motor.

![Image of Chas Campell](image2.jpg)

Chas used his motor to drive a series of shafts, one of which has a heavy flywheel mounted on it, like this:
The final shaft drives a standard electrical generator and Chas found that he could power electrical equipment from that generator, electrical mains equipment which required greater current that his mains-driven motor did.

Chas then took it one stage further and when the system was running at full speed, he switched his mains motor over from the wall socket to his own generator. The system continued to run, powering itself and driving other equipment as well.

Conventional science says that this is impossible, which just goes to show that conventional science is out of date and needs to be upgraded to cover systems like this where excess energy is flowing in from the local environment. Here is a diagram of how Chas Campbell's system is set up:

James Hardy has put a video on the web, showing a variation of this same principle. In his case, the flywheel is very light and has simple paddles attached around the rim of the wheel:
He then aims a powerful jet of water from a high-powered water pump, directly at the paddles, driving the wheel round with a rapid series of pulses. The shaft, on which the wheel is mounted, drives a standard electrical generator which lights an ordinary light bulb:

The really interesting part comes next, because he then unplugs the electrical supply to the water pump and switches it over to the generator which the wheel is driving. The result is that the pump powers itself and provides excess electricity which can be used to power other electrical equipment. The arrangement is like this:

Once again, conventional science says that this is impossible, which in turn, demonstrates that conventional science is out of date and needs to be expanded to include these observed facts.

**Permanent Magnets** provide continuous power. This is because the poles of the magnet form a dipole, unbalancing the zero-point energy field near the magnet, and causing a continuous flow of energy which we call “lines of magnetic force”. This should be obvious as a magnet can support its own weight on the vertical face of a

---

Permanent Magnets provide continuous power. This is because the poles of the magnet form a dipole, unbalancing the zero-point energy field near the magnet, and causing a continuous flow of energy which we call “lines of magnetic force”. This should be obvious as a magnet can support its own weight on the vertical face of a
refrigerator, for years on end. Conventional science says that permanent magnets can't be used as a source of power. However, the reality is that conventional science just doesn't know the techniques necessary for extracting that power. The lines of magnetic flow around any magnet are symmetrical and in order for a magnet to provide a useful directional force, it is necessary to arrange magnets in such a way that their combined magnetic field is no longer symmetrical. Doing that is not easy, but there are many alternative methods. Magnets are attracted to iron and that principle along with several other techniques have been successfully use by the New Zealander, Robert Adams who produced a motor which is, typically, at least 800% efficient. This, of course, is impossible according to conventional science. Robert was told that if he shared the information, he would be killed. He decided that at his age of seventy, being killed was not a major thing, so he went ahead and published all the details.

Present day motors driven by electricity are always less than 100% efficient as they are deliberately wound in a symmetrical way in order to make them inefficient. The Adams motor looks like a motor driven by electrical pulses, but it is not. The motor power comes from the permanent magnets mounted on the rotor and not from an electrical pulse applied to the electromagnets attached to the stator. The magnets are attracted to the metal cores of the stationary electromagnets. This provides the driving power of the motor. The electromagnets are then powered just enough to overcome the backwards drag of the magnets when they have just passed by the cores of the electromagnets.

The system works like this:

1. The magnets are attracted to the iron cores of the electromagnets, rotating the drive shaft and powering the motor.

2. The moving magnets generate electrical power in the windings of the electromagnets and this power is used to charge the driving battery.

3. When the permanent magnets reach the electromagnets, a small amount of electrical power is fed to the windings of the electromagnets in order to overcome any backward pull hindering the rotation of the drive shaft.

4. When that power supplied to the electromagnets is cut off, the Back EMF pulse is captured and used to charge the driving battery.

5. Although not shown in the diagram above, there are normally additional pick-up coils mounted round the rotor and if they are connected briefly at the right moment, they generate extra current and when they are switched off, their resulting reversed magnetic field also boosts the rotor on it's way, and that can raise the Coefficient Of Performance over 1000. One replication using this technique has an electrical input of 27 watts and a 32 kilowatt output.

When operated in this way, the Adams Motor has output power far in excess of the input power needed to make it run. The design confuses conventional science because conventional science refuses to accept the concept of energy flow into the motor, from the local environment. This is all the more strange, considering that windmills, water wheels, hydro-electric schemes, solar panels, wave-power systems, tidal power systems and geothermal energy systems are accepted and considered perfectly normal, in spite of the fact that they all operate on energy flowing in from the local environment. It is difficult to avoid the conclusion that vested interests are working hard to prevent conventional science accepting the fact that free-energy is all around us and there for the taking. Perhaps it is the case that they want us to go on paying for fuel to burn to "make" energy to power our homes and vehicles.
Another example of magnet power being used in the design of a powerful motor comes from Charles Flynn. He uses a similar method of electrical screening to prevent magnetic drag hindering the drive shaft rotation. Instead of using electromagnets, Charles uses permanent magnets on both the rotor and the stator, and a flat coil of wire to create the blocking fields:

![Diagram of Rotor and Stator with Coil Off]

When the coil does not have current flowing through it, it does not produce a magnetic field and the South pole of the rotor magnet is attracted equally forwards and backwards by the North pole of the stator magnet. If there are two coils as shown below, and one is powered and the other is not powered, the backward pull is cancelled out and the forward pull causes the rotor to move forwards:

![Diagram of Rotor and Stator with Coils On and Off]

Conventional science takes a quick glance at this arrangement and proclaims that the motor efficiency has to be less than 100% because of the large electrical pulse needed to make the shaft turn. This just demonstrates a complete lack of understanding of how the motor operates. There is no "large electrical pulse" because the motor is not driven by electrical pulses, but instead it is driven by the attraction of many pairs of magnets, and only a very small electrical pulse is applied to cancel the backward drag as the magnets move past. To put this in context, the powerful prototype motor built by Charles ran at 20,000 rpm and the power for the coils was supplied by an ordinary 9-volt "dry-cell" battery quite incapable of supplying heavy currents.

The motor is easily made more powerful by using a stator magnet on both side of the rotor magnet, as shown here:

![Diagram of Rotor and Stator with Coils On and Off Double Magnet Configuration]

There is no real limit to the power of this motor as layer after layer of magnets can be mounted on a single drive shaft as shown here:
The electrical pulses to the screening coils can be synchronised by the light from Light-Emitting Diodes mounted in the timing section, shining through holes in a timing disc attached to the drive shaft of the motor. The light falling on light-dependant resistors on the other side of the disc, provide the switching for the coil-powering electricity.

**Aerial systems.** We are surrounded by so much energy that a simple aerial and earth connection can draw in very large amounts of electrical power from the local environment.

**Thomas Henry Moray** ran frequent public demonstrations during which he lit banks of light bulbs to show that useful amounts of energy could be drawn from the environment:
Moray's device could produce output powers up to fifty kilowatts and it had no moving parts, just a simple aerial and an earth. In spite of the frequent demonstrations, some people would not believe that this was not a hoax, so Moray invited them to choose a place and he would demonstrate the power available at any location they wanted.

They drove fifty miles out into the countryside and picked a really isolated spot away from all power lines and the very few commercial radio stations in the area. They set up a very simple aerial estimated by one observer to be just fifty seven feet long and only seven or eight feet off the ground at its lowest point:

The earth connection was an eight-foot length of gas pipe which was hammered into the ground. There is no significance in the earth connection being a gas pipe, as that was used just because it was to hand at the time. The bank of lights being powered by Moray's device, grew brighter as the gas pipe was driven further and further into the ground, providing a better and better earth connection. Moray then demonstrated that when the aerial was disconnected, the lights went out. When the aerial was connected again, the lights were lit again. He then disconnected the earth wire and the lights went out and stayed out until the earth wire was connected again. The sceptics were completely convinced by the demonstration (which is most unusual for sceptics as sceptics often refuse to accept anything which contradicts their current beliefs).

Moray's is one of several excellent and very successful devices which I can't tell you exactly how to replicate (because the details were never revealed and Moray was intimidated into silence) but the important point here is that a 57-foot aerial raised just 8-feet from the ground can provide kilowatts of electrical power at any location, if you know how to do it.
Moray's demonstrations were highly unpopular with some people and he was shot at in his car. He put bullet-proof glass in his car, so they came into his laboratory and shot at him there. They succeeded in intimidating him into stopping his demonstrations or publishing the exact details of how to replicate his aerial power system.

**Lawrence Rayburn** has developed an aerial system with one part raised thirty feet above the ground. He powers his farm with it and has measured more than 10 kilowatts being drawn from it.

**Hermann Plauson** has a patent which reads more like a tutorial on how to extract useful power from an aerial. He describes installations where one producing 100 kilowatts of excess power he calls a "small" system as each of his aerials can capture up to a kilowatt and he used many aerials.

**Frank Prentice** has a patent on an ‘aerial’ system where he drives a wire loop alongside a long length of wire mounted just seven or eight inches (200 mm) above the ground. His input power is 500 watts and the power drawn from the system is 3,000 watts, giving an excess of 2.5 kilowatts (COP=6):

![Diagram of Frank Prentice's aerial system]

**Nikola Tesla**, probably the most famous person in the free-energy field, has a patent on an aerial system which uses a shiny metal plate with insulated faces as the main component of his aerial. As is common in this field, a high-quality capacitor is used to store the energy initially and then that power is pulsed through a step-down transformer which lowers the voltage and raises the current available, as shown here:

![Diagram of Nikola Tesla's aerial system]

Instead of using an aerial, it is possible to use a **Tesla Coil** which produces very high currents if the primary winding is placed in the middle of the secondary winding and not at one end which is the usual configuration. With one method, Tesla directs the output on to a single metal plate and powers a load between the plate and the earth.

**Don Smith** demonstrates this in a video currently on YouTube. He uses a capacitor made from two metal plates with a sheet of plastic between them, instead of Tesla's insulated single plate. The load is powered between the capacitor and earth. The video shows Don using a 28-watt hand-held Tesla Coil and producing what looks like several kilowatts of power in the earth line.
Don points out that the output power is proportional to the square of the voltage and the square of the frequency: So if you double the frequency and double the voltage there will be 16 times as much output power.

Tariel Kapanadze demonstrates this in a web video of his interview for Turkish TV. It shows him making an earth connection by burying an old car radiator, and then lighting a row of light bulbs from a Tesla Coil style fuel-less device. While the commentary is not in English, the video is very informative. You will notice that this is a substantial power output coming from a device built with a very basic style of construction where bare wires are twisted together to form an electrical connection.

When the starting battery is removed, the equipment is held in the air to show that it is self-contained and self-powered. This is another confirmation that free-energy is all around us and ready to be taken by anyone who knows how. Tariel is seen here lighting a row of five light bulbs hanging from a broom handle placed across the backs of two chairs - not exactly a high-tech, high-cost form of construction this!

This is a picture of his circuit housing, spark gap and output transformer:

However, I can’t provide you with the exact details as Tariel has never revealed how he does it and there is every indication that he never will. He says that if he told how it worked, then “you would laugh as it is so simple”.
The Colman / Seddon-Gillespie 70-year battery. A quite different approach to getting fuel-less power was taken by Colman and Seddon-Gillespie who developed a tiny tube of harmless chemicals - copper, zinc and cadmium:

They found that if his tube was subjected to a few seconds of high-frequency electromagnetic radiation, then it became radioactive for about one hour. During that time, a kilowatt of electrical power could be drawn continuously from this tiny tube. Near the end of the hour, another burst of electromagnetic waves keeps the tube radioactive and maintains the output current. Lead shielding is used to make this a safe device to use. They have a patent on this device. The expected working life of one of these tubes is estimated as being seventy years.

Electrolysis. Michael Faraday did a really excellent job of investigating how much energy was required to change water from it's liquid state into a mixture of hydrogen gas and oxygen gas. Conventional science has latched on to this information and refuses to believe that it is not the last possible word on electrolysis.

This is akin to saying that the fastest a man can propel himself over the ground is by running, and refusing to accept the fact that there might be a later invention of a bicycle which would allow a much faster human-powered speed over the ground.

This is maintained in spite of the fact that a patent has been awarded to Shigeta Hasebe for a different style of electrolysis, using magnets and spiral electrodes like this:

In his patent, Shigeta indicates his disappointment that his laboratory tests only showed an efficiency of ten times greater than that of Faraday while his calculations showed that he could be getting twenty times the Faraday result. The different method, along with the use of powerful magnets at the top and bottom of his electrode pairs, bypassed the limits which Faraday had established by changing the working conditions.
Stanley Meyer of the USA discovered a method of splitting water into its gas form, using very little power. Stan's work has been replicated by Dave Lawton and many other people. For example, Dr Scott Cramton has produced the "HHO" gas mix produced by the electrolysis of water, at a rate of 6 litres per minute with a power input of just 36 watts (12 volts at 3 amps). This is dramatically better than Faraday thought was possible and it allows power production through recombining that HHO gas to give water again, as the power produced is well above the amount of power needed to split the water in the first place. It should be remarked in passing, that most of the power produced when HHO is recombined into water, does not come from the hydrogen (even though in its HHO form it is typically four times more energetic than hydrogen gas), but from charged water clusters which are generated during the electrolysis process.

John Bedini of the USA has patented a system for the rapid charging of batteries with a pulsed waveform. Using banks of batteries tends to be very expensive, very space-consuming and replacement batteries are needed at frequent intervals, giving the user a disposal problem and additional cost. Batteries have the serious restriction that they get damaged and their life shortened if the rate of discharge is less than 20 hours. So a 100 Amp-Hour battery can only manage a 5 amp current (60 watts) if it is not to be damaged.

John Bedini's spike-generating system can charge several batteries at the same time. The snag is that you can't use the batteries to power equipment while they are being charged, so you need two sets of batteries. The system is easy to make and use. The best performance that I have come across is where there is thirteen times more power output than the power input.

There are several variations on John's pulser. The most common is a bicycle wheel with ferrite permanent magnets attached to the rim:

As the wheel spins, the approaching magnet generates a voltage in one winding of an electromagnet. This triggers a circuit which powers a second winding of the electromagnet. This pulse pushes the magnet away, keeping the wheel spinning. When the power to the coil is cut off, the resulting "Back EMF" voltage spike is fed to the batteries being charged. If the spike is sharp enough, it can cause an inflow of additional energy from the local environment. Interestingly, the rate at which the wheel rotates is directly proportional to the amount of charge in the batteries being charged. Here is a picture of Ron Pugh's high-quality construction of a Bedini pulse charger:
Conclusion:
The term "Free-Energy" generally means a method of drawing power from the local environment, without the need to burn a fuel. There are many different successful methods for doing this and these methods span many countries and many years.

The amount of power which can be collected can be very high and the few kilowatts needed to power a household is most definitely within the reach of most of the devices mentioned.

************

In this brief introduction, not much detail has been given about the devices mentioned and only a small selection of devices has been covered. Much more detail is available in the various chapters of this eBook.

The 'bottom line' is that energy can definitely be drawn from the local environment in sufficient quantities to supply all of our needs. For whatever reason, conventional science appears determined not to accept this basic fact and denies it at every opportunity. It seems likely that vested financial interests are the root cause of this refusal to accept the facts. The true scientific method is to upgrade scientific theory in the light of observed fact and new discoveries, but the true scientific method is not being followed at the present time.

To conclude this introduction, let us consider some of the many ways which can be used to gather energy from the zero-point energy field in readiness for use in our daily tasks. Here are some of those methods:

People looking for free-energy generators generally have no idea what is involved. In the UK, household mains appliances have a 13-Amp fuse, limiting them to 3 kilowatts of power before the fuse burns out. House wiring is run in a ring which allows each power socket to be fed by two lengths of mains wiring, so that the current is supplied from two directions, doubling the current available at each socket. Ten kilowatts from a battery inverter would need to carry a massive 926 Amps which is far more than the starter motor current in a vehicle and that 926 Amps is more than 70 times the UK household fuse rating.

To determine how much electricity you use in a day, you list everything electrical that you use and how long you have each item on for during the day. For example, a 100-watt bulb which is on for 8 hours, uses 0.1 kilowatts multiplied by 8 hours which is a total of 0.8 kilowatt-hours (which is the ‘Unit’ used by power companies to charge their customers). So, if you are charged 15 pence per Unit, then that bulb being on for eight hours will cost you 0.8 x 15 = 12 pence during that one day.

The power rating of each item of equipment is normally shown on a plate or sticker on the back of the unit. To give you a general idea of typical power ratings, here is a list:

Light bulb: 100 watts, Kettle: 1.7 to 2.5 kilowatts, Cooker: 7 kilowatts, Hot plate: 1.2 kilowatts, Dishwasher: 2 kilowatts, Washing machine: 2.25 kilowatts maximum but during most of the cycle it is much less than that, Tumble dryer: 2 to 2.5 kilowatts, TV set: 50 to 100 watts, Radio: 10 watts, DVD player: 50 watts, Computer: 150 watts, Music system: 100 watts, Fridge/freezer: 500 watts maximum, but very little during a day as it is off most of the time, Air conditioning: anything from 1 kilowatt to perhaps 4 kilowatts, depending very much on the actual A/C unit, Fan: 50 watts.

A very effective way to determine the actual power draw of any item of household equipment is to use a cheap, mains watt-meter such as the one shown here. Equipment can be plugged into it and the watt-meter plugged into the mains. It will then tell you the actual power draw and the cumulative power ‘consumption’ for any item of equipment. Using it on a fridge or fridge-freezer is very informative as the cumulative reading shows the actual amount of current draw over a day, and at night, with the lower temperatures and nearly zero opening of the door, the current draw is very much lower than the peak current draw. A domestic watt-meter is low-cost as they are made in large volumes. The one shown below is a fairly typical unit.
If you manage to buy a free-energy generator, it is likely to be expensive. However, if you examine what items of household equipment are costing you the most to run, it is quite possible that a fairly small generator could make a major difference to your electricity costs.

**Already on sale:**

Even though the people who have been denying that free-energy is possible and suppressing inventors and inventions for more than a hundred years now, they do slip up on some things, possibly thinking that the general public are just not smart enough to see the facts. For example, portable air conditioning units are on sale and some provide heating as well as cooling. In the sales literature, the sellers state quite clearly that the heat output is substantially greater than the electrical input, typically 2.6 to 3.0 times greater. They point out very clearly that if you heat with electricity, then you can reducing your heating bills to one third by using their equipment. Here are three typical examples of this:

This is the ElectriQ “Air Cube” AC9000E with 7000 BTU capacity and in 2015 retails for £220 from [www.appliancesdirect.co.uk](http://www.appliancesdirect.co.uk). Intended for rooms of up to 18 square metres floor space, it uses 900 watts maximum input for cooling and 750 watts maximum input for 2 kilowatts of heating. That is three quarters of a kilowatt input for 2 kilowatts of output, so the Coefficient Of Performance which is output divided by the user’s input is 2.67 or heating bills would drop to 37.5% of what they were. This is very interesting as we are repeatedly told that COP greater than 1 is impossible and “there is no such thing as a free meal”. Fortunately, the ElectriQ company disagrees.
This is the Climachill Ltd. PAC12H (KYD32) 12000 BTU air conditioner, in 2015 retailing at £312 and when heating it has a COP of about 3.0 with a 3.5 kilowatt performance with an input just over 1 kilowatt. Climachill Ltd. Also fails to understand that “there is no such thing as a free meal” and that it is impossible to have a greater output than the input.

This is the Electrolux EXP09HN1WI retailing in 2015 at £336 and providing cooling and 2.32 kilowatt heating with a COP=2.82 meaning that for an output of 2.32 kilowatts, the required input is 823 watts. Supplied by many different retailers.

There are many other portable air conditioning units including much larger versions. What they all have in common is an output which is much larger than the input. The average refrigerator also has a performance nearly three times greater than the power needed to operate it.

You may disagree, but it is clear to me that if I can get 3 kilowatts of heating for 1 kilowatt of input power, then I am receiving 2 kilowatts of free-energy.

I hope that you can see from the long list of methods presented in this introduction, that there is nothing actually strange or weird about the concept of using free-energy or self-powered generators. Therefore, I invite you to examine the facts, read the information in this eBook and the additional information on the website http://www.free-energy-info.tuks.nl/ and make up your own mind on the subject. Please note that this is not a fixed body of information and this eBook normally gets a significant upgrade on a regular basis Consequently, I suggest that you download a new copy say, once per month in order to stay up to date with what is happening. Good luck with your research.

The “Scientists”
People who are not familiar with free-energy, sometimes wonder why free-energy generators are not on sale in the local shops and why ‘scientists’ claim that these things are not possible. There are a number of reasons. One reason is that they have been taught to consider all physical things as part of a “closed system” where all outside influences have been excluded. That is a nice idea for performing analysis but it must not be thought to have anything much to do with real systems in the real world because there is no such thing in this universe as a closed system. If you think you can make a closed system, then I would be delighted if you would tell me how. You system would have to exclude gravity, cosmic particles, heat, light, all electromagnetic influences, magnetic effects, longitudinal waves, the zero-point energy field and everything else you can think of. So far, nobody has ever managed to construct a closed system and some experiments are carried out in deep mines in an attempt to lower some of the effects which we just cannot block. So, while a “closed system” is a nice idea, you will never encounter one.
Another reason is that scientists not only are not aware of current technology, but they are not even aware that they don’t know the relevant facts. It seems to be a strange feature of people who have received a university degree, that they are smarter than other people, when in fact, all that the degree shows is that they have sat through long periods listening to what the professors have to say, and the professors are frequently wrong and the graduates have been misled (and that is not a case of ‘sour grapes’ as I have more letters after my name than are in my name, and I assure you that university graduates can be lacking a great deal of factual information). For example, ‘scientific experts’ have performed calculations and say that the laws of physics shows that an electrical generator cannot be run on the gas mix which is produced from water when electricity is passed through it. This is a typical conclusion which is totally wrong considering that people in isolated areas have been getting their daily electricity from generators whose only fuel appears to be water. Let’s examine their approach.

1. They say that water consists of two molecules of Hydrogen and one molecule of Oxygen. That is nearly right, and fish should be very thankful that they are not completely right. They then say that the amount of current needed for splitting water into a gas mix is shown by Faraday’s experiments. What they are not aware of is that Bob Boyce, Stan Meyer and Shigeta Hasebe have each produced ten times the Faraday results and each using completely different methods. A factor of 10 in a calculation makes a major difference.

2. They then calculate the energy produced when hydrogen is burnt. That is a major mistake as the gas produced by electrolysis of water is not hydrogen but instead is a mixture of highly charged single hydrogen atoms and highly charged single oxygen atoms. That mix is generally called “HHO” and has a recombination energy which is usually four or five times greater than hydrogen gas. HHO is so active and energetic that compressing it to a pressure over 15 pounds per square inch (“15 psi”) causes it to ignite spontaneously. This means that the ‘scientific’ calculations are already low by a factor of at least 40.

3. They are not aware that if a fine spray of cold water droplets or ‘mist’ is added to the incoming air, that the water converts to flash-steam on ignition of the HHO, producing high pressure inside the cylinder of the generator and causing the generator to act as an internal combustion steam engine.

As a result of these details, the ‘scientific’ calculations which show that a generator cannot be self-powered are completely wrong, as are many of the ‘scientific’ pronouncements made by ignorant ‘scientists’.

However, moving on, probably the most important reason for the rubbish spouted by scientists and university researchers is a human problem. Universities have to maintain their standing and prestige by constantly publishing research papers. Those research papers are produced as the result of research work done by graduates under the guidance of a professor. That work costs money which is provided by rich people as ‘grants’. The rich people are normally rich because they have a lucrative business, and they can bring pressure to bear on the Professor, not to allow any research which would compete with their existing business profits. That way, the output from the main universities is controlled and is any honest researcher is not willing to go along with what is being said, then that researcher is blacklisted and even ridiculed by his former colleagues, and he finds it impossible to get any further research position anywhere. Scientific information has been suppressed for more than a hundred years now.

So, the result of these things is that the straightforward reality of free-energy devices is denied (tongue in cheek generally) by scientists who don’t want to be blacklisted and who are fully aware that what they are stating is actually lies. The internet is making things difficult for them, but they are still doing a fine job of fooling most of the people for most of the time, banking on a general lack of knowledge by the public.

Chapter 1: Magnet Power

Note: If you are not at all familiar with basic electronics, you might find it easier to follow parts of this chapter if you read chapter 12 first.

One thing which we are told, is that permanent magnets can’t do any work. Oh yes, magnets can support themselves against the pull of gravity when they stick on your refrigerator, but, we are told, they can’t do any work. Really?

What exactly is a permanent magnet? Well, if you take a piece of suitable material like ‘mild’ steel, put it inside a coil of wire and drive a strong electrical current through the coil, then that converts the steel into a permanent magnet. What length of time does the current need to be in the coil to make the magnet? Less than one hundredth of a second. How long can the resulting magnet support its own weight against gravity? Years and years. Does that not strike you as strange? See how long you can support your own body weight against gravity before you get tired. Years and years? No. Months, then? No. Days, even? No.

Well if you can’t do it, how come the magnet can? Are you suggesting that a single pulse for a minute fraction of a second can pump enough energy into the piece of steel to power it for years? That doesn’t seem very logical, does it? So, how does the magnet do it?

The answer is that the magnet does not actually exert any power at all. In the same way that a solar panel does not put any effort into producing electricity, the power of a magnet flows from the environment and not from the magnet. The electrical pulse which creates the magnet, aligns the atoms inside the steel and creates a magnetic “dipole” which has the same effect that the electrical “dipole” of a battery does. It polarises the quantum environment surrounding it and causes great streams of energy flow around itself. One of the attributes of this energy flow is what we call “magnetism” and that allows the magnet to stick to the door of your refrigerator and defy gravity for years on end.

Unlike the battery, we do not put it in a position where it immediately destroys its own dipole, so as a result, energy flows around the magnet, pretty much indefinitely. We are told that permanent magnets can’t be used to do useful work. That is not true.

ShenHe Wang's Permanent Magnet Motor.
This is a picture of a Chinese man, ShenHe Wang, who has designed and built an electrical generator of five kilowatt capacity. This generator is powered by permanent magnets and so uses no fuel to run. It uses magnetic particles suspended in a liquid. It should have been on public display at the Shanghai World Expo from 1st May
2010 to 31st October 2010 but the Chinese government stepped in and would not allow it. Instead, they would only allow him show a wristwatch-size version which demonstrated that the design worked but which would be of no practical use in power generation:

Most inventors don't seem to realise it, but almost every government is opposed to members of the public getting hold of any serious free-energy device (although they are happy to use these devices themselves). Their objective is to dominate and control ordinary people and a major factor in that is to control the supply and cost of power. A second method used everywhere is to control money, and without noticing it, governments manage to take away about 78% of people's income, mainly by concealed methods, indirect taxes, charges, fees, …. If you want to know more about it, then visit www.yourstrawman.com but please understand that the reason why free-energy devices are not for sale in your local shop has to do with political control and vested financial interests and has nothing whatsoever to do with the technology. All technological problems have been solved, literally thousands of times, but the benefits have been suppressed by those in power.

Two of Mr Wang's 5 kilowatt generators successfully completed the Chinese government's mandatory six-month “Reliability and Safety” testing programme in April 2008. One large Chinese consortium has started buying up coal-fired electricity generating stations in China in order to refurbish them with pollution-free large versions of Wang's generator. Some information on the construction of the Wang motor is available here: http://www.free-energy-info.tuks.nl//Wang.pdf.

The motor consists of a rotor which has four arms and which sits in a shallow bowl of liquid which has a colloidal suspension of magnetic particles in it:
There is a patent on the motor but it is not in English and what it reveals is not a major amount.

It was Mr Wang's intention to give his motor design to every country in the world and invite them to make it for themselves. This very generous attitude does not take into account the many vested financial interests in each country, not the least of which is the government of that country, which will oppose the introduction of any device which taps into free-energy and which, consequently, would destroy their continuous streams of income. It is even possible that you would not be allowed to go to China, buy one and bring it back with you for use at home.

It is not easy to arrange permanent magnets in a pattern which can provide a continuous force in a single direction, as there tends to be a point where the forces of attraction and repulsion balance and produce a position in which the rotor settles down and sticks. There are various ways to avoid this happening. It is possible to modify the magnetic field by diverting it through a soft iron component.
There are many other designs of permanent magnet motor, but before showing some of them, it is probably worth discussing what useful work can be performed by the rotating shaft of a permanent magnet motor. With a home-built permanent magnet motor, where cheap components have been used and the quality of workmanship may not be all that great (though that is most definitely not the case with some home construction), the shaft power may not be very high. Generating electrical power is a common goal, and that can be achieved by causing permanent magnets to pass by coils of wire. The closer to the wire coils, the greater the power generated in those coils. Unfortunately, doing this creates magnetic drag and that drag increases with the amount of electrical current being drawn from the coils.

There are ways to reduce this drag on the shaft rotation. One way is to use an Ecklin-Brown style of electrical generator, where the shaft rotation does not move magnets past coils, but instead, moves a magnetic screen which alternatively blocks and restores a magnetic path through the generating coils. A commercially available material called “mu-metal” is particularly good as magnetic shield material and a piece shaped like a plus sign is used in the Ecklin-Brown generator.

John Ecklin’s Magnetic-Shielding Generator.
John W. Ecklin was granted US Patent Number 3,879,622 on 29th March 1974. The patent is for a magnet/electric motor generator which produces an output greater than the input necessary to run it. There are two styles of operation. The main illustration for the first is:

Here, the (clever) idea is to use a small low-power motor to rotate a magnetic shield to mask the pull of two magnets. This causes a fluctuating magnet field which is used to rotate a generator drive.

In the diagram above, the motor at point ‘A’ rotates the shaft and shielding strips at point ‘B’. These rectangular mu-metal strips form a very conductive path for the magnetic lines of force when they are lined up with the ends of the magnets and they effectively shut off the magnet pull in the area of point ‘C’. At point ‘C’, the spring-loaded traveller is pulled to the left when the right-hand magnet is shielded and the left hand magnet is not shielded. When the motor shaft rotates further, the traveller is pulled to the right when the left-hand magnet is shielded and the right hand magnet is not shielded. This oscillation is passed by mechanical linkage to point ‘D’ where it is used to rotate a shaft used to power a generator.

As the effort needed to rotate the magnetic shield is relatively low, it is claimed that the output exceeds the input and so can be used to power the motor which rotates the magnetic shield.

The second method for exploiting the idea is shown in the patent as:
Here, the same shielding idea is utilised to produce a reciprocating movement which is then converted to two rotary motions to drive two generators. The pair of magnets ‘A’ are placed in a housing and pressed towards each other by two springs. When the springs are fully extended, they are just clear of the magnetic shield ‘B’. When a small electric motor (not shown in the diagram) moves the magnetic shield out of the way, the two magnets are strongly repelled from each other as their North poles are close together. This compresses the springs and through the linkages at ‘C’ they turn two shafts to generate output power.

A modification of this idea is the **Ecklin-Brown Generator**. In this arrangement, the movable magnetic shielding arrangement provides a direct electrical output rather than a mechanical movement:

Here, the same motor and rotating magnetic shield arrangement is used, but the magnetic lines of force are blocked from flowing through a central I-piece. This I-piece is made of laminated iron slivers and has a pickup coil or coils wound around it.

The device operates as follows:

In the position shown on the left, the magnetic lines of force flow **downwards** through the pickup coils. When the motor shaft has rotated a further ninety degrees, the situation on the right occurs and there, the magnetic lines of force flow **upwards** through the pickup coils. This is shown by the blue arrows in the diagram. This reversal of magnetic flux takes place four times for every rotation of the motor shaft.

While the Ecklin-Brown design assumes that an electric motor is used to rotate the mu-metal shield, there does not seem to be any reason why the rotation should not be done with a permanent magnet motor.
Toroidal shapes are clearly important in many devices which pull in additional energy from the environment. However, the Ecklin-Brown generator looks a little complicated for home construction, the principle can be used with a much more simple style of construction where the cores of the output coils are straight bars of suitable material such as ‘soft’ iron or perhaps the more readily available masonry anchors:

If using the masonry anchors, be sure to cut the conical end off as it alters the magnetic effect in an undesirable way. Using a hand hacksaw and a vise, cutting the end off is a very easy thing to do and that allows an ordinary helical coil to be wound either directly on the shaft or on a simple bobbin which slides on to the shaft. With any such coil, the voltage produced increases as the number of turns in the coil increases. The maximum current draw depends on the thickness of the wire as the thicker the wire, the greater the current which it can carry without overheating.

We can use an ordinary magnet or set of magnets at each end of the straight core to cause a strong magnetic field to flow through the core of our coil. As the motor spins the two screening arms they pass alternately between the magnet at one end of the core and then the magnet at the other end of the core, creating a fluctuating magnetic field passing through the coil.

The drawing shows just one output coil, but there could be two coils:
Or there could be four coils:

![Side View Diagram](image1)

![End View Diagram](image2)

The coils can be connected in parallel to increase the output current, or they can be connected in series (in a chain configuration) to increase the output voltage. While the drawings show the shields connected directly to the motor drive shaft (a short length of plastic sleeving from a piece of wire would probably be used to help with alignment of the motor shaft and the shielding axle) there is no reason why the shielding should not be on a separate axle mounted in bearings and driven by a belt and pulley wheel arrangement.

With a separate shielding axle, allows a long, stiff axle to be used and that allows there to be additional coils and magnets. The result could be like this:
Howard Johnson's Permanent Magnet Motor.

Returning to permanent magnet motors themselves, one of the top names in this field is Howard Johnson. Howard built, demonstrated and gained US patent 4,151,431 on 24th April 1979, from a highly sceptical patent office for, his design of a permanent magnet motor. He used powerful but very expensive Cobalt/Samarium magnets to increase the power output and demonstrated the motor principles for the Spring 1980 edition of Science and Mechanics magazine. His motor configuration is shown here:

The point that he makes is that the magnetic flux of his motor is always unbalanced, thus producing a continuous rotational drive. The rotor magnets are joined in stepped pairs, connected by a non-magnetic yoke. The stator magnets are placed on a mu-metal apron cylinder. Mu-metal is very highly conductive to magnetic flux (and is expensive). The patent states that the armature magnet is 3.125" (79.4 mm) long and the stator magnets are 1" (25.4 mm) wide, 0.25" (6 mm) deep and 4" (100 mm) long. It also states that the rotor magnet pairs are not set at 120 degrees apart but are staggered slightly to smooth out the magnetic forces on the rotor. It also states that the air gap between the magnets of the rotor and the stator are a compromise in that the greater the gap, the smoother the running but the lower the power. So, a gap is chosen to give the greatest power at an acceptable level of vibration.

Howard considers permanent magnets to be room-temperature superconductors. Presumably, he sees magnetic material as having electron spin directions in random directions so that their net magnetic field is near zero until the electron spins are aligned by the magnetising process which then creates an overall net permanent magnetic field, maintained by the superconductive electrical flow.
The magnet arrangement is shown here, with the inter-magnet gaps assessed from the drawing in Howard's patent:

Position 1

Position 2

Position 3

Note that Howard Johnson did not draw the inter-magnet gaps as equal distances.

A magazine article on this can be seen at [http://newebmasters.com/freeenergy/sm-pg48.html](http://newebmasters.com/freeenergy/sm-pg48.html).
The “Carousel” Permanent Magnet Motor/Generator.
US Patent 5,625,241, included in the Appendix, presents the specific details of a simple electrical generator powered by permanent magnets alone. This generator can also be used as a motor. The construction is not particularly complicated:

![Diagram](image1)

It uses an arrangement where permanent magnets are associated with every second coil set around the rotor. Operation is self-powered and the magnet arrangement is clearly defined:

![Diagram](image2)

And the physical arrangement of the device is not particularly complicated:
This is a patent which is definitely worth reading and considering, especially since it is not a complicated presentation on the part of the authors, Harold Ewing, Russell Chapman and David Porter. This seemingly very effective generator appears to be overlooked at the present time. It seems quite clear that permanent magnet motors are a wholly viable option for the home constructor and they are capable of substantial power outputs over long periods, however, it should be noted that motors using magnets alone are notoriously difficult to get operational and while it can be done, motors which use moving shielding or pulsed electrical shielding are much more viable for the first-time constructor – motors such as the Charles Flynn motor or the Stephen Kundel motor.

**Robert Tracy's Permanent Magnet Motor.**
Some people have opted for permanent magnet motors where the field is shielded at the appropriate moment by a moving component of the motor. Robert Tracy was awarded US Patent Number 3,703,653 on 21st November 1972 for a “Reciprocating Motor with Motion Conversion Means”. His device uses magnetic shields placed between pairs of permanent magnets at the appropriate point in the rotation of the motor shaft:

**Ben Teal's Electromagnet Motor.**
Motors of this kind are capable of considerable power output. The very simple motor, originally built by Ben Teal using wood as the main construction material, was awarded US Patent Number 4,093,880 in June 1978. He found that, using his hands, he could not stop the motor shaft turning in spite of it being such a very simple motor design:
The motor operation is as simple as possible with just four switches made from springy metal, pushed by a cam on the rotor shaft. Each switch just powers its electromagnet when it needs to pull and disconnects it when the pull is completed. The resulting motor is very powerful and very simple. Additional power can be had by just stacking one or more additional layers on top of each other. The above diagram shows two layers stacked on top of one another. Only one set of four switches and one cam is needed no matter how many layers are used, as the solenoids vertically above each other are wired together in parallel as they pull at the same time.

The power delivered by the Teal motor is an indication of the potential power of a permanent magnet motor which operates in a rather similar way by moving magnetic shields to get a reciprocating movement. Placing a resistor and capacitor across each switch contact both suppresses sparks and feeds current back to the battery when the contact opens, and this extends the battery life considerably.
The Jines Permanent Magnet Motor.
James E. Jines and James W. Jines were awarded US Patent 3,469,130 on 23rd September 1969 “Means for Shielding and Unshielding Permanent Magnets and Magnetic Motors Utilising the Same” and which is in the Appendix. This magnet motor design uses selective shielding of the drive magnets to produce a continuous force in one direction. It also has a mechanical arrangement to progressively adjust the shielding to adjust the power of the motor.
This is a very interesting design of magnetic motor, especially since it does not call for any materials which are not readily available from many suppliers. It also has the advantage of not needing any form of exact adjustment or balancing of magnetic forces to make it operate.

Stephen Kundel’s Permanent Magnet Motor.
Stephen Kundel’s motor design is shown in full detail in his patent which is shown on page A - 968 of the Appendix. It uses a simple oscillating motion to position the “stator” magnets so that they provide a continuous rotational force on the output shaft:

![Figure 1A](image)

Here, the yellow arm marked 38, rocks to the right and left, pushed by a solenoid coil 74. There is no obvious reason why this rocking motion could not be achieved by a mechanical linkage connected to the rotating output shaft 10. The three arms 20, 22 and 24, being pivoted at their upper points, are pushed into a central position by the springs 34 and 35. The magnets 50, 51 and 52, are moved by these arms, causing a continuous rotation of the output drive shaft 10. The movement of these magnets avoids the position where the magnets reach a point of equilibrium and lock into a single position.
Figures 2 and 3 show the position of the magnets, with the Figure 3 position showing a point in the output shaft rotation which is 180 degrees (half a turn) further on than the position shown in Figure 2.

Some other, more powerful magnet arrangements which can be used with this design are shown in the full patent in the Appendix.

This design does not seem to appeal to many constructors in spite of the fact that it must be one of the easiest magnet motors to set up and make work. The output power level can be as big as you want as additional layers of magnets can be added. The operation is very simple and it can, perhaps, be seen more easily if just one lever arm is considered. The lever arm has just two working positions. In one position it acts on one set of rotor magnets and in the second position it acts on a second set of rotor magnets. So, we will look at each set in turn. If there are two magnets near each other, one fixed in position and the other free to move like this:

The magnets have a strong attraction to each other because of the North and South poles attracting each other. However, as the two South poles repel each other, the movement of the approaching magnet is not directly along the green arrows shown but initially is in the direction shown by the red arrow. This situation continues with the moving magnet approaching he fixed magnet and the pull between them getting stronger all the time. But, the situation changes immediately the moving magnet reaches it's closest point to the fixed magnet. Momentum starts to carry it past, but at that point the direction of the pull between the magnets starts to oppose the onward movement of the moving magnet:

If the fixed magnet remains in that position, then the moving magnet will oscillate briefly and come to a halt directly opposite the fixed magnet like this:
The attraction forces between the two magnets is now wholly horizontal and there is no force on the movable magnet to cause it to move. This is simple stuff, understood by anyone who has examined permanent magnets in order to see what they do. Stephen Kundel is well aware of this, and so he moves the “fixed” magnet rapidly out of the way before the reverse-direction pull slows the moving magnet down. He moves the magnet sideways and slides another one into position like this:

The new magnet is now much closer to the moving magnet and so has a much greater influence on it. The poles of the new magnet match the poles of the moving magnet which causes them to push apart very strongly, driving the moving magnet onwards in the direction it was moving in. The moving magnet moves very quickly and so gets out of the range of the fixed magnets quite quickly, at which point, the “fixed” magnets of the stator are moved back into their original position where they act in the same way on the next moving magnet attached to the rotor.

This very simple operation only requires a small force to move the stator magnets sideways between their two positions, while the force between the stator magnets and the rotor magnets can be high, producing considerable rotational power to the axle on which the rotor discs are attached.

The efficiency of the system is further boosted because when the stator magnets are in the first position shown, the second “fixed” magnet is not sitting idle but instead, it acts on the magnet of the next rotor disc:

For this, the magnets attached to Rotor disc 2 have to be positioned so that their poles are the reverse of those attached to Rotor disc 1. Stephen uses a loudspeaker to wobble the horizontal bar on which the stator magnets are mounted, backwards and forwards as a loudspeaker has that mechanism already built into it. Don Kelly's
permanent magnet motor also uses this very simple idea of moving the stator magnets out of the way at the appropriate moment.

Charles “Joe” Flynn's Permanent Magnet Motor.
Patent US 5,455,474 dated 3rd October 1995 and shown in full in the Appendix, gives details of this interesting design. It says: “This invention relates to a method of producing useful energy with magnets as the driving force and represents an important improvement over known constructions and it is one which is simpler to construct, can be made to be self starting, is easier to adjust, and is less likely to get out of adjustment. The present construction is also relatively easy to control, is relatively stable and produces an amazing amount of output energy considering the source of driving energy that is used. The present construction makes use of permanent magnets as the source of driving energy but shows a novel means of controlling the magnetic interaction or coupling between the magnet members and in a manner which is relatively rugged, produces a substantial amount of output energy and torque, and in a device capable of being used to generate substantial amounts of energy.”

The patent describes more than one motor. The first one is like this when seen from the side:

An exploded view, shows the different parts clearly:
This construction is relatively simple and yet the operation is powerful. The power is provided by three magnets, shown shaded in blue and yellow. The lower magnet is in the form of a disc with the poles arranged on the large, circular, flat faces. This is the stator magnet which does not move. Positioned above it is a disc made of non-magnetic material (shaded in grey) and which has two magnets embedded in it. This disc is the rotor and is attached to the central vertical shaft.

Normally, the rotor would not rotate, but between the two discs there is a ring of seven coils which are used to modify the magnetic fields and produce powerful rotation. The powering up of these coils is very simple and it is arranged by shining a beam of Ultra Violet light from one of the Light-Emitting Diodes through a slot in an optical-timing disc attached to the rotating shaft. The LEDs and the photo-transistors are aligned with the centres of the seven coils. The position and width of the slot controls which photo-transistor gets switched on and for how long it remains powered up. This is a very neat and compact arrangement. The really interesting part of the design is how the coils modify the magnetic fields to produce the output power of the device. The orientation of the magnet poles can be swapped over, provided that this is done for all three magnets.
Shown here is the situation when one of the rotor magnets has rotated to where it is above one of the coils which is not yet powered up. The South pole of the rotor magnet is attracted to the North pole which is the entire upper face of the stator magnet as shown by the three arrows. If a voltage is applied to the coil, then this magnetic coupling is disrupted and altered. If any torque is developed as a result of the coil being powered up, then it will be developed to either side of the energised coil. If the coil is not powered up, then there will be full attraction between the magnets and no rotational force will be produced. You will notice that there are two rotating magnets (an even number) and seven coils (an odd number) so when one of the rotor magnets is above a coil, then the other isn’t. This staggering of the two positions is essential for generating smooth, continuous rotational torque and self-starting without any need to rotate the shaft manually.

The diagram above shows a piece from both sides of the rotor disc, to explain the operation of the coils. On the left, magnet 56 overlaps coil 32 and coil 34. Coil 32 is powered up and this breaks the magnetic link on the left hand side of magnet 56. But, coil 34 is not powered up, so the attraction between magnet 56 and the disc magnet under the coils remains. Even though this attraction is at a downward angle, it creates a push on the rotor, driving it towards the right as shown by the red arrow.

While this is happening, the situation around the other side of the rotor disc, is shown on the right. Here, magnet 54 is above coil 36 and that coil is not powered up, so there is no resulting drive in either direction - just a downward pull on the rotor magnet, towards the stator magnet below it. The adjacent coil 38 is also not powered up and so has no effect on the rotation. This method of operation is very close to that of the motor design of Robert Adams described in the next chapter. It is important to understand that this method of operation is nothing like that of the John Bedini pulsed motor where the rotation of a disc is caused by the electrical pulse applied to a coil creating a repulsion thrust to a rotor magnet. Instead, here, the coil acts as a magnetic shield, being provided with the minimum possible power to do its job. The coil is, in effect, a shield which has no moving parts, and so is a very clever mechanism for overcoming the tendency for the rotor magnets to lock on to the stator magnets and preventing rotation.

At any moment, six of the seven coils in this design are inactive, so in effect, just one coil is powered. This is not a major current drain. It is important to understand that the power of this motor is provided by the permanent magnets pulling towards each other. Each of the two magnets applies a horizontal pull on the rotor every seventh of a turn, that is, every 51.1 degrees in the rotation. As the coils are an uneven number, the rotor gets a magnetic pull every 25.5 degrees in the rotation, first from one rotor magnet and then from the other rotor magnet.

It follows then, that the power of the motor can be increased by adding more magnets. The first step in this search for additional power is to add a second disc magnet and coils on the other side of the rotor, so that there is a second pull on the magnet. This has the added advantage that it balances the downwards pull of the first disc magnet with an upward pull, giving an enhanced and balanced horizontal thrust as shown here:
The coil switching with the additional layer of coils is shown here:

This produces a larger horizontal thrust. While this design goes for optimum performance, I suggest that a much more simple form of construction with a ring of standard circular neodymium magnets could be used instead of one large disc magnet, and ordinary circular coils placed on top of the circular magnets, and this allows large diameter rotors to be constructed, the larger diameter giving greater output shaft power:

To increase the power of the output shaft further again, additional sets of magnets and coils can be added as shown here:
It should be remembered that the timing section shown above could be replaced by a NE555 timer circuit which generates a steady stream of On / Off pulses. When those pulses are fed to the coils, the motor rotates, slaving itself to the pulse rate. This gives an immediate speed control for the motor as well as avoiding the need for the precise positioning of the slotted disc which allows the LEDs to shine directly on to the phototransistors at the appropriate instant. If that approach is taken, then the timing section shown above would be omitted.

The circuitry that Charles specifies for powering the coils to block the magnetic fields of the permanent magnets uses N-channel MOSFETs and is very simple. Here is his circuit for driving one of the coils:
Just five components are used. The current through the coil is controlled by a transistor. In this case it is a Field-Effect Transistor usually called a "FET". The most common type of FET is used, namely an "N-channel" FET which is the rough equivalent to an NPN transistor as described in Chapter 12. A FET of this type is switched off when the voltage on it's "gate" (marked "g" in the diagram) is 2.5 volts or lower. It is switched on when the voltage on it's gate is 4.5 volts or more.

In this circuit we want the FET to switch on when the motor's timing disc is in the right position and be off at all other times. This is arranged by shining the light from a Light-Emitting Diode or "LED" through a hole in the timing disc which rotates with the shaft of the motor. When the hole is opposite the LED for the coil which is to be powered up, light shines through the hole and on to a light-sensitive device, Charles has opted to use a Light-Sensitive transistor, but a light-dependent resistor such as an ORP12 could be used instead. When the light shines on the "Opto1" device in the circuit diagram, it's resistance falls dramatically, raising the voltage on the gate of the FET and switching it on. When the timing disc hole moves past the LED, the light is cut off and the FET gate voltage drops down, switching the FET off. This arrangement causes the coil of the motor to be switched on and off at just the right time to give a powerful rotation of the motor shaft. In the circuit, the resistor "R1" is there to make sure that the current flowing through the LED is not excessive. The resistor "R2" has a low value compared to the resistance of "Opto1" when no light falls on it, and this holds the gate voltage of the FET down to a low value, making sure that the FET is completely off.

As you can see, this is basically a very simple circuit. However, as one of these circuits is used for each coil (or each pair of coils if there is an even number of coils in this slice of the motor), the circuit in the patent looks quite complicated. It is actually very simple. The resistor "R1" is used to limit the current flow through all of the LEDs used and not just one LED. You could, of course, use one resistor for each LED if you wanted to. The circuit for powering two coils (and not showing the timing disc) looks like this:

![Circuit Diagram](image.png)

The section inside the green dashed line being the identical circuit for the second coil. This addition to the circuit is made for each coil, at which point, the motor is ready to run. If, as would be normal, several layers of magnets are being used, then the coils positioned above each other can be connected in a chain like this:
Connecting several coils "in series" (in a chain) like this, reduces the number of electronic components needed and it makes sure that the pulses to each of these coils is at exactly the same instant. Alternatively, it is possible to wire these coils across each other "in parallel", the choice is generally dictated by the resistance of the coils. The patent drawing shown above seems to indicate that there is a big gap between the LEDs and the optical devices. This is probably not the case as most people would choose to keep the gap between the LED and the light-dependent device as small as possible, mounting them so that they are just clear of the timing disc on each side of it.

In this patent, Charles Flynn remarks that this magnet motor can be used for almost any purpose where a motor or engine drive is required and where the amount of energy available or required to produce the driving force may vary little to nil. Charles has produced motors of this type which are capable of rotating at very high speed - 20,000 rpm and with substantial torque. Lesser speeds can also be produced, and the motor can be made to be self-starting. Because of the low power required to operate the device, Charles has been able to operate the motor using just a nine volt, off-the-shelf dry battery.

One application which seems most appropriate for this motor design is the Frenette heater shown in Chapter 14. Using this motor to drive the discs inside the heater drum would produce a heater which appears to be driven by just a nine-volt battery. However, while that is the appearance, the reality is that the power of this motor comes from the permanent magnets and not from the battery. The battery current is only used to prevent the backward pull of the magnets and it is not used to drive the motor.

While the use of a timing disc is a very satisfactory arrangement, it is also possible to use electronic circuitry instead of the mechanical timing disc, the opto devices and the LEDs. What is needed here is a device which produces a series of voltage pulses which can be used to drive the gate voltage of each FET from below 2.5 volts to over 4.5 volts. It looks as if the well-known 555 timer chip would be suited to this task and it would certainly run off the nine-volt battery. However, we have more than one set of coils which need to be run. For example, if we have say, four sets of coils to drive by powering up four different FET transistors one after the other, then we could use a "Divide-by-Eight" chip, like the 4022 chip. This chip can be set to divide by any number from two to eight. All that is needed to select the number to divide by, is one connection between two of the pins on the chip.
The output voltage on the pins marked "1", "2", "3" and "4" goes high one after the other as shown in the diagram above. So, each of these output pins would be connected to the FET gates in that order and the FETs would get switched on in that same order.

With the 4022 chip, the connections for the rate of division are as follows:

- For 'Divide by 7' operation, connect pin 10 to pin 15
- For 'Divide by 6' operation, connect pin 5 to pin 15
- For 'Divide by 5' operation, connect pin 4 to pin 15
- For 'Divide by 4' operation, connect pin 11 to pin 15
- For 'Divide by 3' operation, connect pin 7 to pin 15
- For 'Divide by 2' operation, connect pin 3 to pin 15

When using a circuit like this, the pulse rate from the 555 chip is set to a very low value like half a second, so that the motor shaft can get started. Once it gets moving, the pulse rate is gradually increased to speed the motor up. One advantage of this method is that it allows speed control, and if the motor was being used to power a Frenette heater, then the speed control would also act as a temperature control for the heater.

A possible 555 chip circuit might be:
As this allows the speed to be controlled and when the required speed is reached, the pulse width can then be adjusted to give the minimum current draw to maintain that speed. There are, of course, many other suitable circuits which could be used instead of this one and Chapter 12 will fill you in on some of them as well as explaining how circuits work and how to build them.

If it so happens that it is difficult to find suitable circular magnets with the poles on opposing faces, then I suggest that it should be possible to use standard rectangular magnets throughout and rectangular coils as shown here:

And while this arrangement is not as magnetically efficient as a circular magnet, it does have the convenience of allowing the construction of a rotor of any chosen size. Ideally, unlike the stator shown above, there should be an odd number of magnets, or failing that, an odd number of coils. Alternatively, the rotor could have an odd number of magnets so as to allow self-starting. But, it should be noted that if the motor is to be driven by an electronic pulsing system, then it is very much more simple to have an even number of magnets on the stator and start the motor moving by hand. This is because with an odd number of stator magnets, the opto sensors are not exactly opposite each other and so do not fire together. With an even number of stator magnets, the coils which are 180 degrees apart can be wired together as they fire at exactly the same time. With the slotted optical timing disc, the slots are exactly opposite each other and match the width of the rotor magnets, but the coils (nearly) opposite each other are not powered on and off at exactly the same time, although their powered arcs are likely to overlap for part of their operation. This could be catered for electronically by using a monostable delay for the coil on the opposite side of the disc.

The objective of each coil is to just, and only just, cancel out the magnetic field of the permanent magnet underneath it. The magnetic field produced by the coil depends on the current flowing in the coil, the number of turns in the coil and the area of the coil. The current flowing depends on the diameter of the wire and the voltage applied to it. It is probably necessary to mount just one magnet on the stator and experiment with the coil until
your current drive and coil allow the rotor to spin freely. Whatever the coil result is, should be ok for all of the magnets even though they are likely to vary in strength a bit.

Steorn's Magnetic Devices.
The Irish company Steorn have produced a system which is almost identical to the Charles Flynn magnet motor just described. They call their device "Orbo" and its operation is pretty much the same. The advance made by Steorn is that they have devised a very clever magnetic masking system using ferrite toroids wound with a copper wire coil. This is a slick method of switching magnetic attraction on and off. When the coil carries a sufficient current it generates a circular magnetic field spiralling around the toroid and not going outside the toroid. This field does not have an attraction for outside magnets. It makes no difference if the direction of the current flow through the coil is reversed as the resulting magnetic field just spins around the toroid in the opposite direction and performs exactly the same magnetic blocking of the ferrite ring which forms the toroid. If no current flows, then the copper wire does not block off the influence of the ferrite ring and the permanent magnets on the rotor are strongly attracted to it, causing the rotor to spin.

On their web site [www.steorn.com](http://www.steorn.com), Steorn illustrate their design like this:

![Steorn's Magnetic Devices Diagram](image)

In this implementation, eight ferrite rings are mounted on the stator in four locations ninety degrees apart. These are wound with copper wire coils which can be powered by a battery, via a timing mechanism. The rotor has embedded in it, eight pairs of small permanent magnets, also spaced ninety degrees apart.

In exactly the same way as the Adams motor described in chapter 2, the current through the coils is set to the minimum level which allows the rotor to spin freely. The timing mechanism is then switched in and the motor and the rotor given a spin. The rotor magnets are strongly attracted to their corresponding ferrite rings mounted on the stator posts and this accelerates the rotor.

If no current is passed through the coils, then the rotor will oscillate backwards and forwards for a short time before coming to rest with the magnets as close to the ferrite rings as possible. To prevent this happening, the timing circuit senses when the magnets reach the ferrite rings, and passes that minimum current through the coils, trapping the rings inside a magnetic field which has no effect on the rotor magnets. The momentum of the rotor causes it to spin on past the stator rings to a position where the magnets are closer to the next rings than they are to the ones which they have just passed, at which point, the current is cut off and the magnetic attraction to the ferrite rings returns. This is identical to one mode of operation of the Adams motor.

The next step is also identical to that of the Adams motor, namely, to add on some pick-up coils to convert some of the rotating magnetic energy into electrical energy, either to recharge the driving battery or to power other equipment, or both.

Steorn's arrangement for doing this is to add an additional disc, containing permanent magnets, to the rotor and positioning wire coils opposite those magnets as is normal for a generator. Steorn choose to show the resulting energy charging up the battery again:
Video presentations on this style of motor/generator are at:
http://www.youtube.com/watch?v=AXamGLyRkt8&NR=1
http://www.youtube.com/watch?v=rg3rLqYMzN4&feature=related and
http://jnaudin.free.fr/steorn/indexen.htm

On 28th October 2015, Steorn announced their latest product called the Power Cube which looks like this:

This box contains a Lithium-Ion battery, a recharging circuit and one USB-C output port. This is the latest version of the USB family of ports and is capable of supplying 2.1 amps at 5 volts, which is capable of recharging a computer tablet or a mobile phone. If the battery is drained, then the internal recharging circuit can recharge the internal battery twice per day. The sale price is staggeringly high at €1,200 and that is likely to encourage people to offer the equivalent performance at a much lower price, which I suppose has to be seen as a good thing.

We tend to think of this style of magnet-powered motor as being low-power. This is probably because it is often the case that the demonstration proof-of-principle implementations shown are minor devices. These motors can be very powerful and the one shown here, designed and built by Mr Sung of China has an output power of 20 kilowatts or twenty-seven horsepower:
And another design which has a larger diameter and about 144 magnets has a reported output of 225 horsepower:

You will notice that each ring of magnets is positioned further around the rim of the cylinder providing powerful pulses from 64 magnets every 22.5 degrees of rotation, so it is little wonder that the motor has considerable shaft power. Some of the coils can be switched to collect power if the working conditions do not need the full shaft output power, charging the drive battery. The rotating inner cylinder has permanent magnets mounted on it.

**George Soukup’s Permanent Magnet Motor.**

There used to be a video on the web, showing a magnet motor built on the “V” style of magnet placement which has two sets of permanent magnets spaced like this:
This style of magnet arrangement (North magnets shown in blue and South in red) has a locking point where the switch from wide spacing to narrow spacing occurs and this causes the rotation to stop there.

The implementation shown in this video has the V magnets spaced rather more widely apart as shown here:

The taper is much less pronounced with an inner gap some four times greater than the gap to the outer ring. It also appears that the last inner magnet has a greater gap around the drum than the remaining ring of magnets.

The housing is very simple looking, with an evenly spaced ring of twelve holes to take long magnets with alternating North and South magnetised areas along their length. You will notice from the photographs, that George has cavities to take up to twelve stacks of stator magnets, although he only uses any five of them for his demonstrations.
The housing has considerable clearance for the drum and magnets. The rear shaft bearing is just set into the back of the housing:

The front has two sheets of acrylic, one to hold the insert magnets in place and one to provide the shaft's front bearing support:
As there is no commentary with the video it is a little difficult to pick up all of the details, but it seems that positioning stator magnets allows the motor to overcome the normal sticking point of the typical V-motor arrangement. The video shows various arrangements including the non-symmetrical grouping shown here where four or five consecutive magnets are used and the remaining slots left empty:

Dietmar Hohl’s Permanent Magnet Motor

If you would like to make a simple motor of this type, then the information provided by Dietmar Hohl, passed to me by Jes Ascanius of Denmark, shows you how. He uses 20 mm diameter round neodymium magnets 10 mm thick, stacked in pairs in the stator of this layout:

This shows a magnetic gate arrangement built on a flat piece of Medium-Density Fibreboard 30 mm thick. The holes drilled in it are 20.1 mm in diameter and positioned so as to take two of the 10 mm thick magnets stacked together. The holes are drilled at an angle of 63 degrees to the horizontal or 27 degrees to the vertical, whichever way you prefer to think of it. On one side of the board, the inserted magnets have their North poles facing upwards, while on the other side of the board, the magnets are inserted with their South poles facing upwards. Dietmar shows six holes to take bolts or screws to fasten the piece of MDF to a larger board or table. Those do not form any part of the magnetic system and can be omitted. A video of one version of it in action can be found at [http://www.free-energy-info.tuks.nl//Vtrack.mpg](http://www.free-energy-info.tuks.nl//Vtrack.mpg).

The gate operates by causing a stack of ten of the magnets to roll along the V-shaped track and pass smoothly across the junction with the next set of V-positioned magnets. There can be as many of these V-sets as you want and the magnet stack will still keep rolling. This is one of the few magnetic gate designs which adapts to drum operation as a motor rotor.
The magnets are positioned at an angle in order to use the magnetic fields at the edge of the magnets. They are stacked in pairs in order to increase their power. The power of the motor depends on the strength of the magnets, how close the stator magnet stacks are to the VF-track magnets and the number of stacks of stator magnets. If you decide to construct one of these motors, then it is suggested that you make things easier for yourself by keeping the curvature low, using three or four of the Vs. With Dietmar’s dimensions, a 2-V drum would be 216.5 mm (8.5”) in diameter, a 3-V drum would have a 325 mm (12.8”) diameter and a 4-V drum a diameter of 433 mm (17”) and those dimensions include the 30 mm (1 3/16”) strip which holds the magnets, so the inner drum diameters are 30 mm less in each case.

When making the motor drum, it is possible to use a flexible material to hold the magnets. This allows the strip to be laid out flat while the holes are drilled, and then attached to the outside of a rigid drum with a 60 mm lesser diameter than the ones mentioned above. Jes Ascanius of Denmark shows how a jig can be made to make drilling the holes easier:

This one has had a length of copper pipe inserted at the correct angle, in order to direct the drill bit at the exact angle required. This motor has been successfully replicated by Jes Ascanius of Denmark who used 10 mm magnets which were to hand, and again with square magnets which were pushed into round holes and not even angled in this proof-of-concept implementation which only took one hour to build using scrap material to hand, and which did work:
With Dietmar’s design using angles magnet pairs, the number of magnets needed is quite high. For a single V, there are 58 magnets. For a 2-V version, 106 magnets. For a 3-V version, 154 magnets and for a 4-V version, 202 magnets if there is only one stack of stator magnets, so ten extra magnets need to be added to the count for each additional ten-magnet stack of stator magnets. The motor power is likely to increase as the diameter increases as the lever arm that the magnet has to turn the drum, increases – double the diameter to (almost) double the power.

Simple Permanent Magnet Motors

It is very difficult to use the power of permanent magnets to make a motor powered by them alone. The Dietmar Hohl design shown above is one of the very few which can readily be made and tested at home. The problem is that almost all magnets have a symmetrical magnetic field, while what is needed for a magnet-powered motor is an asymmetrical magnetic field. Consequently, magnets have to be combined in ways which distort their normal field shape. You will notice that in the Hohl motor, the drive magnets are angled and that is an important feature of using magnets in motors.

Schools currently teach that the magnetic field surrounding a bar magnet is like this:

![Magnetic Field Diagram](image)

This is deduced by scattering iron filings on a sheet of paper held near the magnet. Unfortunately, that is not a correct deduction as the iron filings distort the magnetic field by their presence, each becoming a miniature magnet in its own right and alters the magnetic properties of the space around the magnet in the plane of the iron filings. More careful measurement shows that the field actually produced by a bar magnet is like this:

![Actual Magnetic Field Diagram](image)

There are many lines of force, although these diagrams show only two of them. In reality, the lines of force at the corners fan out in three dimensions, with curved, circular-flowing lines above the the top of the magnet, circular lines below the lower face of the magnet. These lines of force are roughly in the shape of a football with the corner of the magnet in the centre of the football. Actually, there are many layers of these lines of magnetic force, so it is like having a whole series of gradually bigger and bigger footballs all centred on the corner of the magnet. It is extremely difficult to draw those lines and show them clearly. Howerd Johnston’s book “The Secret World of Magnets” will give you a good idea of the actual lines of force around a bar magnet. The arrangement of these lines of magnetic force is not generally known and if you Google ‘magnetic lines of force images’ you will only find the fiction taught in schools. However, the important fact is that there is a rotating magnetic field at each corner of a typical bar magnet. It follows then that if a row of magnets is placed at a an angle, then there will be a resulting net field in a single direction.
For example, if the magnets are rotated forty five degrees clockwise, then the result would be like this:

With this arrangement, the opposing corners of the magnets as shown here, are lower down and so there should be a net magnetic force pushing to the right just above the set of magnets. However, the situation is not as simple and straightforward as you might imagine. The additional lines of magnetic force which have not been shown in the diagram above, act further out from the magnets and they interact, creating a complex composite magnetic field. It is frequently found that after four or five magnets that a short gap needs to be left before the line of magnets is continued on.

Two boys; Anthony and Andreas, have used this magnet arrangement to create a magnetic track and they have a lot of fun, sending a magnet sliding between two of these rows of angled magnets. Initially, they used the cheaper ceramic magnets and got a very satisfactory movement when using a neodymium magnet as the moving component:

You will notice that they have managed a row of 18 ceramic magnets on each side of their track and the results which they are getting are very good. They have three videos on the web at the present time:

https://www.youtube.com/watch?v=Vo2-Qb3fUYs
https://www.youtube.com/watch?v=VeXrFfw4RSU
https://www.youtube.com/watch?v=VTbFfEEE_qU

The moving magnet is made up of four 12 mm x 12 mm x 12 mm (or half-inch by half inch by half inch) neodymium magnets attached North - South - North - South - North - South - North - South.
They have not disclosed all of the details of what they are using (accidentally rather than by intention). The ceramic stator magnets are 48 mm x 20 mm x 10 mm with the poles on each of the main faces. They position each magnet with it's North pole facing towards the track and they angle the magnets at 45 degrees. There is a 15 mm gap between the stator magnets and the moving magnets on both sides of the track. Wooden strips direct the moving magnets.

Neodymium magnets have very different characteristics to those of ceramic magnets (and that is not just strength of the magnetic field). It is not unusual for experimenters to find that devices will work well with one type of magnet but not with the other type. Here the developers have also tried using two sets of five angled neodymium magnets on each side of their track and the result was a more powerful thrust on their moving magnets.

The magnets are held in place in this picture, by wooden dowels driven into the base plank. They used these in order to avoid any magnet-fastening material which could alter the magnetic field.

The next step would be for them to power a motor using their magnetic track technique. However, this has been tried many times and the conclusion is that it is VERY hard to change a straight magnetic track into one which forms a complete circle. Therefore, I would suggest the following arrangement:
Here, a simple disc rotor has four magnets (of the type used to move down the magnetic track) attached to the underside of the disc and positioned so that they move through four short sets of four, or at the outside, five angled stator magnets as the disc spins. It does not matter if the rotor shaft is horizontal or vertical. If the disc spins well, then sets of two air-core pick-up coils can be positioned between each of the stator magnet arrays so that electricity is generated as the rotor magnets pass by overhead. If a constructor decides to attach two rotor discs to the one rotor shaft, then the two rotors should be positioned so that the rotor shaft gets pushed every 45 degrees of rotation rather than every 90 degrees as shown here. This style of motor is definitely within the scope of the average person to build should they be inclined to do so.

I have been asked to say how I personally would go about constructing a prototype of this nature. As I have very limited constructional skills, I would do it like this:

For the bearing, I would pick a computer cooling fan, as these have very good bearings and if one is not to hand inside an old, obsolete computer, then they can be bought very, very cheaply. The diameter of the fan is not important. These fans generally look something like this:

As the part of the fan which spins round does not normally project above the stationary frame, a spacing disc of wood or plastic is needed to provide the clearance. The disc is glued to the centre of the fan using perhaps, Impact Evostick, epoxy resin or super glue. It would then look like this:
A square of wood can then be screwed to the spacer, like this:

And as I am hopeless at creating good-quality mechanical devices, I would then hold a pencil very steadily against a support and give the wood a spin, so that the pencil draws a perfect circle exactly centred on the bearing of the fan. Then, marking the wood and the spacer so that there is no doubt as to which way round the wood is attached to the spacer, I would unscrew the wood and cut around the pencil line very carefully, smoothing the edges of the disc gently with fine sandpaper. Screwing the disc back in place, a spin should confirm that the edge of the disc stays steadily in place with no wavering of the edge. Actually, if the disc is not perfect, that is not a major problem as it is the rotor magnets which need to be positioned accurately, and for that, another pencil line can be produced by spinning the disc when the desired position has been determined.

Permanent magnets vary enormously in size and strength, so when magnets are purchased, it is a matter of testing them using a track of the type used by Anthony and Andreas. The stator magnets are angled at about 45 degrees to the track and with just four on each side, it is a case of finding the spacing between the two sets of angled magnets which pushes the stator magnets furthest along the track.

**Muammer Yildiz’s Permanent Magnet Motor.**
Muammer Yildiz has developed a powerful permanent magnet motor, patented it, and demonstrated it to the staff and students of a Dutch university. During the demonstration, the mechanical power output was estimated at 250 watts and immediately after the demonstration, the motor was completely taken apart to show that there were no hidden power sources. There is a video showing this demonstration, located at: [http://pesn.com/2010/04/22/9501639_Yildiz_demonstrates_magnet_motor_at_Delft_University/](http://pesn.com/2010/04/22/9501639_Yildiz_demonstrates_magnet_motor_at_Delft_University/)
DEVICE HAVING AN ARRANGEMENT OF MAGNETS

ABSTRACT
The device has a rotating axial drive shaft 5 supported so that it rotates inside a stator 2, which is surrounded by an outer stator 3. The rotor is firmly connected to the drive shaft. The outer stator has dipole magnets 6 which are positioned on the inner surface of a circular cylinder 9. These outer magnets are evenly spaced around the surface of the surrounding cylinder.

DESCRIPTION
This invention is a device for generating an alternating magnetic field that interacts with a stationary magnetic field. The interaction of a stationary magnetic field with an alternating magnetic field has been used for some time, for example in brushless DC motors and in magnetic levitation.

One object of this invention is to provide an improved device for generating an alternating magnetic field that interacts with a stationary magnetic field. This is achieved as described in Claim 1, by the special arrangement of the dipole magnets of the inner stator, the rotor and the outer stator which creates a magnetic effect which keeps the rotor floating freely between the inner stator and the outer stator, and this acts as a magnetic bearing.

Surprisingly, it has been shown that the special layout of the dipole magnets of the inner stator, the rotor and the outer stator during rotation of the rotor, generates an alternating magnetic field which allows a largely loss-free movement of the rotor as it spins between the inner stator and the outer stator. This very useful effect can be used for a variety of technical applications, for example, a particularly low-friction bearing is preferred for supporting a shaft which has to rotate at high speed.

In the following description, when mathematical terms, especially geometric terms, are used - terms such as “parallel”, “perpendicular”, “plane”, “cylinder”, “angle”, etc. as is typical when producing technical drawings, but it must be understood that these things are never achieved in practice, due to the manufacturing tolerances of the components. It is therefore important to realise that this description refers to the ideal situation, which will never be achieved. Therefore, the reader needs to understand that generally accepted tolerances will be involved in practice.
The output shaft spins around one axis, called the “shaft axis”. The shaft itself is preferably constructed as a straight cylinder of circular cross-section.

In a preferred embodiment of this invention, the magnets project slightly out of the inner stator. This is also the case for both the rotor and the outer stator. A partial overlap of two magnets is achieved when a plane perpendicular to the shaft axis, passes through both of the two magnets and the two magnets are considered to overlap if this situation occurs.

A partial overlap of three magnets occurs when a plane perpendicular to the shaft axis runs through each of the three magnets. The degree of overlapping does not affect the description and the amount of overlap of any two of the three magnets can be anything from 1% to 100%, where the magnets overlap completely.

In a particularly preferred embodiment of the invention, the magnets of the inner stator and the rotor are able to align completely. In addition to this, the outer stator is constructed so that it can be rotated around the shaft axis so that the contact ratio between the magnets of the rotor and the magnets of the outer stator can be adjusted to give any degree of overlap from 0% to 100%.

Three imaginary cylinders are produced. One by the magnets of the inner stator, a second by the rotor magnets as they spin around the shaft axis and the third is created by the magnets of the outer stator. The axes of these three cylinders is the same as the shaft axis.

Ideally, the rotor will have the shape of a drum or a cup, that is, a hollow cylinder with a circular cross-section or a piece of pipe whose one end face is covered by circular disk. In the centre of the disc, the rotor has a hole through which the shaft passes. The disc can also have a collar which is used to clamp the rotor to the shaft by means of a bolt passing through the drive shaft or by grub screws tapped into the collar. Whichever method is used, the rotor magnet assembly is connected securely to the drive shaft. The use of a clamping screw has the advantage of allowing the rotor to be taken apart for maintenance or repair. The hollow cylinder section of the rotor, is arranged so that there is a small air gap between it and both the inner and outer stators.

The hollow rotor cylinder has two, or more, permanent magnets mounted on it. These are equally spaced around the circumference of the rotor cylinder and positioned so as to be parallel to the drive shaft axis. The outer stator is cylindrical in shape and surrounds the rotor, leaving a small air gap between them and its axis is aligned with the drive shaft axis. Ideally, the magnets mounted on the inside of the outer stator cylinder, are aligned with the drive shaft axis and their pole faces are at right angles to the shaft axis. That is, a line drawn through the North and South pole faces of these magnets will point at the drive shaft, and so one pole face will face the rotor.

It is also possible for the magnets of the outer stator to be rod-shaped and to form a complete ring around the inner face of the outer stator cylinder. If this is done, then the magnetic rings need to be separated from each other by non-magnetic spacers and the whole length of the outer stator will be covered with these magnetic rings and spacers. In this case, the inner and outer stators are mounted in a fixed relationship to each other by means of brackets or other mounting methods.

Ideally, the rotor is held in position by the magnetic fields of the two stators and “floats free” between them. This is the preferred method. However, it is possible for the drive shaft to run the entire length of the device and to be supported in roller bearings.

One possible construction is to have both of the stators made in two separate parts. These need to be exactly symmetrical relative to the drive shaft axis. The outer stator pieces can also be arranged to be capable of rotational adjustment relative to the inner stator which always has a fixed position. Another option with this particular arrangement is to have the distance of the outer stator components adjustable, so that the air gap between the rotor and the outer stator magnets can be manually adjusted.

An angle “alpha” is defined as the angle between the magnetic axis of a magnet of the inner stator and a tangent to the circumference of the inner stator at that point. An angle “beta” is defined as the angle between the magnetic axis of a rotor magnet and a tangent to the rotor circumference at that point. An angle “gamma” is defined as the angle between the magnetic axis of a magnet of the outer stator and a tangent to the circumference of the outer stator at that point. In a preferred embodiment of this invention, each of these angles is between 14 degrees and 90 degrees.

It is a particular advantage if the permanent magnets of both the inner and outer stator have a either a rectangular or trapezoidal cross-section when seen as being cut by a plane perpendicular to the shaft axis. It is also particularly advantageous if the rotor magnets have a circular cross-section when viewed as being cut by that plane perpendicular to the shaft axis. Other, non-symmetrical magnet cross-sections are possible, such as trapezoidal, triangular, or irregularly shaped cross sections.
It is possible for all of the magnets of the inner stator to have identical shapes. Similarly, it is possible for all of the magnets of the outer stator to have identical shapes. It is also possible for all of the rotor magnets to have the same shape. However, the positioning of the magnetic North and South poles of the various magnets will not be identically positioned as will be seen from the following detailed description.

The magnets of the inner stator, the rotor and the outer stator have a magnetic orientation which causes them to repel each other at every angular position of the rotor. For example, the magnets of the inner stator can have their North poles facing outwards and in that case, the magnets on the rotor will have their North poles facing inwards towards the inner stator. Similarly, the magnets of the outer stator would then have their South poles facing inwards in order to repel the (outer) South poles of the rotor magnets.

Further features, details and advantages of the invention will be apparent from the following description of an embodiment of the invention and the associated drawings as shown here:

DETAILED DESCRIPTION

Fig.1 shows a schematic representation of the device having an inner stator 2, a rotor 1 and an outer stator 3, which are arranged coaxially around the shaft axis 50 of a pivoting rod-shaped shaft 5. The cylindrical inner stator 2 has at each end, an end cap 13 which is in the form of a circular disc with a ball-race bearing 11 mounted on it. The bearing 11, maintains the position of the inner stator 2 relative to shaft 5. The drive shaft 5 is normally made from a non-magnetic material such as plastic, (not steel) and typically, has a diameter of 10 mm to 40 mm and a length of 100 mm to 400 mm.

The inner stator 2 has a core 12 with magnets 8 mounted on it’s outer surface. The inner stator 2 is held stationary by a mounting device 4, which is secured in position in a mechanical housing (not shown), and is held firmly fixed in this way.

The rotor 1 consists of two mirror-image rotor drums, each with a pipe section and a circular disc section which is clamped rigidly to drive shaft 5 by means of grub screws 10. Each of the rotor drums has magnets 7 mounted on it. These magnets 7, are positioned in five distinct places and they have one magnetic pole facing towards the shaft and the other pole facing radially outwards.

The rotor drums are positioned so that there is a cylindrical air gap between them and the inner stator 2. This air gap is usually of the order of 3mm to 50 mm. Although the two halves of the rotor are separated by the clamping mechanism 4 which prevents the inner stator from rotating, the rotor halves are positioned so that the magnets within them are balanced and so there is no irregular force generated when shaft 5 is spun at high speed. At the ends of the rotor drums there are magnets 700 as the objective of this design is to have the rotor suspended magnetically.
The outer stator 3 is composed of two separate half cylinders 9. Each of these cylinders 9, contains magnets 6 mounted on it’s inner face. Although each section of the outer stator consists of a hollow cylinder, the outer ends of the stator housing form a complete disc which surrounds the drive shaft 5 and forming a complete enclosure rather than leaving the device open at the ends. There is an air gap between the faces of the magnets mounted on the inner surface of the cylindrical frame 9 and the faces of the magnets mounted on the rotor. These sets of magnets face each other and the air gap between them is also typically 3 mm to 50 mm. The magnets on each of the stators are parallel to the shaft axis 50. The outer stators is constructed so that it can be moved relative to the inner stator, thus altering their magnetic overlap. This alteration can be made by moving the outer stator when the motor is actually running.

The magnets designated 6, 7, and 8, are dipole magnets and in a preferred embodiment, these are permanent magnets, for example, consisting of SmCo (samarian cobalt) and/or NdFeB (neodymium/iron/boron). It is also possible for one or more of these magnets to be an electromagnet. The magnetic flux density of the magnets 6, 7, and 8 is preferably in a range from 0.4 to 1.4 Tesla.

The frame is preferably made from a non-magnetic material such as aluminium with a wall thickness from 2 mm to 10 mm.

**Fig. 12a** shows an inner stator frame made from a non-magnetic material (such as aluminium or copper). The frame 12 has a circular cylinder 120 which has attached to it’s outer surface, radial ribs 121. Each of these ribs extends along the central axis of the cylinder 120 along the full length of the cylinder, that is, from its’ base to the top surface. The ribs are distributed uniformly over the cylinder circumference, forming grooves 122. Cylinder 120 has a central hole along it’s axis for shaft 5 to run through. Both of the end surfaces of cylinder 120 are recessed to accommodate one of the ball bearings 11. The diameter of the stator core 12 is typically 50 mm to 500 mm with a length of 100 mm to 300 mm. The width of the ribs 121 is generally not more than 100 mm and is usually about 20% of the length of the ribs 121.
Fig. 12b shows a schematic representation of the inner stator 2. The inner stator 2 is composed of the inner stator frame 12, the magnets 8 and the end caps 13. The magnets 8 are of equal length but their length is less than the length of the stator core 12. These magnets form the outer surface of the stator. They are seated in the grooves 122 and held in position by the ribs 121. The first magnet 8-1 is inserted flush with the end cap 13. The other magnets 8 each have an axial offset V along the shaft axis 50 arranged so that there is an even stepping of the magnets with the final magnet 8-10 butting up against the second end plate 13. The axial offset V is the total overall gap W divided by (n - 1), where n is the number of magnets and so, V varies with the number of magnets used. In a typical arrangement, V is 5% of the length of the magnets 8.

The end caps 13 have a diameter of 50 mm to 500 mm and a thickness of 5 mm to 20 mm. A typical length for the magnets 8 is 100 mm. The magnet dimensions are arranged so that when they are positioned in the grooves 122, the inner stator 2 has a substantially uniform outer surface.

Fig. 13 shows an opened-out view of the outer surface of the inner stator 2. Here, ten magnets 8 are arranged with even spacing. The under side of the magnets taper in the direction of the shaft axis 50 and so they have a lesser width near the centre of the stator than they do at the outside surface. The first magnet 8-1 is positioned
with its end face aligned with the base 125 of the inner stator core 12. The remaining nine magnets (8-2 to 8-10) are each offset by the amount V with the last magnet 8-10 reaching the top surface of the inner stator core 126.

Fig.14 shows a cross-section through the inner stator 2 along the plane A--A of Fig.12b. The inner stator 2 has a hollow cylinder 120, through which the central axis of the shaft 5 passes. Running along the outer surface of the cylinder are the ribs 121. The hollow cylinder 120 typically has a diameter of 100 mm and a length of 170 mm. In the gaps formed between the ribs 121 the magnets 8 are placed. When seen in the plane A--A these magnets have a trapezoidal cross-section. These magnets have two magnetic poles and the magnets are positioned so that the magnetic axis 80 which runs through the two poles is radial within the section plane A--A. An angle \( \alpha \) formed at the intersection of the magnetic dipole axis 80 of a magnet 8 and the tangent 81 to the ribs 121 can have a value between 14 degrees and 90 degrees. In the case shown in Fig.14 the angle alpha is 90 degrees.
**Fig. 15a** shows the fastening device 4 in a view perpendicular to the shaft axis 50. The fastening device 4 has an inner hollow cylinder 40 with a smaller radius and an outer fixing ring plate 41 with larger radius. The inner hollow cylinder 40 and the outer ring fastening plate 41 are connected together. The hollow cylinder 40 is used for receiving and fixing the inner stator 2 by means of screws 10. The fastening ring 41 is part of a mechanical housing (not shown) for holding the device firmly positioned.

![Fig. 15b](image)

**Fig. 15b** shows the fastening device 4 in a view in the direction of the shaft axis 50. The mounting ring plate 41 has at its periphery, four screws 10 for attachment to the mechanical housing of the hollow cylinder 40 which has on its circumference, a number of screws 10 for fixing the inner stator in place.

![Fig. 16](image)

**Fig. 16** is a view of the rotor 1, which is clamped to shaft 5 by means of the screws 10. The rotor 1 consists of two separate drums attached to a central hollow shaft. Mounted in its outer surface are a series of magnets 7 sunk into circular holes. The rotor itself is constructed using a non-magnetic material such as aluminum or copper. The distance between the two rotor drums is 15 mm and they have an outer diameter of 165 mm, a height of 70 mm and a wall thickness of 26 mm. Each rotor drum has a top surface annular disk 102, into which two or more magnets 700 are sunk. These are positioned uniformly around the circumference of the disc as shown in the diagram. The magnetic dipole axis of magnets 700 is parallel to the shaft axis 50.
**Fig. 17a** is a schematic representation of the possible orientations of the rotor magnets 7 when seen as viewed looking parallel to the shaft axis 50. The magnetic dipole axis 70 of rotor magnets seven is in a plane which is radial to the shaft axis 50. The angle $\beta$ [beta] between the magnetic dipole axis 70 and the tangent 71 breaks through the outer periphery of the hollow cylinder 101 of the rotor 1 and this angle can have values between 14 degrees and 90 degrees.

**Fig. 17b** is a schematic view of one rotor drum and part of the inner stator 2, where the view is perpendicular to the shaft axis 50. The rotor 1 is clamped to the shaft 5 by the screws 10 and held rigidly in position. The shaft 5 passes through a ball bearing inset into the inner stator 2 and so can rotate freely relative to the inner stator. The rotor has two drum, or bell-shaped, sections which surround the inner stator. The rotor 1 has a hollow cylindrical section 101, which extends away from the top surface 102. Since the inner stator is fixed and prevented from rotation by it's anchoring device (component 4 in Fig. 1), the rotor spins the hollow cylinder 101 around it. The hollow cylinder 101 of rotor 1 is separated from the inner stator 2 by an annular air gap G1. The hollow cylinder 101 of rotor 1 has magnets 7 sunk into holes in it. The top surface 102 of the rotor 1 also has holes in it and these are used to install the magnets 700 in it.
Fig. 18a shows the outer surfaces of the two halves of the rotor drum 1 laid out flat instead of curved into a circle in the X–Y plane shown in Fig. 16. This surface is perpendicular to the shaft axis 50 and rows of magnets 7 are positioned in rows 701 to 708. Each of these rows is slightly offset in relation to the row beside it, resulting in a zig-zag layout of the magnets 7.

Fig. 18b shows, in enlarged detail, the positioning of the magnets 7 shown in Fig. 18a. The centres of the magnets 7 in the rows 705 and 706 have a constant separation f between their edges. The distance between any two adjacent rows, say, 705 and 706, is chosen so that the arrangement is as shown in Fig. 18b with constant magnetic separation of length d between the edges of the magnets in adjacent rows. For example, the magnets 7051 and 7052 are exactly the same distance apart as magnets 7061 and 7062 the adjacent row 706. Also, the centres of the three magnets 7051, 7052 and 7061 form an isosceles triangle. This relationship holds for all of the
magnets in all seven series 701 to 708. Although the magnets 7 are shown in the diagrams as being circular, they could well be other shapes such as square or hexagonal.

The length $d$ ranges from about 3 mm to 50 mm. A distance which is particularly preferred, is 5 mm. The distance $f$ ranges from about 10 mm to 70 mm.

**Fig. 19a** shows a longitudinal section through the mechanical housing for the device, i.e. a section parallel to the shaft axis 50. The mechanical housing includes the support piece 4 for clamping the inner stator 2 to prevent it from rotating, the mount 19 for guiding the movable halves of the outer stator 3, and a rotating threaded rod 14 which can move both halves of the outer stator 3 relative to the rotor and/or the inner stator 2. The gear shaft 14 has two threaded sections with threads which run in opposite directions (right-hand and left-hand threads). The rotation of this shaft causes the two halves of the outer stator housing to move in a symmetrical manner in opposite directions, inwards or outwards. The guide devices 19 are mounted on the gear shaft 14 and so they only move in one plane. The outer cylindrical sections 9 which house the outer stator 3 are firmly attached to the end caps 19. Typically, this mechanical housing has a height of 400 to 600 mm, a width of 400 mm and a depth of 530 mm.

**Fig. 19b** is a section through the outer stator 3, the section plane is perpendicular to the shaft axis 50. The outer stator 3 has arranged in it, a ring of non-magnetic fasteners 18, between which magnets 6 are secured. For reasons of clarity, only some of the magnets 6 are shown although these magnets are mounted on the entire circumference of the outer stator 3. The size of the magnets 6 and the non-magnetic fasteners 18 is chosen so that they form a hollow cylinder whose central axis is in the direction of the shaft axis 50. The magnetic dipole axis 60 of the magnets 6 are perpendicular to the shaft axis 50. An angle $\gamma$ [gamma] between the magnetic dipole axis 60 and a tangent 61 to the outer periphery of the hollow cylindrical outer stator 3 is between 14 degrees and 90 degrees. The outer stator 3 is connected to the mounting block 4, which includes the mounting columns 20.
Fig. 20 is a perspective view of the mechanical housing for the device. Additional practical details are available in the patent.

Donald Kelly's Permanent Magnet Motor.
In 1979, Mr Kelly was granted a patent on a permanent magnet motor design. He comments that apart from it being very difficult to generate sufficient power to mechanically move the stator magnets slightly to achieve continuous rotation, the resulting rate of revolutions is very low. For those reasons, he has opted to move the stator magnets slightly using small DC motors. His design is included here as it is a concept which is relatively easy to understand. The overall idea is not unlike that of Stephen Kundel who rocks the stator magnets with a solenoid, as shown earlier in this chapter. The objective here is to use a small electrical current to generate a powerful rotation far greater than would be possible from the electrical current itself, and so, produce what is in effect, a power multiplication through the use of permanent magnets. A slightly reworded copy of his patent is shown in the Appendix.

The operation is a simple strategy. Eight sets of magnets are mounted on rocker arms. These have two main positions. In the first position, the rocker magnets attract the magnets mounted on the rotor. When the rotor moves because of this attraction and reaches a point where there is about to be a backward drag on the rotor, the position of the rocker arms is altered so that the first set of rocker magnets are moved out of the way to a position where they have little effect due to their increased distance from the rotor magnets. This rocker movement also
moves magnets of the opposite polarity which push the rotor magnets on their way. In this design, the attraction and the push are applied to different sets of magnets. If the attraction is on magnets 1, 3, 5, etc. then the push is on magnets 2,4,6, etc. But, in spite of this, the pull and push are applied to every rotor magnet as it passes. The power needed to operate the electric motors is minimal as the power of the motor is provided by the magnets. Instead of two tiny motors, it would be possible to operate the rocker arms using small solenoids and if the motor is used to power an electrical generator, then the design could be made self-powered by using some of the electrical output to provide the necessary input power. The sketch above shows just one layer of the motor, but there can be as many layers as you like, each driving the single output shaft, and increasing it's power with every layer.

**Mike Brady's “Perendev” Magnet Motor.**

One of the most widely known permanent magnet motors is the "Perendev" motor, which catches the imagination of most people. It is said that dozens of these motors have been made and sold as motor/generators with an output of not less than 100 kilowatts. As far as I am aware, this has not been confirmed, nor have there been independent tests made on the motor other than a brief test by Sterling Allan. However, let me stress again that it is very difficult to get any permanent-magnet-only motor operating and it is much easier to start with one like the Adams motor shown in Chapter 2, or the Charles Flynn motor shown earlier in this chapter. Please notice as well, that the magnets used in this design are non-standard magnets and so will be difficult to get and probably very expensive because of that and specialised magnetic shielding is used.

Mike's Patent Application WO 2006/045333 A1 dated 4th May 2006 is shown in the Appendix. In mid 2010, Mike had so much difficulty in getting his design into commercial production that his financial backers are most unhappy with the situation, and if Mike is having difficulty in replicating it (as did Howard Johnson with his magnet motor) then a newcomer to this field would be well advised to stick with magnet motors which use movement of the stator magnets, such as Don Kelly, Stephen Kundel and others, or magnet motors using mechanical or electrical shielding such as the Charles Flynn motor, the Robert Tracy motor, or the Jines motor.

**Magnetic shielding from Pasi Mäkilä**

A method of blocking a magnetic field using simple materials, comes form Pasi Mäkilä of Finland. His video showing this is at [https://www.youtube.com/watch?v=14ayyu9PVSI](https://www.youtube.com/watch?v=14ayyu9PVSI) and he concentrates on placing shielding around a cylindrical magnet:
However, when used as general shielding, a series of flat steel and aluminium layers can be used and while Pasi uses aluminium sheet 1.5 mm thick and zinc-plated steel which is 1 mm thick he suggests using thinner sheets. He suggests using four layers of steel with a sheet of aluminium between the steel sheets and perhaps one or more layers of aluminium on the outside. Pasi's main aim is to share this arrangement to allow people to make permanent magnet motors. One arrangement which may well be worth trying out is to use the shielding to block the backward drag of rotor magnets passing stator magnets, perhaps like this:

![Diagram of magnetic motor design](image)

With this arrangement, the South poles of the rotor magnets are attracted to the exposed North poles of the stator magnets, causing the rotor to rotate. As soon as a rotor South passes the stator North pole, the stator shielding blocks the reverse pull which would normally slow the rotor down.

We then have the repulsion of the North pole of the stator magnet and the North pole of the rotor magnet. To block that, a short length of shielding is placed beside the north pole end of the rotor magnet. It would probably be an advantage to run the stator north pole shielding over the top and underside of the rotor magnet to cause major magnetic blocking.

This magnetic motor design is just a suggestion and has not yet been built and tested.

**The Twin Rotor Suggestion**

When you are considering shielding magnets using iron or steel, you need to remember that fridge magnets stick to refrigerators because the refrigerators are made of steel. This demonstrates the fact that there is an attraction between magnets and iron or steel. Consequently, if a magnet is shielded with steel so that it blocks the whole of the magnetic field of the magnet, a second magnet will be attracted to that metal shielding material. At [http://www.youtube.com/watch?v=vUcWn1x3Ts](http://www.youtube.com/watch?v=vUcWn1x3Ts) there is, at the present time, a video by "magneticveil" where he proposes the use of this feature of simple shielding in the construction of a magnet motor.

He suggests using two rotors geared together. The rotors have magnets on them, but for the purposes of explanation, just one pair of magnets are shown here:

![Diagram of twin rotor system](image)
Each magnet is attracted to the metal shield material between the rotors. This causes the rotors to rotate in the direction shown by the red arrows. The magnets are drawn to the nearest point to the shield which they can reach as shown here:

At this point you would expect the rotors to stop moving and lock into a stationary position. However, the interesting idea is to adjust the shape of the shield like this:

At the end of the shield, its width is reduced and tapered so that the magnetic field from the magnet behind it exactly matches the attraction of the magnet on the near side of the shield. This has the effect of giving a completely neutral zone at the tip of the shield, with neither an attraction or a repulsion in that region. The degree of tapering depends on the strength of the magnets, the thickness and material of the shield and the spacing between the magnets and the shield, and it needs to be discovered by experiment.

This neutral zone stops there being a major pull between the magnets and the shield, and so momentum carries the rotors on past the end of the shield. This produces a situation like this:

Here, the magnets have moved past the shield and are repelling each other strongly. They are beyond the axles of the rotors, so the repelling force produces a turning effect on each rotor. This is the situation with just one pair
of magnets, but each rotor will have many magnets on it. This produces an additional turning effect. Consider just one other pair of magnets, in the same position as our first diagram:

The pull between the magnets “A” and the shield, adds to the rotation caused by the push between the unshielded magnets. This arrangement of magnets and shield should allow continuous rotation of both rotors and the motor can be stopped by removing the shield.

It should be noted that this arrangement uses magnets in repulsion mode. That is, the outward-facing poles of the magnets on both rotors are the same. There have been reports of permanent magnet motors where the magnets were in repulsion mode, and while these motors ran well, it was found that after about three months, the magnets lost their magnetisation. If at all possible, magnets should be used in their attraction mode. This is not possible in the above twin-rotor arrangement, so if one is being constructed, it might be a good idea to arrange the physical construction in such a way that the rotor magnets can easily be removed. This allows remagnetisation of the magnets, or alternatively, their replacement if very cheap types are used.

The Permanent Magnet Motor of Victor Diduck
In US patent application number US2007/0296284 of 27th December 2007, there is shown a convincing design for a powerful permanent magnet motor. Here is one of the embodiments from that patent – one which looks reasonably easy to build.

Abstract:
A magnetic motor having a magnetic drive assembly magnetically coupled to a magnetic slave assembly. The drive assembly has at least one drive magnet. In one embodiment the drive magnet is mounted on a cowling. In another embodiment the drive magnet is mounted on a drive wheel. The slave assembly has at least one slave wheel mounted on a slave shaft. At least one slave magnet is mounted on the slave wheel. In one embodiment slave magnets are mounted in grooves running diagonally across the face of the slave wheel. In another embodiment the slave magnets are mounted in notches cut into the slave wheel. The drive magnet is magnetically coupled to the slave magnet with the poles arranged in a like-faces-like orientation. The gap between the drive magnet and slave magnet can be adjusted in order to optimise the magnetic coupling between them. The slave wheel and its slave shaft are caused to rotate by the magnetic coupling between the drive magnet and the slave magnet. The slave shaft can be coupled to an output device such as an electric generator.

BACKGROUND OF THE INVENTION
There have been a number of attempts to perfect magnetic motors; for instance, U.S. Pat. No. 4,151,431 issued to Howard Johnson. However, in most such devices no working models have been achieved. In order to make a permanent magnet motor operate it is necessary to accomplish a switching function equivalent to that accomplished in electric motors by brushes, commutators, alternating current, or other means. In permanent magnet motors magnetic leakage must be shielded so as to reduce energy lost as eddy-current energy. A proper combination of materials, geometry, and magnetic concentration is required in order to be able to construct a magnetic motor that can operate continuously.

SUMMARY OF THE INVENTION
A magnetic motor is provided comprising a magnetic drive assembly magnetically coupled to a magnetic slave assembly. The magnetic slave assembly includes a rotatable slave shaft upon which is mounted at least one rotatable slave wheel. Upon the slave wheel is mounted at least one slave magnet. The magnetic drive assembly...
includes at least one drive magnet which is magnetically coupled to the slave magnet in a like-faces-like orientation. As a result of the magnetic coupling between the drive magnet and the slave magnet, magnetic forces produced between the coupled drive magnet and slave magnet drive the rotatable slave wheel, making it rotate and therefore causing the slave shaft to rotate. The slave shaft is coupled to an output device such as the armature of an electric generator.

The slave assembly is coupled to a frame. The slave wheels are fixed to the shaft so that the wheels rotate together. Each slave wheel has embedded in its surface a plurality of slave magnets set in indentations cut into the slave wheel. One pole of each slave magnet is exposed and facing outwards from the surface of the slave wheel, and the other magnet pole faces the slave wheel. Either the north pole or the south pole of the slave magnets may face outward, as long each magnet has the same pole facing outwards.

In one embodiment the indentations in the slave wheels for receiving the slave magnets form spaced apart, parallel grooves running from one side of the surface of the slave wheel to the other for receiving the slave magnets. The angle of each groove across the surface of the slave wheel is preferably about 35 degrees with respect to horizontal. The direction of orientation of the grooves of the other of the slave wheels is also about 35 degrees off of the horizontal, but in the opposite direction to that of the first wheel.

In another embodiment the indentations in the slave wheels for receiving the slave magnets are notches cut into the slave wheel at measured and equal intervals along the edges of the wheel, intervals of 45 degrees being preferred.

In this “cowling” embodiment of the invention, the magnetic drive assembly comprises a pair of non-magnetic cowlings surrounding and substantially enclosing each of the slave wheels. Each pair of cowlings forms a semi-circular surface having a diameter slightly larger than the diameter of its respective slave wheel. The concave curvature of the cowlings faces the slave wheels. Mounted on the convex surface of the cowlings is a plurality of permanent drive magnets. The drive magnets are mounted so that they present to the slave magnets the same pole as the slave magnets present to the drive magnets; i.e., like-faces-like: north-to-north or south-to-south. Neither the cowlings nor their drive magnets rotate.

In the various embodiments, the gap between the drive magnets and the slave magnets is adjustable.

**BRIEF DESCRIPTION OF THE DRAWINGS**

Further features and advantages of the invention will be apparent from the following detailed description taken in conjunction with the accompanying drawings, where:

*Fig.1* is a perspective view of the cowling embodiment of the magnetic motor with fly wheels attached.
Fig. 2 is partially disassembled perspective view of the cowling embodiment of the magnetic motor.

Fig. 3 is a diagram of the magnet placement on the cowling.
Fig. 4 is a schematic diagram of one slave wheel of the cowlings embodiment showing the position of the permanent magnets.

Fig. 5 is a schematic diagram of another slave wheel of the cowlings embodiment showing the position of the permanent magnets.
DETAILED DESCRIPTION OF THE INVENTION

In the various embodiments of the invention there is generally provided a magnetic drive assembly and a magnetic slave assembly, with a magnetic field coupling the drive assembly to the slave assembly such that when the drive assembly rotates it causes the slave assembly to rotate. The coupling is entirely magnetic, where no chains, gears, pulleys, worm drives or other physical couplers are required.

Fig.1 and Fig.2 show a first embodiment of the invention, referred to herein as the “cowling” embodiment. In this embodiment the magnetic slave assembly of the magnetic motor 101 comprises two solid non-magnetic slave wheels 102 and 202, most clearly seen in Fig.2. The slave wheels are mounted on a slave shaft 201. Fig.1 shows an embodiment in which optional fly-wheels 301, 401 are mounted on slave shaft 201. The fly-wheels may be conveniently mounted at or near the ends of the slave shaft. A device 1301 for generating electric current is provided that is directly coupled to the slave shaft, or indirectly coupled through a fly-wheel, as shown in Fig.1, or through some other element of the magnetic slave assembly.

Except for elements noted herein, the invention is constructed of a non-magnetic material. Phenolic plastic or ceramic materials are currently preferred for the slave wheels and drive wheels, but a wide variety of non-magnetic materials is acceptable so long as the material does not create or exacerbate eddy currents. The diameter of the slave wheels in currently operating models is approximately 10 inches (250 mm), and the width approximately 5 inches (125 mm). The optimum dimensions of the slave wheels will be determined by the specific application of the invention.

As seen in Fig.2, each slave wheel has a plurality of grooves running from one side to the other. One such groove is designated 701. The grooves in one wheel are oriented at an angle of about 35 degrees to the slave wheel edge, while the grooves of the second wheel are oriented at about 35 degrees to the opposite edge, as can be seen clearly in Fig.2.
Fig. 4 and Fig. 5 demonstrate the orientation of the grooves and the placement of the slave magnets. The rectangles 104 and 105 represent the surfaces of the slave wheels as if they were laid out flat. The grooves in slave wheel 104 slope downwards from left to right at an angle of about 35 degrees to the horizontal. The grooves in slave wheel 501 slope upward from left to right at an angle of about 35 degrees to the horizontal. In Fig. 4, grooves 204, 404, 604, and 804 are representative of the grooves in one slave wheel. Grooves 205, 405, 605, and 805 of the slave wheel represented in Fig. 5 are representative of grooves in the other slave wheel. Slave magnets are fitted into the grooves. In Fig. 4, representative slave magnets are 304, 504, 704, 904, 1004, and 1104. The preferred position of the slave magnets is that two adjacent grooves have magnets positioned at their ends as shown with 304, 504, and 704 in grooves 204 and 404. The next groove 604 has a single slave magnet 904 centrally placed. This pattern of two grooves with end magnets and the third with a central magnet is repeated. The preferred embodiment has a total of 9 grooves and 15 slave magnets per slave wheel. Fig. 5 shows that the same pattern is used in the second slave wheel, for instance in the manner in which slave magnets 305, 505, 705, 905, 1005, and 1105 are positioned in grooves 205, 405, 605, and 805.

In the preferred embodiment, the north pole of each slave magnet faces outwards from the groove; however, having the south pole facing outwards produces equally satisfactory results. The magnets can be glued into place or otherwise firmly fixed so they do not shift. The attractive forces these magnets produce if opposite poles are allowed to make magnetic contact requires approximately 1200 ft. lbs. to overcome. Slave and drive magnets are permanent magnets and have the same pole facing outwards, producing repulsive forces on the order of a measured 38 gauss.

The magnetic drive assembly of the "cowling" embodiment comprises paired clam-shell cowlings 601a, 601b and 501a, 501b, best seen in Fig. 2, which shows the cowlings in an open position, exposing the slave wheels. Fig. 1 shows the cowlings in the closed position, in which the invention operates. Crank handles 1001, 1101 operate worm-drives to provide for opening and closing the cowlings in order to adjust the gap between the cowlings and the slave wheels, and, hence, the gap between the drive magnets and the slave magnets.

Fig. 1 also shows drive magnets 701, 801 placed on the outer surface of cowlings 501a and 601a respectively. A plurality of ferro-magnetic bolts 901 penetrate the clam-shell cowling through threaded holes. These bolts modify the magnetic field and eliminate dead spots. The placing of the drive magnets and bolts is discussed below.

From Fig. 1 it can be seen that the combined curvature of the paired clam-shell cowlings results in them nearly surrounding their respective slave wheel when in the closed position. That is, each member of a cowling pair surrounds somewhat less than 180 degrees of the slave wheel's circumference so that when juxtaposed in the closed position, together they surround nearly 360 degrees of the slave wheel circumference.
**Fig. 3A** and **Fig. 3B** represent a pattern for mounting the slave magnets on the outside, or convex, surface of one pair of cowlings. The figure represents the cowling-halves 103, 703 as if they were laid flat. Guide lines are provided in the figure to indicate the longitudinal bisecting lines 403 and horizontal lines 503 dividing each cowling into eighths.

With respect to the cowling-half shown in **Fig. 3A**, two permanent drive magnets, 203, 303 are glued to the outside surface of the cowling on line 403 bisecting the cowling longitudinally. One drive magnet 203 is placed approximately one eighth of the way from one end. The second drive magnet 303 is placed three eighths of the way from the opposite end. Ferro-magnetic bolts 603 are inserted in the cowling through threaded holes. The purpose of the bolts is to modify the magnetic field to eliminate dead spots.

With respect to the cowling-half shown in **Fig. 3B**, drive magnet 803 is placed three eighths of the way from one end, and drive magnet 903 is placed one eighth (one sixteenth?) of the way from the other end. Again, ferro-magnetic bolts 603 are provided for eliminating dead spots in the magnetic field.

The diameter across each slave wheel is approximately 10 inches (250 mm). Measured from the bottom of groove 404 the diameter is 9 inches (225 mm). Consequently, the arc length from the bottom of one groove to the bottom of an adjacent groove is $\pi$ inches (i.e., 3.14 inches or 80 mm).

The drive magnets are glued or otherwise firmly fixed to the outer or concave surfaces of the cowlings. Assuming that the slave magnets have been mounted in the grooves of the slave wheels with the north pole facing outwards, the north pole of each drive magnet is fixed against the cowling surface so that like poles face one another. As the cowlings are moved toward the slave wheels by turning the cranks 1101, 1001 the drive magnets repel the slave magnets, causing the slave wheels to rotate.

Adjustment of the spacing between the cowlings and the slave wheels by means of cranks 1101, 1001 adjusts the strength of the interaction of the fields of the drive magnets and slave magnets and, hence, the torque on the slave wheels.

As shown in **Fig. 1**, fly-wheels 301, 401 can optionally be mounted on the slave shaft. The preferred position is at or near the end of the shaft.

Slave shaft 201 thus turns as a result of the magnetic force from the cowlings being applied to the slave wheels. This shaft can be coupled to an output such as the armature of a generator 1301, either directly or through a flywheel, as shown. Alternatively, the magnetic motor could itself drive a hydraulic pump of a transmission,
thereby reducing the number transmission components and the overall complexity of transmissions. Many different applications for this motor become obvious once it is realised that by using very strong permanent drive magnets useful power can be generated.

It is possible to vary the dimensions of the slave wheels. Presently, the preferred diameter is approximately 10 inches and a width of 5 inches. The motor can operate with the slave shaft 201 vertical or horizontal. While aluminium is a suitable material for the motor, the use of a hard plastic or ceramic materials have also been used with success. Photic plastic is presently preferred.

By using two slave wheels rather than just one, any dead spots in one wheel will be compensated for by the other wheel. The upper limit of the number of slave wheels is not yet known. The lower limit is one.

The Permanent Magnet Motor of Harold Miller and Andrew Colson
A very large, very heavy and rather expensive permanent magnet motor can be seen operating at these locations: https://www.youtube.com/watch?v=Q2JTwbIpf6o
https://www.youtube.com/watch?v=WWggsnpEk_s

This is a powerful, self-starting motor and it has a development forum here: http://www.energeticforum.com/renewable-energy/20583-miller-colson-magnetic-motor.html

This is a reciprocating design and in theory, reciprocating motion is not nearly as effective as a purely rotational system such as the Charles Flynn or the Robert Adams designs. However, here is an excerpt from the patent:

Permanent magnet drive apparatus and operational method

Abstract:
A magnetic drive apparatus includes first and second magnet carriers carrying first and second permanent magnet arrangements. An intermediate magnet carrier positioned between the first and second magnet carriers carries a third permanent magnet arrangement. The magnet carriers are arranged for rotation relative to each other such that the magnet arrangements produce magnetic interactions which result in power stroke forces causing the magnet carriers to undergo relative reciprocation in first and second stroke directions during power zone portions of the relative rotation. The magnetic interactions impart substantially no power stroke forces during dead zone portions of the relative rotation. The dead zones include magnet carrier relative rotation positions
wherein opposing magnetic poles are mutually coaxially aligned but produce a substantially equal balance of push and pull magnetic forces. The apparatus may be synchronised so that the dead zones coincide with top dead centre and bottom dead centre relative reciprocation positions.

Description:

BACKGROUND OF THE INVENTION

1. Field of the Invention
The present invention relates to mechanical drives that convert input forces or torques (applied at a drive input) to output forces or torques (delivered at a drive output). More particularly, the invention concerns reciprocating drive systems that perform force or torque conversion by way of magnetic field interactions between permanent magnets.

2. Description of the Prior Art
By way of background, there are numerous patents, published patent applications and other literature proposing the use of permanent magnets to actuate reciprocating drive devices, such as motion converters, power transmitters, motors and other apparatus. In many cases, the proposed devices reflect conceptions that have likely never been built, and which would be unlikely to produce practical benefits if they ever were constructed. This is not to say that such disclosures are inoperative. Indeed, many permanent magnet drive systems have been constructed, and one need only consult the popular YouTube website to see various videos depicting such devices.

Yet no one, it seems, has approached permanent magnet drive construction from the standpoint of an engine designer having in mind basic principles of reciprocating engine operation. An apparently unrecognised requirement is the need to periodically relax the drive components in order to facilitate continuous reciprocating movement. As far as known, this problem has not been addressed to date and may be one reason why permanent magnet reciprocating drives have largely remained the domain of hobbyists and tinkerers.

SUMMARY
An advance in the art is provided by a magnetic drive apparatus having a novel magnet arrangement that is particularly suited for reciprocating operation. In an embodiment, the magnetic drive apparatus includes first and second magnet carriers carrying first and second permanent magnet arrangements. An intermediate magnet carrier is positioned between the first and second magnet carriers, and carries a third permanent magnet arrangement. The intermediate magnet carrier and the first and second magnet carriers are arranged for rotation relative to each other (relative rotation). During such relative rotation, the magnet arrangements produce magnetic interactions that result in power stroke forces. The power stroke forces cause the intermediate magnet carrier and the first and second magnet carriers to undergo reciprocation relative to each other (relative reciprocation) in first and second stroke directions during power zone portions of the relative rotation. The magnetic interactions impart substantially no power stroke forces during dead zone portions of the relative rotation. The dead zones encompass relative rotational positions of the magnet carriers wherein opposing magnetic poles of the first, second and third permanent magnet arrangements are mutually coaxially aligned but produce a substantially equal balance of push and pull magnetic forces. The relative rotation and the relative reciprocation between the intermediate magnet carrier and the first and second magnet carriers can be synchronised so that the dead zones occur proximate to top dead centre and bottom dead centre relative reciprocation positions of the magnet carriers (which is where relaxation of power stroke forces is desired), and so that the power stroke forces occur between the top dead centre and bottom dead centre relative reciprocation positions (which is where maximum magnetic force is desired).

In an embodiment of the magnetic drive apparatus, a transition zone exists at each transition between one of the dead zones and one of the power zones. Each transition zone represents a transition period between the magnet carriers experiencing substantially no power stroke forces and substantially maximum power stroke forces.

In an embodiment of the magnetic drive apparatus, the first permanent magnet arrangement, the second permanent magnet arrangement and the third permanent magnet arrangement each comprise a set of magnets arranged in a magnet pattern. The magnets are oriented on their respective magnet carriers to present a first magnetic pole on a first magnet carrier side and a second magnetic pole on a second magnet carrier side. Each magnet pattern may have an even number of magnets. On any given magnet carrier side, there may be an equal number of N and S poles arranged in at least a first n-magnet grouping having n adjacent magnetic poles of a first polarity and at least a second n-magnet grouping having n adjacent magnetic poles of a second polarity, with “n” being an even number.
In an embodiment of the magnetic drive apparatus, the first magnet carrier has an interior side that faces a first side of the intermediate magnet carrier to form a first magnetic interaction zone, and the second magnet carrier has an interior side that faces a second side of the intermediate magnet carrier to form a second magnetic interaction zone. In this configuration, the power stroke forces will be imparted when all opposing magnetic poles in the first and second magnetic interaction zones are coaxially aligned in the power zone portions of relative magnet carrier rotation to either mutually repel or attract each other. In particular, the power stroke forces will produce relative reciprocation in a first direction when opposing magnetic poles in the first magnetic interaction zone are all coaxially aligned to mutually repel each other while opposing magnetic poles in the second magnetic interaction zone are all coaxially aligned to mutually attract each other. Conversely, the power stroke forces will produce relative reciprocation in a second direction when opposing magnetic poles in the first magnetic interaction zone are all coaxially aligned to mutually attract each other while opposing magnetic poles in the second magnetic interaction zone are all coaxially aligned to mutually repel each other. The power zones may also extend for some rotational distance on either side of the coaxial alignment positions.

In an embodiment of the magnetic drive apparatus, each dead zone includes a relative rotation position of the magnet carriers wherein one half of the opposing magnetic poles in the first and second magnetic interaction zones are coaxially aligned to mutually repel each other and the other half of the opposing magnetic poles in the first and second magnetic interaction zones are coaxially aligned to mutually attract each other. The dead zones may also extend for some rotational distance on either side of the coaxial alignment positions.

In an embodiment of the magnetic drive apparatus, a main shaft may extend through each of the magnet carriers. The main shaft may have a central longitudinal axis and may be rotatable about, and capable of reciprocation along, the longitudinal axis. A first end portion of the main shaft may be adapted for operative coupling to an input component that rotates the main shaft. A second end portion of the main shaft may be adapted for operative coupling to an output component that is driven by reciprocation of the main shaft. The main shaft may be rotatably coupled to either the intermediate magnet carrier or the first and second magnet carriers, such that rotation of the main shaft about its longitudinal axis produces the relative rotation between the intermediate magnet carrier and the first and second magnet carriers. The main shaft may be axially coupled to either the intermediate magnet carrier or the first and second magnet carriers, such that reciprocation of the main shaft along its longitudinal axis produces the relative reciprocation between the intermediate magnet carrier and the first and second magnet carriers in the first and second stroke directions. For example, the intermediate magnet carrier may be fixed to a main shaft for both reciprocation and rotation therewith, and the first and second magnet carriers may not be operatively connected to the main shaft at all.

In an embodiment of the magnetic drive apparatus, the first and second magnet carriers may be arranged for adjustable positioning toward and away from the intermediate magnet carrier in order to adjust the strength of the magnetic interactions. The position of the first and second magnet carriers may be adjusted towards or away from the intermediate magnet carrier by a power-driven magnet carrier positioning system.

In another aspect of the disclosed subject matter, a magnetic drive torque converter apparatus is provided by combining a magnetic drive apparatus as disclosed here, with an input component and an output component. The input component may be coupled to either the intermediate magnet carrier or the first and second magnet carriers to produce the relative rotation between the intermediate magnet carrier and the first and second magnet carriers. The output component may be coupled to either the intermediate magnet carrier or the first and second magnet carriers so that the relative reciprocation between the intermediate magnet carrier and the first and second magnet carriers in the first and second stroke directions actuates the output component.

In an embodiment of the magnetic driver torque converter apparatus, the magnetic drive apparatus may include a main shaft that extends through each of the magnet carriers. The main shaft may be as previously described, having a central longitudinal axis and being rotatable about, and capable of reciprocation along, the longitudinal axis. A first end portion of the main shaft is coupled to the input component, which rotates the main shaft. A second end portion of the main shaft is coupled to the output component, which is driven by reciprocation of the main shaft. As mentioned above, the main shaft may be rotatably coupled to either the intermediate magnet carrier or the first and second magnet carriers, such that rotation of the main shaft about its longitudinal axis produces the relative rotation between the intermediate magnet carrier and the first and second magnet carriers. Likewise, the main shaft may be axially coupled to either the intermediate magnet carrier or the first and second magnet carriers, such that reciprocation of the main shaft along its longitudinal axis produces the relative reciprocation between the intermediate magnet carrier and the first and second magnet carriers in the first and second stroke directions.

In an embodiment of the magnetic drive torque converter apparatus, a synchronisation device is used to synchronise the main shaft with respect to its rotational and reciprocation positions so that the dead zones coincide with the main shaft being near the top dead centre and bottom dead centre positions. For example, the main shaft may be synchronised so that the dead zones are centred on the top dead centre and bottom dead
centre positions. Alternatively, the main shaft may be synchronised so that the dead zones are dynamically adjusted in position or size.

In an embodiment of the magnetic drive torque converter apparatus, the synchronisation device may be provided by the input component, the output component, and a sensor/feedback system for controlling the input component based on positioning of the output component.

In an embodiment of the magnetic drive torque converter apparatus, the input component may include a rotary drive motor and the output component may include a crankshaft connected to the main shaft by a connecting rod. In that case, the sensor/feedback system may include a sensor arranged to sense rotation of the crankshaft and a controller operable to control the rotary drive motor in response to a crankshaft position signal from the sensor.

In another aspect of the disclosed subject matter, a magnetic drive apparatus is embodied as a two-magnet carrier apparatus instead of a three-magnet carrier apparatus. The two-magnet carrier apparatus includes opposing first and second magnet carriers instead of the first, second and intermediate magnet carriers provided in the three-magnet carrier apparatus. The two opposing magnet carriers respectively carry opposing magnet arrangements that are configured to produce magnetic interactions when the opposing magnet carriers undergo relative rotation. The magnetic interactions produce power stroke forces that cause the opposing magnet carriers to undergo relative reciprocation in first and second stroke directions during power zone portions of the relative rotation. The magnetic interactions produce substantially no power stroke forces during dead zone portions of the relative rotation. The dead zones comprise relative rotational positions of the magnet carriers wherein opposing magnetic poles of the opposing magnet arrangements are mutually coaxially aligned but produce a substantially equal balance of push and pull magnetic forces. The relative rotation and relative reciprocation between the magnet carriers are synchronised so that the dead zones occur near the top dead centre and bottom dead centre relative reciprocation positions of the magnet carriers, and so the power zones occur between the top dead centre and bottom dead centre relative reciprocation positions.

In another aspect of the disclosed subject matter, a set of plural magnetic drive apparatus may be powered by one or more input components to drive a single output component. Each set of plural magnetic drive apparatus may include two or more three-magnet carrier drive apparatus, two or more two-magnet carrier drive apparatus, or any desired combination of one or more three-magnet carrier apparatus and one or more two-magnet carrier apparatus.

In another aspect of the disclosed subject matter, a magnetic drive method is provided. In an example embodiment of the method, opposing magnet carriers are provided that respectively carry opposing magnet arrangements. Relative rotation is induced between the opposing magnet carriers to produce magnetic interactions. The magnetic interactions produce power stroke forces that cause the opposing magnet carriers to undergo relative reciprocation in first and second stroke directions during power zone portions of the relative rotation. The magnetic interactions produce substantially no power stroke forces during dead zone portions of the relative rotation. The dead zones encompass relative rotational positions of the magnet carriers wherein opposing magnetic poles of the opposing magnet arrangements are mutually coaxially aligned but produce a substantially equal balance of push and pull magnetic forces. The relative rotation and the relative reciprocation of the magnet carriers may be synchronised to achieve a desired effect. For example, the synchronisation may include timing the relative rotation and relative reciprocation of the magnet carriers so that the dead zones are centred on top dead centre and bottom dead centre relative reciprocation positions, and so that the power zones occur between the top dead centre and bottom dead centre relative reciprocation positions. Alternatively, the synchronisation may include timing the relative rotation and relative reciprocation of the magnet carriers so that the dead zones are dynamically adjusted in position or size.

In another aspect of the disclosed subject matter, a magnetic drive apparatus has opposing magnet carriers respectively carrying opposing magnet arrangements. The opposing magnet arrangements have opposing magnetic poles and are configured to produce magnetic interactions when the opposing magnet carriers undergo relative rotation. The magnetic interactions produce power stroke forces that cause the opposing magnet carriers to undergo relative reciprocation in first and second stroke directions during power zone portions of the relative rotation. The relative rotation further includes rotational dead zones wherein the opposing magnetic poles of the opposing magnet arrangements are mutually coaxially aligned to define an equal number of same-polarity and opposite-polarity opposing pole pairs.

BRIEF DESCRIPTION OF THE DRAWINGS
The foregoing and other features and advantages will be apparent from the following more particular description of example embodiments, as illustrated in the accompanying Drawings, in which:

DETAILED DESCRIPTION OF THE EXAMPLE EMBODIMENT

Turning now to the drawings, which are not necessarily to scale, like reference numerals will be used to represent like elements in all of the several views. As will be described below in connection with various alternative embodiments, a magnetic drive apparatus as disclosed herein may be used to convert a rotary input received from an input power source to a reciprocating output that may be used to drive a load. The rotary input may be continuous or intermittent, uni-directional or bi-directional. The reciprocating output may comprise a repeating cycle of reciprocal strokes. The magnetic drive apparatus uses permanent magnet arrangements that are each configured in a selected magnet pattern to create magnetic interactions as the magnet arrangements are rotated relative to each other by the input power source. These magnetic interactions deliver reciprocating power in each reciprocal stroke direction (power strokes). Advantageously, the magnetic interactions also produce well-defined dead zones of substantially no net magnetic force that can be made to occur near the end of each reciprocal stroke. During each dead zone, the net magnetic forces delivered by the permanent magnet arrangements essentially "switch off". This allows the power stroke forces to momentarily relax and quiesce between power strokes, thus ensuring smooth continuous reciprocating operation.

Turning now to Fig1 to Fig.4, diagrammatic views of an example three-magnet carrier magnetic drive apparatus 2 are shown in order to illustrate the general principles of operation of the subject matter disclosed here. In the illustrated embodiment, the left-hand end of the magnetic drive apparatus 2 has a first magnet carrier 4 carrying a first permanent magnet arrangement 6 with a set of permanent magnets 6A. The right-hand end of the magnetic drive apparatus 2 has a second magnet carrier 8 carrying a second permanent magnet arrangement 10 with a set of permanent magnets 10A. An intermediate magnet carrier 12 is placed between the first and second magnet carriers and carries a third permanent magnet arrangement 14 with a set of permanent magnets 14A.

The magnet carriers 4, 8 and 12 have respective first and second sides 4A/4B, 8A/8B and 12A/12B that define a magnet carrier thickness dimension. Although the magnet carriers 4, 8 and 12 are shown as being disk-shaped, other magnet carrier configurations could also be used (e.g., polygonal, star shaped, etc). The magnet carriers 4, 8 and 12 may be fabricated using any suitable metal or non-metal material of sufficient strength and rigidity to handle the magnetic forces, including but not limited to aluminium, titanium, stainless steel, polymers, fibre-reinforced composites, etc. In the case of metals, it is preferred that the material be substantially non-magnetic (such as aluminium or titanium) or only mildly magnetic (such as stainless steel). Materials that are more magnetic (such as mild steel) may also be used provided it is understood that these materials may influence the magnetic fields of the magnets 6A, 10A and 14A.

The magnets 6A, 10A and 14A are illustrated as being disc magnets that are axially magnetised so as to have a north magnetic polarity on one magnet face and a south magnetic polarity on the opposite magnet face. Each magnet 6A, 10A and 14A has a central longitudinal axis extending between its north and south poles. This axis represents the principal magnetic field axis of the magnets 6A, 10A and 14A. Any suitable permanent magnet
material may be used to fabricate the magnets 6A, 10A and 14A. Preferably, magnets with strong magnetic field properties will be used, such as rare earth magnets comprising neodymium iron boron (NeFeB) or samarium cobalt (SmCo). Although less desirable due to their lower magnetic field strength, other types of magnets could also be used, including alnico magnets comprising aluminium, nickel and cobalt in addition to iron, or ceramic magnets comprising ferrite material. Different magnet shapes may also be used. For example, instead of the magnets 6A, 10A and 14A being disc-shaped, the magnets could be spherical, kidney-shaped, banana-shaped, etc. Also, instead of each of the magnets 6A, 10A and 14A being a single magnet, some or all of the magnets could be implemented as a coaxial stack of two or more magnets with their magnetic poles aligned for mutual attraction.

The magnet carriers 4, 8 and 12 may carry their respective magnets 6A, 10A and 14A in any suitable manner. For example, each magnet carrier 4, 8 and 12 may formed with magnet-carrying cut-outs of suitable size and shape. If the magnets are disk-shaped as shown in Figs.1-4, the magnet carrier 4 may be formed with four circular cut-outs 4C that receive the four magnets 6A. Similarly, the magnet carrier 8 may be formed with four circular cut-outs 8C that receive the four magnets 10A, and the magnet carrier 12 may be formed with four circular cut-outs 12C that receive the four magnets 14A. If desired, the thickness of the magnets 6A, 10A and 14A from one magnet face to the other may be selected to match the thickness of the magnet carriers 4, 8 and 12. Alternatively, the magnets 6A, 10A and 14A could be thicker or thinner than the thickness dimension of their respective magnet carriers 4, 8 and 12. Any suitable magnet retention technique may be used to retain the magnets 6A, 10A and 14A in position. For example, the embodiment of Fig.8 to Fig.12B (described in more detail below) shows an example technique for securing the magnets 6A, 10A and 14A on the magnet carriers 4, 8 and 12 using magnet retainer plates.

The first permanent magnet arrangement 6, the second permanent magnet arrangement 10, and the third permanent magnet arrangement 14 are configured to produce changing magnetic interactions when a rotary input (not shown in Figs.1-4) imparts relative rotation between the intermediate magnet carrier 12 and the first and second magnet carriers 4 and 8. In Figs.1-4, the relative rotation between the intermediate magnet carrier 12 and the first and second magnet carriers 4 and 8 is represented by arrows “A”, “B” and “C”. In Fig.1, the intermediate magnet carrier 12 and the first and second magnet carriers 4 and 8 are shown in a first relative rotational position. In Fig.2, the intermediate magnet carrier 12 and the first and second magnet carriers 4 and 8 are shown in a second relative rotational position following 180° of relative rotation between the intermediate magnet carrier 12 and the first and second magnet carriers 4 and 8. Fig.3 and Fig.4 show relative rotational positions that are midway between the relative rotational positions of Fig.1 and Fig.2.

There are various ways that the magnetic drive apparatus 2 may be constructed to facilitate relative rotation between the intermediate magnet carrier 12 and the first and second magnet carriers 4 and 8. For example, the intermediate magnet carrier 12 could be coupled to an input component and rotated by itself while the first and second magnet carriers 4 and 8 remain fixed against rotation. Conversely, the first and second magnet carriers 4 and 8 could be coupled to an input component and rotated together while the intermediate magnet carrier 12 remains fixed against rotation. The first and second magnet carriers 4 and 8 could either rotate in the same direction or in opposite directions. A further alternative would be to rotate the intermediate magnet carrier 12 in one direction while rotating the first and second magnet carriers 4 and 8 in the opposite direction. An example of the first approach is described in more detail below in connection with the constructions shown in Fig.7 and in Figs.8 to 12B. In these constructions, the intermediate magnet carrier 12 is mounted to a main shaft that is free to rotate independently of the first and second magnet carriers 4 and 8. The first and second magnet carriers 4 and 8 are fixed against rotation by a support frame assembly.

There are also various ways that the magnetic drive apparatus 2 may be constructed to facilitate relative reciprocation between the intermediate magnet carrier 12 and the first and second magnet carriers 4 and 8. For example, the intermediate magnet carrier 12 could be coupled to an output component to cause reciprocation while the first and second magnet carriers 4 and 8 remain fixed against reciprocation. Conversely, the first and second magnet carriers 4 and 8 could both be coupled to an output component to cause reciprocation while the intermediate magnet carrier 12 remains fixed against reciprocation.

An example of the first approach is described in more detail below in connection with the constructions shown in Fig.7 and in Figs.8 to 12B. In these constructions, the intermediate magnet carrier 12 is mounted on a main shaft which is free to reciprocate independently of the first and second magnet carriers 4 and 8. The first and second magnet carriers 4 and 8 are fixed against reciprocation by a support frame assembly.

It should be noted that any magnet carrier that is adapted to reciprocate in order to produce relative reciprocation between the intermediate magnet carrier 12 and the first and second magnet carriers 4 and 8 may also be adapted to rotate in order to produce relative rotation between the intermediate magnet carrier and the first and second magnet carriers. Similarly, any magnet carrier that is fixed against reciprocation may also be fixed against rotation. For example, as described in more detail below in connection with the constructions shown in Fig.7 and
in Figs.8-12B, the intermediate magnet carrier 12 may be adapted to both rotate and reciprocate while the first and second magnet carriers 4 and 8 remain fixed against rotation and reciprocation. Conversely, the first and second magnet carriers 4 and 8 could be adapted to both rotate and reciprocate while the intermediate magnet carrier 12 remains fixed against rotation and reciprocation. As a further alternative, any magnet carrier that is adapted to reciprocate may be fixed against rotation, and visa versa. For example, the intermediate magnet carrier 12 could be adapted to reciprocate but not rotate while the first and second magnet carriers 4 and 8 are adapted to rotate but not reciprocate. Conversely, the first and second magnet carriers 4 and 8 could be adapted to reciprocate but not rotate while the intermediate magnet carrier 12 is adapted to rotate but not reciprocate.

In the embodiment of Figs.1-4, the number of magnets 6A, 10A and 14A in each respective permanent magnet arrangement 6, 10 and 14 is four. The magnets 6A, 10A and 14A are spaced equally from each other and are symmetrically arranged about the centres of their respective magnet carriers 4, 8 and 12 in a four-sided polygonal pattern (corresponding to the number of magnets) that is square and balanced. Each magnet pattern on any given magnet carrier side 4A/4B, 8A/8B or 12A/12B includes a first pair of adjacent magnetic poles of a first polarity (e.g., N-polarity) and a second pair of adjacent magnetic poles of a second polarity (e.g., S-polarity). In the square four-magnet patterns shown in Figs.1-4, a first two opposing sides of each magnet pattern have magnetic poles of the first polarity and a second two opposing sides of the magnet pattern have magnetic poles of the second polarity. Magnetic poles that are diagonal from each other in each square magnet pattern are of opposite polarity. As discussed in more detail below, magnet arrangements with more than four magnets may also be constructed.

In each of Figs.1-4, the second side 4B of the first magnet carrier 4 faces the first side 12A of the intermediate magnet carrier 12 to form a first magnetic interaction zone 15A. The first side 8A of the second magnet carrier 8 faces the second side 12B of the intermediate magnet carrier 12 to form a second magnetic interaction zone 15B. With this magnet configuration, the changing magnetic interactions produced by magnet carrier relative rotation impart power stroke forces to the magnet carriers 4, 8 and 12 that produce the above-mentioned reciprocating output. In particular, power stroke forces will be imparted when all opposing magnetic poles in each of the first and second magnetic interaction zones 15A and 15B are aligned to either mutually repel or attract each other.

The power stroke forces produce relative reciprocation between the magnet carriers 4, 8 and 12 in a first direction when opposing magnetic poles in the first magnetic interaction zone 15A all mutually repel each other while opposing magnetic poles in the second magnetic interaction zone 15B all mutually attract each other. Conversely, the power stroke forces produce relative reciprocation between the magnet carriers 4, 8 and 12 in a second direction when opposing magnetic poles in the first magnetic interaction zone 15A all mutually attract each other while opposing magnetic poles in the second magnetic interaction zone 15B all mutually repel each other.

The magnet carriers 4, 8 and 12 may be said to be in “power zone” portions of their relative rotation when the magnetic interactions produce the above-described power stroke forces. There is one power zone for each power stroke direction. Power zone positions of the magnetic drive apparatus 2 are exemplified by Fig.1 and Fig.2. Fig.1 illustrates the magnetic drive apparatus 2 at the centre of a first power zone in which the magnetic interactions produce power stroke forces in a first direction. The intermediate magnet carrier 12 and the first magnet carrier 4 are pushed apart due to each magnetic pole on side 12A of the intermediate magnet carrier being mutually coaxially aligned with an opposing magnetic pole of like polarity on side 4B of the first magnet carrier. This pushing force is represented by the arrows “D”. As can be seen, the magnet carriers 4 and 12 are rotatably positioned such that there are two N-N interactions and two S-S interactions in the magnetic interaction zone 15A. At the same time, the intermediate magnet carrier 12 and the second magnet carrier 8 are pulled together due to each magnetic pole on side 12B of the intermediate magnet carrier being mutually coaxially aligned with an opposing magnetic pole of opposite polarity on side 8A of the second magnet carrier. This pull force is represented by the arrows “E”. As can be seen, the magnet carriers 8 and 12 are rotatably positioned so that there are two N-S interactions and two S-N interactions in the magnetic interaction zone 15B.

Fig.2 illustrates the magnetic drive apparatus 2 at the centre of a second power zone in which the magnetic interactions produce power stroke forces in a second direction. As noted above, this state follows 180° of relative rotation (from the position shown in Fig.1) between the intermediate magnet carrier 12 and the first and second magnet carriers 4 and 8. The intermediate magnet carrier 12 and the first magnet carrier 4 are pulled together due to each magnetic pole on side 12A of the intermediate magnet carrier being mutually coaxially aligned with an opposing magnetic pole of opposite polarity on side 4B of the first magnet carrier. This pull force is represented by the arrows “E”. As can be seen, the magnet carriers 4 and 12 are rotatably positioned so that there are two N-S interactions and two S-N interactions in the magnetic interaction zone 15A. At the same time, the intermediate magnet carrier 12 and the second magnet carrier 8 are pushed apart due to each magnetic pole on side 12B of the intermediate magnet carrier being mutually coaxially aligned with an opposing magnetic pole of like polarity on side 8A of the second magnet carrier. This pushing force is represented by the arrows “D”. As can be seen, the magnet carriers 8 and 12 are rotatably positioned so that there are two N-N interactions and two S-S interactions in the magnetic interaction zone 15B.
It should be noted that the power zones extend beyond the coaxial alignment positions of the magnetic poles shown in Fig.1 and Fig.2, so that each power zone has a rotational range or “width” that spans a portion of one revolution of the magnet carrier relative rotation. Each power zone will thus start prior to the opposing magnetic poles of the magnet arrangements 6, 10 and 14 being rotated into mutual coaxial alignment and will end subsequent to the mutual coaxial alignment position. Power stroke forces will be generated at any given relative rotation position of the magnet carriers 4, 8 and 12 within each power zone.

The magnet arrangements 6, 10 and 14 may be said to be in “dead zone” portions of their relative rotation when there are substantially no power stroke forces acting on the magnet carriers 4, 8 and 12. In the four-magnet arrangements 6, 10 and 14 of Figs.1-4, there is one well-defined dead zone centred between each well-defined power zone, and each relative reciprocation cycle comprises two power zones separated by two dead zones. The dead zones exist when opposing magnetic poles of the first magnet carrier 4, the second magnet carrier 8 and the intermediate magnet carrier 12 are mutually coaxially aligned but produce a substantially equal balance of push and pull magnetic forces. In the dead zones, one half of the opposing magnetic poles in the first and second magnetic interaction zones 15A and 15B are aligned to mutually repel each other and the other half of the opposing magnetic poles being of opposite polarity.

In particular, in each of Fig.3 and Fig.4, the magnet carriers 4, 8 and 12 are rotatably positioned such that there is one N-N interaction, one S-S interaction, one N-S interaction and one S-N interaction in each magnetic interaction zone 15A and 15B. Like the power zones, the dead zones extend beyond the coaxial alignment positions of the magnetic poles, such that each dead zone has a rotational range or “width” that spans a portion of one revolution of relative magnet carrier rotation. Each dead zone will thus start prior to the opposing magnetic poles of the magnet arrangements 6, 10 and 14 being rotated into coaxial alignment, and will end subsequent to the coaxial alignment position.

The centre of the dead zone shown in Fig.3 corresponds to 90° of magnet carrier relative rotation from the power zone rotational position of Fig.1. The centre of the dead zone shown in Fig.4 corresponds to 90° of magnet carrier relative rotation from the power zone rotational position of Fig.2. In both of these dead zone positions, the opposing magnetic poles in each magnetic interaction zone 15A and 15B are mutually coaxially aligned, but their polarities are such as to create net magnetic forces of substantially zero as a result of two of the opposing magnetic poles being of the same polarity and the other two opposing magnetic poles being of opposite polarity.

In a prototype implementation of the magnetic drive apparatus 2, which was constructed in accordance with Fig.8 to Fig.12B (discussed in more detail below), the four magnets 6A, 10A and 14A on each respective magnet carrier 4, 8 and 12 were implemented with 3 inch diameter, 1 inch thick, grade N52 neodymium disk magnets from K & J Magnetics, Inc. (one inch = 25.4 mm). Each magnet 6A, 10A and 14A was axially magnetised and was rated by the manufacturer as producing a maximum push/pull force of approximately 360 pounds. The magnets 6A, 10A and 14A were arranged on their respective magnet carriers 4, 8 and 12 so that the magnet centres were 2.75 inches from the magnet carrier centres. The stroke length of the magnet carrier relative reciprocation was 5.5 inches. At the end of each stroke, the separation between the closest together magnet carriers resulted in a minimum spacing between opposing magnets (pole face to pole face) of 1.125 inches. At mid-stroke, the separation between the magnet carriers was equal, and resulted a maximum spacing between opposing magnets (pole face to pole face) of 3.875 inches. In tests conducted on this prototype, the power zones and the dead zones each spanned approximately 90° of magnet carrier relative rotation at all relative reciprocation positions. Similar results would be expected for other magnetic drive apparatus implementations wherein the magnet arrangements each have four magnets arranged in a balanced square magnet pattern.

The relative rotation and relative reciprocation between the intermediate magnet carrier 12 and the first and second magnet carriers 4 and 8 can be synchronised so that the dead zones and the power zones occur at selected portions of magnet carrier relative reciprocation. Fig.1 shows a power zone which is centred proximate to the mid-point of a first power stroke in a first direction. Fig.2 shows another power zone that is centred proximate to the mid-point of a second power stroke in the opposite direction. Fig.3 shows a dead zone that is centred between the end of the power stroke of Fig.1 and the beginning of the power stroke of Fig.2. This may be referred to as the bottom dead centre relative reciprocation position of the magnet carriers 4, 8 and 12. Fig.4 shows another dead zone that is centred between the end of the power stroke of Fig.2 and the beginning of the power stroke of Fig.1. This may be referred to as the top dead centre relative rotation position of the magnet carriers 4, 8 and 12.
Fig. 5 shows a timing disk that represents another way to view the synchronisation shown in Fig. 1 to Fig. 4. In this illustration, both the magnet carrier relative rotation and the magnet carrier relative reciprocation are expressed in angular terms. The synchronisation is such that for every degree of relative magnet carrier rotation, there is one degree of relative magnet carrier reciprocation. The dead zones are centered at the 0° top dead centre and 180° bottom dead centre relative reciprocation positions, and the power zones are centered between the dead zones. It will be appreciated that expressing the magnet carrier relative reciprocation in angular terms is permissible because the relative reciprocation represents periodic motion. Using an angular expression of the relative reciprocation is more convenient than using the actual magnet carrier relative displacement because the latter is implementation-specific. For example, if the relative reciprocation of the magnet carriers 4, 8 and 12 represents simple harmonic motion, the standard equation: 
\[ d = A \cos(\theta) \]

where \( d \) is the magnet carrier relative displacement, \( A \) is the maximum magnet carrier relative displacement from the mid-stroke position that occurs at \( \theta = 0° \) and \( \theta = 180° \). Other equations govern different types of periodic motion. For example, if the relative reciprocation of the magnet carriers 4, 8 and 12 behaves like a piston coupled to a crankshaft via a connecting rod (as it does in the embodiment of Figs. 8-12B below), the magnet carrier relative displacement will be given by the standard equation:
\[ d = r \cos(\theta) + \left( l^2 - r^2 \sin^2(\theta) \right)^{1/2} \]

As stated, Fig. 5 shows a synchronisation scheme in which, for every degree of relative magnet carrier rotation, there is one degree of relative magnet carrier reciprocation. At the 0° position marked “TDC”, the magnet carriers 4, 8 and 12 are in the top dead centre relative reciprocation position and are rotationally positioned at the center of a first dead zone. At approximately 45° of relative rotation/reciprocation of the magnet carriers 4, 8 and 12, the end of the first dead zone is reached and the magnet carriers transition into a first power zone that produces power stroke forces in a first direction. The center of this power zone is at approximately the 90° relative rotation/reciprocation position. At approximately 135° of relative rotation/reciprocation of the magnet carriers 4, 8 and 12, the end of the first power zone is reached and the magnet carriers transition into a second dead zone. At the 180° position marked “BDC”, the magnet carriers 4, 8 and 12 are in the bottom dead centre relative reciprocation position and are rotationally positioned at the center of the second dead zone. At approximately 225° of relative rotation/reciprocation of the magnet carriers 4, 8 and 12, the end of the second dead zone is reached and the magnet carriers transition into a second power zone that produces power stroke forces in a second direction. The center of this power zone is at approximately the 270° relative rotation/reciprocation position. At approximately 315° of relative rotation/reciprocation of the magnet carriers 4, 8 and 12, the end of the second power zone is reached and the magnet carriers transition back to the first dead zone. The 0° TDC position is reached again after another 45° of relative rotation/reciprocation of the magnet carriers 4, 8 and 12.

As noted above, the starting and ending positions of the power zones and dead zones are approximate. This is because the transition from power zone to dead zone and from dead zone to power zone does not occur instantaneously. Advantageously, however, these transition zones (designated as “flip” zones in Fig. 5) have
been determined to be quite short, and did not exceed approximately 5° of relative rotation/reciprocation in the above-described prototype implementation of the magnetic drive apparatus 2. Each transition zone represents a transition period between the magnet carriers 4, 8 and 12 experiencing substantially no power stroke forces and substantially maximum power stroke forces. It should be noted that characterising the dead zones as producing “substantially no power stroke forces” does not necessarily mean there are exactly zero net forces within the dead zones. However, no dead zone forces have been observed to exceed more than several pounds, and were orders of magnitude less than the power stroke forces in the prototype implementation of the magnetic drive apparatus 2. Moreover, these very small dead zone forces occur away from the dead zone centres, and have no effect on the reciprocal operation of the magnetic drive apparatus 2.

As described below in connection with the example construction shown in Figs.8-12B, the synchronisation shown in Figs.1-5 may be established and maintained by a feedback system that monitors the relative reciprocation between the magnet carriers 4, 8 and 12 and uses this information to control the relative rotation of the magnet carriers. Alternatively, a mechanical timing system could be provided wherein the relative rotation and relative reciprocation between the magnet carriers 4, 8 and 12 are synchronised using a mechanical coupling arrangement. If desired, the synchronisation may be adjusted so that the magnet carrier relative rotation is advanced or retarded with respect to the magnet carrier relative reciprocation. For example, the dead zone relative rotation positions may be shifted so that the dead zones are centred either before or after the TDC and BDC relative reciprocation positions. As in an automotive engine, the magnet carrier relative rotation could be dynamically advanced and retarded to adjust the dead zone positions according to the speed of the magnet carrier relative reciprocation. It would also be possible to dynamically advance and retard the magnet carrier relative rotation with respect to the magnet carrier relative reciprocation at selected times during each revolution of relative rotation. This will have the effect of adjusting the size of the dead zones relative to the power zones. For example, if it is desired to decrease the dead zone width while increasing the power zone width, the magnet carrier relative rotation can be dynamically retarded (slowed down) within the power zones and dynamically advanced (sped up) within the dead zones. Similarly, if it is desired to increase the dead zone width while decreasing the power zone width, the magnet carrier relative rotation can be dynamically advanced (sped up) within the power zones and dynamically retarded (slowed down) within the dead zones.
Figs. 6A-6H presents additional views of the relative rotation/reciprocation cycle of the magnet carriers 4, 8 and 12 using the synchronisation scheme shown in Figs. 1-5. Each of Figs. 6A-6H shows a 45° incrementation of the relative rotational and reciprocation positions of the magnet carriers 4, 8 and 12. The centre portion of each
The figure shows the magnet carrier relative reciprocation position (in angular terms). The left hand portion of each figure depicts the relative rotational positions of the first magnet carrier 4 and the intermediate magnet carrier 12. The alignment of the opposing magnets in the first magnetic interaction zone 15A (see Figs.1-4) is also shown, as are the polarities of each pair of opposing magnets (i.e., the polarities of the magnets 14A on the first side 12A of the intermediate magnet carrier 12 and the polarities of the magnets 6A on the second side 4B of the first magnet carrier 4). The right hand portion of each figure depicts the relative rotational positions of the second magnet carrier 8 and the intermediate magnet carrier 12. The alignment of the opposing magnets in the second magnetic interaction zone 15B (see Figs.1-4) is also shown, as are the polarities of each pair of opposing magnets (i.e., the polarities of the magnets 14A on the second side 12B of the intermediate magnet carrier 12 and the polarities of the magnets 10A on the first side 8A of the second magnet carrier 8).

As an interpretive guide, the left-hand portion of Figs.6A-6H is a view looking from the second side 4B of the first magnet carrier 4 towards the first side 12A of the intermediate magnet carrier 12. The right-hand portion of Figs.6A-6H is a view looking from the second side 12B of the intermediate magnet carrier 12 towards the first side 8A of the second magnet carrier 8. In the positions where the opposing magnets overlap (i.e., Figs.6A, 6C, 6E and 6G), the letter (S or N) at the centre of each depicted magnet pair is the polarity of the magnet 14A on the intermediate magnet carrier 12, and the offset letter (S or N) is the polarity of its opposing magnet 6A or 10A on the first or second magnet carrier 4 or 8. In the positions where the opposing magnets do not overlap (i.e., Figs.6B, 6D, 6F and 6H), the magnets 14A of the intermediate magnet carrier 12 are shown as being above the opposing magnets 6A or 10A of the first or second magnet carriers 4 or 8. In a similar vein, when the polarities of opposing magnet pairs are discussed below, the first polarity will be that of a magnet 14A of the intermediate magnet carrier 12 and the second polarity will be that of a magnet 6A of the first magnet carrier 4 or a magnet 10A of the second magnet carrier 8 (depending on whether the first or second magnetic interaction zone 15A or 15B is being discussed). When magnet pair polarities are enumerated below, they will start in the upper left quadrant of each magnet arrangement and continue in clockwise order.

**Fig. 6A**

Fig.6A shows the magnet carriers 4, 8 and 12 in a 0° relative rotation/reciprocation position. In this position, the magnetic interactions in the first magnetic interaction zone 15A are S-N, S-S, N-S and N-N. The magnetic interactions in the second magnetic interaction zone 15B are N-N, N-S, S-S and S-N. In each magnetic interaction zone 15A and 15B, half of the opposing magnet pairs are coaxially aligned for mutual attraction and the other half are coaxially aligned for mutual repulsion. Thus, Fig.6A depicts a dead zone that is centered at the 0° TDC relative reciprocation position of the magnet carriers 4, 8 and 12. As can be seen, this dead zone is approximately 90° wide.

**Fig. 6B**

Fig.6B shows the magnet carriers 4, 8 and 12 in a 45° relative rotation/reciprocation position. In this position, the relative rotation of the magnet carriers 4, 8 and 12 is halfway between the midpoints of the dead zone and the power zone rotational positions. The magnet carriers 4, 8 and 12 are thus in a transition zone wherein the magnetic forces are changing from the substantially net zero condition of a dead zone to the full magnetic force condition of a power zone.
Fig. 6C shows the magnet carriers 4, 8 and 12 in a 90° relative rotation/reciprocation position. In this position, the magnetic interactions in the first magnetic interaction zone 15A are N-N, S-S, S-S and N-N. All of the opposing magnet pairs in this magnetic interaction zone are coaxially aligned with like polarities so that the first magnet carrier 4 and the intermediate magnet carrier 12 repel each other with maximum push force. The magnetic interactions in the second magnetic interaction zone 15B are S-N, N-S, N-S and S-N. All of the opposing magnet pairs in this magnetic interaction zone are coaxially aligned with opposite polarities so that the second magnet carrier 8 and the intermediate magnet carrier 12 attract each other with maximum pull force. Fig. 6C therefore depicts a first power zone that is centered at the 90° relative reciprocation position of the magnet carriers 4, 8 and 12. As can be seen, this power zone is approximately 90° wide.

Fig. 6D shows the magnet carriers 4, 8 and 12 in a 135° relative rotation/reciprocation position. In this position, the relative rotation of the magnet carriers 4, 8 and 12 is half way between the mid-points of dead zone and power zone rotational positions. The magnet carriers 4, 8 and 12 are thus in a transition zone wherein the magnetic forces are changing from the full magnetic force condition of a power zone to the substantially net zero condition of a dead zone.

Fig. 6E shows the magnet carriers 4, 8 and 12 in a 180° relative rotation/reciprocation position. In this position, the magnetic interactions in the first magnetic interaction zone 15A are N-N, N-S, S-S and S-N. The magnetic interactions in the second magnetic interaction zone 15B are S-N, S-S, N-S and N-N. In each magnetic interaction zone 15A and 15B, half of the opposing magnet pairs are coaxially aligned for mutual attraction and the other half are coaxially aligned for mutual repulsion. Thus, Fig. 6E depicts a dead zone that is centered at the 180° BDC relative reciprocation position of the magnet carriers 4, 8 and 12. As can be seen, this dead zone is approximately 90° wide.
Fig. 6F shows the magnet carriers 4, 8 and 12 in a 225° relative rotation/reciprocation position. In this position, the relative rotation of the magnet carriers 4, 8 and 12 is half way between the midpoints of dead zone and power zone rotational positions. The magnet carriers 4, 8 and 12 are thus in a transition zone wherein the magnetic forces are changing from the substantially net zero condition of a dead zone to the full magnetic force condition of a power zone.

Fig. 6G shows the magnet carriers 4, 8 and 12 in a 270° relative rotation/reciprocation position. In this position, the magnetic interactions in the first magnetic interaction zone 15A are S-N, N-S, N-S and S-N. All of the opposing magnet pairs in this magnetic interaction zone are coaxially aligned with opposite polarities so that the first magnet carrier 4 and the intermediate magnet carrier 12 attract each other with maximum pull force. The magnetic interactions in the second magnetic interaction zone 15B are N-N, S-S, S-S and N-N. All of the opposing magnet pairs in this magnetic interaction zone are coaxially aligned with like polarities so that the second magnet carrier 8 and the intermediate magnet carrier 12 repel each other with maximum push force. Fig. 6G therefore depicts a power zone that is centred at the 270° relative reciprocation position of the magnet carriers 4, 8 and 12. As can be seen, this power zone is approximately 90° wide.

Fig. 6H shows the magnet carriers 4, 8 and 12 in a 315° relative rotation/reciprocation position. In this position, the relative rotation of the magnet carriers 4, 8 and 12 is half way between the mid-points of dead zone and power zone rotational positions. The magnet carriers 4, 8 and 12 are thus in a transition zone wherein the magnetic forces are changing from the full magnetic force condition of a power zone to the substantially net zero condition of a dead zone.
Turning now to Fig. 7, the magnetic drive apparatus 2 is shown in an example construction 2A wherein the intermediate magnet carrier 12 is adapted for rotation and reciprocation while the first and second magnet carriers 4 and 6 are adapted to remain fixed against rotation and reciprocation. In the magnetic drive apparatus construction 2A, a main shaft 16 is arranged to extend through central bores 4D, 8D and 12D that are respectively formed in the magnet carriers 4, 8 and 12. The main shaft 16 is substantially straight and has a central longitudinal axis 18 that is substantially parallel to the longitudinal axes (and magnetic field axes) of the magnets 6A, 10A and 14A.

The main shaft 16 is arranged for simultaneous rotation and reciprocation. A first end portion 20 of the main shaft 16 is adapted for operative coupling to an input component 21, shown diagrammatically in Fig. 7, that rotatably drives the main shaft. For example, as described in more detail below in connection with Figs.8-12B, the input component 21 may be provided by a rotary drive motor. A second end portion 22 of the shaft 16 is adapted for operative coupling to an output component that is driven by reciprocation of the main shaft 18. In Fig. 7, an example rotary output component 23, which may be implemented as a crankshaft, is shown diagrammatically. Alternatively, a reciprocating output component, such as a pneumatic or hydraulic piston, could be arranged to be driven by reciprocation of the main shaft 18. The addition of the input and output components 21 and 23 to the magnetic drive apparatus construction 2A forms a magnetic drive torque converter apparatus that converts an input torque applied by the input component to an output torque delivered by the output component 23.

The main shaft 16 is rotatably coupled to the central opening 12D of the intermediate magnet carrier 12, but is free to rotate within the central openings 4D and 8D of the first and second magnet carriers 4 and 8. The rotatably coupled intermediate magnet carrier 12 rotates with the main shaft 16 but the non-rotatably coupled first and second magnet carriers 4 and 8 will not rotate, and will preferably be fixed against rotation. In this way, rotation of the main shaft 16 about its longitudinal axis 18 by the input component 21 will produce relative rotation between the intermediate magnet carrier 12 and the first and second magnet carriers 4 and 8. The main shaft 16 is also axially coupled to the central opening 12D of the intermediate magnet carrier 12, but is free to reciprocate through the central openings 4D and 8D of the first and second magnet carriers 4 and 8. The axially coupled intermediate magnet carrier 12 reciprocates with the main shaft 16 but the non-axially coupled first and second magnet carriers 4 and 8 will not reciprocate, and will preferably be fixed against reciprocation. In this way, reciprocation of the main shaft 16 along its longitudinal axis 18 will produce relative reciprocation between the intermediate magnet carrier 12 and the first and second magnet carriers 4 and 8 in first and second stroke directions.
Turning now to Figs. 8-12B, the magnetic drive apparatus 2 is shown in a further example construction 2B that uses the rotating/reciprocating main shaft arrangement described in connection with the example construction 2A of Fig. 7. As in the case of Fig. 7, Figs. 8-12B depict a magnetic drive torque converter apparatus because the magnetic drive apparatus construction 2B is coupled to input and output components, namely, an input motor 36 and a crankshaft assembly 40 (both of which are described in more detail below). In the magnetic drive apparatus construction 2B, the intermediate magnet carrier 12 is again rotatably and axially coupled to the main shaft 16 while the first and second magnet carriers 4 and 8 are not coupled to the main shaft in any way. As shown in Figs. 10A-10C, the first and second magnet carriers 4 and 8 are of larger diameter than the intermediate magnet carrier 12. This allows the magnet carriers 4 and 8 to be conveniently secured to a support frame assembly 24 (see Fig. 8) that holds and positions the first and second magnet carriers at a desired spacing. The support frame assembly 24 also carries the main shaft 16.

The support frame assembly 24 is constructed with a set of four longitudinal spool assemblies 26 that interconnect the first and second magnet carriers 4 and 8, but not the intermediate magnet carrier 12. The spool assemblies 26 also mount a set of stabilising plates 28, 30 and 32 that are oriented substantially parallel to the magnet carriers 4 and 8. As shown in Figs. 10A and 10C-10E, each spool assembly 26 may include an elongated rod 26A that extends through corresponding apertures formed in the magnet carriers 4 and 8, and in the stabilising plates 28, 30 and 32. Each spool assembly 26 may also include a set of spacers 26B that mount on the elongated rod 26A between each pair of adjacent magnet carriers and/or stabilising plates in order to properly space these components. As can be seen in Figs. 8 and 9, each spool assembly 26 is shown to have four spacers 26B, one between the stabilising plate 28 and the first magnet carrier 4, the second between the first magnet carrier 4 and the second magnet carrier 8, the third between the second magnet carrier 8 and the stabilising plate 30, and the fourth between the stabilising plate 30 and the stabilising plate 32. The ends of the elongated rods 26A are threaded to receive retaining members 26C that secure the support frame 24 together. It will be appreciated that other arrangements for spacing the various magnet carriers and stabilising plates may also be used, such as separate spacing rods connected between each pair of spaced components.
As best shown in Fig. 11, the stabilising plate 28 is located adjacent to the first magnet carrier 4 and is used to support the main shaft 16 proximate to its first end portion 20. In particular, stabilising plate 28 carries an input coupling assembly 34 on one side of a central opening 28A which accommodates the main shaft 16. The input coupling assembly 34 is internally configured to support the main shaft 16 for low friction reciprocating motion while imparting rotational forces to it. The motor 36 is connected to the input coupling assembly 34 to serve as a rotary input component which rotates the main shaft 16 during operation of the magnetic drive apparatus 2. The stabilising plate 30 is located adjacent to the second magnet carrier 8 and is used to support the main shaft 16 near its second end 22. In particular, stabilising plate 30 has a central opening 30A which supports a ball bearing assembly 38 to rotatably support the main shaft 16. The stabilising plate 32 is located adjacent to stabilising plate 30. It has a large central opening 32A which accommodates the main shaft 16, as well as components of the crankshaft assembly 40, which is mounted on the outside of stabilising plate 32. The crankshaft assembly 40 serves as a rotary output component that is driven by reciprocation of the main shaft 16 during operation of the magnetic drive apparatus construction 2B.

As best shown in Figs. 8, 9 and 11, each of the magnet carriers 4, 8 and 12 includes a respective pair of magnet retainer plates 42, 44 and 46 in order to secure their respective magnets 6A, 10A and 14A in position. The magnet retainer plates 42, 44 and 46 may be formed from any material that does not adversely affect the magnetic interactions between the magnets 6A, 10A and 14A. They may be respectively secured to the magnet carriers 4, 8 and 12 using any suitable mounting technique, such as with counter-sunk machine screws 48, as shown in Figs. 10A, 10B and 10C.

As can be seen in Fig. 11, the central bore 12D of the intermediate magnet carrier 12 is fixed on the main shaft 16 for rotation and reciprocation with it, for example, using a keyed shaft coupling arrangement (not shown). As also shown in Fig. 11, the central bores 4D and 8D of the first and second magnet carriers 4 and 8 are spaced from the main shaft 16 so that the main shaft is free to rotate and reciprocate relative to the first and second magnet carriers.

As can be seen in Figs. 8, 9 and 11, the support plates 28 and 32 may include mounting members 50 for securing the support frame 24 to a support surface (not shown). The input motor 36 may likewise include mounting members 52 for securing the motor a support surface (not shown). The input motor 36 may be operatively connected to the input coupling assembly 34 in any suitable manner, such as by using a flanged coupling connection 54. The input coupling assembly 34 includes a base housing 56 that may be bolted or otherwise fixed to the outside of the support plate 28. As shown in Fig. 11, the input coupling assembly 34 further includes a ball-spline unit 58 whose outside diameter is rotatably connected to the base housing 56 via a ball bearing assembly 60. The inside diameter of the ball-spline unit 58 includes plural longitudinal rows of ball bearing elements 62 arranged to engage corresponding longitudinal splines 64 that may be formed proximate to the first end portion 20 of the main shaft 16. The ball bearing elements 62 impart rotational forces to the main shaft 16 while allowing the shaft to reciprocate back and forth with minimal friction. A flanged cover tube 66 mounts to the end face of the ball-spline assembly 58, and is used to carry one side of the flanged coupling connection 54. The other side of the flanged coupling connection attaches to the output shaft of the motor 36. The cover tube 66 is long enough to accommodate the reciprocating movement of the first end portion 20 of the main shaft 16 in it.
With continuing reference to Figs.8, 9 and 11, the crankshaft assembly 40 may be configured with a pair of crankshaft support plates 68 that are carried by the stabilising plate 32. The crankshaft support plates 68 are provided with main bearings (not shown) that rotatably carry a crankshaft 70. The crankshaft 70 includes a pair of counter weight/crank arm members 72. As shown in Fig.9, a central portion of each counter weight/crank arm member 72 has an outwardly extending main journal 73 that is rotatably mounted to the main bearing of one of the crankshaft support plates 68. As additionally shown in Fig.9, and also in Fig.11, the crank arm end of each counter weight/crank arm member 72 supports one end of a connecting rod journal 74. The connecting rod journal 74 is attached to one end of a connecting rod 76 via a suitable bearing arrangement.

The other end of the connecting rod 76 is rotatably attached to a main shaft coupling assembly 78 via a clevis connection. As additionally shown in Figs.12A and 12B, the coupling assembly 78 is rotatably mounted to the second end portion 22 of the main shaft 16 so that the main shaft is free to rotate relative to the coupling assembly. The coupling assembly 78 may be configured with a tubular housing 80 into which is inserted a suitable bearing 82 (e.g., a flanged oilite bearing) that receives the second end portion 22 of the main shaft 16. A bolt 84 (Fig.11) that threads on to reduced diameter post at the main shaft second end portion 22 may be used to retain the coupling assembly 78 on the main shaft 16 during reciprocation of the main shaft. The coupling assembly 78 includes a clevis 86 which is pinned to the connecting rod 76 with a bushed clevis bolt arrangement 88. It will be seen from Figs.11, 12A and 12B that the coupling assembly 78 will allow free rotation of the main shaft 16 at its second end portion 22 due to the bearing 82. At the same time, the coupling assembly 78 will transmit the reciprocal motion of the main shaft 16 in its first and second stroke directions through the connecting rod 76 to the crankshaft 70, thereby causing the crankshaft to rotate. As can be seen in Fig.9, an output end 82 of the crankshaft 70 may be connected to a desired output load (not shown).

As previously noted, in a prototype implementation of the magnetic drive torque converter apparatus shown in Figs.8-12B, the four magnets 6A, 10A and 14A on each respective magnet carrier 4, 8 and 12 were implemented with 3 inch diameter, 1 inch thick, grade N52 neodymium disk magnets from K & J Magnetics, Inc. Each magnet 6A, 10A and 14A was axially magnetised and was rated by the manufacturer as producing a maximum push/pull force of approximately 360 pounds. The magnets 6A, 10A and 14A were arranged on their respective magnet carriers 4, 8 and 12 so that the magnet centres were 2.75 inches from the magnet carrier centres. The stroke length of the magnet carrier relative reciprocation was 5.5 inches. The crank arm length provided by the crank arm portion of counter weight/crank arm members 72 was 2.75 inches. The length of the connecting rod 76 was 10 inches. The magnet carriers 4, 8 and 12 were 1 inch thick and the magnet retainers 42, 44 and 46 were 0.25 inches thick. At the end of each stroke, the separation gap between the closest together set of opposing magnet retainers (i.e., 42/44 or 46/44) was 0.625 inches, so that the minimum spacing between opposing magnets (pole face to pole face) was 0.625+(2*0.25) = 1.125 inches. At mid-stroke, the separation gap between each set of opposing magnet retainers (i.e., 42/44 and 46/44) was 3.375 inches, so that the maximum spacing between opposing magnets (pole face to pole face) was 3.375+(2*0.25) = 3.875 inches.

The magnetic drive torque converter apparatus shown in Figs.8-12B may be synchronised in any suitable manner so that rotation of the main shaft 16 is timed with respect to rotation of the crankshaft 70 (as driven by reciprocation of the main shaft). As shown in Figs.8 and 9, an example synchronisation device 90 may include a sensor 92 that monitors crankshaft position (e.g., a rotary encoder), and a signal-carrying feedback circuit 94 that provides a crankshaft position signal to a programmable servo controller 96 (e.g., implemented as a programmable digital device) that controls the input motor 36 (via a control circuit 97) according to the position signal. Any of various existing robotic servo controller systems may be used for this purpose. Other types of synchronisation device could also be used to synchronise operation of the illustrated magnetic drive torque converter apparatus, including but not limited to, a mechanical timing system that mechanically couples the input drive motor's rotary input to the crankshaft's rotary output.

The concept of synchronising a magnetic drive apparatus as disclosed here was discussed above. In the magnetic drive torque converter apparatus of Figs.8-12B, the servo controller 96 is programmed to control the main shaft's rotational position based on the angular position of the crankshaft 70, which corresponds via a definable mathematical relationship to the main shaft's reciprocation position (see discussion of Fig.5 above). As previously noted, the magnetic dead zones can be made to coincide with the main shaft 16 being near its top dead centre and bottom dead centre reciprocation positions, and so the magnetic power zones occur between these positions. As also noted, the servo controller 96 could also be programmed to synchronise rotation of the main shaft 16 so that the dead zones are dynamically advanced or retarded with respect to the top dead centre and bottom dead centre reciprocation positions, or to vary the position or size of the dead zones.

Figs.13A-13H illustrate the rotational and reciprocation positions of the intermediate magnet carrier 12 with respect to the first and second magnet carriers 4 and 8 during two reciprocal strokes of the illustrated magnetic drive torque converter apparatus. In these figures, the main shaft 16 is synchronised by the servo controller 96 so that the two dead zones are centred at the 0° and 180° reciprocation positions of the main shaft, and so that the
power zones are centred at the 90° and 270° reciprocation positions. Figs.13A-13H thus correspond to the timing arrangement shown in Figs.6A-6H, respectively. Each dead zone and each power zone is approximately 90° wide.

Fig.13A shows the intermediate magnet carrier 12 at the 0° TDC reciprocation position and in the middle of a first dead zone. Fig.13B shows the 45° reciprocation position of the intermediate magnet carrier 12 where the intermediate magnet carrier is transitioning out of the first dead zone and into a first power zone. Fig.13C shows the 90° reciprocation position of the intermediate magnet 12 where the intermediate magnet carrier is in the middle of the first power zone. Fig.13D shows the 135° reciprocation position of the intermediate magnet carrier 12 where the intermediate magnet carrier is transitioning out of the first power zone and into a second dead zone. Fig.13E shows the 180° BDC reciprocation position of the intermediate magnet carrier 12 where the intermediate magnet carrier is in the middle of the second dead zone. Fig.13F shows the 225° reciprocation position of the intermediate magnet carrier 12 where the intermediate magnet carrier is transitioning out of the second dead zone and into a second power zone. Fig.13G shows the 270° reciprocation position of the intermediate magnet 12 where the intermediate magnet carrier is in the middle of the second power zone. Fig.13H shows the 315° reciprocation position of the intermediate magnet carrier 12 where the intermediate magnet carrier is transitioning out of the second power zone and returning to the first dead zone.

Fig.14 illustrates a further magnetic drive apparatus construction 2C where magnet carrier spacing adjustment capability is provided. This construction is substantially similar to the construction 2B of Figs.8-12B, except that the position of the first and second magnet carriers 4 and 8 are dynamically adjustable during operation in order to change their spacing relative to the intermediate magnet carrier 12, and thereby adjust the strength of the magnetic interactions. To achieve this effect, the spool assemblies 26 can be modified by removing the spacing members 26B on each side of the first and second magnet carriers 4 and 8 to expose the threaded rods 26A. The first and second magnet carriers 4 and 8 may then be modified so that they receive the threaded rods 26A. Rotation of the threaded rods 26A will thus re-position the first and second magnet carriers 4 and 8 towards or away from the intermediate magnet carrier 12 (depending on the direction of rod rotation). If needed, additional spacing members (not shown) may be added to maintain the positions of the stabilizing plates 28, 30 and 32 relative to each other. Rod rotation members, such as pulleys 98, may be mounted to one end of each threaded rod 26A. The rod rotation members may be driven by a suitable drive mechanism. For example, if the pulleys 98 are used, the drive mechanism may include a drive motor 100 coupled to the pulleys 98, such as by way of a drive belt 102. The drive motor 100 may be connected to a suitable control system (not shown) that adjusts the positioning of the first and second magnet carriers 4 and 8 whenever it is desired to relax the magnetic interaction forces, such as at start-up time.
Although each of the magnetic drive apparatus embodiments discussed above are based on permanent magnet arrangements with four magnets each, other magnet arrangements would also be possible. Examples include, but are not limited to, magnet arrangements comprising eight magnets, twelve magnets, sixteen magnets, twenty magnets, twenty-four magnets, etc. Like the illustrated four-magnet arrangements, these alternative magnet arrangements may be configured as a symmetrical magnet pattern that defines a polygonal shape corresponding to the number of magnets in each arrangement. Magnet arrangements having two (or more) polygonal magnet patterns in a nested relationship would also be possible. On each magnet carrier side, the magnet pattern may comprise n-magnet groupings with n adjacent magnetic poles of like polarity in each grouping. In this way, magnet carrier relative rotation will produce changing magnetic interactions each time the opposing magnetic poles are rotatably advanced into mutual coaxial alignment. As in the case of the previously-described four-magnet arrangements, there will be magnet carrier relative rotation positions wherein all opposing magnetic poles in the magnetic interaction zone between any two opposing magnet carriers are coaxially aligned in either NN or NS relationships. In other magnet carrier relative rotation positions, the opposing magnetic poles in the magnetic interaction zone between any two opposing magnet carriers will be coaxially aligned in both NN and NS relationships, with the number of NN and NS relationships being equal. In general, it is expected that these characteristic will be produced by any magnet arrangement having an even number of magnets, an equal number of N and S poles on any given magnet carrier side, and wherein the N and S poles are arranged in magnet groupings having an even number of adjacent magnets of like-polarity.

Although the magnetic drive apparatus constructions disclosed thus far have three magnet carriers 4, 8 and 12 arranged to form dual magnetic interaction zones 15A and 15B, other constructions would also be possible. For example, a magnetic drive apparatus in accordance with the present disclosure may be constructed with two opposing magnet carriers arranged to form a single magnetic interaction zone. As in the previous constructions, the opposing magnet arrangements are configured to produce magnetic interactions when the opposing magnet carriers undergo relative rotation.

FIGS. 15-18 illustrate an example magnetic drive apparatus construction 2D representing a single-magnetic interaction zone embodiment that uses two magnet carriers. In the magnetic drive apparatus construction 2D, there is only the first magnet carrier 4 and the intermediate magnet carrier 12 providing a single magnetic interaction zone 15A. The second magnet carrier 8 and the second magnetic interaction zone 15B are not present. The magnetic interactions in the magnetic interaction zone 15A during relative rotation of the opposing magnet carriers 4 and 12 (see arrows “A” and “B”) produce power stroke forces that cause the magnet carriers to undergo relative reciprocation in first and second stroke directions during power zone portions of the relative rotation.

The power zones are illustrated in Figs.15 and 16, and are characterised by opposing magnetic poles of the opposing magnet arrangements 6 and 14 being mutually coaxially aligned and producing maximum push or pull magnetic forces. In particular, Fig.15 shows a first power zone where the magnet carriers 4 and 12 are repelled away from each other (see arrows “D”), and Fig.16 shows a second power zone where the magnet carriers are attracted toward each other (see arrows “E”). The magnetic interactions produce substantially no power stroke forces during dead zone portions of the relative rotation. The dead zone positions are exemplified in Figs.17 and 18, and are characterised by opposing magnetic poles of the opposing magnet arrangements 6 and 14 being mutually coaxially aligned but producing a substantially equal balance of push and pull magnetic forces. As in the previous embodiments, relative rotation and reciprocation may be synchronised so that the dead zones coincide with top dead centre and bottom dead centre relative reciprocation positions of the magnet carriers 4 and 12, and so that the power zones occur when the magnetic drive apparatus is between the top dead centre and bottom dead centre relative reciprocation positions. Likewise, the relative rotation and reciprocation could be synchronized so that said dead zones are dynamically adjustable in position or size.
It will be appreciated that additional magnetic drive apparatus constructions may be implemented using multiple sets of magnet carriers. One example configuration is shown by the magnetic drive apparatus construction 2E of Fig.19. The magnetic drive apparatus construction 2E is based on the magnetic drive apparatus construction 2A of Fig.7, except that there are two sets of magnet carriers, each comprising the first, second and intermediate magnet carriers 4, 8 and 12, mounted on the main shaft 16. As in the magnetic drive apparatus construction 2A, an input drive component 21 is coupled to the first end portion 20 of the main shaft 16. The second end portion 22 of the main shaft 16 is operatively coupled to a single rotary output 23, such as a crankshaft.

FIG. 19

FIG. 20
**Fig. 20** shows another magnetic drive apparatus construction 2F that is also based on the magnetic drive apparatus construction 2A of **Fig. 7**, except that there are two main shafts 16, each with its own set of first, second and intermediate magnet carriers 4, 8 and 12. Each main shaft 16 has its own input drive component 21 coupled to the first shaft end portion 20. However, the second end portion 22 of each main shaft 16 is coupled to a single rotary output 23, such as a crankshaft.

It will be appreciated that the embodiments of **Figs. 19 and 20** could have any number of magnet carrier sets. As shown, each magnet carrier set could have three magnet carriers forming two magnetic interaction zones. Alternatively, some or all of the magnet sets could be based on the embodiment of **Figs. 15-18**, with two magnet carriers forming one magnetic interaction zone.

[www.free-energy-info.com](http://www.free-energy-info.com)
[www.free-energy-info.co.uk](http://www.free-energy-info.co.uk)
There are three categories of pulsed system and we will consider each in turn. These are drive-pulsed systems, energy-tapping pulsed systems and gravity free-energy pulsing systems. Here we will look at systems where an electrical pulse is used to cause the device to operate by creating a temporary magnetic field caused by electric current flowing through a coil or “electromagnet” as it is often called. Many of these systems are rather subtle in the way that they operate. One very well-known example of this is

**The Motor/Generator of Robert Adams.**
The late Robert Adams, an electrical engineer of New Zealand designed and built several varieties of electric motor using permanent magnets on the rotor and pulsed electromagnets on the frame of the motor (called the “stator” because it does not move). He found that if they were configured correctly, then the output from his motors exceeded their input power by a large margin (800%).

The diagram of his motor intended to show the basic operating principle is shown here:

If a motor is built like this, then it will most certainly work but it will never reach 100% efficiency let alone exceeding the 100% mark. It is only with a specific configuration which is hardly ever publicised that high performance figures can be achieved. While Robert has shown several different configurations, in order to avoid confusion I will describe and explain just one of them. I am indebted to several of Robert's friends and colleagues for the following information and I should like to express my thanks to them for their help and support in bringing you this information.

First and foremost, high performance can only be achieved with the clever use of power collection coils. These coils need to be positioned accurately and their power collection restricted to just a very short arc of operation by connecting them to, and disconnecting them from, the output circuit at just the right instant so that the back EMF generated when the current draw stops, actually contributes to the drive of the rotor, speeding it on it's way and raising the overall efficiency of the motor/generator as a whole.

Next, the shape of the magnets used is important as the length to width proportion of the magnet alters the pattern of it's magnetic fields. In direct opposition to the diagram shown above, the magnets need to be much longer than their width (or in the case of cylindrical magnets, much longer than their diameter).
Further, a good deal of experimentation has shown that the size and shape of the electromagnets and pick-up coils has a major influence on the performance. The cross-sectional area of the core of the pick-up coils should be four times that of the cross-sectional area of the permanent magnets in the rotor. The reverse is true for the cores of the drive coils as their cores should have a cross-sectional area of just one quarter of the rotor magnet cross-sectional area.

Another point which is almost never mentioned is the fact that big circuit gains will not be achieved unless the drive voltage is high. The minimum should be 48 volts but the higher the voltage, the greater the energy gain, so voltages in the 120 volts (rectified US mains voltage) to 230 volts (rectified mains voltage elsewhere) should be considered. Neodymium magnets are not recommended for drive voltages under 120 volts.

This is one of Robert's test circuits:

Notice that the cores of the "generator" pick-up coils are very much wider than the cores of the drive coils. Also notice the proportions of the magnets where the length is much greater than the width or diameter. The four generator windings are mounted on a single disc allowing them to be moved through an angle to find the optimum operating position before being locked in position and the two drive coils are mounted separately and held clear of the disc. Notice also that the power pick-up coils are much wider compared to their length than the drive coils are. This is a practical feature which is explained in greater detail later.

The DC input is shown passing through Robert's custom-made contactor switch which is mounted directly on the shaft of the motor/generator. This is a mechanical switch which allows an adjustable On / Off ratio, which is known as the "Mark/Space Ratio" or, if the "On" period is of particular interest, the "Duty Cycle". Robert Adams indicates that when the motor is running and has been adjusted to it's optimum performance, then the Mark/Space ratio should be adjusted to minimise the On period and ideally get it down to about 25% so that for three quarters of the time, the input power is actually switched off. There are various ways of achieving this switching while still having a very sharp turn on and turn off of the power.

Robert considered mechanical switching of the drive current to be a very good option although he was not opposed to using the contact to power a transistor to do the actual switching and so reduce the current through the mechanical contacts by a major factor. His reasons for his preference for mechanical switching are that it gives very sharp switching, needs no electrical power to make it operate and it allows current to flow in both
directions. The current flow in two directions is important because Robert produced various ways of getting the motor to feed current back into the driving battery, allowing it to drive the motor for long periods without lowering its voltage hardly at all. His preferred method of switching is shown here:

![Timing Gear - Top View](image1)

This switching gear operates as follows: The timing disk is bolted securely to the drive shaft of the motor and its position is set so that the electrical switch-on occurs when the rotor magnet is exactly aligned with the drive coil core. Adjustment of that timing is done by loosening the locking nut, rotating the disc very slightly and clamping the disc in position again. A spring washer is used to keep the assembly tight when the device is running. The disc has a star-shaped piece of copper sheet set into its surface and two silver-tipped, copper arm "brushes" slide across the surface of the copper star.

One of these two brushes is fixed in position and slides across the copper star near the drive shaft, making a permanent electrical connection to it. The second brush slides alternatively on the non-conducting surface of the disc and then over the conducting arm of the copper. The second brush is mounted so that its position can be adjusted and, because the copper arms taper, that alters the ratio of the "On" time to the "Off" time. The actual switching is achieved by current flowing through the first brush, through the copper arm and then through the second brush. The brush arms shown in the diagram above rely on the springiness of the copper arm to make a good brush-to-copper electrical connection. It might be preferred to use a rigid brush arm, pivot it and use a spring to ensure a very good contact between the brush and the copper star at all times.

The adjustment of the On to Off time, or "Mark/Space Ratio" or "Duty Cycle" as the technical people describe it, could perhaps do with some description. If the moveable brush is positioned near the centre of the disc, then,
because of the tapering of the copper arms, the part of the non-conducting disc that it slides over is shorter and
the part of the conducting copper arm with which it connects is longer, as the two sliding paths are about the
same length, the current is on for about the same length as it is off, giving a Mark/Space ratio of about 50% as
shown here:

![Diagram showing the Mark/Space ratio of about 50%](image1)

If, instead, the moveable brush is positioned near the outside edge of the disc, then because of the tapering of the
copper arm, the On path is shorter and the non-conducting Off path is very much longer, being about three times
as long as the On path, giving a Mark/Space ratio of about 25%. As the moveable brush can be positioned
anywhere between these two extremes, the Mark/Space ratio can be set to any value from 25% to 50%.

![Diagram showing the Mark/Space ratio of about 25%](image2)

The two brushes can be on the same side of the drive shaft or on opposite sides as shown. One important
feature is that the brushes touch in a position where the disc surface is always moving directly away from the
brush mounting, causing any drag to be directly along the arm and giving no sideways loading on the brush. The
diameter of the device is usually one inch (25 mm) or less.

You will also notice that the output is switched although the diagram does not give any indication of how or when
that switching takes place. You will notice that the diagram has angles marked on it for the optimum positioning of
the pick-up coils, well, an Adams Motor builder with a forum ID of "Maimariati" who achieved a Coefficient Of
Performance of 1,223, found that the optimum switching for his motor is On at 42 degrees and Off at 44.7
degrees. That tiny 2.7 degree part of the rotor turn gives a substantial power output and cutting the output current
off at that point causes the back EMF of the coils to give the rotor a substantial additional boost on its way. His
input power is 27.6 watts and the output power is 33.78 kilowatts

Now for some practical details. It is suggested that a good length for the power pick-up coils can be determined
by using the “paper clip test”. This is done by taking one of the permanent magnets used in the rotor, and
measuring the distance at which that magnet just begins to lift one end of a 32 mm (1.25 inch) paper clip off the
table. The optimum length of each coil from end to end is exactly the same as the distance at which the paper
clip starts to lift.
The core material used in the electromagnets can be of various different types including advanced materials and alloys such as 'Somalloy' or 'Metglas'. The power pick-up coil proportions are important as an electromagnet becomes less and less effective as its length increases, and eventually, the part furthest from the active end can actually be a hindrance to the effective operation. A good coil shape is one which you would not expect, with the coil width being, perhaps 50% greater than the coil length:

Contrary to what you would expect, the device draws in energy from the local environment better if the end of the pick-up coil farthest from the rotor is left unaffected by any other part of the device and the same applies to the magnet facing it. That is, the coil should have the rotor at one end and nothing at the other end, that is, no second rotor behind the coil. The speed at which the voltage is applied to, and removed from, the coils is very important. With very sharp voltage rises and falls, additional energy is drawn from the surrounding environmental energy field. If using transistor switching, then the IRF3205 FET has been found to be very good and a suitable driver for the FET is the MC34151.

If using a Hall-effect semiconductor to synchronise the timing, say the UGN3503U which is very reliable, then the life of the Hall-effect device is much improved if it is provided with a 470 ohm resistor between it and the positive supply line, and a similar 470 ohm resistor between it and the negative line. These resistors in series with the Hall-effect device effectively “float” it and protect it from supply-line spikes.

Here, two electromagnets are driven by the battery via Robert's 4-arm commutator which is mounted on the rotor shaft. Some of the recommendations given by Robert are the opposite of what you would expect. For example, he says that a single rotor construction tends to be more electrically efficient than one where several rotors are mounted on a single shaft. Robert is against the use of reed switches and he recommends making one of his commutators.

At one stage, Robert recommended the use of standard transformer shims for constructing the cores of the electromagnets. This has the advantage that matching bobbins for holding the coil windings are readily available and can still be used for pick-up coils. Later on, Robert swung towards the use of solid cores from the old PO Series 3000 telephone relays and eventually said that electromagnet cores should be solid iron.
The diagrams presented by Robert show the magnets located on the rim of the rotor and pointing outwards. If this is done, then it is essential that the magnets in the rotor are firmly attached on at least five of their six faces and the possibility of using a ring of non magnetic material such as duct tape around the outside should be considered. That style of construction also lends itself to streamlining the rotor by having a completely solid construction, although it might be remarked that the motor would run better and more quietly if it were enclosed in a box which had the air pumped out of it. If that is done, then there will be no air resistance and because sound can't pass through a vacuum, quieter operation is bound to result.

While this may sound a bit complicated, there is no reason why it should be. All that is needed is two discs and one central disc which is the thickness of the magnets, with slots cut in it, the exact size of the magnets. The assembly starts with the lower disc, magnets and central disc. These are glued together, probably with epoxy resin, and that holds the magnets securely on four faces as shown here:

Here, the magnets are attached on the lower face, the right and left faces, and the unused pole face, and when the upper disc is attached, the upper faces are also secured and there is the minimum of air turbulence when the rotor spins:
There is a "sweet spot" for the positioning of the power pick-up coils and it will usually be found that this is two or three millimetres away from the rotor. If that is the case, then there will be room for an outer band of duct tape on the rim of the rotor to provide additional protection against the failure of the magnet attachment method.

High-power versions of the motor/generator need to be enclosed in a metal box which is earthed as they are quite capable of generating a substantial amount of high frequency waves which can damage equipment such as oscilloscopes and create TV reception interference. There would probably be an improvement in performance as well as a reduction in sound if the box was airtight and had the air pumped out of it. If that is done, then there will be no air resistance as the rotor spins and since sound does not pass through a vacuum, quieter operation is possible.

Experienced rotor builders do not like the radial magnets style of construction because of the stresses on the magnet attachments if high rotational speeds are reached. It should not need to be said, but it is obviously a major requirement to keep your hands well away from the rotor when the motor is running as it is perfectly possible to be injured by the high-speed movement if you are careless. Please remember that this presentation must not be considered to be a recommendation that you build or use any device of this nature and it must be stressed that this text, in common with the entire contents of this eBook, is intended to be for information purposes only and no representations or warranties are implied by this presentation. Should you decide to construct, test or use any device, then you do so entirely at your own risk and no liability attaches to anybody else if you sustain any kind of injury or property damage as a result of your own actions.

Because of the mechanical stresses caused during rotation, some experienced constructors feel that the magnets should be embedded in the rotor as shown here where they are kept well clear of the rim of a rotor which is made from a tough material. This is so that the outer strip of the material prevents the magnets breaking loose and becoming dangerous high-speed projectiles, which at best would destroy the electromagnets and at worst could injure someone quite badly:

It needs to be remembered that the proportions of the magnets are for the magnet length to be more than the diameter, so in cases like this where circular magnet faces are to be used, the magnets will be cylindrical and the rotor needs to have a significant thickness, which will depend on the magnets which are available locally. The magnets should be a tight push-fit in their holes and securely glued in place.
Robert Adams has used this construction style as well. However, if an arrangement like this is used, then there will be a substantial sideways pull on the rotor as it reaches the electromagnet core, tending to pull the magnets out of the rotor.

It is important that the rotor should be perfectly balanced and have the minimum amount of bearing friction possible. This calls for precision construction and either roller or ball bearings. The construction style shown above has the distinct advantage that it has an open end to both the magnet and the coils and this is believed to facilitate the inflow of environmental energy into the device.

It may be my ignorance showing here, but I have a problem with this version. The difficulty as I see it is that the magnet/core pull and the subsequent drive thrust when the coil is powered, form a "turning couple" as they both try to rotate the axle in the same direction. This places a substantial loading on the axle bearings, usually amplified by the radius of the rotor being greater than the distance from the rotor to the axle bearings. This load will be in the tens of kilograms range and will be applied and reversed perhaps forty times per second. To me, that appears like a vibration load and is directly opposed to the "perfectly balanced" rotor operation being sought. The radial magnet arrangement generally shown by Robert Adams does not have any of this kind of loading at all because the coils are exactly opposite each other and their loads cancel each other out exactly. The choice is, of course, up to the builder and his assessment of the advantages and disadvantages of the different styles of construction.

Robert Adams has produced some additional notes on his motor/generator design:

THE 1996 ADDENDUM TO THE ADAMS MOTOR MANUAL
By Dr. Robert G. Adams, New Zealand.

Once construction of an Adams Motor Generator is completed and successful running has been attained, should the reader desire to carry out an efficiency analysis, he should use conventional measuring instruments AS A GUIDE ONLY. At this point I refer the reader to reading the section entitled 'Established Methods of Testing Electric Motor and Transformer Efficiency' and other relevant information in this update. On reading this section, it will become clear to the reader that establishment teaching of THERMODYNAMICS and testing procedures using the conventional measuring instrumentation DO NOT COMPUTE WITH THE TRUTH, with either conventional motors or the Adams Motor.

The question is - 'how can any electrical device claim to operate around the order of 70 - 90% efficiency and yet require a cooling facility, whether it be a motor or a transformer, without which the device would disintegrate?'

If an Adams motor can operate on load alongside a conventional motor of the same rating and, load for load, at a temperature of less than half that of the conventional machine with a claimed efficiency rating of 70 - 90%, then the Adams device will be operating around the order of 3 times that of the conventional motor, and it is, in
addition, not required to **radiate wasted energy** with a cooling fan.

The correct method in testing a switched reluctance motor is to integrate $E \times I_{av}$ with the machine switching frequency using standard measuring instruments, the result of which is often ironically very close, if not identical, with results of the calorimetric tests, and this is obtained using the equation first outlined in the Adams Motor Manual, i.e., $I_{av} \times E \times \text{Duty Cycle}$, corroborated by the New Zealand Electricity Department 1976 and Lucas Electrical Industries, Research Division, United Kingdom 1976.

If you construct an Adams Motor which appears to be running well and is operating under load without getting hot, i.e., around the order of 20 - 15 degrees or less above ambient of 20 degrees, then it will, if calculations are carried out correctly, be operating beyond unity.

Calorimetric testing analyses, as outlined in this Addendum, is an expensive, time-consuming exercise, is complex to calculate and requires considerable experience and skill. This procedure is not recommended to those who are not very, very well prepared with the above prerequisites.

**NEW SCIENCE**

THE ADAMS SUPER-POWER MULTI-POLAR MAGNET

I have for many years, theorised the existence of four poles interacting in any magnet. There is little doubt that two poles dominate from what is observed, and taught, in classical texts.

However, since my discovery of engineering magnets into forming four poles - and, in so doing, quadrupling the energy - surely some light has been shed on the theory of the existence of four poles. Bruce Cathie and I will investigate this further when time permits.

A rectangular or cube magnet, when engineered into the Adams technology, becomes a unit consisting of four twin poles, each face containing a north and a south pole, separated by a zero vortex in the centre of each of the four twin poles, and all displaying similar energies.

Ironically, but not unexpectedly, this super twin-pole magnet is a very valuable adjunct to further advancement of the Adams Motor technology. The energy found on the edges of each of the four faces is very high-25 per cent of the total energy of the full face.

The present lab magnets are approximately three-quarters-of-an-inch cube. The edge of any face will hold a five-kilogram steel or iron block in mid-air. When the full face of the magnet is attached to metal, a force of beyond 20 kg is required to remove it. In my presentation to the NEXUS Conference, I advised tests would be carried out this month to determine the load required to remove the magnet.

The dice-sized magnet was attached to a steel plate on a ceiling rafter and, with the aid of a chain, a 15-kilogram block was first attached to it; then a 4.7-kg block added on with a nylon rope; then another 200-gram block was attached; then, a fourth 200-gram block. The magnet still hanging fast, a 100-gram block was added; then...wait for it...CRASH to the floor. The magnet was still attached to its anchor on the roof-rafter!

A magnet, approximately three-quarters-of-an-inch cube, weighing only 60 grams. capable of holding a weight of beyond 20 kilograms in mid-air. 333.333 times its own weight? Will this at last have something of an effect on the closed ignorant minds of conventional science?

The way now must surely be clear that space/gravity energy via electromagnetic forces of permanent magnets is not impossible nor difficult to harness. The space/gravity energies are clean, non-exhaustible and free. The Adams technology has proved this and leaves no grounds for dispute.

Einstein's sacrosanct theories of relativity, and the laws of thermodynamics, are the most remarkable and inexplicable aberrations ever recorded in scientific history. These draconian false teachings have been instrumental in impeding the process of science towards free, clean energy.

**CLASSICAL THEORY AND ADAMS TECHNOLOGY**

The classical theory of magnetism from the textbooks attributes the phenomenon to the motion of electrons within the atoms of molecules. There is evidence that the orbital electrons in an atom not only revolve about the nucleus of the atom, but also each individual electron spins about an axis through its centre. It is believed that in highly
magnetic materials, each atom has many more electrons spinning in one direction than in another.

In the sub-microscopic region, i.e., the "domain", many of these atoms with electron spin in one direction create a magnetic field which effectively supplements the field engendered by the revolving electrons. Each domain thus becomes a tiny magnet. When the domains are in random state, the substance as a whole is not a magnet. The application of an external magnetic field will reorient the domains and produce a magnet in the way described above.

When the application of an external magnetic force has been applied and all the domains have been aligned, the condition of MAGNETIC SATURATION has been reached, and any further increase in strength of the external force field will not increase the magnetisation any further. With the advent of the Adams Permanent Magnet Technology, is it not further evidence that conventional text teachings have reached the stage when they should be rewritten?

From the observations of certain lab experiments with ball-bearings, it is the opinion of the discoverer that the elections circulate in conjugate pairs and have a spin opposite to that of rotation, and that the spin is four times greater than that of the orbital rotation. I note also that conventional texts prefer not to state direction of spin, nor velocity relative to orbital motion.

I do not therefore subscribe to the statement that "in highly magnetic materials, each atom has many more electrons spinning in one direction than in another I feel such a condition cannot pertain in light of my discoveries.

Also to be addressed is the matter of the massive energy increase resulting from the Adams applied technology. Are man-made scientific laws once again violated? If the magnetic material is saturated when subjected to an external energy source, the Adams technology must then be gating space/gravity energy.

There is overwhelming evidence that space/gravity energy can be concentrated, focused and/or magnified by permanent magnets.

PERMANENT MAGNETS AND EFFICIENCY

THIS REPORT REFERS TO AN INHERENT CHARACTERISTIC OF PERMANENT MAGNETS DISCOVERED SOME 19 YEARS AGO, BY ROBERT ADAMS OF NEW ZEALAND AND RECENTLY VALIDATED:

A LENGTHY AND IN DEPTH PROGRAMME OF THE TESTING OF MANY MAGNETS OF DIFFERENT ENERGY PRODUCT AND COMPOSITIONS IN ADAMS MOTORS HAS NOW BEEN COMPLETED.

AS I AM COLLABORATING WITH DR. HAROLD ASPDEN OF THE UNITED KINGDOM IN THE ABOVE AND OTHER MATTERS, BOTH DR. ASPDEN AND MYSELF HAVE DECIDED THAT IT IS NOW THE APPROPRIATE TIME TO BRING THIS NEWS REPORT INTO THE NEXUS READERSHIP ARENA, SINCE OUR COLLECTIVE FINDINGS OF THE EXTENSIVE TEST ANALYSES, CARRIED OUT IN THE MOST RECENT PERIOD, HAVE CONCURRED.

IN ADDITION TO THE ABOVEMENTIONED, I WAS, EARLIER THIS YEAR, COMMISSIONED BY A JAPANESE CORPORATION TO BUILD AN ADAMS MOTOR INCORPORATING THEIR Y.T. SUPER MAGNETS, WITH THEIR VIEW TO INCREASING THE EFFICIENCY OF THE ADAMS MOTOR. THIS PROGRAMME WAS DULY CARRIED OUT. THE RESULTS WERE AS I HAD PREDICTED, I.E., THERE WAS NO INCREASE IN EXCESS ENERGY FOUND.

THIS REPORT IS IMPORTANT FROM TWO DIFFERENT ASPECTS. FIRSTLY, IT PUTS TO REST ERRONEOUS CLAIMS BY CERTAIN INVENTORS, ENGINEERS AND SCIENTISTS ALIKE THAT POWERFUL MAGNETS BUILT INTO ELECTRIC MOTORS WILL YIELD VERY HIGH EFFICIENCY OR BEYOND UNITY. THIS NOTION IS NOTHING MORE THAN AN ASSUMPTION ADOPTED LETHARGICALLY OVER THE YEARS. SECONDLY, IT WILL SAVE A LOT OF PEOPLE OUT THERE A LOT OF TIME AND DISAPPOINTMENT IN PURSUITING HIGH EFFICIENCY FROM MAGNETS OF HIGH ENERGY PRODUCT AS CLAIMED POSSIBLE BY
CERTAIN PEOPLE. I WOULD REFER THE READER, AT THIS POINT, TO MY PAPER PUBLISHED IN NEXUS MAGAZINE, APRIL - MAY 1993 ISSUE, PAGE 47.

RULE NO. 1: NO MAGNET, IRRESPECTIVE OF IT’S INHERENT ENERGY COUNT CAN, IN ANY WAY, GOVERN THE EFFICIENCY RESULTS OF AN ELECTRIC MOTOR.

RULE NO. 2: INPUT POWER REQUIREMENT CLIMBS IN PROPORTION TO THE ENERGY PRODUCT OF THE MAGNET/S USED, WHICH AUTOMATICALLY CANCELS OUT ANY POSSIBILITY OF INCREASE IN EFFICIENCY. FOR GREATER EFFICIENCY ONE MUST PURSUE THE IMPROVEMENT OF OTHER IMPORTANT LOGICAL FACTORS, I.E., MACHINE DESIGN, ETC.

NOTE: THE LAWS OF THE PERMANENT MAGNET, LIKE THE LAWS OF THE UNIVERSE, POINT TO CERTAIN CONSTANT INHERENT CHARACTERISTICS, ONE OF WHICH DEMONSTRATES THAT EFFICIENCY REMAINS CONSTANT WHEN MAGNETS ARE EMBRACED IN A MAN-MADE DEVICE, IRRESPECTIVE OF THE MAGNET ENERGY PRODUCT.

FOR SUCCESSFUL HIGH EFFICIENCY RESULTS IT IS SUGGESTED THAT ONE BRUSHES ASIDE THE IMPORTANCE OF MAGNETS IN RELATION TO EFFICIENCY AND CONCENTRATES ON MATERIALS, ELECTRICAL AND MECHANICAL DESIGN IN THE REST OF THE MACHINE AND, OF COURSE, CONSIDER THAT INGENUITY IS A PRIME INGREDIENT IN THIS EXERCISE.

DURING THE 1970’S I DISCOVERED, ON CHANGING MAGNETS OF LOWER ENERGY PRODUCT FOR HIGHER ENERGY TYPES IN MY PULSED MOTOR/GENERATOR, THAT THERE WAS AN INCREASE IN POWER OUTPUT, BUT NO CHANGE IN MOTOR EFFICIENCY. THERE WAS, DURING THE EARLY SEVENTIES, MUCH TALK AND SPECULATION OF GREATER EFFICIENCIES BEING POSSIBLE WITH THE ADVENT OF MORE POWERFUL MAGNETS APPEARING OVER THE HORIZON IN THE NEAR FUTURE. WHEN EVENTUALLY SAMARIUM-COBOLT CAME ON THE SCENE IN THE USA, IT WAS, HOWEVER, A LONG WAY FROM BECOMING GENERALLY AVAILABLE ELSEWHERE.

WHEN I EVENTUALLY OBTAINED A SUITABLE SET OF SAMARIUM-COBOLT MAGNETS, I INSTALLED THEM IN ONE OF MY MOTORS AND WAS NOT SURPRISED TO FIND, ONCE AGAIN, THAT THE MACHINE POWER INCREASED BUT THE EFFICIENCY STILL REMAINED UNCHANGED.

IN MORE RECENT TIMES I HAVE CARRIED OUT A PROGRAMME USING SEVERAL DIFFERENT KINDS OF MAGNETS OF VARYING ENERGY PRODUCT FIGURES, FROM A FEW HUNDRED GAUSS TO MEGAGAUSS SUPER POWER MAGNETS. NOW THAT MY PROGRAMME ON CHECKING MANY DIFFERENT MAGNETS IS COMPLETED, WHICH INCLUDES THE MOST POWERFUL MAGNETS AVAILABLE IN THE WORLD TO DATE, TO WHICH I AM PRIVY, IT HAS BEEN FOUND THAT MY ORIGINAL DISCOVERY IN 1976 VALIDATES THE FACT THAT THE ENERGY PRODUCT OF MAGNETS HAS NO INFLUENCE WHATSOEVER ON THE RESULTS/OUTCOME OF A PERMANENT MAGNET ELECTRIC MOTOR'S EFFICIENCY. THERE WILL BE MUCH DISAPPOINTMENT TO A LOT OF PEOPLE OUT THERE TO LEARN THAT MAGNET ENERGY PRODUCT DOES NOT GOVERN EFFICIENCY IN ANY WAY WHATSOEVER.

THERE IS A CONSOLATION HOWEVER, FOR US ALL, IN THAT THERE ARE TWO VERY SIGNIFICANT ADVANTAGES IN THE USE OF SUPER POWER MAGNETS. ONE IS THE HIGH REDUCTION IN VOLUME AND THE SECOND IS THE EQUALLY HIGH REDUCTION IN WEIGHT. THESE TWO FACTORS, THOUGH NOT ELECTRICAL EFFICIENCIES PER SE, CONTRIBUTE TO THE OVERALL EFFICIENCY IN THE SENSE THAT THEIR USE IN THE MANUFACTURE OF ELECTRIC MOTORS AND GENERATORS MINIMISES PRODUCTION COSTS, WHEREBY MATERIALS AND LABOUR ARE DRastically REDUCED, HENCE PRODUCING LIGHTER, SMALLER AND CHEAPER MOTORS AND GENERATORS.

WITH THE USE OF SUPER MAGNETS IN FUTURE MACHINES, THERE IS PROMISE OF SOMEWHERE AROUND THE ORDER OF HALF OF A KILO HORSEPOWER POSSIBLE - EXCELLENT NEWS FOR PORTABLE POWER GENERATORS.

ESTABLISHED METHODS OF TESTING ELECTRIC MOTOR AND TRANSFORMER EFFICIENCY

In this section I challenge the method/s used in science and industry alike in relation to the testing of electric motor and power transformer efficiencies. The methods referred to are in the form of the well known and the outdated establishment teachings. The establishment will not attempt to take up my challenge because they know full well that my claims are proven.
These outmoded methods have gone on forever over the ages and been taken as gospel never to be questioned. The time has come to pass that these outmoded methods be subject to review. With new energy devices over the horizon, application of establishment testing procedures for these do not and can not give accurate results any more than they do for present day conventional devices.

It is well past time that the establishment science and industry alike be taken to task on this matter, particularly in relation to electric motors and transformers. Test results from universities and establishment facilities of new energy devices I have encountered are not worth the paper they are written on. Let’s start with power transformers. A simple no-moving-parts device. Claims of upwards of 98% efficiency!

I ask one question. Why, in the case of large power transformers, as used for the National grid systems, claiming ratings of around the order of 98% efficiency, do they have to be immersed in large tanks of special transformer cooling oil to keep the transformer at a safe operating temperature? And, in addition, the transformer tank is fitted with oil circulating fins around it’s outer perimeter which, in turn, cool the hot circulating oil and, so too, in many cases these transformers ALSO require a circulating pump? 98% efficiency? If the so-called transformer was indeed around the order of 98% efficiency, it certainly would not be required to be immersed in an oil tank, with it’s ancillary devices, to keep it cool!

Now electric motors.

I ask the same one question. Why do motor manufacturers, claiming upwards of 90% efficiency, provide cooling fans in their machines with their attendant losses in order to keep the machine within a safe operating temperature? Simply because of the heat generated in the machine due to inherent inefficiency losses? What 90% efficiency? If the fan/s were not provided, then the machine would surely self-destruct due to the excessive heat generated.

So much for establishment teachings of efficiency ratings of electric motors and power transformers. I have acquired and tested scores of AC and DC electric motors over many years and failed to find a single one which conforms to the manufacturers data claims.

### ELECTRIC MOTOR TEMPERATURE VERSUS EFFICIENCY

Having been involved in the field of electric motor inventions and investigating efficiency claims by manufacturers and motor inventors alike for the past 30 years, I have failed to find in any of their literature pertaining to technical specification and efficiency figures, any reference of the temperature of the said machines operating under full load conditions.

One may ask - has this most important factor been lost sight of or is it conveniently side-stepped?

The latter I suspect.

You may ask - why?

Would the answer to this possibly be, that to quote operating temperature of the motor in question might give rise to the question in itself as to the true efficiency of the machine?

It is to be heeded that specified efficiency ratings will be inaccurate and deceptive if the vital factor of temperature of the machine running under full load is not stated. It must also be remembered that the DC resistance of the internal windings increases with temperature rise.

Exercising my experience in calorimetry I have checked scores of different AC and DC motor efficiencies and found all of them deficient as regards accuracy - evidence which points to the fact that temperature of the machine running under full load has not been taken into account.

### CONVENTIONAL ELECTRIC MOTORS

Conventional electric motors, whether AC or DC, in the work force are abysmally low in efficiency, including those claiming around the order of 60-90%.

And here is why :-

If a conventional motor with a claimed efficiency of, say, 70% and 10 watts output and a motor of beyond unity and 10 watts output are both loaded equally in an ambient temperature of 20°C, the conventional motor, after 20
minutes running, will have reached a temperature of beyond 100°C; the unconventional motor (beyond unity motor), at the end of 20 minutes, would barely have reached 38°C.

The "loaded operating temperature" of motors around the order of unity and beyond is such that they do not require a cooling fan, nor do they require to be constructed of metal to dissipate the enormous loss of energy as in conventional machines. There is an obvious advantage here too, in that volume and weight are substantially reduced.

Calorimetry is an exacting and critical science. It requires timeless observance of it's principles and precepts and an almost religious attendance to the diagnostics demanded of it's nature. And so, many hundreds of hours of work and substantial monies have been applied to the "final solution" and scepticism may take a bow and accept indeed at least a share of the credit for the results - it's prayer has been answered, albeit "volte-face". All calorimeter-testing analyses and temperature parameter research carried out by myself over the past years, both on the Adams motor as well as other various types of motors, have strongly come out in favour of evidence in support of the fact that these sceptics' methods of testing the Adams Machine, and others, are outmoded and grossly inaccurate. It is almost obligatory to challenge one's sceptics, just, if for no other reason, than for the fun of it: but there is no one I know able to challenge calorimetry.

I have strived for years in an endeavour to explain to people, who really should know better, that the temperature of electric motors at work is of paramount importance and that electrical parameters are of no consequence or even required to be considered. Also that conventional mathematical/electrical measurements do not apply to switched reluctance motors; if applied, they are flawed by straight out accurate temperature measurement of the machine.

**VALUABLE HINTS ON REPLICATION**

1) Use only pure iron for stator/drive windings, not laminated steel core.
2) Wind stators with a resistance in the range of ten to twenty ohms each for a small model.
3) For 2) above, use voltage/s of between 12 and 36.
4) For small machine make contactor star disk one inch maximum diameter.
5) Keep wiring short and of low resistance.
6) For small machine install fuse/holder 500m.a. to 1 amp.
7) Install switch for convenience and safety.
8) Use small bearings. Do not use sealed bearings as these are pre-packed with a dense grease which causes severe drag.
9) Use only silver contacts for pulse switch.
10) If using high-energy-product magnets, vibration becomes a serious problem if constructional materials and design are faulty.
11) Air gap is not critical; however reduction will increase torque and also increase input power in proportion.
12) For higher speed, lower current, series-connected stators recommended.
13) a) If machine stator windings are of low resistance and drawing high current at higher input voltage, it is advisable to install a switching transistor which will completely eliminate sparking at points.
    b) On calculating input power, however, the transistor switch burden must be subtracted from total input.
14) a) Points tuning and pressure are vitally important; experiment will indicate optimum settings.
    b) If, however, all electronic switching process is preferred, i.e., using photo, magnetic, hall effect, etc., then the above in a) is completely eliminated.
15) If constructing a large model involving large super-power magnets, note the following:-
    The greater the magnetic energy product, the greater the power required to drive the machine, the greater the torque, the greater the vibration problem, greater copper content, greater cost etc. Read section on "Permanent Magnets and Efficiency" by Dr. Robert Adams 1996 "Also published in NEXUS April / May 1996 Issue).

**ADAMS MOTOR**

ANALYSIS REPORT FROM (PH.D.SYSTEMS ENGINEERING SCIENTIST) OF DETROIT, OHIO

This is a "Vax" computer system analysis together with computer graphs of the parameters and analysis carried out by the above Scientist, confirming the validity of various claims made by the inventor. The graphs are very comprehensive and therefore of considerable value to aid design work, particularly of the motor proper, of the "Adams" Motor Generator. The following analysis are results of the original Mark I Adams Motor Generator, taken in a magnetic attraction mode.

GENERAL ANALYSIS REPORT RECEIVED
BY THE INVENTOR
Note on battery tests:

I have done a battery charging test and I enclose the results for your examination. As you can see, the input battery voltage stayed virtually constant over the time involved, while the output battery voltage climbed considerably. Are you interested in what the device I was using between the two batteries was? It was a "conventional" RESISTOR. Yes, I actually duplicated your battery charging curves using a resistor, not an Adam's Machine. I hope you find this informative.

Simulation run:

I am including some printouts from my simulation program confirming several of the features you describe in your literature. The plots with angle on the horizontal axis are showing 1/4 of a revolution by one degree increments. The plots with speed on the horizontal axis are showing the effect on the variable speed changes. As you see from the TORQUE-ANGLE PLOT, positive torque is indeed applied twice during each cycle, as you state. The EFFICIENCY VS SPEED PLOT shows the "resonance effect" in a rather dramatic way, don't you think? (Here the lighter shaded area is the area of OVER-UNITY operation). The TORQUE-SPEED PLOT is quite interesting, since the load line intersection with it determines at which speed the motor will run. The simulated coil voltage and coil current waveforms shown are similar to those observed on my scope (and yours according to your diagrams), confirming the basic validity of the simulation equations I have developed. The BATTERY CURRENT VS ANGLE PLOT shows current flowing back into the battery, again as you indicated.

Isn't it interesting that the simulations show areas of operation under certain conditions which will produce over unity results? Maybe we don't have to throw out as much of "conventional" physics as you think we do. Maybe "over unity" has been hidden in conventional physics all along and we just haven't seen it, because we haven't looked in the right way with eyes to see.

SPECIAL REPORT ON A NEW REVOLUTIONARY MOTOR GENERATOR
THE ADAMS THERMO MOTOR GENERATOR - MARK 022/3

New ETHER ENERGY DEVICES are now a reality and the ivory tower protectionism of the Laws of Thermodynamics and Einstein's Relativity has all but collapsed.

Research and development in this new/old vast field is fast gathering momentum worldwide. These new devices include electric motor/generators and solid state units. Present day methods of power generation are destined for the scrap heap.

The scientific establishment has built its imposing edifice of quantum electrodynamics on the basis of secondary results produced from electricity and electromagnetics already in action.

From these actions observed, they form a hypothetical picture, theoretical models of which have consequently consisted served as being reliable for MOST electromagnetic devices, but not all, as when these dogmatic laws were conceived today's inventors and scientists had not as yet invented these new revolutionary electromagnetic devices capable of gating ETHER ENERGY, with one exception being Tesla on the close of the last century, who was suppressed.

If the scientific establishment dogma in relation to NEWTON'S LAWS OF THERMODYNAMICS and EINSTEIN'S RELATIVITY were correct, then none of these new energy devices, including UFOs, could have been invented.

Einstein's sacrosanct theories of relativity and the Laws of Thermodynamics are the most remarkable and inexplicable aberrations ever recorded in scientific history. These draconian false teachings have been instrumental on a wholesale scale in impeding the progress of science towards free clean energy in a propitious era which has since had the fossil fuel magnates laughing all the way to the bank.

There is overwhelming evidence that ether/space energy can be concentrated, focused and/or magnified by permanent magnets. I, for one, have proved this in my original motor generator, 4-pole super power magnets, the Adams Thermo Motor/Generator and other inventions and electromagnetic discoveries not yet disclosed. My success in precipitating heat from ether/space energy manifesting within the stator s of the Mark 022/3 Adams Thermo Electric Motor and successfully harnessing this energy, has proved to be a very significant and exciting event for a world starving for clean economical energy.

The 'ADAMS THERMO MOTOR GENERATOR' is but one of the new energy devices on the horizon with enormous potential. The device is so named as an illustration of it's ability, in addition to it supplying very efficient electrical or mechanical power, to also provide water heating, both at unprecedented economical figures.

Heat is a source of immense energy loss in conventional motors. It was this principal factor in mind that first prompted me to invent a motor that would overcome this energy waste and hence the birth of the original Adams Motor Generator Mark 001 (1968). Ironically, in contrast, over the intervening years, much of my mental research went into the idea of tapping ether energy, in the form of heat, into my original machine. With this task most prominent in my mind, I constantly pondered over the idea of inventing a motor that would, in addition to rendering a very high degree of efficiency, provide etheric energy in the form of heat within the machine which I could then harness by way of heating water.

To achieve this I felt a pressing message to direct most of my efforts into the design of a unique rotor as having, through the years, found little chance, if any, of improving the lot of electric motor stator systems, as has been attempted by many, with most only showing little, if any, improvement in the gaining of higher efficiency.

Two unique engineering factors came to mind quite quickly and were duly implemented into this rotor. The results of the first trial runs were well beyond my expectations; for the size and electrical parameters of the machine, the energy gated from the ether in the form of heat was massive and spontaneous. These results were very exciting.

To construct a machine of this kind requires considerable experience and skill in the design of unconventional new energy devices, in addition to the requirement of experience in the science of thermodynamics, calorimetry and water heating systems. All measures must be exercised to preclude and/or reduce losses as these are many and can be high and include the following:

Conduction, radiation, windage, bearings, magnetics, transistor switching, high windage loss at stator pole faces due to high speeds of 2500 - 4000 rpm of the rotor causing considerable cooling effect - i.e., irretrievable loss of ETHER ENERGY, and thermo insulation losses in stator jackets, holding tank and piping circuitry.
The unique rotor, briefly described, comprises of four neodymium magnets and is driven by only two 180° stators with a large air gap of 1.25mm, has a rotor diameter of 140mm and 19mm in width and the stator faces are small at only 15mm diameter.

The high heat energy referred to, that is gated from ETHER/SPACE, concentrates at the stator windings. The manner in which this heat energy is harnessed from the stator is unique and very efficient, and the result is a machine which develops mechanical power for industrial use and provides hot water in addition - a world first in its class. It represents a boon to industry, hospitals, institutions and domestic dwellings alike. For any particular application it can be designed for power supply generation in addition to providing hot water at economy figures undreamed of. The applications are endless and for the consumer the big bonus is its sheer economy whether you take a small power boat or an ocean-going vessel - fuel costs and weight would be slashed to the bone not to mention the reduced fire risks and as with hospitals, production plants, mills, mining and industry in general, the same benefits would apply.

The machine, because of its unique free water heating advantage, will, of course, be of greater volume than a conventional motor due to the necessary installation criteria of the associated componentry required to harness this primary source of free energy.

The prospect of being now in the position to harness these energies from magnetic forces provides us with a vast new clean source of energy free for the taking.

CALORIMETRIC TEST, TRANSISTOR SWITCH DISSIPATION, AND ELECTRICAL INPUT AND ETHER ENERGY OUTPUT

</tbody>
</table>

Now 45 watts of transistor switch is the total dissipation of both the machine and switch, so we are faced with a paradox in that electrical calculation total input power = 33 watts versus 45 watts of the transistor total input (calorimetrically measured). This to me indicates that etheric energy is somehow entering the switching circuit as it gets far hotter than it should for the amount of current which it is switching. This possibility should not be ignored as etheric energy moves and collects on both insulators and conductors alike and collectively in a manner totally foreign to the way in which electricity, as we know it, flows in an electrical circuit.

There is mounting evidence showing up in this unique machine that indicates we have much exciting learning ahead in this new field of energy. For instance, I will cite the following anomaly taken from my day book dated 2.6.96:

Throughout a test run on the above date, as is usual, random checks were taken of the stator jackets’ water temperature and it was found throughout the one hour test run that the NORTH POLE had now taken the higher heat potential from the SOUTH POLE - with a difference, however; instead of the usual 2 to 3 degree variation from one day to another between the two poles, on this occasion the NORTH POLE was operating at a temperature of 33 degrees beyond that displayed by the SOUTH POLE. There were no electrical instrumentation variations whatsoever during this period of the test run and, further, there was no sign of variation in machine performance. These anomalous discoveries are not new to me; they simply convince me further that “It is highly probable that, at any or all times in the future, the most any of us will ever know about nature is nothing” (Dr. Robert Adams 1996).

NOTE:
UNLOADED PERFORMANCE TEST - It is to be noted that the outlined test run was carried out free-running, i.e., the machine was operating without mechanical or electrical load applied. On application of loading, however, input power increase is minimal, where ether heat energy increases dramatically in proportion.

A new machine of higher power, greater dimensions and of anticipated improved efficiency is, at present, under construction. The results of its performance will be interesting to see and they also will be published internationally in due course.

RECOMMENDED READING:
THE OVER-UNITY RELUCTANCE MOTOR EXPERIMENT

One can build an Adams motor and prove that over-unity operation is a reality. However, most academic researchers would deem this to be a waste of time since it is recognised as being a 'crank' pursuit seen as an attempt to create a 'perpetual motion' machine.

My task, experimentally, therefore is to present something far more straightforward that can be assembled and tested in a school physics laboratory or at home using a standard transformer kit costing a few dollars. All one then needs is an instrument to read amps and volts and a variable mains power voltage supply.

I did this experiment to satisfy myself that what I said at the Denver meeting in Colorado holds up. I am glad I did the experiment because it told me something new and important.

I had thought that, in order to access free energy from ferromagnetism, I would need to power the magnetic core above the 'knee' of the B-H curve, where the magnetism builds up by the atomic electron spins being forced into alignment rather than merely flipping through 180°. Here I have to be careful because I have a very thorough grounding in ferromagnetism and I should avoid terminology unfamiliar to readers.

It must be said, however, that there is no way forward for anyone involved in real research on free energy from ferromagnetism unless that person understands the physics of the subject. The hit and miss ventures of those who build permanent magnet 'free energy' machines and get them to work anomalously only guide others equipped with the right training to take the research forward. I say 'only' because this is a simple situation. Those with the knowledge do not want to believe that 'free energy' is possible. Those without the knowledge cannot prove their case, because they cannot speak the scientific language that applies. However, once on the scent and believing in what is possible, but not knowing why, those 'experts' on magnetism will move rapidly in advancing the technology in the real commercial world.

So, here I aim to point at an introductory lesson or experiment and, to back this up, I commend those attempting this to read about the basic principles of magnetism as explained by an engineer - not a physicist! The best book that I know of for this purpose is one authored by a professor who was one of the examiners of my Ph.D. thesis. His book tells the reader in simple language how magnetism develops as domains reorientate their action and further his book tells the reader about anomalous energy aspects, including the unsolved mystery of extremely high loss anomalies (a factor of 10 greater than theory predicts). I refer to a book sold in students paperback edition by the Van Nostrand Company (Princeton, New Jersey), published in 1966 and authored by F. Brailsford under the title: Physical Principles of Magnetism'.

If the reader belongs to a university and that book can be accessed from the library, then that reader will, I feel, after performing the following experiment, be able to make sense of the 'free energy' opportunities now confronting the world of magnetism. The Brailsford book is not, of course, necessary as a preliminary to the experiment but it can help in onward thinking. Indeed, as an aside, I mention that when I spoke recently about the Floyd Sweet device to one of our mutual collaborators here in U.K. I was gratified to hear that he too has a copy of the Brailsford book.

The experiment is simplicity itself, considering the energy issue involved. Take a standard transformer kit and assemble the laminations so that there is what is virtually an air gap in the core. Be prepared to reassemble the core partially with different width gaps. I cut pieces of card of 0.25 mm thickness and performed the experiment in ten repeat assembly stages, using 0 to 9 card thicknesses.

The idea of the experiment is to create an excited core state in which there is a known amount of energy stored in the air gap. If the AC frequency is 60 Hz this means that in 1/240th of a second an amount of energy is supplied as inductance energy that can meet the needs of the air gap. Note that I consistently made estimates of energy that were worst-case from our 'free energy' perspective. Therefore, the extra energy supplied that is stored as inductance in the ferromagnetic core itself, rather than the air gap, is ignored. The plan is to compare that energy
with the mechanical energy that we could take from the gap if the poles thereby formed were to close together and do work as if in an electromagnet. Textbooks tell us that the energy determined by the flux density in the gap represents that mechanically available energy. So, we need, for each air gap thickness, to measure the flux that crosses the air gap. We do this by wrapping a search coil around the part of the core that is on the side of the air gap remote from the magnetising coil and measuring the voltage induced in that search coil. It may be verified, by having a separate search coil on the magnetizing coil side of the gap, that the flux traversing the gap and linking the test search coil is nearly the same but a little less than that on the magnetizing side. So, in our worst-case analysis we may rely on the mechanical energy calculated from the weaker flux measured in the test search coil. That flux must be less than the flux in the gap.

By adjusting the current at successive gap thicknesses to ensure that the voltage sensed by the test search coil is always the same, we then know that the gap energy available as mechanical work increments linearly with gap thickness. For each such measurement we record the current registered as input to the magnetising coil.

If we now multiply the current by the voltage measured, allowing for the turns ratio as between the magnetizing winding and the test search coil, we can find the volt-amp input, which in the absence of losses is the reactance or inductive power. This allows us to compare the power output potentially available mechanically from such an air gap, if it were in a reluctance motor structure, compared with the reactive power supplied to set up that potential.

It is found that the mechanical power is appreciably greater than the input power, thereby demonstrating that 'free energy' is to be expected.

Now, one does not even need to worry about the calculations to find the reactive power input by multiplying volts and amps and allowing for the coil turns ratio. It suffices to plot the curve of current for different air gap thicknesses. Since the flux crossing the gap has fixed amplitude, as measured by a constant voltage reading, that means linear increase in mechanical power with air gap, so if the current were to increase at a rate that curves upwards with increasing air gap we would see a discrepancy representing a loss but if it curves downwards then that means that there is a 'free energy' source.

The experiment is very positively in showing the downward curve and so gives the 'free energy' answer, but, to my surprise, with the coil arrangement shown in Fig. 2, I found that the 'free energy' becomes available well below the knee of the B-H curve at quite normal flux densities! Even at one fifth of magnetic saturation levels the excess free energy potential can exceed the input power and give a twice-unity factor of performance. It is, therefore, no wonder that at higher flux densities one can aim for a 700% performance, as the Adams motor has shown.

On reflection, the reason, of course, is that magnetism set up by a coil on a magnetic core progresses as flux around the core circuit by virtue of a 'knock-on' effect owing to internal domain flux rotation. This is essential and is usually attributed to a flux leakage reaction, as otherwise magnetism remote from a magnetising coil could not navigate the bends in the core. That flux rotation, which is dominant above the knee of the B-H curve, for a system with a magnetising coil coextensive with the length of the core, is brought into effect at low flux densities if the coil only embraces one part of the core.

I regard the experiment just described as a crucial experiment proving the viability of over-unity-performing reluctance drive motors and believe it should become standard in all teaching laboratories concerned with electrical engineering and eventually, as physicists see the aether in its new light, also in all high school physics laboratories.
SWITCHED RELUCTANCE MOTORS

On April 16, 1993, the first day of the New Energy Symposium in Denver on which participants heard about the 'free energy' motor of New Zealander Robert Adams, the Financial Times in U.K. published an article on 'switched reluctance motors'. This article described how a U.K. company Switched Reluctance Drives Limited has become the world leader in that field.

The significance of this as a news item is that there has been a rapid convergence on the transition point at which the electronics needed to control the reluctance motor becomes so cheap that it is predicted that induction motors will soon be replaced on a large scale.
Those of us interested in the 'free energy' theme should see this as opening the door for the new energy technology based on the principles used in the Adams motor. There is a window of opportunity which has been opened by the arrival of the conventional switched reluctance motor at the breakeven point where it can replace the conventional motor on a cost comparison basis. This new kind of motor is one which relies on the magnetic pull across the pole faces to set up the drive torque. It is not one needing force interaction between magnetic field and current in a winding. Accordingly, this is the technology of the Adams motor which allows the extra pull powered by the 'free energy' drawn through the ferromagnetic flux-rotation of the quantum spins to be accessed.

In the light of the report in the Financial Times and the recent media attention to the Adams motor in Australia I have, on my return from the Denver meeting, drawn the Adams motor to the attention of the U.K. power industry magazine 'Electric Review'. As a result their reporter on new technology published an article entitled 'Reluctance motor has 100%-plus efficiency' in 9th July 1993 issue.

The article should arouse U.K. engineering interest in the 'free energy' possibility, since I have shown the design feature by which one can understand the 'free energy' source and so calculate its input. As might be expected the leading U.K. 'switched reluctance expert' consulted on this proposition has been reluctant to concede that one might go above 100% in electrical generating efficiency, but in the light of the next comment one wonders if a crack has now opened in the establishment defences.

**********

When getting ball-race bearings for an application like this, please be aware that "closed" bearings such as these are not suitable as supplied:

This is because this type of bearing is usually packed with dense grease which completely destroys its free motion, making it worse as a bearing than a simple hole-and-shaft arrangement. However, in spite of this, the closed or "sealed" bearing is popular as the magnets tend to attract dirt and dust and if the device is not enclosed in a steel box as is necessary for the high power versions, then having the seal is considered to be an advantage. The way to deal with the grease packing is to soak the bearing in an isopropyl solvent cleaner to remove the manufacturer's grease, and then, when it has dried out, lubricate the bearing with two drops of a high quality thin oil. If it is intended to house the motor/generator in an earthed, sealed steel box then an alternative type of bearing which might be suitable is an open design like this:

especially if the air is removed from the box. Some constructors prefer to use ceramic bearings which are supposed to be immune to dirt. One supplier is http://www.bocabearings.com/main1.aspx?p=docs&id=16 but as with everything else, these choices have to be made by the builder and will be influenced by his opinions.
I'm not sure where it came from, but here is a circuit diagram showing a transistor drive and the return of the back EMF of the drive coils to the driving power supply. Using this method, about 95% of the drive current can be returned, lowering the current draw enormously:

The diode feeding the power back to the supply is a Shotky type because of it's high-speed operation. It needs to be able to handle the peak pulse power and so should be one of the more robust types. What this circuit does not have is the very important switching on the output coils circuit. Another strange item is the way that the FET sensor is arranged with two sensors rather than one and with an additional battery. While it must be admitted that the current draw of the FET gate should be very low, there still does not seem to be much reason to have a second power supply. One other peculiarity in this diagram is the positioning of the drive coils. With them offset as shown, it has the effect of them being at an angle relative to the rotor magnets. It is not at all clear if this is an advanced operating technique or just poor drawing - I am inclined to assume the latter although I have no evidence for this other than the circuit design and the low quality of the original drawing which had to be improved considerably to arrive at the diagram shown above.

The coil generator output should be fed into a capacitor before being passed to whatever equipment is to be powered by the device. This is because the energy is being drawn from the local environment and is not conventional energy. Storing it in a capacitor converts it to a more normal version of electrical power, a feature which has also been mentioned by Don Smith and by John Bedini although their devices are quite different in operation.

The DC resistance of the coil windings is an important factor. The overall resistance should be either 36 ohms or 72 ohms for a complete set of coils, whether they are drive coils or power pick-up coils. Coils can be wired in parallel or in series or in series/parallel. So, for 72 ohms with four coils, the DC resistance of each coil could be 18 ohms for series-connected, 288 ohms for parallel connected, or 72 ohms for connection in series/parallel where two pairs of coils in series are then wired in parallel.

To help with assessing the wire diameter and length which you could use, here is a table of some of the common sizes in both American Wire Gage and Standard Wire Gauge:

So far, we have not discussed the generation of the timing pulses. A popular choice for a timing system is to use a slotted disc mounted on the rotor axle and sensing the slots with an "optical" switch. The "optical" part of the switch is usually performed by UV transmission and reception and as ultra violet is not visible to the human eye, describing the switching mechanism as "optical" is not really correct. The actual sensing mechanism is very simple as commercial devices are readily available for performing the task. The sensor housing contains both a UV LED to create the transmission beam, and a UV dependent resistor to detect that transmitted beam.

Here is an example of a neatly constructed timing mechanism made by Ron Pugh for his six-magnet rotor assembly:

![Timing Mechanism](image)

This device happens to be one which is supplied by [www.bayareaamusements.com](http://www.bayareaamusements.com) under their product code number: OP-5490-14327-00. As the slotted disc rotates, one of the slots comes opposite the sensor and allows the UV beam to pass through to the sensor. That lowers the resistance of the sensor device and that change is then used to trigger the drive pulse for whatever length of time the slot leaves the sensor clear. You will notice the balanced attachment method used by Ron to avoid having an unbalanced rotor assembly. There can be two timing discs, one for the drive pulses and one for switching the power pickup coils in and out of the circuit. The slots in the power pick-up timing disk will be very narrow as the switch-on period is only about 2.7 degrees. For a six-inch diameter disc where 360 degrees represents a circumference length of 18.85 inches (478.78 mm) a 2.7 degree slot would be only 9/64 inch (3.6 mm) wide. The arrangement for an axial magnet rotor set-up could be like this:
So to recap, the things which are necessary for getting an Adams Motor output into the serious bracket are:

1. A performance of COP>1 can only be achieved if there are power pick-up coils.
2. The rotor magnets need to be longer than they are wide in order to ensure the correct magnetic field shape and the rotor must be perfectly balanced and have bearings as low-friction as possible.
3. The face area of the rotor magnets needs to be four times that of the drive coil cores and one quarter the area of the core of the power pick-up coils. This means that if they are circular, then the drive coil core diameter needs to be half the diameter of the magnet and the magnet diameter needs to be half the diameter of the power pick-up core. For example, if a circular rotor magnet is 10 mm across, then the drive core should be 5 mm across and the pick-up core 20 mm across.
4. The drive voltage needs to be a minimum of 48 volts and preferably, a good deal higher than that.
5. Do not use neodymium magnets if the drive voltage is less than 120 volts.
6. The drive coils should not be pulsed until they are exactly aligned with the rotor magnets even though this does not give the fastest rotor speed.
7. Each complete set of coils should have a DC resistance of either 36 ohms or 72 ohms and definitely 72 ohms if the drive voltage is 120 volts or higher.
8. Collect the output power in large capacitors before using it to power equipment.

It may also be possible to boost the output power further, by using the Coil-Shorting technique shown in the section of this chapter on the RotoVerter.

If you want the original drawings and some explanation on the operation of the motor, then two publications from the late Robert Adams can be bought from www.nexusmagazine.com where the prices are quoted in Australian dollars, making the books look much more expensive than they actually are.
http://www.totallyamped.net/adams/index.html is a really impressive collection of well-informed practical material on building and using an Adams motor with details of sensors and how they work, core materials and their performances and how to locate the "sweet spot" - very highly recommended web site.

In 1999, two Australian men, John Christie and Ludwig Brits took Robert Adams’ design and patented it, calling it the Lutec. Their patent was issued in 2003 and considering that the 1995 patent of Robert Adams and Harold Aspden was in place, it is not clear to me how the Lutec patent could have been issued. However, it is encouraging to see a successful implementation of Robert’s design. They achieved COP=5 at a net one kilowatt power output, but made the major mistake of attempting to manufacture and sell the generators which would have cut into the profits of the oil companies, and as a result, they no longer offer the units and as far as I am aware, never sold one. The idea was that these 1 kilowatt modules could be stacked one on top of the other to generate higher outputs.

Here is a re-worded extract from their patent:

System for Controlling a Rotary Device

Abstract
A system for controlling a rotary device, the system comprising a controller and a rotary device, which has a stator and rotor, wherein the controller is connected to the rotary device to control rotation of the rotary device, and wherein the controller is adapted to periodically energise the energising coils of the device to create a magnetic field of a polarity which induces the rotor to rotate in a single direction and wherein the controller is switched off so as to de-energise the energising coil when other forces, being forces other than those resulting from the energising coil, produce a resultant force which induces rotation of the rotor in that direction.

Description:

FIELD OF THE INVENTION
The present invention relates to motors which are used for generating a torque and generators which are used for generating electricity.

BACKGROUND OF THE INVENTION
A typical electric motor consists of a stator and rotor. The operation of an electric motor is based on the principle that an electric current through a conductor produces a magnetic field, the direction of current in an electro-magnetic such as a coil of wire determines the location of the magnets poles and like magnetic poles repel and opposite magnetic poles attract.

The stator which is typically called the field structure establishes a constant magnetic field in the motor. Typically, the magnetic field is established by permanent magnets which are called field magnets and located at equally

2 - 32
spaced intervals around the rotor. The rotor or armature typically consists of a series of equally spaced coils which are able to be energised to produce a magnetic field and thus north or south poles.

By keeping the coils energised the interacting magnetic fields of the rotor and the stator produce rotation of the rotor. To ensure that rotation occurs in a single direction, a commutator is typically connected to the windings of the coils of the rotor so as to change the direction of the current applied to the coils. If the direction of the current was not reversed, the rotor would rotate in one direction and then reverse its direction before a full cycle of rotation could be completed.

The above description typifies a DC motor. AC motors do not have commutators because alternating current reverses its direction independently. For a typical AC motor such as an induction motor the rotor has no direct connection to the external source of electricity. Alternating current flows around field coils in the stator and produces a rotating magnetic field. This rotating magnetic field induces an electric current in the rotor resulting in another magnetic field. This induced magnetic field from the rotor interacts with the magnetic field from the stator causing the rotor to turn.

An electric generator is effectively the reverse of an electric motor. Instead of supplying electricity to coils of either the stator or rotor, the rotor or armature is rotated by physical forces produced by a ‘prime mover’. In effect a generator changes mechanical energy into electrical energy.

SUMMARY OF THE INVENTION
The present invention is aimed at providing an improved rotary device which operates with improved efficiency compared to conventional rotary devices. The present invention is also concerned with providing a system for controlling a rotary device which is able to generate electrical and/or mechanical energy.

According to the present invention there is provided a system for controlling a rotary device, the system comprising a controller and a rotary device which has a stator and rotor, wherein the controller is connected to the rotary device to control rotation of the rotary device, and with the controller adapted to energise periodically, at least one energising coil of the device to create a magnetic field of a polarity which induces the rotor to rotate in a single direction and where the controller is switched off so as to de-energise the energising coil when other forces, being forces other than those resulting from the energised energising coil produce a resultant force which induces rotation of the rotor in the single direction.

Preferably the controller is adapted to energise the energising coil for a period during which the resultant force from the other forces acts to rotate the rotor in the opposite direction, whereby the force applied by the energising coil overcomes, being greater than, the resultant force. The controller is preferably adapted to switch off to de-energise the energising coil before the resultant force is zero. The controller preferably is adapted to switch off to de-energise the energising coil for a period before the resultant force is zero, and to allow back EMF induced by other forces to urge the rotor to rotate in the single direction before the resultant force is zero. Preferably, the resultant force excludes forces arising from back-EMF.

The energising coil may be adapted to be energised by the controller through a predetermined angle of a complete revolution of the rotor. Alternatively the energising coil is adapted to be energised by the controller for a predetermined period of time for each revolution of the motor. Preferably then, each energising coil is energised more than once during a single revolution (cycle) of the rotor. Each energising coil may be energised each time the resultant force applies a force to the rotor in the opposite direction. Each energising coil may be energised by a periodic pulse applied by the controller. The periodic pulses are preferably all of the same sign.

Each of the energising coils are energised whenever the resultant force is in the opposite direction and then for a period less than the period during which the resultant force changes from zero to a maximum and back to zero.

In one embodiment, the stator has at least one energising coil. The rotor may have at least one magnetic field generator which is able to generate a magnetic field which interacts with the magnetic field generated by each energising coil when energised, to apply a force to rotate the rotor in one direction. Each energising coil preferably includes a magnetic interaction method which is adapted to either repel or attract the magnetic field generator.

In another embodiment, the magnetic interaction means is adapted to attract the magnetic field generator. The magnetic interaction means may comprise a ferrous body or body of another substance which is attracted by a magnet. The magnetic field generator may be a permanent magnet. The magnetic interaction means may be an iron core or a permanent magnet. Preferably the magnetic field generator comprises a permanent magnet, or member attracted to a magnet.
The stator preferably comprises a plurality of energising coils evenly spaced around the rotor. Each energising coil is preferably an electromagnet. Preferably each energising coil includes the magnetic interaction means through its coil. Preferably the rotor comprises a plurality of evenly spaced magnets.

In one embodiment, the rotor comprises a plurality of evenly spaced permanent magnets which may all be of the same polarity. The evenly spaced magnetic field generators may be energisable coils simulating magnets. Preferably the poles of the magnetic field generating means are all the same. The magnetic poles produced by energised energising coils may be the same as that for the magnetic field generators.

The magnetic field generators for the stator may be permanent magnets. Preferably the rotor has several energising coils and a commutator. The rotor may be an armature and the stator may be a field winding. Preferably the rotor magnetic field generator is energised by an external power supply being DC or AC current. The stator magnetic interaction means may be energised by coils operating on AC or DC current.

According to one embodiment the stator includes at least one induction coil which is adapted to have a current induced in it by the magnetic field generator of the rotor. Each induction coil may be separate from each energising coil. Each induction coil may also be an energising coil. Each energising coil may be adapted to be connected to an output circuit whereby current induced in each energising coil is output to the output circuit.

It is preferred that switching circuitry is adapted to rectify current induced in the induction coils and that the rectifying occurs just before each energising coil is energised by the power supply. Preferably current output to the output circuit is adapted to be used to run an electric device. The controller preferably comprises a switching circuit which is adapted to connect each energising coil to an output circuit when no current is generated to energise the energising coil and the controller provides a switching circuit. The controller may be a rotary switch with at least one contact which is aligned with each magnetic field generator and with at least one contact aligned with the permanent magnets of the rotor.

The rotary switch may have the same number of contacts as the number of Magnetic field generators; normally being magnets. Each contact may have a width that varies with vertical height and taper in width from the top to the bottom. Ideally, the rotary switch comprises adjustable brushes which are able to be moved vertically. The rotary switch and rotor may be located on coaxial central axis and mounted on a common axial. Preferably the rotor switch is mounted in a separate chamber from the rotor.

In one embodiment, each energising coil is positioned so as to repel an adjacent magnet when energised. Each energising coil may be adapted to be energised by back-EMF only for a predetermined period of each cycle which occurs after current to the energising coil is switched off.

In a further embodiment, each energising coil is adapted to attract the magnetic field generator of the rotor. The present invention contemplates a number of variations to the components making up the systems described above. For example the current, voltage, magnetic field generated, the number of poles of magnets for the rotor/stator may all vary and accordingly will effect the timing of switching of the energising coils. The rotary device may have a greater number of magnetic poles generated on the stator/field winding than in the rotor/armature or vice versa. In one embodiment, the number of poles on both of these are the same.

It is preferred that the switching of the energising coils, which is controlled by the controller, is adapted to maximise the influence of back-EMF produced. It is preferred that the energising coils are effectively provided with a pulsed electric current of minimum duration, which duration is enough to maintain rotation of the rotor and produce a desired output of torque or current.

**BRIEF DESCRIPTION OF THE DRAWINGS**

Preferred embodiments of the present invention will now be described by way of example only with reference to the accompanying drawings in which:
Fig. 1 shows a cross-sectional front view of a rotary device as a control therefore in accordance with a first embodiment of the invention;

Fig. 2 shows a top view of the controller shown in Fig.1,

Fig. 3 shows a side view of the controller shown in Fig.1;
**Fig. 4A** shows a schematic view of a system for controlling rotary device in accordance with the first embodiment of the present invention;

**Fig. 4B** shows a schematic view of the rotary device shown in **Fig. 4A**;
Fig. 5 shows a graphical representation of force versus angular position of permanent magnet M1 of the system shown in Fig.4A:

Fig.6 shows a series of four graphs of input current versus angular movement of each permanent magnet of the system shown in Fig.4A:
Fig. 7 shows a graphical representation of input voltage versus input current for each coil of the rotary device shown in the system of Fig. 4A;

Fig. 8 shows a schematic diagram of variation of natural magnetic attraction versus angular displacement of a rotor having a single permanent magnet and a stator having a single energising coil, in accordance with a second embodiment of the present invention;
Fig. 9 shows a graphical representation of magnetic field versus angular displacement in accordance with the second embodiment of the present invention.

Fig. 10 shows a graphical representation of induced induction versus angular displacement of the permanent magnet in accordance with the second embodiment of the present invention; and
Fig. 11 shows a further graphical representation of induced induction electro-magnetic force versus angular displacement of the permanent magnet in accordance with the second embodiment of the present invention.

DETAILED DESCRIPTION OF THE DRAWINGS

As shown in Fig. 4A according to the first embodiment of the invention a system is provided consisting of a rotor 11 having four permanent magnets M1, M2, M3, M4 which are evenly spaced at 90° with respect to each other.
The system includes a stator 12 consisting of three electromagnet energising coils A, B, C which are spaced 120° apart from each other.

Each of the coils A, B, C is connected in circuit with a power supply of 54 volts and a switch RS1, RS2, RS3. Each of the contacts RS1, RS2, RS3 are part of a rotary switch 13 having contacts 14, 15, 16, 17 which are spaced apart at 90° with respect to an adjacent contact.

The rotary switch 13 is provided with contact brushes 18, 19 and is mounted on an axle 20 which is the same or common with the axle of the rotor 11.

Each of the contacts 14, 15, 16, 17 is specially configured with a trapezoidal shape, with the two non-parallel sides consisting of a straight side 21, and a tapered side 22 which tapers outwards from top side 23 to bottom side 24. The result is that each contact increases in a width moving from the top side to the bottom side 24.

The brush 18 is able to be moved vertically relative to the contacts 14, 15, 16, 17 while the brush 19 is in constant contact with the base. Although Fig.1 only shows the rotary switch 13 having a single series of four contacts 14, 15, 16, 17, for the three-coil stator shown in Fig.4A, there would in fact be, preferably, three contact discs on the axle 20. Each contact disc would have contacts for a respective one of the coils A, B, C, but each brush for the other discs would be offset by 30° and 60° respectively.
A description of the operation of the system shown in Fig.1 to Fig.4A will now be set forth below. If it is assumed that the magnets M1, M2, M3, M4 are initially aligned as shown in Fig.4A with magnet M1 opposite one end of coil A, coil A is energised whenever one of the magnets M1 to M4 is aligned opposite it and for a predetermined time after the permanent magnet has passed it.

As shown in Fig.6 coil A is energised by contact RS1 providing an electrical connection through the rotary switch 13. This occurs by one of the contacts 14 to 17 being aligned in contact with brush 18. At this time, current is applied from the power source VA and continues to be applied until the brush 18 is no longer in contact with one of the contacts 14 to 17.

For the three coil/four pole arrangement of the first embodiment, it is preferred that the brushes are moved to a vertical position where the width of each contact is sufficient for each of the switches RS1, RS2 and RS3 to be closed for 12° 51′, 50″ of the rotation of the rotor 11. After this time the switches RS1 to RS3 are open and no more current is delivered to any one of the coils A to C. When the current to each of the coils is switched off a back EMF is induced in each of the coils A to C and then back EMF represented by item Z results in current being maintained in each of the coils for an additional small period of time after the contacts RS1 to RS3 are opened. By switching the coils A to C in the above manner the rotor 11 can be induced to rotate with a lower amount of input current to the stator than would be required if current was delivered constantly to the coils A to C.

Table 1 below shows the resultant force on the rotor 13 for angular positions of the magnets M1 to M4 for angular displacements of magnet from 5° to 30°.

As shown when the magnets of the rotor 13 are rotated 50 at a time the resultant force on the rotor changes from a counter clockwise force from 5° to 15° to a clockwise force from 15° to 30°. At 0°, 15° and 30° the resultant
force on the rotor is 0 so that if the permanent magnets of the rotor were aligned in any of these orientations there would be no resultant force to urge the rotor either clockwise or anti clockwise.

As shown in Fig. 5 a plot of magnitude of resultant force applied to the rotor against angular displacement of the rotor shows a sinusoidal curve having a cycle of 30°. For a full 360° rotation of the rotor the rotor would experience 12 cycles of variation in resultant force.

What Table 1 and Fig. 5 show is that unless an additional force is applied to rotate the rotor clockwise or counter-clockwise, the rotor will not be able to spin continuously in either direction. If it is desired to rotate the rotor clockwise, then the force must overcome the counter-clockwise resultant force which occurs from 0 to 15°, 30° to 45°, 60° to 75° etc through the whole 360° rotation of the rotor.

Because each of the coils A to C has an iron core even when the coils are not energised the natural magnetic attraction occurring between each magnet and the iron cores results in each magnet M1 to M4 attempting to move in a direction to the closest iron core. Whenever a magnet is opposite an iron core the magnetic attraction is greatest and there is no force applied by that magnet to move the rotor either clockwise or counter-clockwise. Likewise when a magnet is positioned midway between adjacent iron cores, there is also a resultant force of 0 which translates to no resultant force being applied to the rotor to rotate it in either direction by that magnet.

As shown in Fig. 5 and Table 1, if magnet M1 is moved 5° clockwise, there is a natural attraction between the magnet M1 and iron core of coil A to pull the magnet M1 in a counter-clockwise direction. If the resultant forces applied by the other magnets were sufficient to overcome the attraction between permanent magnet M1 and the iron core of coil A the rotor would still manage to move clockwise. However, as shown in Table 1 the angular position of the other magnets M2 to M4 results in an overall counter-clockwise resultant force. To overcome the resultant force, it is necessary to produce a pole X at coil A of like polarity to magnet M1 and thus push M1 away from coil A.

As shown in Fig. 5 the strength of the magnetic repelling action between coil A and magnet M1 must be sufficient to overcome the resultant force urging the rotor to move counter-clockwise.

A current could be applied to the coil A for an angular displacement of 15° of magnet M1, but it is preferred that coil A be energised only for 12° 51′ 50″ angular displacement of magnet M1. By applying current to coil A for this period of angular displacement a minimum amount of current is applied to coil A in order to overcome the counter-clockwise resultant force which occurs for 0° to 15° of angular displacement of magnet M1.
Although current can be applied to coil \textbf{A} for longer than this period it has been discovered that by applying current for this period a back-EMF is induced in coil \textbf{A} which adds to the repulsive force applied to magnet \textbf{M1} by coil \textbf{A}. Every time one of the magnets \textbf{M1} to \textbf{M4} is aligned with coil \textbf{A} at 0°, coil \textbf{A} is energised for 12° 51' 50" of angular displacement of that magnet. Thus as shown in Fig.6, current ends up being applied to coil \textbf{A} at 0° to 12° 51' 50", and from 90° to 102° 51' 50" and from 180° to 192° 51' 50" and from 270° to 282° 51' 50".

A similar switching pattern is applied to coils \textbf{B} and \textbf{C}. For example coil \textbf{B} is energised when magnet \textbf{M2} has moved 30° to when it has moved 42° 51' 50" and likewise coil \textbf{C} is energised when magnet \textbf{M3} has moved 60° to 72° 51' 50". It is preferred that the rotor has a diameter of 230 mm and that each coil has a resistance of 6.8 ohms.
Fig. 7 shows a graphical representation of input voltage versus input current for a coil resistance of 6.8 ohms and for a four pole rotor which is 230 mm in diameter. The exact timing sequence for switching coils on and off will vary depending on the parameters of the rotary device and the controller. Accordingly by varying the input voltage, coil resistance and overall impedance of the input circuit for each coil the duration during which a coil must be turned on will change. In fact, there are many factors which can change the timing sequence of switching the coils on, and some of these are summarised below:

The Stator
The variables include the choice of material used in constructing the stator iron core, the number of stator iron cores and their positioning as well as the physical size, section area and shape of the stator iron cores.

Rotor
The physical size and magnetic strength and shape of the polarised permanent magnetic body as contained in the rotor, the number of polarised permanent magnetised bodies being contained in the rotor, the positioning and spacing of the same, the use of all like polarities of permanent magnetic bodies or the use of alternating polarities for the permanent magnetic bodies.

Stator Coil
The physical size of the coils being positioned on to the stator iron core, the type of wire used to wind the coils, such as copper, silver, aluminium or others. The shape and cross-sectional areas of the winding wire, such as round, square, triangular, rectangular and others; the number of turns and layers wound on to the coil and consequent ohms resistance; the method of winding on to a coil holder, single winding, double winding, double winding same direction, double winding opposite direction, left to right or right to left, interwoven winding, whether the above examples would be wound on to a single coil holder.

Speed of Rotor
This can be controlled by the length of the directed (input) DC current (on and cut-off period) and/or the control of the supply voltage used to supply the stator coils.

Other variations that may be made to the system include the following:

a. The coils can be connected in series, parallel, or series parallel.

b. It is only when the north/south arrangements of the permanent magnets are used in the rotor that even numbers of permanent magnets are necessary, but not necessarily even numbers of pairs of stator coils positioned in the stator. Furthermore the direction DC current Supplied to the stator coils in the north south arrangement above must be synchronised, meaning that the magnetic field as needed in the stator coil(s) must be of corresponding polarity to the stator coil(s), iron core end, which faces the permanent magnets.
c. When using permanent magnets which are all of the same polarity, then any number of permanent magnets in the rotor may be used providing there is sufficient room to contain them at even spacings on the rotor.

d. The spacings between the permanent magnets must be exact, if too close to each other the directed DC current will become less effective, if too far apart the full potential will not be obtained.

e. It is possible to have various combinations of permanent magnet and stator coil iron cores similar but not restricted to the following:
   i. Three magnets in the rotor, one to three stator coils can be used.
   ii. Five permanent magnets in the rotor, one to five stator coils can be used.
   iii. Nine permanent magnets in the rotor one to three or nine stator coils can be used.
   iv. The output varies with each combination.
   v. Regardless of the rotor containing even or uneven numbers of permanent magnets the stator can operate with only one stator coil and stator iron core and still be highly efficient but with reduced total output.

f. The stator and rotor should be made from non magnetic materials like wood, plastic, bronze and similar non-magnetic materials.

Although switching is performed in its preferred form by a mechanical rotary switch, it can also be performed by solid state electronics or other switching devices. The length of the ON period for each coil is the physical length ratio. When the brushes are in contact with the conductive part of the rotary switch and the non-conductive part. This ratio is referred as the frequency or number of ratios in one second. The output produced by the rotary device can be mechanical and electrical at the same time or may be mainly electrical or mainly mechanical. The reason for this will be explained with reference to the second embodiment in which it is assumed the stator has a single energising coil with an iron core and the rotor has a single permanent magnet.

When the rotor's permanent magnet is rotated very slowly by hand in the clockwise direction it is possible to determine the point where the natural magnetic attraction between the rotor's permanent magnet and the stator's iron core occurs. When the leading edge of the permanent magnet has reached point A as shown in Fig.8, the Natural Magnetic Attraction begins and increases exponentially until the centre of the permanent magnet is aligned at point B opposite the iron core 30. If the permanent magnet is rotated away from point B the Natural Magnetic Attraction will be at a maximum at point B and then decrease exponentially from that maximum until the trailing edge of the permanent magnet has reached point C where it then ceases.

When the rotor is moved clockwise at a constant speed and an oscilloscope is connected to the stator coil it is possible to observe the movement of the permanent magnet between point A and point B and then between point B and point C as shown in Fig.9.
An induced induction curve is then apparent on the oscilloscope and this induced induction produces a sine wave curve 31. Furthermore the induced induction between point A and point B is a negative going induced induction in this instance and the induced induction between point B and point C is a positive going induced induction in this instance. It is also noted that the negative-going and positive-going induced induction curves are exactly the same but opposite to each other.

When the permanent magnet begins to induce a negative-going induction in the stator coil at 0° of the sine wave curve 31, the induction induced is then at 0. At 90° degrees of the sine wave curve the induced induction is at a maximum and then goes back to 0 when the permanent magnet is aligned with point B, or at 180° of the sine wave curve, when the permanent magnet starts to move away from its alignment with point B or is at 180° of the sine wave curve.

When the permanent magnet start to move away from its alignment with point B and is moving towards point C the now positive-going induced induction is first at 0 at 180° of the sine wave curve, then at a maximum of 270° of the sine wave curve and then back to 0 at 360° of the sine wave curve. It should be noted that 0° and 360° of the sine wave curve are not necessarily the same as point A for 0° and point C for 360° of the sine wave curve. Points A and C are determined by the strength of the rotors permanent magnet and the section area and/or shape of the stator iron core.

The negative-going induced induction between 0° and 180° of the sine wave curve produces an electro-magnetic force in the stator coil and iron core of opposite polarity. The iron core end facing the rotor is of opposite polarity to the permanent magnet in this instance, as shown in Fig.10. The positive-going induced induction between 180° and 360° of the sine wave curve produces an electro-magnetic force in the stator coil and iron core of the same polarity in the iron core end facing the rotor, being of the same polarity as the permanent magnet in this instance. When the permanent magnet reaches point A the natural magnetic attraction between the permanent magnet and the stator iron core is at it’s minimum and starts to move toward point B. When the induced induction then also starts to occur at 0° of the sine wave curve, being somewhere between point A and point B, the natural magnetic attraction has already increased.
When the permanent magnet is at 0° of the sine wave curve and is moving towards point B or 180° of the sine wave curve, the negative-going induced induction in the stator coil is producing an electro-magnetic force (field) in the stator iron core with the iron core end facing the rotor being of an opposite polarity to the permanent magnet and is at zero effect at 0° of the sine wave curve, than to a maximum effect at 90° of the sine wave curve and then back to zero effect at 180° of the sine wave curve.

The permanent magnet is then aligned at point B. There the magnetic attraction force is proportional with the distance and this increases exponentially when moving from point A towards point B. There the stator iron core is fixed and stationary at point B. Accordingly it will be the permanent magnet that moves towards point B.

For example, if the stator iron core was also a polarised permanent magnet of the same strength but of opposite polarity to the permanent magnet, the magnetic attraction force would be at least four times greater because of the distance factor as explained earlier. Furthermore, this would also occur because of the doubling of the magnetic force between the magnetic north and south arrangement. It follows therefore that the magnetic attraction between the permanent magnet and the iron core end facing the rotor increases dramatically when the induced induction in the stator coil produces an electro-magnetic force of the opposite polarity at the stator iron core end facing the rotor as described above. The increase follows the sine wave curve starting from 0° to 90° of the sine wave and the above effect decreases from 90° back to 180° of the sine wave curve.

A combination curve of the natural magnetic attraction and the induced induction in the stator coil, producing an electro-magnetic force at the stator iron coil end facing the rotor of opposite polarity is shown in Fig. 10 from 0° to 180°. For 180° to 360° the stator iron coil and rotor of like polarities are shown. When the permanent magnet is aligned at point B and a direct current is supplied to the stator coil for only a short period starting at point B then the DC current is applied only long enough to overcome the natural magnetic attraction between permanent magnet and the stator's iron core end facing the rotor. The directed DC current as supplied to the
stator coil is producing a like-polarity at the iron core end facing the rotor and thus is repelling the permanent magnet away from point B towards point C. The natural magnetic attraction has thus changed to natural magnetic repulsion due to the like-polarity of the stator iron core end facing the rotor.

The length of the “ON” period has to be sufficient to overcome the natural magnetic attraction and could be as long as until the trailing edge reaches point C where the natural magnetic attraction ceases. However there the positive-going induced induction in the stator coil as produced by the permanent magnet produces an electromagnetic force in the stator or iron core end facing the rotor, producing a like polarity as the permanent magnet starting at 180° of the sine wave curve or point B and zero at that instant. At 270° of the sine wave curve, it is at a maximum and then ends up at zero at 360° of the sine wave curve. In other words at 270° of the sine wave the force is at maximum repulsion and there is induced induction in the stator coil depending on the speed of the rotor. The effect of variation on the speed of the rotor is shown by curves 35 in Fig.11.

As shown in Fig.11 regardless of the speed of the rotor the induced induction in the stator coil is at a maximum at 270° of the sine wave curve.

The ON period can be brought back to the point where the induced induction is great enough to carry the electromagnetic repulsion through to 360° of the sine wave curve and beyond point C. Therefore the greater the rotor speed the shorter the ON period of the input DC current has to be, due to the high induced induction in the stator coil as explained earlier. When the “ON” period is switched off it is called the “cut-off” point. From the cut-off point to 360° of the sine wave curve the repulsion is produced by back-EMF the induced induction in the stator coil as previously explained.

During the ON period, the magnetic repulsion force produced between the stator iron core at point B and the permanent magnet can be viewed as a combined repulsion force. Some of this force is produced by natural magnetic repulsion of the permanent magnet and some by the input DC current as supplied to the stator coil.
Therefore if the induced magnetic force as produced by the input DC current in the stator coil is made equal to that of the permanent magnet with the same polarity, then half of this repulsion force between the on period and the cut-off point, in this instance, is from the natural magnetic repulsion of the permanent magnet as a reaction to the induced magnetic force as supplied by the input DC current to the stator coil. The input DC current as supplied to the stator coil produces the magnetic repulsion force and is the only outside input to the overall system for total movement between point A and point C.

The total input can be summarised as:

a. The combined natural magnetic attraction and the electro-magnetic force as produced by the induced induction in the stator coil between point A to point B.

b. The combined magnetic repulsion force between the permanent magnet and the stator iron core facing the rotor during the on period and the cut-off point.

c. The electro-magnetic repulsion (see induced induction as explained earlier) between the cut-off point and point C.

d. The electro-magnetic repulsion produced by the back-EMF as represented by shaded portion 36 of Fig.11.

In another embodiment of the present invention the stator has two coils positioned at 180° with respect to each other and the rotor has three permanent magnets spaced at 120° apart. As set out in Table 2 below from 0 to 30° the resultant force urges the rotor counter-clockwise. At 30° the resultant force is 0 and from 30° to 90° the resultant force is clockwise. From 90° to 120° the resultant force is counter-clockwise. This completes a full cycle which is repeated three times throughout a 360° rotation of the rotor.

| TABLE 2 |
|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|
| M1  | 5° C  | 10° CC | 15° CC | 20° CC | 25° CC | 30° CC |
| M2  | 65 CW | 60 CW | 45 CW | 40 CW | 35 CW | 30 CW |
| M3  | 65 CC | 70 CC | 75 CC | 80 CC | 85 CC | 90 CC |
| RF  | CC    | CC    | CC    | CC    | CC    | CC  |

With the above configuration of poles and coils, if it is desired to move the rotor clockwise, current would need to be supplied to the coils of the stator to overcome the counter-clockwise force whenever this is counter-clockwise, but as explained previously, current does not need to be supplied to the coil to energise the coil for the full period during which the resultant force is counter-clockwise.

For convenience and ease of explanation the above embodiments have been restricted to permanent magnets on the rotor and coils on the stator However the basic concept behind the invention does not change if the permanent magnets are replaced by coils which are energised to produce the appropriate magnetic poles.

Similarly for an AC rotary device a rotating magnetic field generated by the stator winding or by the rotor/armature winding could similarly be switched to reduce the amount of current required to maintain rotation of the motor in one direction and to maximise the influence of back-EMF on maintaining rotation of the motor in a single direction.

The above principles also apply to generators where coils are energised to produce a magnetic field. In such a situation the coils are switched on for a time sufficient to maintain rotation in the single direction and to maximise the influence of back-EMF which tends to maintain rotation of the rotor/armature in a single direction.

By using the above concept it is possible to produce an output which can be both mechanical and electrical at the same time. Current generated in the stator coil windings can be used as an output and likewise the torque generated by the rotor can be used to supply a mechanical output. Likewise only one or the other form of output may be utilised.
Tewari Paramahamsa’s ‘Reduced Reaction’ Generator

In April 2015, the famous 80-year old Indian scientist Tewari (www.tewari.org) well-known for his use of the homopolar generator to produce large volumes of hydrogen for commercial use, announced his new generator design and his corresponding patent application, shown below, was published. His claim for a Lenz-reduced operation have produced performances between COP=2 and COP=3. Here is a picture of a prototype, which is held together by four spring-loaded straps. The coils are held in place inside the frame and permanent magnets are spun inside those frames:

The principle of operation is simple and elegant. The power output conductors are arranged in such a way so that half of the magnetic field generated by the output current (that is, the magnetic field which opposes the motor spinning the rotor) is in one direction and the remaining half is in the opposite direction, cancelling the effect of the first half. The result is an arrangement where increasing power output has no noticeable effect on the input power. In other words, the Lenz Law drag effect has been effectively overcome. Tewari is due our warmest congratulations for what he has achieved. Being sensible, Tewari does not mention anything about 20 kilowatts of self-powered output, but instead, puts the design forward as being an improvement in the design of existing generators – and it is most certainly that. Here is his patent application:

Reduced Reaction Rotary Alternating Current Generator

Abstract:
A reduced reaction alternating current generator including a hollow stator core, a cylindrical rotor within the stator, a freely rotating shaft coupled to the rotor, a first set of magnets in which the south pole of each magnet is
coupled to the surface of the rotor and the north pole of each magnet is facing the inner surface of the hollow stator core, a second set of magnets in which the north pole of each magnet is coupled to the surface of the rotor and the south pole of each magnet is facing the inner surface of the hollow stator core, and a set of silicon steel pieces coupled to the outer surface of the rotor comprised of individual silicon steel pieces positioned adjacent to and longitudinally in line with each individual magnet within the first set of magnets and each individual magnet within the second set of magnets.

Description:

BACKGROUND OF THE INVENTION
Michael Faraday discovered the principles of electromagnetic induction and invented the rotating electrical generator in 1832. The generator was known as the Unipolar Generator, Acyclic Generator and Disk Generator. This generator operated on the principle that voltage is induced in a conductor in relative motion to an external magnetic field. Moreover, when the conductor is configured as a closed circuit and is in relative motion with an external magnetic field, a current will be induced to flow through that circuit. The induced current itself will generate an induced magnetic field surrounding the conductor. The direction of the induced current is determined by Fleming's right hand rule which states that the magnetic field produced by the current induced in the conductor will repel the external magnetic field which induced the current in the conductor. As such, the induced magnetic field surrounding the conductor and the external magnetic field repel each other so as to create a torque on the conductor which opposes that conductor's movement relative to the external magnetic field. Faraday's generator and all subsequent generators have in common, the production of this counter or back-torque.

The efficiency of an electrical generator is governed by mechanical and electrical limitations. The mechanical limitations include windage and friction of the generator's rotor and bearings. The electrical limitations include electrical impedance within the windings of the generator as well as the above-described counter or back-torque.

A prime mover is attached to a generator so as to cause the rotation of the generator's rotor resulting in the production of either a direct or an alternating current within the generator's conductor and a back-torque which counters the rotation caused by the prime mover. The prime mover may be powered by steam, wind or water. Therefore, the problem with standard generators is that their efficiency is limited due to back-torque generated as a result of current induced within the generator's conductor windings.

DEFINITIONS
The following definitions are provided for convenience and are not to be taken as a limitation of the present invention.

_Fleming's Left Hand Rule_ refers to the effect that when a current flows in a conductor and an external magnetic field is applied across that current flow, the conductor will experience a force perpendicular to both the external magnetic field and the direction of the current flow. The Left Hand Rule can be used to represent three mutually orthogonal axes using the thumb to represent a mechanical force, the first finger to represent a magnetic field and the middle finger to represent the current, each finger positioned at right angles to each other.

_Synchronous generator_ refers to an electrical generator which turns at the same speed as the drive mechanism, also known as the synchronous speed. A synchronous generator produces an alternating current and voltage at a frequency proportional to the rotation speed and to the number of excitation poles internal to the generator.

_Asynchronous generator_ refers to an alternating current generator that uses the principles of induction to produce power. Asynchronous generators operate by mechanically turning their rotor faster than the synchronous speed, giving negative slip.

_Low carbon steel_ refers to steel containing less carbon than other steels. This steel is inherently easier to cold-form due to its soft and ductile nature.

_Grain-oriented electrical steel_ refers to sheet steel used for laminations in power transformers having a silicon level of 3% or less.

SUMMARY OF THE INVENTION
It is the primary purpose of the present invention to overcome the above problems by providing a reduced reaction rotating alternating current generator providing improvement in efficiency characteristics not currently available in standard alternating current generators.
To accomplish this objective, according to one embodiment of the present invention a reduced reaction alternating current generator is disclosed comprising a hollow stator core having an axis comprised of longitudinally positioned sheets laminated with a high permeability magnetic material, the laminated sheets including longitudinally embedded slots in which a conductor winding is laid parallel to the axis, a cylindrical rotor concentric with and positioned inside the hollow stator core comprised of a high permeability magnetic material and a shaft coupled to the rotor and driven by an external source so as to freely rotate the rotor relative to the hollow stator core. The generator comprises a first set of magnets in which the south pole of each magnet is coupled to the surface of the rotor and the north pole of each magnet is facing the inner surface of the hollow stator core, a second set of magnets in which the north pole of each magnet is coupled to the surface of the rotor and the south pole of each magnet is facing the inner surface of the hollow stator core and a set of silicon steel pieces coupled to the outer surface of the rotor comprised of individual silicon steel pieces positioned adjacent to and longitudinally in line with each individual magnet within the first set of magnets and each individual magnet within the second set of magnets.

In addition to the foregoing, other features, objects and advantages of the present invention will become apparent from the following description.

BRIEF DESCRIPTION OF THE DRAWINGS
The following detailed description, which is given by way of example only, will best be appreciated in conjunction with the accompanying drawings in which:

Fig.1 depicts a longitudinal cross-sectional view of a reduced reaction alternating current generator according to an example embodiment of the present invention;

Fig.2 depicts an end cross-sectional view of a reduced reaction alternating current generator according to an example embodiment of the present invention;

Fig.3 depicts a centre cross-sectional view of a reduced reaction alternating current generator according to an example embodiment of the present invention;

Fig.4 depicts a longitudinal cross-sectional view of the flow of magnetic fields emanating from the first set of magnets within a reduced reaction generator according to an example embodiment of the present invention;

Fig.5 and Fig.6 depict the interaction between the magnetic flux originating from the north poles of the first set of magnets and the magnetic flux resulting from an induced current in the conductor winding according to an example embodiment of the present invention;

Fig.7 depicts a longitudinal cross-sectional view of the flow of magnetic fields emanating from the second set of magnets within a reduced reaction generator according to an example embodiment of the present invention; and

Fig.8 and Fig.9 depict the interaction between the magnetic flux originating from the south poles of the second set of magnets and the magnetic flux resulting from an induced current in the conductor winding according to an example embodiment of the present invention.

DETAILED DESCRIPTION OF THE INVENTION
The present invention relates to a reduced reaction rotating alternating current generator providing improvement in efficiency characteristics not currently available in standard alternating current generators.
Fig. 1 depicts a longitudinal cross-sectional view of a reduced reaction alternating current generator according to an example embodiment of the present invention. As shown in Fig. 1, the induction machine 100 comprises a shaft 101, a rotor 102, a stator 103, a first set of magnets 104, a second set of magnets 105 (not shown), a conductor winding 106 and silicon steel pieces 107.

The rotor 102 is a cylinder of high permeability magnetic material attached directly to the shaft 101 using any conventional known method that provides for a secure and permanent bonding under normal operating conditions. The rotor 102 is dimensioned so as to be fully enclosed within the stator 103 while the shaft 101 extends beyond one or both ends of the stator 103.

The shaft 101 is mounted within the stator 103 so as to allow the shaft 101 and the attached rotor 102 to rotate freely within the stator 103 when the shaft 101 is driven by an external drive source. The external drive source is coupled to one end of the shaft 101 that extends beyond the stator 103. The external drive source may be driven either at a variable speed or at a synchronous speed. As such the drive source may be an alternating current (AC) based source or a direct current (DC) based source. The drive source may also be a non-electric based drive source such as a hydro, wind or an internal combustion based source. The means of coupling the drive source to the shaft 101 will be dependent on the type of drive source and any conventionally known means appropriate to that drive source type.

In an example embodiment, the shaft is 30 mm diameter 1018 steel, the rotor is 370 mm diameter 1018 steel and the stator has a 570 mm diameter.

Provisions are made on the cylindrical surface of the rotor 102 for the mounting of the first set of magnets 104 and for the mounting of the second set of magnets 105 near each of the ends of the rotor 102. Provisions are also made for the mounting of the silicon steel pieces 107 on the rotor at positions near the centre of the rotor.

The first set of magnets 104 and the second set of magnets 105 (not shown) are attached to the ends of the rotor cylinder 102 using any conventional method known to provide a secure and permanent bonding under normal operating conditions. Each end of the rotor 102 contains one of the first set of magnets 104 and one of the second set of magnets 105, for a total of four magnets. The first set of magnets 104 are oriented with their north poles facing the stator 103 and their south poles coupled to the rotor 102. The second set of magnets 105 (not shown) are oriented with their south poles facing the stator 103 and their north poles coupled to the rotor 102. The magnets may be permanent magnets or electromagnets.

In an example embodiment, the permanent magnets are Neodymium magnets with a maximum energy product (BH\text{max}) of 48 to 50 MGOe. Moreover, in another example embodiment, the electromagnets are radial pole and are attached to the rotor in a manner generally known in the industry.

The silicon steel pieces 107 are also attached to the rotor 102 using any conventional method known to provide a secure and permanent bonding under normal operating conditions. There is a single silicon steel piece 107.
corresponding to each magnet of the first and second sets of magnets 104 attached to the rotor 102. Each silicon steel piece 107 is positioned in line with its corresponding magnet leaving a predefined distance 109 between silicon steel piece and its corresponding magnet. Each silicon steel piece 107 is comprised of silicon steel which is a speciality steel tailored to have a small magnetic hysteresis area and high magnetic permeability. A high magnetic permeability is defined as having a magnetic saturation level above 1.8 Teslas.

In an example embodiment, the first and second sets of magnets 104, 105 and the silicon steel pieces 107 are each dimensioned to have approximately the same surface area and the distance 109 between silicon steel piece and a corresponding magnet is no more than the length of the magnet in the axial plane.

The rotor 102 and the attached magnets 104, 105 and steel pieces 107 are each sized as to provide for an air-gap 108 of a predetermined size between the outer surfaces of the attached magnets 104, 105 and silicon steel pieces 107 and the inner surface of the stator 103. The air gap is chosen to provide free rotation of the rotor 102 and the attached first and second sets of magnets 104, 105 within the stator 103 as well as the efficient flow of magnetic flux into and out of the stator 103 across the air-gap 108. In an example embodiment, the air-gap 108 is within a range of 3 mm to 10 mm.

The stator 103 is composed of longitudinally placed silicon steel laminates having grains oriented along the path of the magnetic flux that enters and exits the stator 103. The stator 103 also includes longitudinally oriented slots in which the conductor winding 106 is laid, the conductor winding 106 positioned such as to be cut through by the rotating magnetic flux originating from the first and second sets of magnets 104 attached to the rotating motor 102.

In an example embodiment, the stator is comprised of a magnetically inert material, such as PVC piping, of suitable strength to support grain oriented steel lamination sheets.

In an example embodiment, the magnetic flux emanating from the first and second magnets is approximately 10,000 Gauss.

Fig.2 depicts an end cross sectional view of a reduced reaction alternating current generator according to an example embodiment of the present invention. As shown in Fig.2 the first set of magnets 104 with their north poles facing the stator 103 and their south poles coupled to the rotor 102 are positioned at opposing in-line positions on one end of the rotor 102.

Similarly, the second set of magnets 105 with their south poles facing the stator 103 and their north poles coupled to the rotor 102 are positioned at opposing in-line positions on the same end of the rotor 102 at a ninety degree offset from the first set of magnets 104. An identical first set of magnets 104 and second set of magnets 105 are coupled to the other end of the rotor 102 at similar positions.
Fig. 3 depicts a centre cross sectional view of a reduced reaction alternating current generator according to an example embodiment of the present invention. As shown in Fig. 3, a single silicon steel piece 107 is positioned longitudinally in line with each magnet of the first and second sets of magnets 104, 105 (not shown). The position of each silicon steel piece 107 provides for a predefined distance 108 between a silicon steel piece 107 and its corresponding magnet.

In an example embodiment, the distance between a silicon steel piece 107 and its corresponding magnet is equal to the longitudinal length of the magnet.

Referring again to Fig. 1, an electromagnetic force (EMF) is created across the conductor winding 106 embedded within the stator 103 when the magnetic flux emanating from the first set of magnets 104 and from the second set of magnets 105 cut through the conductor winding 106 as the rotor 102 rotates. Looking in the direction of arrow C in Fig. 1, with the rotor 102 turning in a clockwise direction and the magnetic flux emanating in a vertically
upward direction from the north poles of the first set of magnets 104, the current generated as a result of the induced electromagnetic force will travel from left to right 110 within the conductor winding 106.

The current direction is as per Lenz's Law which states when an electric current is induced in a conductor, the direction of the induced current is such that its magnetic effect will oppose the action that gives rise to the induced current. As such, the direction of the induced current 110 results in a torque such as to oppose the clockwise rotation of the rotor 102. Specifically, looking in the direction of the arrow C in Fig.1, the interaction between the counter-clockwise magnetic field surrounding the conductor as a result of the induced electromagnetic force and the upward magnetic flux emanating from the north poles first pair of magnets 104 will create a counter-clockwise torque opposing the clockwise rotation of the rotor 102.

Fig.4 depicts a longitudinal cross sectional view of the flow of magnetic fields emanating from the first set of magnets within a reduced reaction generator. As shown in Fig.4, the magnetic flux 401 emanating from the north poles of the first set of magnets 104 travels vertically upwards, across the air gap 108 and into the stator 103 as the magnetic flux 401 rotates with the rotor 102 relative to the stator 103. As this rotating magnetic flux 401 enters the static stator 103, it cuts sideways across the conductor winding 106 embedded within the stator 103 and induces a current within the conductor winding 106.

Within the stator 103, a portion of magnetic flux 402 is now trapped within the grain stampings within the stator 103 and flows longitudinally in an effort to return to a corresponding south pole of the first set of magnets 104. This portion of the magnetic flux 402 is now static relative to the stator 103 and the embedded conductor winding 106. As such, this portion of the magnetic flux 402 flows through and exits the stator 103 without any sideways movement relative to the embedded conductor winding 106 and therefore without inducing a current within the conductor winding 106.

Outside the stator 103, a portion of the magnetic flux 403 crosses the air gap 108 and reaches the surface of a corresponding steel piece 107. The steel piece 107 focuses the magnetic flux 403 within the air gap 108 providing a more efficient and specifically designed path for the magnetic flux 403 to return to a corresponding first set of magnets 104. The magnetic flux 403 passes through the steel piece 107 and returns to a corresponding south pole of the first set of magnets 104 thereby closing the magnetic flux loop between north and south poles of each magnet of the first set of magnets 104.
Fig. 5 and Fig. 6 depict the interaction between the magnetic flux originating from the north poles of the first set of magnets and the magnetic flux resulting from an induced current in the conductor winding. In both Fig. 5 and Fig. 6, the current 110 induced in the conductor winding 106 by the clockwise rotation of the rotor 102 is shown coming out of the page. Moreover, in accordance with the application of the right hand rule, the magnetic flux 501 surrounding the conductor winding 106 as a result of the induced current 110 is shown as having a counter-clockwise rotation.

In Fig. 5, the magnetic flux originating from the first set of magnets is shown traversing the air gap upwards and interacting with the magnetic flux surrounding the conductor winding. As shown in Fig. 5, the magnetic field 401 originating from the first set of magnets 104 is strengthened on the right side of the conductor winding 106 due to the superimposition of the magnetic field 501 induced in the conductor winding 106 in the same direction. However, the magnetic field 401 originating from the first set of magnets 104, is weakened on the left side of the conductor winding 106 due to the superimposition of the magnetic field 501 induced in the conductor winding 106 in the opposite direction. As a result of this interaction, the net magnetic field in the air-gap 108 over the surfaces of the first set of magnets 104 results in the application of a counter-clockwise torque 502 to the rotor 102 which opposes the clockwise rotation of the rotor 102. This is in accordance with Lenz's Law and is confirmed by the right hand rule which shows that a conductor within an upward directed magnetic field and carrying a current in the induced direction (coming out of the page) will experience a counter-clockwise force.
In Fig. 6, the portion of the magnetic flux which is routed back from the stator, downwards across the air gap and through a silicon steel piece is shown interacting with the induced magnetic flux surrounding the conductor winding. As shown in Fig. 6, the magnetic field 403 routed down through the silicon steel piece 107 is strengthened on the left side of the conductor winding 106 due to the superimposition of the magnetic field 501 induced in the conductor winding 106 in the same direction. However, the magnetic field 403 is weakened on the right side of the conductor winding 106 due to the superimposition of the magnetic field 501 induced in the conductor winding 106 in the opposite direction. As a result, on the surface of the silicon steel piece 107, the magnetic field 403 develops a gradient from left to right thus creating a clockwise torque 602 which supports the clockwise rotation of the rotor 102. This is in accordance with Lenz's Law and is confirmed by the right hand rule which shows that a conductor winding 106 within a downward directed magnetic field 403 and carrying a current 110 in the induced direction (coming out of the page) will experience a clockwise force.

Therefore, as a result of this configuration, the conductor winding 106 embedded within the stator 103 is cut at two places by each magnetic flux originating from the north pole of the first set of magnets 104. Specifically, a first time when the magnetic field 401 enters the stator 103 in an upward direction and a second time when the magnetic field 403 exits the stator 103 in a downward direction through a silicon steel piece 107. The net effect is that the clockwise torque generated by the magnetic field 403 rerouted through the silicon steel pieces 107 partially cancels the counter-clockwise torque generated by the magnetic field 401 originating from the north poles of the first set of magnets 104. This results in a partial nullification of the back torque reaction caused by the effect of Lenz's Law reaction and results in a corresponding increase in the efficiency of the machine because the external drive source has to supply less torque to overcome the reduced reaction of the machine.
Fig. 7 depicts a longitudinal cross-sectional view of the flow of magnetic fields emanating from the second set of magnets within a reduced reaction generator. As shown in Fig. 7, the magnetic flux 701 flowing into the south pole of the second set of magnets 105 travels vertically downwards from within the stator 103 and across the air gap 108 as the magnetic flux 701 rotates with the rotor 102 relative to the stator 103. As this rotating magnetic flux 701 exits the static stator 103, it cuts sideways across the conductor winding 106 embedded within the stator 103 and induces a current within that conductor winding 106.

Within the stator 103, a portion of the magnetic flux 702 flows longitudinally along the grain stampings within the stator 103 from a position where the magnetic flux 702 enters the stator 103. This portion of the magnetic flux 702 is static relative to the stator 103 and to the conductor winding 106 embedded within the stator 103. As such, this portion of the magnetic flux 702 enters and flows through the stator 103 without any sideways movement relative to the embedded conductor winding 106 and, therefore, without inducing a current within the conductor winding 106.

Outside the stator 103, a portion of the magnetic flux 703 flows from a north pole of the second set of magnets 105, through a corresponding silicon steel piece 107, upwards across the air gap 108 and into the stator 103. The silicon steel piece 107 focuses the magnetic flux 703 within the air gap 108 providing a more efficient and specifically designed path for the magnetic flux 703 originating from a corresponding second set of magnets 105. The magnetic flux 703 exists the steel piece 107 and enters the stator 103 thereby closing the magnetic flux loop between the south and north poles of each magnet of the second set of magnets 105.

Fig. 8 and Fig. 9 depict the interaction between the magnetic flux originating from the south poles of the second set of magnets and the magnetic flux resulting from an induced current in the conductor winding. In both Fig.8 and Fig.9, the current 110 induced in the conductor winding 106 by the clockwise rotation of the rotor 102 is shown as going into the page. Moreover, in accordance with the application of the right hand rule, the magnetic flux 801 surrounding the conductor winding 106 as a result of the induced current 110 is shown as having a clockwise rotation.
In Fig. 8, the magnetic flux originating from the second set of magnets is shown traversing the air gap downwards and interacting with the magnetic flux surrounding the conductor winding. As shown in Fig. 8, the magnetic field $701$ originating from the second set of magnets $105$ is strengthened on the right side of the conductor winding $106$ due to the superimposition of the magnetic field $801$ induced in the conductor winding $106$ in the same direction. However, the magnetic field $701$ originating from the second set of magnets $105$ is weakened on the left side of the conductor winding $106$ due to the superimposition of the magnetic fields $801$ induced in the conductor winding $106$ in the opposite direction. As a result of this interaction, the net magnetic field in the air-gap over the surfaces of the second set of magnets $105$ results in the application of a counter-clockwise torque $802$ to the rotor $102$ which opposes the clockwise rotation of the rotor $102$. This is in accordance with Lenz's Law and is confirmed by the right hand rule which shows that a conductor within a downwards directed magnetic field and carrying a current in the induced direction (going into the page) will experience a counter-clockwise force.
In Fig. 9, the portion of the magnetic flux originally routed through the steel pieces 107, across the air gap 108 and into the stator is shown interacting with the induced magnetic flux surrounding the conductor winding. As shown in Fig. 9, the magnetic field 703 routed upwards through a steel piece 107 and across the air gap 108 is strengthened on the left side of the conductor winding 106 due to the superimposition of the magnetic field 801 induced in the conductor winding 106 in the same direction. However, the magnetic field 703 is weakened on the right side of the conductor winding 106 due to the superimposition of the magnetic field 801 induced in the conductor winding 106 in the opposite direction. As a result, on the surface of the silicon steel piece 107, the magnetic field 703 develops a gradient from left to right thus creating a clockwise torque 902 which supports the clockwise rotation of the rotor 102. This is in accordance with Lenz's law and is confirmed by the right hand rule which shows that a conductor winding 106 within an upwards directed magnetic field 703 and carrying a current 110 in the induced direction (going into the page) will experience a clockwise force.

Therefore, as a result of this configuration and as described above for the first set of magnets, the conductor embedded within the stator is cut at two places by each magnetic field terminating at the south pole of the second set of magnets. Specifically, a first time when the magnetic field 701 exits the stator 103 in a downward direction and a second time when the magnetic field 703 enters the stator 103 in an upward direction through a silicon steel piece 107. The net effect is that the clockwise torque generated by the magnetic field 703 rerouted through the silicon steel pieces 107 partially cancels the counter-clockwise torque generated by the magnetic field 701 terminating at the south pole of the second set of magnets 105. This results in a partial nullification of the back torque reaction caused by the effect of Lenz's Law reaction and results in a corresponding increase in the efficiency of the machine because the external drive source has to supply less torque to overcome the reduced reaction of the machine.

Lidmotor's Low-voltage Rotor

One very experienced developer whose YouTube ID is “Lidmotor” (because he makes motors from the lids of jars) has a short video at https://www.youtube.com/watch?v=SjWCprVXer8 showing a very simple rotor design with one of his jar lids mounted on a single bearing:

The white lid has four magnets attached to it spaced out evenly around the lid at ninety-degree intervals. Facing them is an air-core coil mounted on a non-magnetic support dowel and wound with 400 turns of ‘30-gauge’ wire on a plastic spool. As ‘Lidmotor’ is American, the ‘30 gauge’ wire is likely to be American Wire Gauge #30 with a diameter of 0.255 mm as opposed to the European Standard Wire Gauge size which has a 0.315 mm diameter. An air-core coil has no effect on the passing rotor magnets IF it is not carrying current. An output coil will cause drag on the rotor if current is being drawn from the coil, and so timed output switching as used by Robert Adams would be needed to not just overcome the drag, but to push the rotor on its way as well.

There are two very important features of this rotor drive design. One is the fact that a supercap (10-Farad, 2.3V) is used to drive the rotor and when supplied with a charge of only 0.5V to 1.0V, can spin the rotor for up to thirty
minutes. That very long time is likely to be a feature of the second important item which is that he has placed an LED across the reed switch used to power the coil. When the reed switch opens, a back-EMF voltage spike occurs and the LED feeds that voltage pulse back into the 100% efficient supercap, recovering most of the current used to drive the rotor. This is the same method as used by Robert Adams in his motor designs. Lidmotor presents his circuit like this:

![Circuit Diagram]

While the circuit shows the magnet operating the reed switch as being 180 degrees around from the coil, the photograph indicates that the switching magnet is one 90 degrees away. Any of the other magnets can be used. The reed switch operation is adjusted to get the best performance. This is done by moving the switch backwards and forwards along the moving path of the magnet to make the switching occur earlier or later. The objective is to push the rotor magnet on its way by pulsing the coil very briefly just after the rotor magnet has passed the centre of the coil. The length of time that the reed switch is closed can be adjusted by moving the switch closer to the magnet for a longer switch-closed time, or further away for a shorter switch closure. It is also possible to alter the closed time by positioning the switch across the path of the magnet travel or parallel to it.

If you are not familiar with a reed switch, it is just a glass tube, filled with an inert gas, and with two overlapping metal strips inside the tube:

![Reed Switch Diagram]

The external magnetic field magnetises the strips and they spring together due to magnetic attraction and spring apart again when the magnetic field moves away. These switches come in various sizes and the smallest version tends to be unreliable and has a very low maximum current capacity. The larger versions are much more robust.

Lidmotor’s circuit is very simple and very effective, even though the rotor will have minimal weight and no significant drag. One wonders if adding a second coil and a diode feeding the supercapacitor, if the system could not become self-running.

**Phemax’s Inertial-Propulsion and Electrical Generation System.**

Phemax Technologies, Inc. have developed what they describe as their ‘sustainable transportation system’ which is based on their inertial-propulsion generation wheel, which uses what they call ‘3-D Coraxial Hybrid Induction’ (CHI), in which ‘Coraxial’ refers to their “combined radial-axial” technique where drive is provided by a radial pulsed magnet system and power extraction is achieved using an axially-orientated magnet/coil system.

Taiwan inventor, Tajen (David) Chi, says that his company, "Phemax Technologies Inc." will be demonstrating their technology in September 2010 at an expo, after which they will allow interested and qualified parties to come to their premises for licensing discussions.

Their device can take the place of the battery component of an electric vehicle or it can be used to supplement...
and recharge a battery bank in the vehicle. At the September exhibition, they will allow visitors to ride their 2 kW test car. David intends to put their test data on the Internet. With a rotational input of 1 NM at 500 rpm, a single inertial-propulsion generation wheel can produce 1 KW of axial generative power.

David also said that a 150W output from his motor actually produces between 180 and 200 watts of mechanical output, while a 1500W output produces a mechanical output of 1800 to 2000 watts (96 Volts at 20 Amps), as measured by a watt meter, speed meter, torque meter, and oscilloscopes. He says that these measurements were made by Michael Hseuh, Vice President and Chief Technology Officer.

Ceramic-based and carbon-based ultra-capacitors are used to return some of the output power to the input in order to keep the machine running continuously without the need for a power supply when the engine is running and providing it's output. When driving a vehicle powered by this device, the mechanical driving torque is provided via a continuously-variable transmission.

At this time, Phemax Technologies, Inc. have a 150-Watt and a 2 kW prototype which they plan to demonstrate in September 2010. He says that they generally run these prototypes for eight hours each day in their lab. The central principle of the Phemax Technologies Inc. process is what they call "CORAXIA" which stands for "combined radial-axial" hybrid induction, abbreviated to "CHI", which is David's surname. They also call this the "3-D Coaxial Hybrid Induction" system. They state that their electromagnetic 3-D arrangement enables the wheel to have both radial flux propulsion and axial flux generation with just a single rotor and two separate stators. As the radial electric drive rotates, the mechanical energy due to the inertia of the wheel and the ground power transmission mechanism enables the wheels of a vehicle to generate electricity as they rotate.

There are two videos showing the device generating electricity, located here: [http://www.youtube.com/watch?v=W_lzpZxxcQ](http://www.youtube.com/watch?v=W_lzpZxxcQ) and [http://www.youtube.com/watch?v=O8rdR-fnO](http://www.youtube.com/watch?v=O8rdR-fnO) here.

Another application is where the electrical output from the device is being used to produce a hydrogen/oxygen gas mix from water using an underwater plasma arc:

David says he is self-taught in this area. He has three patents: Taiwan patent M352472, M372891 and M382655 (which are not in English). From his search of the patent index, the Internet and YouTube, David said he has not yet seen a patent or experimental set-up similar to what they have developed.

This motor/generator is unusual in that it uses pulsed rotor drive on magnets mounted on the circumference of the rotor and simultaneously, it picks up electrical energy from a coil/magnet arrangement mounted on the side faces of the rotor as shown here:
The basic drive/generator unit can be replicated on a single shaft to give increased power, still without increased frictional losses between the drive and the power generation:

It is unusual to see this technique used as it can be difficult to avoid interaction between the different magnetic fields. However, David has been entirely successful in doing this and the arrangement has no transmission losses between the drive motor and the generator as these are integral components of the system.

This system is capable of driving a self-powered air-conditioning unit and a 5 kW proof-of-concept prototype is shown here:
This device is also capable of driving electric lighting and with a 5 kilowatt output self-powered output, it can power most household needs. A typical washing machine has a 2.25 kilowatt maximum electrical draw as does the average tumble-dryer. Most fan-heaters are 3 kilowatts or less when on full output.

If a wind-power generator is already in place, then using the mechanical power of the generator to spin the axle of one of these CHI generators results in a very high-power electricity generation system.

Raymond Kromrey’s Electrical Generator.
Where the objective is to produce electricity from a rotating magnetic field, there has always been a search for some method of either reducing, or eliminating altogether, the drag on the rotor when electric current is drawn from the generator. One design which claims to have very limited drag caused by current draw is the Kromrey design. The main characteristics of this design are said to be:

1. It has almost constant electrical power output even when the rotor speed is altered by as much as 35%.

2. It can continue to operate with it’s electrical output short-circuited, without heating the rotor or causing a braking effect.

3. The production efficiency (electrical output divided by the driving force) is high.

4. The frequency of it’s AC output power can be adjusted to that required by the equipment which it powers.

5. The rotor can be spun at any rate from 800 rpm to 1,600 rpm.

6. The simple construction allows manufacturing costs to be about 30% less than other generators.

7. This generator is recommended for supplying power at or above the 1 kilowatt level.

Here is the patent for this device:

ELECTRIC GENERATOR

My present invention relates to an electric generator which converts magnetic energy into electric energy using two components which can rotate relative to each other, i.e. a stator and a rotor, one having electromagnets or permanent magnets which induce a voltage in a winding which forms part of an output circuit mounted on the other component.

Conventional generators of this type use a winding which whose conductors form loops in different axial planes so that opposite parts of each loop pass through the field of each pole pair, twice per revolution. If the loops are open circuit, then no current flows in the winding and no reaction torque is developed, leaving the rotor free to turn at the maximum speed of its driving unit. As soon as the output winding is connected across a load or is short-circuited, the resulting current flow tends to retard the motion of the rotor to an extent which depends on the intensity of the current and this makes it necessary to include compensating speed-regulating devices if it is necessary to maintain a reasonably constant output voltage. Also, the variable reaction torque subjects the rotor and its transmission to considerable mechanical stresses and possible damage.

It is therefore the general object of this invention to provide an electric generator which has none of the above disadvantages. Another object is to provide a generator whose rotor speed varies very little in speed between open circuit operation and current delivery operation. Another objective is to provide a generator whose output voltage is not greatly affected by fluctuations in its rotor speed.

I have found that these objectives can be achieved by rotating an elongated ferromagnetic element, such as a bar-shaped soft-iron armature, and a pair of pole pieces which create an air gap containing a magnetic field. Each of the outer extremities of the armature carries a winding, ideally, these windings are connected in series, and these coils form part of a power output circuit used to drive a load. As the armature rotates relative to the air gap, the magnetic circuit is intermittently completed and the armature experiences periodic remagnetisations with successive reversals of polarity.

When the output circuit is open, the mechanical energy applied to the rotor (less a small amount needed to overcome the friction of the rotating shaft) is absorbed by the work of magnetisation, which in turn, is dissipated as heat. In actual practice however, the resulting rise in temperature of the armature is hardly noticeable, particularly if the armature is part of the continuously air-cooled rotor assembly. When the output circuit is closed, part of this work is converted into electrical energy as the current flow through the winding opposes the magnetising action of the field and increases the apparent magnetic reluctance of the armature, and so the speed of the generator remains substantially unchanged if the output circuit is open or closed.

As the armature approaches its position of alignment with the gap, the constant magnetic field tends to accelerate the rotation of the armature, aiding the applied driving force. After the armature passes through the gap there is a retarding effect. When the rotor picks up speed, the flywheel effect of its mass overcomes these fluctuations in the applied torque and a smooth rotation is experienced.

In a practical embodiment of this invention, the magnetic flux path includes two axially spaced magnetic fields traversing the rotor axis and substantially at right angles to it. These fields are generated by respective pole pairs co-operating with two axially spaced armatures of the type already described. It is convenient to arrange these two armatures so that they lie in a common axial plane and similarly, the two field-producing pole pairs also lie in a single plane. The armatures should be laminated to minimise eddy currents, so they are made of highly permeable (typically, soft-iron) foils whose principle dimension is perpendicular to the rotor axis. The foils can be held together by rivets or any other suitable method.

If the ferromagnetic elements are part of the rotor, then the output circuit will include the usual current-collecting means, such as slip-rings or commutator segments, depending on whether AC or DC current output is desired. The source of coercive force in the stator includes, advantageously, a pair of oppositely positioned, yoke-shaped magnets of the permanent or electrically energised type, whose extremities constitute the pole pieces mentioned above. If electromagnets are used in the magnetic circuit, then they may be energised by an external source or by direct current from the output circuit of the generator itself.

I have found that the terminal voltage of the output circuit does not vary proportionately to the rotor speed as might be expected, but instead, it drops at a considerably slower rate with decreasing rotor speed. So, in a particular tested unit, this voltage fell to only about half its original value when the rotor speed was dropped to one
third. This non-linear relationship between terminal voltage and driving rate produces a substantially constant load current and therefore, electric output over a wide speed range, at least under certain load conditions, inasmuch as the inductive reactance of the winding is proportional to frequency (and consequently, to rotor speed) so as to drop off more rapidly than the terminal voltage, in the event of a speed reduction, with a resulting improvement in the power factor of the load circuit.

If the magnetic circuit contains only a single pole pair per air gap, the flux induced in the rotating armature will change its direction twice per revolution so that each revolution produces one complete cycle of 360 electrical degrees. In general, the number of electrical degrees per revolution will equal 360 times the number of pole pairs, it being apparent that this number ought to be odd since with even numbers it would not be possible to have poles alternating in polarity along the path of the armature and at the same time to have the North and South poles of each pair at diametrically opposite locations. In any case, it is important to dimension the curved facing faces of the pole pairs in such a manner so as to avoid allowing the armature to bridge between adjoining poles, so it is necessary to make the sum of the arcs spanned by these faces (in the plane of rotation) equal to considerably less than 360 degrees electrical.

The invention will now be described in more detail, reference being made to the accompanying drawings in which:

Fig.1 and Fig1A. illustrate a first embodiment of my invention, shown in axial section and in a cross-sectional view taken on line IA - IA of Fig.1 respectively.
Fig. 2 and Fig. 3 are perspective views illustrating two other embodiments.
Fig. 4 and Fig. 5 illustrate diagrammatically, two output circuit arrangements, one for a DC output and one for an AC output.

Fig. 6 is a somewhat diagrammatic illustration of an arrangement for comparing the outputs of a conventional generator and a generator according to this invention.
The generator 100 shown in Fig.1 and Fig.1A comprises a stator 101 and a rotor 102 which has a pair of laminated armatures 102' and 102", carried on a shaft 103 which is free to rotate in bearings mounted in the end plates 104' and 104", of a generator housing 104 which is made from non-magnetic material (e.g. aluminium) which is rigidly attached to the stator.

Shaft 103 is coupled to a source of driving power indicated diagrammatically by an arrow 110. The stator 101 includes a pair of yoke-shaped laminated electromagnets 101' and 101" whose extremities form two pairs of co-planar pole pieces, designated respectively 101a, 101b (North magnetic pole) and 101c, 101d (South magnetic pole). The pole pieces have concave faces, facing towards the complimentary convex faces 102a, 102d of armature 102' and 102b, 102c of armature 102". These faces whose concavities are all centred on the axis of
shaft 103, extend over arcs of approximately 20° to 25° each in the plane of rotation (Fig.1A) so that the sum of these arcs adds up to about 90° geometrically and electrically.

The stator magnets 101', 101" are surrounded by energising windings 109', 109" which are connected across a suitable source of constant direct current (not shown). Similar windings, each composed of two series-connected coils 106a, 106d and 106b, 106c, surround the rotor armatures 102' and 102", respectively. These coils form part of an output circuit which further includes a pair of brushes 107', 107" which are carried by arms 108', 108" on housing 104 with mutual insulation brushes 107', 107" co-operate with a pair of commuter segments 105', 105" (see also Fig.4) which are supported by a disc of insulating material 105, mounted on shaft 103.

By virtue of the series-connection of coils 106a-106d between the segments 105' and 105", as illustrated in Fig.4, the alternating voltage induced in these coils gives rise to a rectified output voltage at brushes 107' and 107". The unidirectional current delivered by these brushes to a load (not shown) may be smoothed by conventional means, represented by capacitor 112 in Fig.4.
Fig. 2 shows a modified generator 200, whose housing 204, supports a stator 201 essentially consisting of two permanent bar magnets 201' and 201'', extending parallel to the drive shaft 203 (on opposite side of it), each of these magnets being rigid and each having a pair of sole shoes 201a, 201c and 201b, 201d respectively. Rotor 202 is a pair of laminated armatures 202' and 202'', similar to those of the previous embodiment, whose output coils 206a, 206b, 206c and 206d are serially connected between a slip-ring 205', supported on shaft 203 through the intermediary of an insulating disc 205, and another terminal here represented by the grounded shaft 203 itself. Slip-ring 205' is contacted by brush 207 on holder 208, the output of this brush being an alternating current of a frequency determined by the rotor speed.
Fig. 3 shows a generator 300 which is basically similar to the generator 100 shown in Fig. 1 and Fig. 1A. It's shaft 303 carries a pair of laminated soft-iron armatures 302', 302" which can rotate in the air gaps of a pair of electromagnets 301', 301" which have windings 309' and 309". The commutator 305 again co-operates with a pair of brushes 307, only one of which is visible in Fig. 3. This brush, carried on an arm 308, is electrically connected to a brush 313 which engages with a slip-ring 314 positioned on an extremity of shaft 303 which also carries two further slip-rings 315', 315" which are in conductive contact with ring 314 but are insulated from the shaft. Two further brushes 316', 316" contact the rings 315', 315" and respectively are connected to windings 309' and 309". The other ends of these windings are connected to an analogous system of brushes and slip-rings on the extremity of the opposite shaft, and arranged so that the two commutator brushes are effectively bridged across the windings 309' and 309" in parallel. Therefore, in this embodiment, the stator magnets are energised from the generator output itself, it being understood that the magnets 301' and 301" (made, for example, of steel rather than soft iron) will have a residual coercive force sufficient to induce an initial output voltage. Naturally, the circuits leading from the brushes 307 to the windings 309', 309" may include filtering as described in connection with Fig. 4.
Fig. 6 shows a test circuit designed to compare the outputs of a generator of this design, such as the unit 100 of Fig. 1 and Fig. 1A, with a conventional generator 400 of the type having a looped armature 402 which rotates in the gap of a stator magnet 401 which is fitted with energising windings 409', 409''. The two generators are interconnected by a common shaft 103 which carries a flywheel 117. This shaft is coupled through a clutch 118 to a drive motor 111 which drives the rotors 402 and 102 of both generators in unison, as indicated by arrow 110. Two batteries 120 and 420, in series with switches 121 and 421, represent the method of supplying direct current to the stator windings 109', 109'' and 409', 409'' of the two generators.

The rectified output of generator 100 is delivered to a load 122, shown here as three incandescent lamps connected in series, and with a combined consumption of 500 watts. Generator 400, provides current into an identical load 422. Two watt meters 123 and 423 have their voltage and current windings connected respectively in shunt and in series with their associated loads 122 and 422, to measure the electric power delivered by each generator.

When clutch 118 is engaged, shaft 113 with its flywheel 117 is brought to an initial driving speed of 1,200 rpm. at which point, the switch 421 in the energising circuit of the conventional generator 400, is closed. The lamps 422 light immediately and the corresponding wattmeter 423 shows an initial output of 500 watts. However, this output drops immediately as the flywheel 117 is decelerated by the braking effect of the magnetic field on armature 402.

Next, the procedure is repeated but with switch 421 open and switch 121 closed. This energises generator 100 and the lamps 122 light up, wattmeter 123 showing an output of 500 watts, which remains constant for an indefinite period of time, there being no appreciable deceleration of flywheel 117. When the clutch 118 is released and the rotor speed gradually decreases, the output of generator 100 is still substantially 500 watts at a speed of 900 rpm. and remains as high as 360 watts when the speed dropped further to 600 rpm. In a similar test with a generator of the permanent magnet type, such as the one shown at 200 in Fig. 2, a substantially constant output was observed over a range of 1600 to 640 rpm.

**Teruo Kawai's COP=3.18 Magnetic Motor.**

In July 1995, a patent was granted to Teruo Kawai for an electric motor. In the patent, Teruo states that a measured electrical input 19.55 watts produced an output of 62.16 watts, and that is a COP of 3.18. The main sections of that patent are included in the Appendix.
In this motor, a series of electromagnets are placed in a ring to form the active stator. The rotor shaft has two iron discs mounted on it. These discs have permanent magnets bolted to them and they have wide slots cut in them to alter their magnetic effect. The electromagnets are pulsed with the pulsing controlled via an optical disc arrangement mounted on the shaft. The result is a very efficient electric motor whose output has been measured as being in excess of its input.
James Hardy’s Self-Powered Water-Pump Generator.

There is a video on Google which shows an interesting self-powered water-pump driven, electrical generator at: http://www.youtube.com/watch?v=IGpXA6qhH_Q

This is a very simple device where the jet of water from the pump is directed at a simple water-wheel which in turn, spins an electrical alternator, powering both the pump and an electric light bulb, demonstrating free-energy.

Initially, the generator is got up to speed, driven by the mains electrical supply. Then, when it is running normally, the mains connection is removed and the motor/generator sustains itself and is also able to power at least one light bulb. The generator output is normal mains current from a standard off-the-shelf alternator.

James has Patent Application US 2007/0018461 A1 published in 2007 on his design. In that application he points out that a major advantage of his design is the low noise level produced when the generator is running. In the video and the pictures above, the demonstration has the housing opened up in order to show how the generator system works, but during normal use, the compartments are completely sealed.

In his document, James shows the overall system like this:
The housing is divided into three separate compartments. The first compartment has a strong axle shaft running through it, supported on ball or roller bearings – possibly ceramic for this environment. The bearings are protected by being covered by splash guards which keep the water (or other liquid) off them. A waterwheel of almost any type is mounted on the shaft and a high-capacity water pump directs a stream of liquid on to the waterwheel, striking the paddles at right angles in order to provide the maximum impact.

This first compartment is sealed in order to contain all of the liquid inside it and the bottom is effectively a sump for the liquid. A pipe located near the bottom of the compartment feeds the liquid to the pump which is located in the second compartment. The pump boosts the liquid through a nozzle, directing it at the waterwheel. While almost any nozzle will work, it is usual to choose one which produces a concentrated jet of liquid in order to generate the largest possible impact. One would expect that the larger the diameter of the waterwheel, the more powerful the system would be. However, that is not necessarily the case as other factors such as the overall weight of the rotating members might affect the performance. Experimentation should show the most effective combination for any given pump.

The rotating shaft is given a third bearing supported by the side of the final compartment. The shaft then has a large diameter belt pulley mounted on it, the belt driving a much smaller pulley mounted on the shaft of the generator. This raises the rate at which the generator shaft is rotated. If the pump operates on AC mains voltage, then the generator will be one which generates mains voltage AC. If the pump operates on, say, 12 volts, then the generator will be one which generates 12 volts DC. The diagram above, shows the arrangement for a mains voltage system as that is probably the most convenient. If a 12-volt system is chosen, then the inverter can be omitted.

The generator is started by pressing the ‘normally open’ press-button switch marked “A” in the diagram. This passes the battery power through to the 1-kilowatt inverter which then generates AC mains voltage. The switch marked “B” is a “changeover” switch, and for starting, it is set so that it passes the AC power through switch “A” to the pump. This causes the pump to turn on and direct a powerful jet of liquid at the waterwheel, forcing it around and so powering the generator. When the generator gets up to full speed, switch “B” is flipped over, disconnecting the inverter and feeding the generator power through to the pump, keeping it running and supplying additional power to the output power sockets mounted on top of the housing. The press-button switch is released, disconnecting the battery which is no longer needed. Switch “C” is an ordinary On/Off mains switch which is needed if you want to turn the generator off.

A major advantage of this generator system is that the main components can be bought ready-made and so only very simple constructional skills and readily available materials are needed. Another advantage is that what is happening can be seen. If the pump is not working, then it is a simple task to discover why. If the generator is not spinning, then you can see that and sort the problem. Every component is simple and straightforward.

James suggests that a suitable pump is the 10,000 gallons per hour "Torpedo Pump" from Cal Pump, web site: http://www.calpumpstore.com/products/productdetail/part_number=T10000/416.0.1.1.
Georges Mourier’s COP=10,000 Motor/Generator Patent.
This patent from Frenchman Georges Mourier is quite remarkable in that it states clearly in the patent that it has a Coefficient Of Performance of 10,000 with an input power of just 10 watts producing an output of 100 kilowatts, which, considering the massive opposition of the US Patent Office to any claim of output power being greater than the input needed to produce that output, is little short of amazing. This patent contains a fair amount of mathematics where Georges goes about showing why there is a power amplification. This can be ignored by most people as the point to concentrate on is how to build a power-amplifying motor/generator.

US Patent 4,189,654
19th February 1980
Inventor: Georges Mourier

Electrical machine operating as a generator or as an amplifier

Abstract
The invention relates to an electrical machine. The stator 1 is a delay line, in the form of a low-pass filter in the example, formed by inductance 11 and capacitors 12 connected between these inductances and the common conductor 13. The rotor 2 comprises dissipating elements 22 incorporated in circuits 26, separate in the example,
and having a common point 25. It is put in movement by a motor. The machine operates as a high-gain amplifier having a wide band of high-frequency signals applied to the input 14 of the stator, separated from the output 15 by the decoupling zone 30. High powers are obtainable. Application to installations for testing vibration of industrial equipment and to high-power long wave radio transmission.

**Description**

The invention relates to an electrical machine capable of operating as a generator and as an amplifier. The machine comprises a fixed part, or stator, in which moves a moving part designated hereinafter by the term “rotor”, by analogy with the case of machines of the prior art in which the movement in question is a movement of rotation, although this movement may be other than a rotation and in particular a rectilinear translation in the case of the invention.

The stator consists of a line having two conductors which have two input terminals and two output terminals; its rotor comprises resistive elements under conditions which will be described in detail later.

In operation, a wave is propagated between the input terminals and the output terminals in question in this line. Electrical machines are known from U.S. Patent 3,875,484, in which the stator comprises inductances and capacitances incorporated in a transmission line, as in the machines of this invention, along which there is propagated, in operation, an electric wave, but contrary to the case of the invention, this line has only one pair of terminals to which those of the alternating current source are connected. The application of the voltage of this source between these terminals causes the rotation of the rotor of the machine which, as it is operating as a motor, does not have an output. Owing to the structure, a brief indication of which has been given above, the machine of this invention is intended, on the contrary, to operate as a generator or as an amplifier; it has an output constituted by the other pair of terminals of the stator, the rotor being driven by an exterior motor.

A better understanding of the invention will be had from the ensuing description with reference to the accompanying Figures which represent:

![Diagram](image)

**FIG.1**, diagrammatically, the stator assembly and the rotor of a machine to which the invention is applied;
Fig. 2 and Fig. 3, diagrammatically, an embodiment of an electrical circuit of the stator of a machine of the invention and the corresponding diagram;

Fig. 4, diagrammatically, a rotor structure of the machines of the invention;

Fig. 5
Fig. 5, a diagrammatic view of a variant embodiment of the machine of the invention having a stator according to the design of Fig. 2;

Fig. 7 and Fig. 8, diagrammatic views of two variant embodiments of the machine of the invention operating as amplifiers;
Fig. 6 and Fig. 9, two modifications of the machine of the invention operating as generators.
Fig. 1 shows diagrammatically, a machine structure to which the invention is applied, in which the stator 1 and the rotor 2 comprise poles aligned in the direction o → x along which the rotor movement occurs. These poles are marked as 10 and 20 and are repeated with the same horizontal spacing or pitch p in both the rotor and the stator. References 11 and 21 are the inductive windings through which the coupling occurs between a pole of the rotor and a pole of the stator when they align in the course of their movement. 

V_{sn} and V_{rn} are the instantaneous values of the voltages at the ends of these windings, and I_{sn} and I_{rn} are the currents in those coils at the moment of this alignment, n being the number assigned to the pole in each part of the machine. In order to simplify the notations, this index number 'n' will be omitted when mentioning the voltages and currents in question. \( \phi \) designates the magnetic flux and M the coefficient of mutual inductances of this coupling. There are then obtained the following known equations:

\[
\begin{align*}
\phi_s &= L_s I_s + M I_r \\
\phi_r &= M I_s + L_r I_r \\
V_s &= j \omega L_s I_s + j \omega M I_r \\
V_r &= j \omega M I_s + j \omega' L_r I_r
\end{align*}
\]

where \( L_s \) and \( L_r \) are the values of inductances 11 and 21 and \( \phi_s \) and \( \phi_r \) the magnetic flux in these windings.

In these equations, the quantities \( \omega \) and \( \omega' \) are the angular frequencies of the currents in the stator and the rotor respectively; \( \omega = 2 \pi f \), where \( f \) is the corresponding frequency. For equal phase differences between two successive poles of the stator and rotor, the pulses \( \omega \) and \( \omega' \) in the relation:

\[
\omega' = \omega - \beta u \ldots . (5)
\]

where \( \beta \) is in accordance with the usual definition the constant of propagation of the magnetic field wave along the stator, and \( u \) is the speed at which the rotor moves in front of the stator in the direction of the reference axis o → x in the case of the machine of the embodiment of Fig.1.

\[
\beta = \frac{2 \pi}{\Lambda} = \frac{\omega}{v \phi}
\]

if \( \Lambda \) and \( v \phi \) respectively are the wavelength and the phase velocity in the stator.

In the embodiment of the machine of this invention having a stator in the form of a low-pass filter transmission line with an input 14 and an output 15, and the inductances 11, charge-accumulating elements 12 mounted between these inductances, and a common conductor 13 as shown in Fig.2 and Fig.3, there is added to the foregoing equations the following equation:

\[
\frac{V_s}{I_s} = - \frac{2}{j C_s \omega} (1 - \cos \alpha) \ldots . (6)
\]

where \( \alpha \) is equal to \( \beta_p \) and \( C_s \) is the value of the capacitors 12 (Fig.2) included in the construction of the filter, it being observed that there is obtained with the notations of Fig.3:

\[
I_s = \frac{-J_s}{1 - \exp (-j \alpha)} \quad \text{and} \quad V_s = U_s (1 - \exp (j \alpha)), \quad \text{with} \quad U_s = -j \frac{J_s}{C_s \omega}
\]
There is also added:

\[ \mathbf{V}_r + R_r \mathbf{I}_r = 0 \quad \ldots \ldots \ldots (7) \]

the equation for a rotor constructed, as shown in Fig. 4, by separate resistive circuits each of which comprises, in addition to the foregoing, coupling inductance \( 21 \), a resistor \( 22 \) of value \( R_r \).

By eliminating the magnitudes of flux, voltage and current between the homogeneous equations (1), (2), (3), (4), (6) and (7) and by replacing \( \omega' \) with its expression taken from equation (5), there is obtained an equation in \( \beta \) whose roots have an imaginary part, whence it results that the variation with respect to time of the wave propagated along the stator in the direction \( o \cdots x \) of Fig. 1, whose amplitude is proportional, in accordance with the conventional notation, to \( \exp j(\omega t - \beta x) \), undergoes an amplification in the course of this propagation.

The equation in question is:

\[ (\beta - \frac{\omega}{u}) + \frac{j}{u} \left( \frac{L_r}{R_r} \beta^2 \right)(\beta^2 - \beta_1^2) = j \frac{\beta_1^2}{u} \frac{L_r}{R_r} \frac{M^2}{L_r L_s} \left( 1 - \frac{M^2}{L_r L_s} \right) \quad \ldots \ldots (8) \]

with \( \beta_1^2 = \omega^2 C_s L_s \left( \frac{1}{\rho^2} (1 - \frac{M^2}{L_r L_s}) \right) \)

and assuming that \( \alpha \) is small, that is to say, that the machine has a large number of phases in the electro-technical sense of the word, the roots of which will be calculated by their relative difference \( z \) from a reference value chosen to be equal to \( \omega / u \), which is but little different, under the conditions of operation of the machines of the invention, from the quantity \( \beta_1 \) defined above; there is obtained:

\[ z = \frac{\beta - \beta_1}{\beta_1} \text{ and } \beta = \beta_1(1 + z) \quad \ldots \ldots (9) \]

The foregoing ratio \( \omega / u \) is none other than the value of \( \beta \) in synchronous machines, in which \( \omega' \) is null (equation 5). In the machines of this invention, \( \omega' \) is non-zero: these machines operate in the asynchronous manner.

The equation in \( z \) is written:

\[ z^2 + 2j\gamma z - j\gamma = 0 \quad \ldots \ldots (8') \]

in the particular case of a coupling coefficient

\[ \mu = \frac{M^2}{L_r L_s} \frac{1}{\frac{1}{2}} \]

It has two roots having an imaginary part. The machine is capable of amplifying a signal applied to the input of the stator. The order of magnitude of this amplification is shown below as an example. The expression of these roots is:

\[ z = -j\gamma \pm j\sqrt{\gamma^2 - j\gamma} \quad \ldots \ldots (10) \]

with:

\[ z = \frac{R_r}{L_r} \frac{1}{2u\beta_1} \]

to which the following numerical values correspond for a certain number of values of \( \gamma \). The amplified wave corresponds to the root \( Z^+ \).

The gain $g$ in power per unit length of the stator is, according to equation (9) is:

$$g \text{ db/m} = 8.7\beta_1 \text{(imaginary part of } z)$$

In the given example, this gain reaches its maximum value for the wave corresponding to $z^+$, for $\gamma$ between 0.1 and 0.3. The imaginary part of $z$ is then in the neighbourhood of 0.15, which gives for $g$, in respect of a stator whose length is 5 wavelengths ($x = 5$), about 40 decibels. It will be observed that the corresponding propagation constant $\beta$ differs only slightly in absolute value from the constant $\omega/u$ corresponding to synchronous operation. The machine of this invention operates under conditions which differ only slightly from synchronous operating conditions.

The wave passing through the stator is amplified in the manner of an electromagnetic wave which is propagated along the delay line of wave propagating tubes employed in hyper frequency described, among others, by J. R. Pierce in "Travelling Wave Tubes", Van Nostrand Co, 1950. The amplification occurs, as for these tubes, in a wide band around the central frequency.

In the foregoing, the rotor has been represented, for ease of description, with a structure having poles (reference 20 in the Figures). With the scope of the invention the rotor could be in the form of the well-known squirrel-cage structure of asynchronous machines. The above calculations remain valid in giving to the notion of resistance and to the notion of inductance the significance they have in this case.

The foregoing properties have been established by means of simplifying hypotheses which permit a clearer presentation. These properties apply generally to all machines whose stator and rotor would have the indicated electrical structure, even in the case of an operation which would differ slightly from these hypotheses in the neighbourhood of synchronous frequency. Moreover, the case was considered of a coupling by inductance between the rotor and the stator with a mutual coefficient $M$. Within the scope of the invention, this coupling could also be of an electrostatic nature between the conductors of the stator and rotor; similar equations would be obtained by substituting for the coefficient $M$ the coefficient of electrostatic influence between the conductors in question, for the quantity $L_r$ that, $C_r$, of the capacitance of each circuit of the rotor and, after intervention between $L_s$ and $C_s$. In this case $V_r$ (equation 7) represents the voltage drop at the terminals of the capacitance of the rotor.

The machine of this invention is also capable of operating as a generator, as will be seen below. A few embodiments of the structure of the machine of this invention will be given here.

![Fig.5](image)

**Fig.5** shows a first modification of this structure comprising a stator in accordance with the low-pass filter diagram of **Fig.2**. The rotor is a squirrel-cage, the reference numerals 32 and 33 are the bars and the end faces. In operation, it is driven by a rotor (not shown) which rotates it in the direction of the arrow about axis $X$ which is common to the rotor and the stator of the machine. A source of alternating voltage 40 is applied to input 14 of the
stator, and applied to the output 15 is a load 36, the impedance of which is equal to the characteristic impedance of the line of which the stator is part. In this arrangement of revolution about the axis X, a decoupling zone 30 separates the input and output of the stator. Further, in this zone, and in order to avoid any risk of coupling between input and output of the stator by the circuits of the rotor, there is provided any damping device considered necessary, an embodiment of which is given below.

The different elements of the filter constituting the stator are damped by the resistors 16, and 18 which are connected as shown in the Figure between the windings 11 and the conductor 13 common to the terminals of the capacitors 17 and 19.

Such a machine operates as an amplifier of the signal applied to the input of the stator with a gain which is of the order of 40 db in the numerical example given above. Such machines may be used as supply sources for high-power vibrators for the testing of industrial equipment of all kinds. They have the advantage over presently-known installations of this type of avoiding the steep leading edges and the high frequencies which result in their spectrum. Output powers of 100 kilowatts may be obtained with 10 watts applied at the input, with frequencies ranging up to 50 kHz. The same machine may be used as a high-power amplifier in radio broadcasting.

Fig.7 and Fig.8 give two other modifications of the arrangement of the circuits of the rotor in which the same reference numbers indicate the same components as in the preceding Figures. In Fig.8, the coupling between the rotor and stator is electrostatic. It occurs between conductors 34 and 35 when they face each other in the course of the rotation of the rotor.
In Fig. 7, 110 and 112 designate the two constituent parts of the self-inductances associated with each one of the poles 10 of the stator, and 210 and 212 the parts of the self-inductances of each pole 20 of the rotor. In both Fig. 7 and Fig. 8, 25 is a common conductor and 26 indicates all of the elements associated with each pole of the rotor. In the modification of Fig. 8, an example is given of the construction of the damping device 31 in the zone 30. A rail 38 is earthed through resistor 37 and through a contact (not shown) of the circuits of the rotor out along this rail 38 when they pass through the zone 30.

The same machine is capable of operating as a generator (Fig. 6 and Fig. 9).

Fig. 6 represents a machine whose stator is connected as a high-pass filter: each pole winding is connected at one end to the common conductor 13 and at the other end to two capacitors 12, as shown above. The filter thus constructed has a phase velocity which varies very rapidly with the frequency and in the direction opposed to that of the flux of electrical energy (inverse wave). The rotor has a velocity rather close to that of the phase velocity whereas the energy flows back to the load 36 in the opposite direction. The upstream side (for the energy) of the filter terminates on the characteristic impedance 42 of the filter. A generator is obtained in this way having a
frequency which is determined within a wide band by the speed of rotation of the rotor. In the example shown in
the Figure, the rotor has a squirrel-cage structure.

The machine of Fig.9 differs from that of Fig.6 by the addition of supplementary capacitors $120$ arranged in
parallel with the inductances $11$. The circuit thus obtained is an inverse wave band-pass filter. The width of its
band-pass is determined by the respective values of the capacitors $12$ and $120$. The phase velocity remains
rapidly variable as a function of the frequency. The machine operates as a generator, the frequency of which,
depends only very slightly on the velocity of rotation of the rotor.

The “RotoVerter” Power Amplification System.
Not all pulsed-drive systems use permanent magnets as part of their drive mechanism. For example, the
RotoVerter, designed by Hector D Peres Torres of Puerto Rico, and which has been reproduced by several
independent researchers, producing at least 10 times more output power than the input power, uses standard
three-phase electric motors instead of magnets.

This system has been reproduced by several independent researchers and it produces a substantial power gain
when driving devices which need an electrical motor to operate. At this time, the web site:
http://panacea-bocaf.org/rotoverter.htm has considerable details on how to construct the device as do the
http://www.scribd.com/doc/2965018/HighEfficiencyForElectricMotors and the
http://www.scribd.com/doc/26347817/RV-Energy-Saving-X documents. The outline details are as follows:

The output device is an alternator which is driven by a three-phase mains-powered, 3 HP to 7.5 HP motor (both of
these devices can be standard ‘asynchronous squirrel-cage’ motors). The drive motor is operated in a highly non-
standard manner. It is a 240V motor with six windings as shown below. These windings are connected in series
to make an arrangement which should require 480 volts to drive it, but instead, it is fed with 120 volts of single-
phase AC. The input voltage for the motor, should always be a quarter of its rated operational voltage. A virtual
third phase is created by using a capacitor which creates a 90-degree phase-shift between the applied voltage
and the current.
The objective is to tune the motor windings to give resonant operation. A start-up capacitor is connected into the circuit using the press-button switch shown, to get the motor up to speed, at which point the switch is released, allowing the motor to run with a much smaller capacitor in place. Although the running capacitor is shown as a fixed value, in practice, that capacitor needs to be adjusted while the motor is running, to give resonant operation. For this, a bank of capacitors is usually constructed, each capacitor having its own ON/OFF switch, so that different combinations of switch closures give a wide range of different overall values of capacitance. With the six capacitors shown above, any value from 0.5 microfarad to 31.5 microfarad can be rapidly switched to find the correct resonant value. These values allow combined values of 0.5, 1.0, 1.5, 2.0, 2.5, 3.0, 3.5, ......by selecting the appropriate switches to be ON or OFF. Should you need a value greater than this, then wire a 32 microfarad capacitor in place and connect the substitution box across it to test higher values step by step to find the optimum value of capacitor to use. The capacitors need to be powerful, oil-filled units with a high voltage rating - in other words, large, heavy and expensive. The power being handled in one of these systems is large and setting one up is not without a certain degree of physical danger. These systems have been set to be self-powered but this is not recommended, presumably because of the possibility of runaway with the output power building up rapidly and boosting the input power until the motor burns out.

The Yahoo EVGRAY Group at [http://groups.yahoo.com/group/EVGRAY](http://groups.yahoo.com/group/EVGRAY) has a large number of members many of whom are very willing to offer advice and assistance. A unique jargon has built up on this forum, where the motor is not called a motor but is referred to as a “Prime Mover” or “PM” for short, which can cause confusion as “PM” usually stands for “Permanent Magnet”. RotoVerter is abbreviated to “RV” while “DCPMRV” stands for “Direct Current Permanent Magnet RotoVerter” and “trafo” is a non-standard abbreviation for “transformer”. Some of the postings in this Group may be difficult to understand due to their highly technical nature and the extensive use of abbreviations, but help is always available there.

To move to some more practical construction details for this system. The motor (and alternator) considered to be the best for this application is the “Baldor EM3770T” 7.5 horsepower unit. The specification number is 07H002X790, and it is a 230/460 volts 60Hz 3-phase, 19/9.5 amp, 1770 rpm, power factor 81, device.

The Baldor web site is [www.baldor.com](http://www.baldor.com) and the following details should be considered carefully before trying any adaption of an expensive motor. The following constructional photographs are presented here by kind permission of Ashweth of the EVGRAY Group.

The end plate of the drive motor needs to be removed and the rotor lifted out. Considerable care is needed when doing this as the rotor is heavy and it must **not** be dragged across the stator windings as doing that would damage them.
The second end-plate is then removed and placed on the opposite end of the stator housing:

The fan is removed as it is not needed and just causes unnecessary drag, and the rotor is inserted the opposite way round to the way it was removed. That is, the housing is now the other way round relative to the rotor, since the rotor has been turned through 180 degrees before being replaced. The same part of the shaft of the rotor passes through the same end plate as before as the end plates have also been swapped over. The end plates are bolted in position and the rotor shaft spun to confirm that it still rotates as freely as before.

To reduce friction to an absolute minimum, the motor bearings need to be cleaned to an exceptional level. There are various ways of doing this. One of the best is to use a carburettor cleaner spray from your local car accessories shop. Spray inside the bearings to wash out all of the packed grease. The spray evaporates if left for a few minutes. Repeat this until the shaft spins perfectly, then put one (and only one) drop of light oil on each bearing and do not use WD40 as it leaves a residue film. The result should be a shaft which spins absolutely perfectly.

The next step is to connect the windings of the two units. The motor (the “Prime Mover”) is wired for 480 volt operation. This is done by connecting winding terminals 4 to 7, 5 to 8 and 6 to 9 as shown below. The diagram shows 120 volts AC as being the power supply. This is because the RotoVerter design makes the motor operate at a much lower input than the motor designers intended. If this motor were operated in the standard way, a 480 volt 3-phase supply would be connected to terminals 1, 2 and 3 and there would be no capacitors in the circuit.
It is suggested that the jumpering of the motor windings is more neatly done by removing the junction box cover and drilling through it to carry the connections outside to external connectors, jumpered neatly to show clearly how the connections have been made for each unit, and to allow easy alterations should it be decided to change the jumpering for any reason.

The same is done for the unit which is to be used as the alternator. To increase the allowable current draw, the unit windings are connected to give the lower voltage with the windings connected in parallel as shown below with terminals 4, 5 and 6 strapped together, 1 connected to 7, 2 connected to 8 and 3 connected to 9. This gives a three-phase output on terminals 1, 2 and 3. This can be used as a 3-phase AC output or as three single-phase AC outputs, or as a DC output by wiring it as shown here:
The motor and the alternator are then mounted securely in exact alignment and coupled together. The switching of the direction of the housing on the drive motor allows all of the jumpering to be on the same side of the two units when they are coupled together, facing each other:

The input drive may be from an inverter driven from a battery charged via a solar panel. The system now needs to be ‘tuned’ and tested. This involves finding the best ‘starting’ capacitor which will be switched into the circuit for a few seconds at start-up, and the best ‘running’ capacitor.

To summarise: This device takes a low-power 110 Volt AC input and produces a much higher-power electrical output which can be used for powering much greater loads than the input could power. The output power is much higher than the input power. This is free-energy under whatever name you like to apply to it. One advantage which should be stressed, is that very little in the way of construction is needed, and off-the-shelf motors are used. Also, no knowledge of electronics is needed, which makes this one of the easiest to construct free-energy devices available at the present time. One slight disadvantage is that the tuning of the “Prime Mover” motor depends on its loading and most loads have different levels of power requirement from time to time. A 220 Volt AC motor can also be used if that is the local supply voltage.

If an alternator is being driven by the RotoVerter motor (the “Prime Mover”) but although the shaft is being rotated rapidly there is no output voltage, then it is likely that the alternator has been sitting around unused for a long time and has lost the magnetic properties which it needs at start-up. To fix this, connect each of the three output windings, one at a time, across a car battery for about five seconds to develop some magnetism and the alternator will then work. This is a one-off thing only needed after a long period of inactivity.

It is not essential to construct the RotoVerter exactly as shown above, although that is the most common form of construction. The Muller Motor mentioned earlier, can have a 35 kilowatt output when precision-constructed as Bill Muller did. One option therefore, is to use one Baldor motor jumpered as the “Prime Mover” drive motor and have it drive one or more Muller Motor style rotors to generate the output power:
T. J. Chorister in America has used a Rotoverter style circuit for some time now. He uses a 200V 3-phase electric motor driven by a single-phase 120V 60 Hz mains. He says: The hot wire goes direct to one phase, and it also goes through a ‘run’ capacitor to the second phase, also thru an inductor to the 3rd phase. You have to experiment with the values of the capacitor and inductor in order to get the smoothest running of the motor. Often you will not even need a switched starting capacitor. Generally, a one-horsepower motor will output about three-quarters of a horsepower. However, the arrangement will be much more efficient than a single phase motor. The neutral is not needed, but be sure to use a ground connected to the frame of the motor.

Run capacitors pass about 1-amp for each 22 microfarads of its capacity and so they act as current limiters when in series in an AC circuit. Inductors should have wire which is thick enough to carry the current needed by the motor. I have no guidelines for inductors, so just try it (if you can measure one leg of the motor winding, then that would be about right for the inductor). The inductor value is adjusted by trial and error until you find the value where the motor runs most smoothly.

If a starting capacitor is needed, then just parallel a starting capacitor and switch and connect a bleeder resistor to the run capacitor. The circuit is like this:

Power Boosting Through Coil Short-Circuiting.
The RotoVerter output and the Muller Motor/Generator output (and possibly, the Adams Motor output) can be increased very substantially by a technique developed by "Kone" the moderator of the EVGRAY Yahoo forum already mentioned. The technique is to place a dead short-circuit across each output coil, just as the magnetic field of that coil reaches a maximum. This is done five times in rapid succession and can boost the output power by an estimated factor of 100 times.
On the surface, it appears complete madness to place a short-circuit across the very output which you are generating as the whole point of the exercise. However, it is not as mad as it seems. At the peak point, the coil itself contains a large amount of energy and when a short-circuit is placed across it, the result is quite unusual. The effect of short-circuiting an iron-cored coil has been demonstrated by Ron Pugh of Canada with a bench test using this equipment:

![Image of bench test equipment showing short-circuiting an iron-cored coil]

Here, a device for measuring magnetic fields is sensing the magnetic field of the coil as the rotor magnets move past the coil. The measurement is done with the coil operating normally and then again, with the coil short-circuited. The results are shown in these oscilloscope displays:

![Oscilloscope display of magnetic field measurement](image)

**OPEN COIL**

**SHORT-CIRCUITED COIL**

Quite surprisingly, the magnetic field is reversed by the short-circuit. If we consider just the first half of the cycle:
You will notice that when the open coil has a very strong positive position (relative to a North magnetic pole), the short-circuited coil has a strong reading of the opposite polarity. Therefore, at any given instance near the peak, there is the potential for a major magnetic reversal if the coil were to be switched from the red area into the blue area and back again. You might imagine that if the coil short-circuiting were performed very rapidly, that there would be a result like this:

However, this is not really possible with an iron-cored coil as it is not able to reverse it's magnetisation rapidly enough to produce this effect. Coils with iron cores might get up to 3,000 reversals per second although 1,000 would probably be a more realistic figure. For higher frequencies, a ferrite core could be used and for yet higher frequencies again, an iron-dust epoxy-encapsulated core is needed. For unlimited frequencies, an air-core coil is used.

In the RotoVerter / Muller Motor example where Kone has demonstrated major energy gains, the arrangement is different to Ron Pugh's bench-test example. Firstly, the magnets on the rotor present two poles to the coil as they pass by, giving a full, even sine wave output. Secondly, Kone uses an air-core coil and he has the fast switching implemented to take advantage of that coil type:
This screen shot shows exactly the same effect with the oscillating pulses plunging down to exactly where the negative trace would be at that time during each of the short-circuited periods. The display is showing a twenty-volt peak-to-peak waveform with each complete sine wave cycle taking 2 milliseconds.

Instead of the original gradual magnetic rise to a single peak, there are now five very sharp magnetic reversals, each of which are substantially larger than the original peak. It is the change of magnetic flux in the pick-up coil which produces the output power, so it can be seen that with this additional switching, a massive increase in flux change has been produced in the output coil. This increase is both a larger magnetic swing and a much greater rate of change of the flux, and as the rotor is spinning at some 1,800 rpm and has many magnets in it, the overall magnetic power increases by a major factor. Please note that in the following diagrams produced by Kone, the rotor magnet has a South pole which reaches the pick-up coil first, followed by a North pole passing the coil. This produces an excellent sine wave output in the coil.

The additional switching is performed by a mechanical brush and contact system and the power collection circuit used for the short-circuited coil is:

```
"STAGE ONE" (coil shorts, cap fills up)
N magnets  S
aircoil
AC source
AC series cap 6uf 660V
DC cap 33uf 450V
FWBR

note: coil shorts by sw1 at sinewave peaks

sw1
sw2
analog ammeter
6 ohm resistive load
sw3
```

and when the coil is not short-circuited, the circuit is:

```
"STAGE TWO" (cap unloads to load while source disconnects)
N magnets  S
aircoil
AC source
AC series cap 6uf 660V
DC cap 33uf 450V
FWBR

sw1
sw2
analog ammeter
6 ohm resistive load
sw3
```
Doug Konzen has been developing this circuitry and generously sharing his results freely. His web site is at http://sites.google.com/site/alternativeworldenergy/shorting-coils-circuits and his most recent practical circuit is:

There is a video on the web where coil-shorting is used on the output from a replication of John Bedini's Window Motor. John's Window Motor is a cylinder with magnets mounted in it, spun inside a large coil by a pulsed motor:

The motor can be a self-runner, but for the coil-shorting demonstration, it was just spun briefly by hand, producing voltage pulses of about 16 volts. When the coil-shorting is switched on, those pulses rise to about 440 volts even though the coil shorting was not the optimum five times at peak (which would probably have raised the voltage pulses to about 1,600 volts). The oscilloscope displays of the test shown on video are:
I’m told that this coil-shortening technique is used in industry but is considered to be a ‘trade secret’. Details of John Bedini’s Window Motor can be found at http://www.fight-4-truth.com/Schematics.html.

Raoul Hatem’s Magnetic Coupling System.
Generally, the RotoVerter has very low input power when not loaded and about a 90% energy reduction when under load. The ideal situation is where there is a constant load as the tuning of the RotoVerter does depend to some degree on the load. However, the RotoVerter performance can be increased very substantially by using the techniques introduced by Raoul Hatem in 1955, which conventional science will not accept because according to current theory, any such energy gain has to be “impossible” and so, cannot happen no matter what evidence there is:

Raoul Hatem’s heretical statement is that using spinning magnets draws in energy from the environment, allowing a system to have COP>1. His method is to use a motor (whether RotoVerter or not) to spin a heavy rotor disc with 36 powerful rare-earth magnets mounted on it. Then, using an identical heavy disc with magnets mounted on a generator to give a magnetic coupling between the motor and the generator can give not just coupling, but an energy gain as well, an energy gain which Hatem says is 20 times:
The heavy rotor provides some flywheel effect which helps with the operation of the system. Even with one motor as shown above, there is an energy gain as demonstrated in a recent video demonstration of the effect at http://www.dailymotion.com/video/xi9s9b_moteur-magnetique-de-leon-raoul-hatem_webcam#.UaGyVTcr6Bo where a simple system produces 144 watts of excess power. However, the really big gains are got when several generators are driven by just the one motor. In passing, it may be remarked that there are two separate energy gain systems operating here. Firstly, the rotating magnetic field acts directly on the excess electrons in the local environment, drawing them into the system just as the fluctuating magnetic field of the secondary winding of any transformer does. Secondly, the rotors are receiving a rapid stream of drive pulses, and as Chas Campbell has demonstrated, that draws in excess energy from the gravitational field.

Anyway, you will notice that the powerful magnets used have their North poles outwards on one rotor while the adjacent rotor has the South poles outwards. The very strong attraction between these opposite poles cause the generator disc to rotate in step with the motor disc. This process allows many generators to be driven by just the one motor as shown here and in the photograph above:

For ease of drawing, the diagram above shows only eight magnets per rotor disc, but you will notice in the photograph (and in the video) that there are three stepped rows of magnets on each rotor:

You will also notice that direction of the stepping is reversed on every second rotor disc in order for the magnets to match each other in position as they rotate in opposite directions. The relevant patent on this is FR 2,826,800 of January 2003. Hatem has an interesting video at: https://www.youtube.com/watch?v=3UJZ9hDQnyA&ebc=ANyPxKp3VkBwv2Iy9UZEWFogEY TYOSbmmUDqY a5zZ88hiyitlUlniyVjUzu6hUluHgoT2. 
Lawrence Tseung’s COP=3.3 Pulsed-Flywheel.

Lawrence has been presenting his theory of lead-out energy which indicates that excess energy is drawn from the environment when there is an impact. The method of producing this effect which he has followed is to create an unbalanced wheel and demonstrate that excess energy is produced. It should be stressed that energy is never created or destroyed and so, when he measures more energy in his device than the energy which he uses to power it, energy is not being created but is instead, being drawn in from the local environment. Lawrence has recently demonstrated a prototype to members of the public:

This simple device was demonstrated to have 3.3 times as much output power as the input power needed to make it operate. This is an early prototype which was demonstrated in October 2009 and Lawrence and his helpers are working on to produce more advanced models which have kilowatts of excess electrical power.

Mr Tseung remarks: "The Lee-Tseung Lead-Out Energy Theory was first disclosed to the world on 20th December 2004 at Tai Po, in Hong Kong. The Lead-Out Energy Theory basically says that one can lead-out (or bring-in) Energy from the surrounding environment into a Lead-Out Energy Machine. The total Input energy is equal to the sum of the Supplied Energy plus the Lead-Out Energy. For example, if the supplied energy is 100 units and the lead-out energy is 50 units, the device's total Input Energy will be 150 units. This means that the Output Energy can be more than the Supplied Energy of 100 units provided by the person using the device.

If we ignore the small loss of energy caused by less than 100% efficiency of the device itself, then the Output Energy will be the whole of the 150 units. If we use 50 of the output energy units and feed back 100 of the output units as the Supplied Energy, then that Supplied Energy can again lead-out another 50 units of excess output Energy for us to use. Thus a Lead-Out Energy Machine can continuously lead-out pollution-free, virtually inexhaustible and readily available energy for us to use. We do not need to burn any fossil fuel or pollute our environment. The two examples of Lead-Out energy which we access are Gravitational and Electron-Motion energy.

The Lead-Out Energy theory does not violate the Law of Conservation of Energy. The Law of Conservation of Energy has been used as a roadblock for the so called “Overunity” devices. The patent offices and the scientific
establishment routinely dismiss an invention as belonging to the impossible “perpetual-motion machine” category if the inventor cannot identify the energy source of his invention.

We got the help of Mr. Tong Po Chi to produce a 60 cm diameter Lead-Out Energy machine in October 2009. The Output Energy of that device is greater than the Input Energy by a factor of 3 times. These results are confirmed by voltmeters and ammeters measuring the Input and Output energies.

The Tong wheel has been shown at two Open Shows in Hong Kong (Inno Carnival 2009 and Inno Design Tech Expo) in November and December 2009. Over 25,000 people have seen it. The Better Hong Kong Radio Show has video recorded it, the discussions being conducted in Chinese. At this time, the Tong wheel is at the Radio Studio available for experts to view and examine with their own instruments.

The Tong wheel has a diameter of 600 mm and this large size is considered to be important. It has 16 permanent magnets mounted on its rim and 15 air-core coils mounted around it on the stator. There is one position sensor. The coils can be switched to act as drive coils or as energy collection coils:

With this arrangement, if the positions the switches as shown for ten of the fifteen coils shown here, then they act as drive coils. The sensor is adjusted so that the drive circuit delivers a brief energising pulse to those coils just after the magnets have passed their exact alignment position with the coils. This causes them to generate a magnetic field which repels the magnets, thrusting the rotor around.

The pulse is very brief, so very little power is needed to accomplish this pulsing. As mentioned before, any number of coils can be switched to provide this driving force. With this particular wheel construction by Mr Tong, the best number has been found to be ten drive coils.

The power pick-up is achieved by gathering the electricity generated in some of the coils as the magnets move past them:
In this particular arrangement, five of the coils gather energy while ten provide the drive. For the sake of simplicity, the diagram shows the five collection coils adjacent to each other and while that would work, the wheel is better balanced if the drive coils are evenly spaced out around the rim. For that reason, this switching would actually be selected to give five sets of two drive coils followed by one pick-up coil as that gives a perfectly balanced thrust on the wheel.

The two diagrams above are shown separately in order to make it clear how the drive switching and the power pick-up switching are arranged. The full design arrangement and the balanced switching are shown in the following diagram which indicates how the full design is implemented on this particular implementation of the wheel design. The sensor can be a coil feeding a semiconductor switching circuit, or it can be a magnetic semiconductor called a Hall-effect device which can also feed a semiconductor circuit. An alternative would be a reed switch which is a simple mechanical switch encased in an inert gas inside a tiny glass envelope. Suitable switching circuits are described and explained in chapter 12 of this eBook.
Mr Tseung remarks that the large wheel size is due to the fact that the Pulse Force takes time to impart the impulse to the wheel and lead-out energy from the environment into the system. If you want to see this actual wheel, you can email Dr. Alexandra Yuan at ayuan@hkstar.com to make an appointment. The Tong wheel is located at the Better Hong Kong Radio Studio in Causeway Bay, Hong Kong. Just say that you want to see the Lead-Out Energy Machine. The demonstration can be in English or in Chinese. Ideally, there should be a group of at least six visitors with one or more being a qualified engineer or scientist, and you are welcome to bring your own cameras and/or test equipment. It is planned to produce a version which has a 300 watt output, and another with a 5 kilowatt output. Educational kits are also planned.

If you decide to replicate this particular design, then to raise the output power level you might consider putting another set of coils around the wheel and either using them as fifteen additional energy pick-up coils or alternatively, pulsing the wheel twice as often. Adding one or more additional rotor discs to the same rotating shaft is also an option and that has the advantage of increasing the rotor weight and improving the effect of the impulses on the rotor.

The diameter of the wire used to wind the coils is a design choice which has a wide scope. The thicker the wire, the greater the current and the larger the impulse given to the wheel. The coils are normally connected in parallel as shown in the diagrams.

Because of the way magnetic field strength drops off with the square of the distance, it is generally considered good design practice to make the coils one and a half times as wide as they are deep, as indicated in the diagrams above, but this is not a critical factor. This design is, of course, a version of the Adams motor described at the start of this chapter. Although motors of this kind can be built in many different ways, the construction used by Mr Tong has some distinct advantages, so here is a little more detail on how I understand the construction to be carried out.
There are two side pieces which are attached together by sixteen cross timbers, each of which are held in place by two screws at each end. This produces a rigid structure while the construction method is as simple as is possible, using readily available materials which are worked with the most basic of hand tools. The construction also allows the motor to be taken apart completely without any difficulty, transported as a “flat-pack” package and then assembled at a new location. It also facilitates people who want to see the motor taken apart after a demonstration in order to assure themselves that there is no hidden power source.

Each of the cross timbers provide a secure mounting platform for an electromagnet and it’s associated switch. In the implementation by Mr Tong, there appears to be just the one rotor, configured as shown above with sixteen permanent magnets mounted in it’s rim. The magnetic poles of these magnets are all orientated in the same direction. That is to say, the magnetic poles facing outwards are all either South or all North poles. It is not critical whether the outward facing poles are North or South as Robert Adams used both arrangements with great success, but having said that, most people prefer to have the North poles facing outwards.

Robert has always said that one rotor was enough, but his techniques were so sophisticated that he was able to extract kilowatts of excess power from a single small rotor. For us, just starting to experiment and test a motor of this type, it seems sensible to stick with what Mr Tong has experienced success. However, this build by Mr Tong is not his final motor but just one in a series of continuously improved motors.

The following diagram shows an arrangement which has three rotors attached to a single shaft and while you may choose to construct this with just one rotor, if the cross timbers are long enough, then one or two extra rotors can be added in very easily at a later date.
Here, just two of the cross timbers are shown. The electromagnet coils used by Mr Tong are air-core as that type have the least effect on the passing magnets. However, electromagnets with cores tend to be much more powerful for any given current flowing through them. In theory, the core should be made of lengths of insulated iron wire as that would reduce power loss through eddy currents flowing in the core, but Robert actually recommends solid metal cores, and as he was the most experienced person in this field, paying attention to what he said seems sensible.

The core material needs to be a metal which magnetises easily and powerfully, but which does not retain any of its magnetism when the current stops flowing. Not many metals have those characteristics and soft iron is usually recommended. Nowadays, soft iron is not always readily available and so a convenient alternative is the central bolt of a masonry anchor which has excellent properties:

The shaft of the bolt can be cut quite easily with a hacksaw, but be sure to remove (or file down) the head of the bolt as the increase in diameter has a marked effect on the magnetic properties of the electromagnet core if it is left in place. The bolt shown above is a M16 x 147 mm masonry anchor bolt with a bolt diameter of 10 mm. Some makes of dry-ink felt white-board markers have a rigid body which fits the 10 mm bolt exactly and provide an excellent tube for constructing an electromagnet bobbin.

With a core in the electromagnets, the rotor gets additional rotating power. Initially, the magnets on the rotor are attracted to the electromagnet cores, giving the rotor a turning force which does not require any current to be supplied. When the rotor magnets are at their closest point to the electromagnet cores, the windings are powered up briefly and that gives the rotor magnets a strong push away, causing the rotor to spin.

There are many different designs of simple drive circuits and it is probably worth trying out different types to see which works best with your particular build of motor. In the same way, there are many kinds of collection circuits for taking off some of the excess power generated. The most simple of these is just a diode bridge, perhaps feeding a battery and charging it up for use at a later time. If you get sophisticated with the collection circuit and just take power off for a very short period of time at the correct moment, the cutting off of the current draw, causes a back-EMF magnetic pulse in the collection electromagnet which causes it to give the rotor an extra drive push – both current collection and rotor drive in one combined package.
Here are two of the most simple circuits possible, one for drive and one for power collection. The drive circuit transistor is switched on by a voltage generated in the grey coil by a rotor magnet passing by. The transistor then feeds a large current pulse to the black coil, driving the rotor on its way. The neon and the diode are there to protect the transistor and a physical layout for this circuit might be:

![Diagram of simple drive circuit](image)

The 1K variable resistor is adjusted to give the best performance and the On/Off switch is optional. More advanced circuits, such as the one on page 2 - 9 can also be tried and the performance compared. Generally speaking, I would expect a three-rotor version to give a better performance than a single rotor implementation, but experimentation is needed.

**Art Porter’s Magnetic System.**
Art uses an electromagnet with a ring magnet mounted on the core. When the coil is pulsed so as to augment the field of the permanent magnet, Art says that his prototype produces 2.9 times the field strength of the permanent magnet on it’s own. When the coil is pulsed in the direction which opposes the field of the permanent magnet, the resulting magnetic field is zero.

This is a very serious change of magnetic field which can be used in different applications. One which Art has implemented is using the arrangement to power a crankshaft motor. Art shows several different motor builds including this one:
With this arrangement, Art states that 95% of the motor power comes from the permanent magnet. Art’s website is at http://www.gap-power.com/index.html and he has a very interesting, lengthy video showing all of the details at http://www.gap-power.com/videos/Full%20Length%20Video.wmv.

In the video, Art attempts to apply Ohm’s Law in an attempt to analyse the operation and is puzzled when the oscilloscope readings do not match his Ohm’s Law calculations. He thinks that there is a contradiction between the oscilloscope and Ohm’s Law, which he repeatedly stresses is a law of Nature, and he concludes that one of them has to be wrong. In actual fact, neither are wrong because Ohm’s Law only applies to DC current flow in resistive circuits, and Art is not using steady DC current or a resistive load.

Applying short DC pulses to a substantial coil of wire is the equivalent of applying AC to that inductor. Ohm’s Law does not apply due to the inductance of the coil. There is a Power Factor involved and Back EMF voltage pulses, so the oscilloscope readings are what is needed to calculate the input and output powers.

This arrangement is almost identical to that used in the Charles Flynn magnet motor described in chapter 1, and very close to the techniques used by Robert Adams in a properly tuned Adams Motor as shown at the start of this chapter. In my opinion, the effect which Art is exploiting would best be used if a large pick-up coil is placed against the end of the electromagnet core and the drive coil pulsed at the coil’s (high) resonant frequency as that will minimise the input power and maximise the output power. Stacking those units in a bank could well produce a very sizeable excess electrical output. Our thanks are due to Art and his colleagues for sharing their research work freely for others to replicate and progress further.

DC Motor Efficiency
Commercially available DC motors are deliberately designed and manufactured to have extremely poor performance. In my opinion, the reason for this is that a properly designed electric motor could easily do away with the need for using internal combustion engines in vehicles and that would not suit the oil companies or their owners, the New World Order cartels. Worse still, electric motors with COP>1 open the way to self-powered free-energy systems and that would never do!!

The video: http://torrentdb.in/95d95cff2bbC8039ed9/Peter-Lindemann-Electric-Motor-Secrets.torrent is available on the web and I strongly recommend that you watch all of it. It presents the basic facts very nicely. In brief outline, present day motors act both as a motor and as a generator of electrical power, but they are deliberately wound so that the power generation is used to oppose the input power and so produce a completely crippled output. During World War II, a German Engineer re-wired a standard electric motor and made it self-powered, that is, it ran and produced mechanical output power without the need for any input power once it had been started. That shows the potential of a properly constructed electric motor with the same size and general structure of any commercial electric motor.

Presumably, he did that by adding extra brushes and using some of the windings in generator mode with their output powering the drive windings which were arranged asymmetrically. There was also one other man who achieved self-powered re-wiring of a motor, but neither of those men made their information public knowledge.

The con job which has been run on us for many decades now is to wind the motor in such a way that the magnetic fields inside the motor oppose each other. When a current is passed through a coil of wire, it stores energy in that coil, and when the current flow is cut off, that energy needs to flow back out of the coil and it will do so in the reverse direction. This is sometimes called back-EMF (“Electro-Motive Force”) although many people are not happy with that description. However, no matter what you call it, there is energy stored in the coil and that energy can be used to do useful work. But, the motor manufacturers choose to wind the motor so that instead of extracting that useful power, they use it to oppose a major part of the input power, creating a weak motor which heats up due to the wasted energy.
Contributor “UFOpolitics” points out that a deliberate mis-design of electric motors has, for the last 130 years, been presented to us as the only way to make and operate such motors. He states that because the windings are arranged in a symmetrical way, that a braking effect is produced which reduces the output power of the motor by anything from 50% to 90%. That is, a properly wound motor would have anything from twice to ten times the output power for the same input power. This mis-design guarantees that present day motors are always less than 100% efficient and always heat up when run. This mis-design is caused by using symmetrical windings in the motor.

Standard motor wiring is quite different and the killer effect is caused by having two windings which face each other, powered simultaneously with currents flowing in opposite directions. This causes a complete conflict between the magnetic fields and that destroys the efficiency of the motor: A very experienced experimenter has started a forum thread on the energetic-forum, both to explain this and to show new and more advanced construction methods and to answer questions and encourage replications and further developments. The forum is at: [http://www.energeticforum.com/renewable-energy/11885-my-asymmetric-electrodynamical-machines.html](http://www.energeticforum.com/renewable-energy/11885-my-asymmetric-electrodynamical-machines.html) and is definitely worth visiting, especially if you are good with mechanical devices. The experimenter uses the forum ID of “UFOpolitics” and he has produced an animated video in an attempt to explain the basic problems with present day DC electric motors: [http://www.youtube.com/watch?v=Mj4rV0Aol-Q&feature=channel&list=UL](http://www.youtube.com/watch?v=Mj4rV0Aol-Q&feature=channel&list=UL). He points out that a problem winding in the standard DC motor looks like this:

![Diagram of a DC motor showing input current, effective voltage, resistance, and EMF](image)

The input current for any winding is fed in through a single pair of brush contacts. The generated electrical power “Ec” is not extracted and is forced to oppose the input energy “Ea”, leaving only a fraction of the input power to actually run the motor. It is likely that a motor of this type will only operate at 25% of it’s potential efficiency.

“UFOpolitics” has produced and demonstrated a simple way of overcoming this problem while using the existing motor housing, magnets and brush contacts. He does this by extracting the generated electrical power as a useful output and so preventing that useful power being used against the motor’s operation. To implement this, he adds one additional pair of brushes and re-winds the motor coils like this:
Here, one pair of brushes is at the top and one pair at the bottom of the ‘armature’ (the bit that rotates inside the motor housing and provides the mechanical power output). The coils are rewound to form a series of separate vertical coils, connecting to one brush terminal at the top and one brush terminal at the bottom as shown above.

The input power is between the terminals on the left and flows through the coil shown in brown. The current flow generates a magnetic field, causing rotation because of the Permanent magnets marked “N” (for a magnet which has its North pole facing the coils) and “S” (for a magnet which has its South pole facing the coils). The black zig-zag line represents the resistance to current flow of the wire and brush contacts.

The coil shown in green on the right represents that same coil at a later moment when it has been disconnected from the power supply and rotated until it reaches that position, at which point, the energy stored in it is taken off as a useful output via the right hand pair of brushes. However, this is just an explanatory diagram and it does not show the very important fact that the discharging coil must not directly face a driving coil, because if it does, then the energy discharge would create a magnetic field which would interfere with the magnetic field of the driving coil and create a major problem.

Right, to say that again, any one coil is powered on the left hand side to drive the armature around and provide the output shaft with turning power (“torque”). Then that rotation disconnects that coil from the input power, leaving the coil charged with energy which has nowhere to go. That charged coil continues round until it hits the second set of brushes, which allow it to discharge through a load and do useful work.

The really clever part of the adaption of the motor is best seen from above the vertical rotor. If, for example, you were to take a five-pole DC motor apart and remove the windings, the shaft and armature body might look like this:
When making an asymmetrical wound rotor, the windings go like this.

The start of the wire is secured at the top and then fed downwards through the opening “A” and back up through the opening “B”. For the small Radio Shack motor, this winding would be 25 turns of # 30 AWG wire (described as radio Shack ‘red’ wire, with a copper wire diameter of 0.255 mm). If you are re-winding a motor armature, please understand that each wire turn needs to be pulled tight in order to make a tight, solid and robust coil which will not vibrate unduly when the armature is spinning.

The end of the wire marked “FINISH” is not cut, but is taken down through opening “A” and this time, up through opening “C”. For clarity, these continuing turns are shown in a different colour, but please realise that it is the same single strand of wire being used throughout:
The final wire turn goes down through opening “A” and finishes at the other end of the body of the armature. In these views, the wire runs down into the paper, each turn forming a cylinder. This view may give you a better visual picture of what the coils are wound on:

The next step is to connect the START and FINISH wire ends of this V-shaped double coil to the “commutator” slip rings which allow current to be passed through the coil at just the right moment. Seen again from one end of the armature, the connections are like this:
The commutator slip rings are connected further up on the drive shaft and the start of the winding wire (shown previously in dark green) is connected to the top commutator sector in the position shown here. The finishing end of the wire is connected to the corresponding commutator sector at the far end of the shaft – that is, the sector directly in line with the upper sector just connected to the start of the wire.

This completes the first of five identical V-shaped coils. The next coil is wound in the same way. The armature is rotated one sector counter-clockwise so that sector “D” replaces “A” at the top and the next coil is wound with the wire starting at the top and going down through opening “D” and up through opening “E”, repeating the same number of turns, and then, without cutting the wire the next set of wires are wound going down through opening “D” and back up through opening “F”. The start of the wire is then connected to the commutator sector which spans between openings “A” and “E” and the end connected to the corresponding commutator sector at the other end of the shaft.

For each of the remaining three windings, the shaft is rotated one position counter-clockwise and the same winding and connecting procedure carried out. When completed, no matter which opening is placed at the top of the view along the shaft, the windings and commutator sector for the wire connections will be identical.

3-Pole Motors
The winding arrangement is slightly different for motors which have three poles (or multiples of three poles such as 6, 9, 12, etc poles). For the very simple 3-pole motors, the armature looks like this:

and with this style of armature, the winds are around the three arms, like this:
And as before, the commutator sectors at the top are duplicated at the bottom, allowing separate input and output circuits for each of the three coils. The windings have many turns, filling the available space and each winding is connected to the slip ring sector directly opposite it, like this:

![Diagram of commutator and brush arrangement]

The Start of each winding is connected to the commutator slip ring sector at the top of the armature and the Finish is connected to the slip ring sector directly below it, that is, the sector which is at the same angle as the top one where the Start of the wire is connected. This allows the brushes which press against the slip ring sectors to connect to both ends of each coil in turn as the armature rotates. Three pole motors are particularly powerful and motors with six poles can be re-wound with pairs of adjacent sectors amalgamated to give three larger sectors. Nine pole motors can have three adjacent sectors wound as a single coil to provide the same effect as a three pole motor, and twelve pole motors can have four adjacent sectors wound as a single coil.

The positioning of the brushes is important. With the three-pole and five-pole arrangements, the brushes are aligned with the gaps between the magnets which surround the armature. However, the re-wound motor can be ‘tuned’ for improved torque and reduced drive current by adapting the motor housing to allow some adjustment of the position of the brush and commutator slip rings relative to the coils. This adjustment need only be slight as the angular movement of the brushes will be small. It is, of course, essential that the upper and lower adjusted positions move by exactly the same angular amount so that every upper commutator slip ring sector remains exactly above it’s corresponding lower slip ring sector. In other words, the commutator slip ring sector at the top and bottom of each coil, must be exactly aligned vertically so that the electrical connections are made and broken at exactly the same instant.

The commutator and brush arrangement are shown here in UFOPolitics’ diagrams:
The Commutator brush marked “G” (for “Generator”) takes away the energy stored in each coil and passes it to an electrical load. The Commutator brush marked “M” (for “Motor”) feeds energy into the coil from the battery which is driving the motor. The red and blue stripes surrounding the armature are two permanent magnets. The magnet shown in red has its South pole facing the armature and the magnet shown in blue has its North pole facing the armature. This creates a magnetic field flowing horizontally across the armature. The five-pole arrangement is like this:

**THREE POLE ASYMMETRICAL MOTOR:**

This is the simplest of the Asymmetrical Windings. All Coils wound in the same direction. But, MUST all be connected to the exactly opposite Commutator Element as stated in colors and arrows with the wires color codes to INPUT. This Motor is either ALL NORTH ROTOR POLES Or ALL SOUTH ROTOR POLES. However, notice it delivers to G (OUT) Dual Coils Charge, while charging One Coil at Input. This Motor is very powerful, and delivers excellent outputs. Same config as all starting wires attach to one comm, and all ends of coils attach to other comm.

**ASYMMETRIC FIVE POLE MOTOR**

P1=Pairs of Coils Start Winding number one (1)
Blue-Red means projecting magnetic fields N/S outwards, towards Stators
All Pairs of Coils wound in same direction of windings, just like winding One Coil.

All Coils must start from same commutator and all end at the other side commutator. Commutators-Elements must be perfectly aligned Upper and Lower.

Wire awg 30 (Red R/S Wire)
M Brush=Motor (Input)
G Brush=Generating Side (Output)
Here, the designation “R/S” stands for “Radio Shack” which is a chain of stores in America. In the forum, that is sometimes changed to “RS” and should not be confused with the large electronics outlet “Radio Spares” whose trademark is “RS”. UFOpolitics has suggested that the cheap 5-pole DC motor available from Radio Shack should be used by experimenters to become familiar with re-winding DC motor coils. Being a cheap product, those motors do not have a particularly high build quality, but they are suitable motors for experiments. Forum members share the details of how they dealt with adapting these and other motors.

I have to admit that motor windings and operation tend to confuse me and I sometimes find it difficult to understand what ‘UFOpolitics’ means when he talks about different winding strategies. However, it seems reasonably clear at this early stage of forum development, that his objective is to produce two things:

1. A very powerful electric motor which can be used in serious forms of road transport as well as for other practical applications, and

2. A powerful motor/generator combination which can produce useful generated electrical power.

While ‘UFOpolitics’ is very patiently going through many of the possible variations on how a DC motor can be wound and connected, and showing various forum members where they have failed to get some of their windings positioned correctly, he has also shown some of the best ways of connecting a re-wound motor used as a driver or “Prime Mover” as some people like to call it, and a re-wound motor which is to be used as an electrical generator. He shows two important ways for making a very effective Motor/Generator combination, as shown here:

It needs to be realised that these arrangements are not conventional arrangements and that the re-wound motors operate in a different way to motors bought ‘off the shelf’. For this reason, it is necessary to isolate the electrical output to prevent current flowing through the load from affecting the operation of the Motor/Generator combination. This can be done by placing a diode in each of the output lines and charging a capacitor bank which is then used to feed whatever load is to be powered. If my understanding is correct, then feeding any cold electricity produced into a capacitor causes the current to become conventional hot electricity. It is not clear if that action is part of this arrangement although the circuitry shown should be used. This is the second version:
'UFOpolitics' comments on these arrangements as follows: As we excite the input of the Motor, the Generator will start producing energy and that additional energy will flow through the Motor Output side because they are connected in series here. Two rectifiers must be connected at both output terminals, Positive and Negative, to avoid back flow from closing the circuit through the load.

As the Motor accelerates, the Generator boosts the energy flow which then runs through the Motor augmenting the Output Fields and when the output is loaded then an ‘Engagement’ of both Machines occurs as they start to compensate each other through their output flows. It should be understood that the Output should be Capacitor Banked in a dedicated Reservoir.

When designing a Generator for a specific, existing Asymmetric Motor machine, it must be understood that Generator Interactions should be considered to run as “Counter Rotation” to the Motor Machine’s originally conceived rotation (which is easily done by just moving brush-lines passing stator bisector angles to the opposite of those needed for a Motor, or alternatively, setting the timing backwards). This will definitively enhance the assisted rotation of both Machines when connected together in this Face-to-Face mode.

As I do not find the forum comments easy to understand, I recommend that you visit the forum and read the posts as you may well understand the conversations easier to follow than I do.

On the forum, ‘Sanskara316’ states “I have re-wound a small 3-volt 3-pole motor. I used an almost dead, 6-volt sealed lead-acid battery to power the motor. This battery just sits at around 4 volts and if given a load, even a small LED, it’s voltage drops to 1 volt. The re-wound motor started very slowly - barely spinning, then after a minute or two it started to spin faster, and I noticed that the voltage on the battery was slowly climbing. I connected a small LED flashlight to the generating side and it lit up. Now the battery voltage under load is around 2+ volts. It’s been running for an hour now and the machine squeals a lot. It is conditioning the battery and the meter cannot be showing what really is happening. The motor draws 300 ma?? – That’s not possible as the battery just doesn’t have that power”. To which ‘UFOpolitics’ remarks: “Well I am glad you have witnessed some of the ‘Effects’… these re-wound motors do recondition batteries…remember, Radiant Energy is taking over the Machine…so Radiant Energy comes out through the Input also… which is the reason why we get high Volts-Amps reading on a meter … these motors use very small amounts of current and volts. Inside the motor, every coil is being ‘Self-Electromagnetically-Pulsed’ because they auto-disconnect from the power source, then the next coil in the sequence is assisted by the first coil when it has rotated to it’s next position, and so on. The commutator switching has become a ‘Self-Oscillator’ for every independently-energised coil.”

Another forum member ‘prochiro’ says: “I have also replicated the battery-charging events that ‘Sanskara316’ indicated. I started with a 12-volt 4 Amp-Hour battery which I had been using with another circuit two weeks ago and had not recharged it after using it for hours. It was sitting at 12.40 volts. I took my best-running re-wound motor, plugged it in direct and ran it. The battery voltage dropped to 12.24 volts and stayed at that level for 30 seconds. The battery voltage then started to rise 1/100 of a volt per minute. When it was at 12.27 volts, I
disconnected the motor (the total run time was less than 5 minutes). I then let it rest for five minutes. At the end of the five minutes, the battery voltage had risen to 12.43 volts and is still at that voltage now. Just think what a larger motor would do on a big battery bank. Everybody needs to document this test as it proves what ‘UFOpolitics’ said.”

New DC motors, and particularly cheap motors, will have brushes which do not mate cleanly with the commutator slip ring sectors and so, when the modification has been made, running the motor for some time allows the brushes to wear in and that raises the efficiency of the electrical connections which in turn, improves the performance of the motor. If you wish to build and test one of these motors, then you can find help and support in the forum with your questions answered and numerous videos and photographs from different experimenters to help you.

**Direct Coupled Motors**

Rob Ellis shows a very strongly built arrangement which has a 100-watt motor driving a 500-watt generator and the output of the generator powers the drive motor and has 400-watts spare for driving other things:

This is shown at [https://www.youtube.com/watch?v=kaDDAFu269s&feature=youtu.be](https://www.youtube.com/watch?v=kaDDAFu269s&feature=youtu.be) and nowadays is a popular style of free-energy device. However, two points need to be mentioned here. First, I suspect that the quoted 400 watts is a calculated figure and as the motor is probably an ordinary commercial unit, it will be wound symmetrically which forces any output drawn from it to oppose the input power, making it so inefficient that its efficiency will never, ever, exceed 100%. If that is the case, then the 100-watt motor may not be able to drive the generator (which is probably also wound in the very ineffective symmetrical style) to its full output power.
Second, there appear to be a flywheel on each of the intermediate gearing shafts, and if that is so, then the inertial effects of those flywheels will draw in energy from the surrounding gravity field, enhancing the overall performance and making it a replication of Chas Campbell’s design in chapter 4.

However, just because the 100-watt motor is driving a generator which is rated at 500-watts does not necessarily mean that the motor can still drive the generator when the generator output is actually 500-watts.

The Infinity SAV Motor / Generator
A Motor/Generator which demonstrates clearly that it outputs substantial power as well as generating its own input power is seen operating at https://www.youtube.com/watch?v=EmdKVecQhXs&feature=iv&src_vid=Qrw6Xj5a0nM&annotation_id=channel%3A56c3c3cf0-0000-2004-bcb5-94eb2c062a9c.

I certainly don’t understand their statement that spinning a magnet past a coil does not produce a force which opposes the passing magnet. However, if this South Korean video is genuine, and it certainly seems to be, then it is a most encouraging step forward. This particular design has 25 rows of 10 neodymium magnets spinning past 250 bi-filar coils of wire and it is demonstrated powering itself while lighting 100 bulbs, driving a fan and operating a heater.

Chapter 3: Motionless Pulsed Systems

Note: If you are not at all familiar with basic electronics, you might find it easier to understand this chapter if you read chapter 12 first.

The pulsed devices mentioned so far have had moving parts but rotating or fluctuating magnetic fields can be created without moving parts. An example of this is Graham Gunderson’s solid-state electric generator shown in US Patent Application 2006/0163971 A1 of 27th July 2006 which is shown on page A-1038 of the appendix. Another example is:

Charles Flynn’s Magnetic Frame.
Another device of this type comes from Charles Flynn. The technique of applying magnetic variations to the magnetic flux produced by a permanent magnet is covered in detail in the patents of Charles Flynn which are included in the Appendix. In his patent he shows techniques for producing linear motion, reciprocal motion, circular motion and power conversion, and he gives a considerable amount of description and explanation on each, his main patent containing a hundred illustrations. Taking one application at random:

He states that a substantial enhancement of magnetic flux can be obtained from the use of an arrangement like this:

![Diagram of Charles Flynn's Magnetic Frame]

Here, a laminated soft iron frame has a powerful permanent magnet positioned in it’s centre and six coils are wound in the positions shown. The magnetic flux from the permanent magnet flows around both sides of the frame.

![Diagram showing magnetic flux flow]

The full patent details of this system from Charles Flynn are in the Appendix, starting at page A - 338.
Lawrence Tseung's Magnetic Frame.
Lawrence Tseung has recently produced a subtle design using very similar principles. He takes a magnetic frame of similar style and inserts a permanent magnet in one of the arms of the frame. He then applies sharp DC pulses to a coils wound on one side of the frame and draws off energy from a coil wound on the other side of the frame.

He shows three separate operating modes for the devices as follows:

(1) No Permanent Magnet, No Lead-Out Energy, Maximum COP = 1

Lawrence comments on three possible arrangements. The first on shown above is the standard commercial transformer arrangement where there is a frame made from insulated iron shims in order to cut down the "eddy" currents which otherwise would circulate around inside the frame at right angles to the useful magnetic pulsing which links the two coils on the opposite sides of the frame. As is very widely known, this type of arrangement never has an output power greater than the input power.

However, that arrangement can be varied in several different ways. Lawrence has chosen to remove a section of the frame and replace it with a permanent magnet as shown in the diagram below. This alters the situation very considerably as the permanent magnet causes a continuous circulation of magnetic flux around the frame before any alternating voltage is applied to the input coil. If the pulsing input power is applied in the wrong direction as shown here, where the input pulses generate magnetic flux which opposes the magnetic flux already flowing in the frame from the permanent magnet, then the output is actually lower than it would have been without the permanent magnet.

(2) Permanent Magnet Opposes Magnetic Flux: COP < 1

However, if the input coil is pulsed so that the current flowing in the coil produces a magnetic field which reinforces the magnetic field of the permanent magnet then it is possible for the output power to exceed the input power. The "Coefficient of Performance" or "COP" of the device is the amount of output power divided by the amount of input power which the user has to put in to make the device operate. In this instance the COP value can be greater than one:

(3) Permanent Magnet Enhances Magnetic Flux: COP > 1

As it upsets some purists, perhaps it should be mentioned that while a square wave input signal is applied to the input of each of the above illustrations, the output will not be a square wave although it is shown that way for clarity. Instead, the input and output coils convert the square wave to a low-quality sine wave which only becomes a pure sine wave when the pulse frequency exactly matches the resonant frequency of the output winding. The oscilloscope display shown here is a typical output power waveform which has nearly 390,000 of these pulses per second.

There is a limit to this as the amount of magnetic flux which any particular frame can carry is determined by the material from which it is made. Iron is the most common material for frames of this type and it has a very definite saturation point. If the permanent magnet is so strong that it causes saturation of the frame material before the input pulsing is applied, then there can't be any effect at all from positive DC pulsing as shown. This is just
common sense but it makes it clear that the magnet chosen must not be too strong for the size of the frame, and why that should be.

As an example of this, one of the people replicating Lawrence's design found that he did not get any power gain at all and so he asked Lawrence for advice. Lawrence advised him to omit the magnet and see what happened. He did this and immediately got the standard output, showing that both his input arrangement and his output measuring system both worked perfectly well. It then dawned on him that the stack of three magnets which he was using in the frame were just too strong, so he reduced the stack to just two magnets and immediately got a performance of COP = 1.5 (50% more power output than the input power).

The Transformers of Thane Heins.
Thane has developed, tested and applied for a patent for a transformer arrangement where the output power of his prototype can be thirty times greater than the input power. He achieves this by using a figure-of-eight double toroid transformer core. His Canadian patent CA2594905 is titled "Bi-Toroid Transformer" and dated 18th January 2009. The abstract says: The invention provides a means of increasing transformer efficiency above 100%. The transformer consists of a single primary coil and two secondary coils.

Magnetic flow is a thousand times easier through iron than it is through air. Because of that fact transformers are generally constructed on a frame made of iron or a similarly magnetic material. The operation of a transformer is nothing like as simple as school teaching would suggest. However, leaving parametric excitation aside for the moment, let us consider the effects of magnetic flow.

The way that off-the-shelf transformers work at the moment is like this:

When a pulse of input power is delivered to Coil 1 (called the "Primary winding"), it creates a magnetic wave which passes around the frame or "yoke" of the transformer, passing though Coil 2 (called the "Secondary winding") and back to Coil 1 again as shown by the blue arrows. This magnetic pulse generates an electrical output in Coil 2, which flows through the electrical load (lighting, heating, battery charging, video displays, or whatever) providing it with the power which it needs to operate.

This is all well and good but the catch is that when the pulse in Coil 2 finishes, it also generates a magnetic pulse, and unfortunately, that magnetic pulse runs in the opposite direction, opposing the operation of Coil 1 and causing it to have to boost it's input power in order to overcome this magnetic flow in the opposite direction, shown here by the red arrows:

This is what makes current scientific "experts" say that the electrical efficiency of a transformer will always be less than 100%. This effect is caused by the magnetic path being symmetrical. Like the flow of electricity, magnetic flow passes along every possible path. If the magnetic path has low magnetic resistance (generally due to having a large cross-sectional area), then the magnetic flow through that path will be large. So, faced with several paths, magnetic flow will go along all of them in proportion to how good each path is for carrying magnetism.
Thane Heins has made use of this fact by making a transformer like this:

This style of transformer has got quite complicated magnetic flows when it is operating, although the diagram above only shows some of the flow paths generated when the input coil “Coil 1” is pulsed. The really interesting result is seen when that input pulse cuts off and we expect return magnetic flow from coil 2 and coil 3. What happens is this:

Assume that coil 2 and coil 3 are identical. The reverse magnetic flux coming out of coil 2 immediately encounters a junction with one path being far easier to use than the other. As a result, the vast majority of that magnetic flow follows the broad path, and only a small percentage flows through the narrow path. The broad path flow meets and is opposed by an identical large flow coming from coil 3, and those flows effectively cancel each other out. This produces a major improvement over an ordinary transformer. But, the small flow reaching the entrance to Coil 1 encounters two identical paths, and only one of those paths goes to coil 1, so the flux divides with half going towards coil 3 and half going through coil 1. That halves the strength of the already small percentage of the original, unwanted reverse magnetic flow into coil 1. The other half runs into the reduced flow from coil 3 and those halves cancel each other out. The overall effect is a really major improvement in the performance of the transformer as a whole.

In the patent document, Thane quotes a prototype test which had a primary coil winding with 2.5 ohms resistance, carrying 0.29 watts of power. The secondary coil 1 had a winding with 2.9 ohms resistance, receiving 0.18 watts of power. The Resistive load 1 was 180 ohms, receiving 11.25 watts of power. The secondary coil 2 had a winding with 2.5 ohms resistance, and received 0.06 watts of power. Resistive load 2 was 1 ohm, receiving 0.02 watts of power. Overall, the input power was 0.29 watts and the output power 11.51 watts, which is a COP of 39.6 and while the document does not mention it directly, the primary coil should be driven at its resonant frequency.
A variation of this arrangement is to attach an outer toroid to the existing bi-toroid arrangement, like this:

![A variation of the arrangement](image)

This prototype, as you can see, is fairly simple construction, and yet, given an input power of 106.9 milliwatts, it produces an output power of 403.3 milliwatts, which is 3.77 times greater.

This is something which needs to be considered carefully. Conventional science say that "there is no such thing as a free meal" and with any transformer, you will get less electrical power out of it than you put into it. Well, this simple looking construction demonstrates that this is not the case, which shows that some of the dogmatic statements made by present day scientists are completely wrong.

At [https://youtu.be/-LBnnL4v8MQ?list=PLkH1zLdXy1Sy3_St1tUwtY_6qiusDkyG9](https://youtu.be/-LBnnL4v8MQ?list=PLkH1zLdXy1Sy3_St1tUwtY_6qiusDkyG9) Thane shows a video where his bi-toroidal transformer is constructed from three ordinary toroids held together with cable ties:

![Thane's bi-toroidal transformer](image)

Thane then goes on to demonstrate the performance of this combination:
The LED associated with the power being fed to the primary winding is so low that no light is visible. The output LED is lit so powerfully that the camera has difficulty in displaying it. The dummy load is a single resistor placed across the third winding and there is a major performance difference when it is plugged into place. This video demonstrates very clearly, the difference caused by using a bi-toroidal transformer.

This simple and elegant modification of the humble transformer, converts it into a free-energy device which boosts the power used to drive it and outputs much greater power. Congratulations are due to Thane for this technique and for his sharing it openly with anyone who is interested.

Professor Markov's Transformers

Professor Gennady Markov, General Director of STC "Virus" and author of many inventions and discoveries, received an international patent for a new a transformer design which he created. His work involves a new law in the field of physics and electrical engineering. He says: In 1831 Faraday discovered electromagnetic induction. Then his ideas were further developed by Maxwell. For more than 160 years following that, no one advanced fundamental electrodynamics by even a single step. Eight years ago, I applied for an international patent, valid in 20 countries, as I had created a transformer, which has already received four Russian patents. My discovery was made despite the "laws" of the great physicist Faraday who said that "magnetic fluxes in a magnetic circuit should be combined separately with the resulting combined flux moving in only one direction. Only then can you have a working transformer".

I dared to do the opposite: take a coil with two identical windings and operate them towards each other. This creates equal magnetic fluxes, moving toward each other, which cancel each other out, but do not destroy each other as Faraday and Maxwell claimed. I determined a new law: ‘The Principle of Superimposition of Magnetic Fields in Ferromagnetic Materials’. The superimposition - is the addition of magnetic fields. The essence of the law is that the magnetic fields are added, cancel each other, but they are not destroyed. And here the important part is "they are not destroyed" and that is the key fact on which my law is based.
I wrote an article on this subject, which was published in the journal "Applied Physics". I demonstrated a transformer at an international exhibition in China, where it caused great interest among scientists and other experts. That transformer had excellent performance and in fact, it can raise or lower the voltage without any need for a secondary winding. My new law allows us, firstly, to create high-power transformers where the weight and size per unit of capacity is 20 to 30 times lower than in conventional Faraday transformers. Second, I created a transformer which, despite its large dimensions and power-handling capabilities, can operate at frequencies up to several megahertz (at the present time, a conventional transformer operates at frequencies of only 30 to 50 Hertz, and if you operate them at 100 Hz or higher, the metal overheats and the transformer breaks down). My transformer can operate safely at frequencies of millions of Hertz.

Conventional transformers tend to be very bulky because they contain a great deal of iron with the weight of a standard 4 MW transformer being 3670 Kg. My 4 MW transformer weighs a total of 370 kg. When constructing a new transformer you can use any quality of steel quality and there are virtually no restrictions on the frequency range in which it can operate. Unlike conventional transformers, a new transformer can be transported from the place of manufacture to the point of use quite easily. This new transformer design gives us a huge opportunity to create a new generation of technology.

Please note that the transformer does not operate at low frequencies. Its frequency range is 10 kHz to 40 MHz, and the voltage needs to be at least 40 volts.

Here is most of Professor Markov's patent EP 844,626:

**Patent Application EP 0844,626**

**27th May 1998**

**Inventor: Gennady A. Markov**

**TRANSFORMER**

**Abstract**

Several types of transformers are proposed which may be used as the main electrical engineering equipment of electric power stations, substations, power lines, in radio engineering, in devices for measuring, automatic control and regulation. At the heart of the invention lies the principle where the primary winding consists of two sections wound and connected to each other in such a way that during operation of the transformer, the magnetic flux created by one section of the primary winding compensates the magnetic flux created by the other section of the primary winding.

The transformer comprises (Fig.2) a magnetic circuit, a primary winding consisting of two sections having an identical number of turns, wound in one direction on a core of the magnetic circuit. The windings of the two sections are connected to each other in such a way that during operation of the transformer, the magnetic flux created by one section of the primary winding compensates the magnetic flux created by the other section of the primary winding.

The developed embodiments of the transformer are distinctive in that the sections of the primary winding are wound on one core of the magnetic circuit (3 embodiments) or on two cores of one magnetic circuit (4 embodiments), in that the direction in which the sections of the winding are wound is different (in one or opposing directions), and consequently there is a different connection of the windings, and are also distinguished by the presence of a secondary winding (in one embodiment there is no secondary winding).

**Description:**

**Background Art**

Transformers are electromagnetic static converters of electrical energy which have two or more inductively coupled windings and are designed for the conversion of a sinusoidal alternating current of one voltage into an alternating current of another voltage with the same frequency.

The principle of operation of a transformer is based on the effect of electromagnetic induction found by M. Faraday in 1831 (B.N. Sergeenko, V.M. Kiselev, N.A. Akimova. Electrical Machines. Transformers. Pub. "Vysshaya Shkola," Moscow, 1989). In accordance with specific features of construction and use, transformers can be divided into power, welding, measuring and special transformers.

*Power transformers*, which are a necessary element of an industrial power network, have attained the most widespread use. Transformers have two basic parts: a magnetic circuit and windings. Furthermore, high-power transformers have a cooling system. The magnetic circuit is the structural base for mounting and fixing windings,
taps and other elements of a transformer, and serve for amplification of the magnetic coupling between the windings.

The part of the magnetic circuit upon which the windings are arranged, is called the ‘core’, the remaining part, closing the magnetic circuit, is called the ‘yoke’. The windings of a transformer serve to create a magnetic field by means of which electrical power is delivered. The winding of the transformer to which electrical power is applied is called the primary winding, while the winding from which power is taken is called the secondary winding.

Known inventions are concerned with the creation of special transformers or with changes of particular structural elements of the transformer; realisation of magnetic circuits from certain materials and their structural appearance, connection of magnetic circuits to each other where there is a number of magnetic circuits n, use of different types of insulation and cooling systems, realisation of the windings, additional elements in order to enhance noise immunity.

A transformer for vehicles is known [PCT (WO), 93/14508]. The small-size, light transformer, comprises a shell-type iron core on which inductively coupled input and output windings are wound. A magnetic element with an air gap is provided between the input and output windings, while a magnetic element creating strong magnetic coupling is located between the output windings. The element is disposed in a gap 5d surrounded by the core and consists of a magnetic circuit without gaps and an insulating plate holding the magnetic circuit and insulating it from the core and windings.

A transformer is known [PCT (WO), 93/16479], in which the core is made from ferromagnetic wire. A spirally wound core from ferromagnetic wire is proposed. The core is used in a differential current sensor in a switch to open a circuit, which operates when there is a short circuit to ground. The ferromagnetic wire is wound in a spiral, the turns of which are parallel to each other and extend over the whole length of the core. The latter is positioned near current lines, with monitoring of a short circuit therein, wherein both lines are connected to a power source. The currents in them flow in opposite directions. The core interacts with a magnetic field created by those currents. Where a ferromagnetic wire is used, it is possible to increase substantially, the surface area of the core without increasing its cross section, and consequently, its size.

A transformer is known [RU, C1, 2041514] consisting of one or several strip cores made from a magnetic alloy comprising silicon, boron, iron and several windings inductively coupled to the core, wherein the magnetic alloy additionally comprises copper and one or several components selected from the group consisting of niobium, tantalum, tungsten, molybdenum, chromium, and vanadium, with the following ratio of alloy components, atom percent: copper - 0.5-2.0; one or several components from the group consisting of niobium, tantalum, tungsten, molybdenum, chromium, vanadium - 2-8; silicon - 5-18; boron - 4-12; iron - balance.

A transformer is known [PCT (WO), 93/18529] comprising 3 or 4 types of insulation units with one winding. Transformers of this type are easily assembled with small expenditure of time.

A current transformer with strip insulation is known [RU, C1, 2046425] comprising a single-turn or multi-turn primary winding and secondary windings which are placed in a damping screen and have terminals. Wherein the windings are secured by means of insertion support and connecting bushings and are covered with epoxy compounds. The transformer is additionally provided with insulation bushings, a screen which is placed on the primary winding, and support clamps. Insulation bushings are mounted in semi-oval slots of the clamps, the damping screen is made open and consists of two parts, with an insulating pad mounted in the gap between the two parts, and the insertion support bushings are mounted on the insulating bushings in a manner adaptable for securing the damping screen.

A high-voltage transformer is known [RU, C1, 2035776] comprising a porcelain housing mounted on a socket on which an active portion enclosed in the housing, is positioned on compressing posts. The active portion consists of a mixed rectangular magnetic circuit with yokes, upper and lower horizontal cores on which windings are positioned. Insulation bushings are mounted in semi-oval slots of the clamps, the windings are secured by means of insertion support and connecting bushings and are covered with epoxy compounds. The transformer is additionally provided with insulation bushings, a screen which is placed on the primary winding, and support clamps. Insulation bushings are mounted in semi-oval slots of the clamps, the damping screen is made open and consists of two parts, with an insulating pad mounted in the gap between the two parts, and the insertion support bushings are mounted on the insulating bushings in a manner adaptable for securing the damping screen.

A winding for a high-voltage transformer is known [PCT (WO), 93/18528]. A connecting element is secured to the conductive portion of the winding to enhance its mechanical properties, and a second connecting element is connected to the aforesaid connecting element by means of insulating elements. Such, a winding can be used as a low-voltage winding with a small number of turns in dry transformers with a resin poured over them.

A heavy-current transformer is known [RU, C1, 2027238] comprising a primary winding disposed on a toroidal core and a secondary winding encompassing the primary winding. Wherein the secondary winding is made by a bundle of flexible conductors placed in the inner cavity of the torus in N sections, and from the outer side of the torus in N-1 sections, where N is the number of turns of the secondary winding, wherein the bundle is arranged in one or more layers on the outer side of the torus.
However, all the known transformers are built according to one principle, in particular - supplying electrical power to the primary winding and taking electrical power from the secondary winding, and they all have these drawbacks: multi-turn secondary windings in step-up transformers, which nevertheless operate in a rather narrow frequency range (50-400 Hz); the limited frequency range of the transformers being related to losses in the magnetic circuit at higher frequencies; high resistance of the windings, i.e. the necessity that the no-load condition of the transformer be taken into account during calculations of the number of turns in the secondary winding to obtain a predetermined output voltage; the complexity of the construction of the transformers when all possible kinds of additional elements, insulation etc. are used to reduce the above drawbacks.

Disclosure of the Invention
At the base of the invention lies the object of creating such a transformer in which the possibility of winding the secondary winding with wire, including wire with a cross-section equal to the cross-section of the primary winding, is realised, and the reduction of the number of turns in the secondary winding of high-voltage transformers and expansion of the number of variants of existing transformers are attained.

This object is achieved in that a construction of a transformer is proposed which comprises a magnetic circuit, at least two windings, inlets for a power supply, outlets for a load, wherein the primary winding consists of two sections with an identical number of turns, the sections being connected to each other in a series circuit.

A transformer is proposed in which two sections of a primary winding are wound in one direction on one core of the magnetic circuit, the sections are connected in a series circuit by connection of the outputs of the windings, and the point of their connection serves as an outlet for the load, while the inputs of the windings of the sections serve as inlets for the power supply.

The above technical result is achieved by creating a transformer, two sections of the primary winding of which are wound in one direction on one core of the magnetic circuit, the sections are connected in a series circuit by connection of the outputs of the windings, and the point of their connection serves as an outlet for the load, while the inputs of the windings of the sections serve as inlets for the power supply.

The aforesaid technical result is achieved by creating a transformer, two sections of the primary winding of which are wound in opposing directions on one core of the magnetic circuit, the output of the winding of the first section and the input of the winding of the second section are connected to each other in a series circuit, while the input of the winding of the first section and the output of the winding of the second section serve as inlets for the power supply. The secondary winding is wound on the same core of the magnetic circuit, over the sections of the primary winding.

The indicated object is achieved by creating a transformer in which both sections of the primary winding are wound in one direction on two cores of one magnetic circuit, the output of the winding of the first section and the input of the winding of the second section are connected to each other in a series circuit, while the input of the winding of the first section and the output of the winding of the second section serve as inlets for the power supply. The secondary winding is wound on both sections of the primary winding, encompassing both cores of the magnetic circuit.

The same technical result is achieved when both sections of the primary winding are wound in one direction on two cores of one magnetic circuit, where the input of the winding of the first section is connected to the output of the winding of the second section, the output of the winding of the first section is connected to the input of the winding of the second section, the points of their connection serve as inlets for the power supply. The secondary winding is wound on both sections of the primary winding, encompassing both cores of the magnetic circuit.

The indicated object is achieved by creating a transformer in which two sections of the primary winding are wound in opposing directions on two cores of one magnetic circuit, both sections are connected to each other by connection of the inputs and outputs thereof respectively, and the points of their connection serve as inlets for the power supply. The secondary winding is wound on both sections of the primary winding, encompassing both cores of the magnetic circuit.

The following lies at the base of the invention: sections of the primary winding are wound and connected to each other in such a manner that the magnetic flux created by one of such sections during operation of the transformer compensates the magnetic flux created by the other section of the primary winding.
If the two sections of the primary winding of the proposed transformer are connected to an alternating current network having a voltage $U_1$, then a current $i_o$ will flow along them. The magnetomotive force of one section of the winding $i_ow_1$ due to the current $i_o$ creates an alternating magnetic flux $F_1$ in the magnetic circuit of the transformer. Similarly, a magnetomotive force $i_ow_2$, which is equal to the mmf of the first section $i_ow_1$, appears in the second section of the winding. Since the sections are connected to each other in a series circuit, the alternating magnetic flux $F_2$ appearing in the second section of the primary winding and directed counter to the magnetic flux $F_1$ will compensate the magnetic flux of the first section $F_1$. However, due to the induction of the mmf the permeability of the magnetic circuit changes.

When the network current drops during half-cycles, restoration of the permeability occurs in the magnetic circuit, and consequently, an electromotive force (emf) is induced in the primary and secondary windings. Wherein, during a half-cycle of current in the primary winding, the voltage in the secondary winding passes through a whole period.

In the case where both windings are wound in opposing directions with an identical number of turns, but are connected to each other in a series circuit by opposing leads (the output of the winding of the first section and the input of the winding of the second section), the magnetic flux in the primary winding $i_o$ will also be equal to zero, i.e. the same technical result can be attained as in the case where the windings of both sections are wound in one direction. When $R_{H1}$ is connected to the secondary winding, the form of the voltage does not change. The output voltage depends on an increase of the number of turns in the secondary winding as compared with the number of turns in the primary winding.

Such a realisation of the proposed transformer results in:
1) a reduction in the number of turns in the secondary winding by 10 to 20 times, and consequently, the dimensions of the transformer are reduced;
2) the possibility of winding the secondary winding with a thick wire having a cross section equal to the cross section of the wire in the primary winding;
3) the secondary winding having a number of turns either greater or less than the number of turns in the primary winding, depending on the necessity of a high voltage at the output of the transformer.

**Brief Description of the Drawings**

Further the invention will be explained by a description of concrete examples of its embodiment and the accompanying drawings in which:

![Diagram](image)

**Best Variants of Carrying Out the Invention**

A transformer in accordance with the invention, according to the embodiment shown in **Fig.1** comprises a magnetic circuit 1, a first section 2 of a primary winding, a second section 3 of the primary winding, \( a_1 \) and \( x_1 \) - the input and output of the winding of the first section, \( a_2 \) and \( x_2 \) - the in and out of the winding of the second section of the primary winding, \( R_{H1} \) - the resistance of a load connected to the first section, \( R_{H2} \) - the resistance of a load connected to the second section of the primary winding. The two sections of the primary winding are wound on the magnetic circuit 1: the first section 2, the second section 3 thereon in one direction, and they have an identical number of turns. The outputs \( x_1 \) and \( x_2 \) of the windings are connected to each other in a series circuit, while the inputs \( a_1 \) and \( a_2 \) of the windings are separately connected to a power supply. A load resistance is connected parallel to each section of the winding: \( R_{H1} \) in the path of the current from the power supply to the first section of the winding and to the point of connection of the windings of the sections, and \( R_{H2} \) correspondingly to the second section of the primary winding.
A transformer in accordance with the invention according to the embodiment shown in Fig. 2 is made similar to the transformer according to the embodiment shown in Fig. 1. A distinction is in the presence of secondary winding 4, which is wound in a third layer on the sections 2 and 3 of the primary winding on the same core of the magnetic circuit 1. A and X designate the inlet and outlet (in and out of the phase) of the secondary winding, $R_H$ - the resistance of the load connected to the leads A and X of the secondary winding.

A transformer in accordance with the invention according to the embodiment according to Fig. 3 is made similar to the transformer according to the embodiment shown in Fig. 2. A distinction is that the sections of the primary winding are wound in opposing directions. The output of the winding of the first section $x_1$ and the input of the winding of the second section $a_2$ are connected to each other in a series circuit, the other leads of the sections $a_1$ and $x_2$ serve as inlets for the power supply.
A transformer in accordance with the invention according to the embodiment shown in Fig.4 is made similar to the transformer according to the embodiment shown in Fig.2. A distinction is that the sections of the primary winding 2 and 3 are wound on two cores of the magnetic circuit 1. The sections are connected to each other via opposite leads - the out of the winding of the first section and the in of the winding of the second section. Secondary winding 4 is wound on both sections of the primary winding and encompasses both cores of the magnetic circuit.

![Diagram](image1)

*FIG. 5*

A transformer in accordance with the invention according to the embodiment shown in Fig.5 is made similar to the transformer according to the embodiment shown in Fig.4. A distinction is that the two sections of the primary winding are wound in opposing directions, the outputs $x_1$ and $x_2$ of the windings of the sections are connected to each other in a series circuit, while the inputs $a_1$ and $a_2$ of the windings of the sections serve as inlets for the power supply.

![Diagram](image2)

*FIG. 6*

A transformer according to the embodiment shown in Fig.6, is made similar to the transformer according to the embodiment shown in Fig.4. A distinction is that the in of the first section $a_1$ and the out of the second section $x_2$, and also the output of the first section $x_1$ and the input of the second section $a_2$ are connected to each other, and the points of their connection serve as inlets for the power supply.
A transformer according to the embodiment shown in Fig. 7, in accordance with the invention, is made similar to the transformer according to the embodiment shown in Fig. 6. A distinction is that the sections are wound in opposing directions, by the inputs \( a_1 \) and \( a_2 \) and by the outputs \( x_1 \) and \( x_2 \) the windings of the sections are connected to each other, and the points of their connection serve as inlets for the power supply.

The principle of operation of the proposed transformer according to the embodiment shown in Fig. 1 is as follows:

1. **Open circuit (no-load conditions)**
   The inputs \( a_1 \) and \( a_2 \) of the windings of sections 2 and 3 are separately connected to a power supply \( U \) (not shown), the outputs \( x_1 \) and \( x_2 \) of the windings of those same sections are connected to each other in a series circuit. A current \( i \) flows through the windings of those sections, this current causes a magnetomotive force \( \text{mmf} \) in each section of the winding which is equal to \( iw \). Since the fluxes in each section are equal and directed in opposing directions they are mutually compensated and reversal of magnetisation of the core does not occur, but as a consequence of maintenance of the principle of superimposition of magnetic fields in a magnetic circuit, the latter interacts with the fields on a microscopic level which results in stressed interaction of a domain structure and a change in the magnetic permeability of the material of the magnetic circuit.

Thus, a change of the current passing through the sections of the primary winding in time results in a change of the permeability, while a change of the latter causes an emf to appear in those windings between the point of connection of the sections and the inputs of the windings, but shifted by phase in time relative to the current passing from the supply source. Due to this, the voltage at the output of the transformer is increased by 10 to 20 times with actually just one primary winding.

2. **Operating mode (with a load connected)**
   The load resistance \( R_{H1} \) is connected in the path of the current \( i \) from the power supply \( U \) to the first section 2 of the winding and to the point of connection of the outputs of the sections, the load resistance \( R_{H2} \) is connected accordingly to the second section 3 of the winding. The current \( i \) from the power supply is passed through the formed closed loop, wherein the primary current \( i \) is increased in each loop proportionally to the load \( R_{H} \), which results in a change of the emf in the loop - an increase of the emf.
At a low load resistance (equal to the resistance of the winding) the voltage $U$ will be equal to the voltage drop on the winding, when the load resistance tends to increase to infinity, the secondary voltage $U$ will increase proportionally, as a result of which the emf at the output of the transformer will increase dozens of times when there is one primary winding.

The principle of operation of the transformer according to the embodiments shown in Fig.2 to Fig.7 is similar to the principle of operation of the transformer according to the embodiment shown in Fig.1. A distinction lies in the presence of a secondary winding 4. Since the primary winding for the mmf in those embodiments remains open, a no-load emf is always induced therein, i.e. a self-inductance current is not created in the winding and all the mmf energy is provided as an emf of the secondary winding. Under such conditions, the intensity of the electric field per unit of length of the conductor of the winding in the secondary winding can exceed by ten times, the intensity of the electric field in the primary winding, which is set by the power supply. As a result the secondary winding can have fewer turns as compared to the primary winding, while the voltage is dozens of times greater than the mains voltage. Wherein the form of the voltage and current in the secondary winding repeats the form of the voltage and current in the primary winding.

Fig.8 shows a stylised dependence of the increase of current and voltage in the primary and secondary windings of a transformer with a ferrite magnetic circuit. It should be noted that the permeability $\mu$ of the magnetic circuit changes with time in the following manner with a sinusoidal form of current: it increases from 0 to $\pi/4$, then from $\pi/4$ to $\pi/2$ it drops, and from $\pi/2$ to $3\pi/4$ the speed of restoration of the permeability again increases and from $3\pi/4$ to $\pi$ the restoration of $\mu$ is slower. As a result of such a change of the magnetic permeability, an emf is induced in the secondary winding at a doubled frequency and there is a complete period of the secondary current for one half-period of the current in the primary winding.

Fig.9 shows a stylised dependence of an increase of current and voltage in the primary and secondary windings of a transformer with a magnetic circuit of sheet steel. With this type of magnetic circuit there is a shift of the form of the primary and secondary current curve from $\pi/6$ to $\pi/4$ while the form of the current is maintained.

The transformation ratio for each type of transformer was determined experimentally. Concrete examples of the operation of different types of transformers are given below in order to better understand the invention. The same results were obtained with embodiments of transformers for which examples are not provided.

**Example 1.**
M600HH-8 K100-60-15 ferrite rings were used as the magnetic circuit. Two sections of the primary winding, one over the other, were wound on a core of the magnetic circuit assembled from four rings. The outputs of the windings of both sections were connected in a series circuit, a load resistance $R_\text{L}$ was connected parallel to each section - one end to the point of connection of the sections, the other - to the inputs of the sections, the inputs of the windings of each section were connected to the power supply. The number of turns in the sections was identical and equal to 60. The transformation ratio for this transformer was 11. The results of measurement of the voltage at the output of the transformer are presented in Table 1, Example 1. Similar results were obtained when the transformer was made with a ferrite U-shaped magnetic circuit.

**Example 2.**
A ring-type magnetic circuit made from sheet steel and designed for a power of 2.5 kW was used as the magnetic circuit. Two sections of the primary winding were wound on the core of the magnetic circuit, wherein both sections were wound in one direction with their outputs connected in a series circuit, the inputs of the sections connected to the power supply. A secondary winding was wound on the primary winding (the direction in which it is wound does not affect the operation of the transformer). The transformation ratio was determined experimentally and was equal to 5. The number of turns of one section of the primary winding was 110, the number of turns of the secondary winding was also equal to 110, the diameter of the wires in the primary and secondary windings was identical and equal to 1.2 mm. A load was connected to the leads of the secondary winding. The voltage was measured at the input of the primary winding and at the output of the secondary winding, i.e. on the load. The results of measurements are presented in Table 1, Example 2.
Example 3.
U-shaped ferrites were used as the magnetic circuit. The magnetic circuit was assembled from four units. Two sections of the primary winding were wound on the two cores of the magnetic circuit, each section on one core. The sections were wound in opposing directions, but with an identical number of turns. The total number of turns in the primary winding was 120. The outs of the windings of the sections were connected in a series circuit, the inputs were connected to a power supply. A secondary winding, encompassing both cores, was wound on the primary winding. The number of turns in the secondary winding was 120. The transformation ratio was determined and found equal to 10. The results are presented in Table 1, Example 3.

Example 4.
A U-shaped magnetic circuit made from sheet steel was used as the magnetic circuit. Two sections of the primary winding were wound on both cores of the magnetic circuit, each section on one core. The sections were wound in one direction, the number of turns in each section was 120. The output of the winding of the first section and the input of the winding of the second section, and also the input of the winding of the first section and the output of the winding of the second section were connected to each other, and the points of their connection were connected to the power supply. The secondary winding was wound on the primary winding, the number of turns in the secondary winding was 120. The transformation ratio of this transformer was 8.5. The results of measurement are presented in Table 1, Example 4.

**Industrial Applicability**
Samples of all types of transformers were made and have been working for from three to five years. All these examples were tested and can serve as electrical engineering equipment in laboratory practice and in industrial enterprises.

**A Lenz-Law-Free Transformer**
This is an extract from a document dated January 2014 by an anonymous author whose ID is “Jack Noskills”. He says: This short paper describes a simple method how to build a Lenz-Law-free resonant transformer. Lenz law is not violated but it is used to create more efficient transformer. Without Lenz law this setup could not work.

First some simple tests are presented which forms foundation of the device. Then based on the results of these tests I built the transformer which confirmed my test results. It is important to understand the method as that will give you understanding. When you understand it, you can build it using different components than I used.

1. **The Effect of capacitors in resonant LC-circuits**
The capacitor’s value in a Parallel Resonant LC-circuit controls the attenuation level of band-stop filter. A low value of $C$ makes the resonant area smaller and attenuation steeper. A high value of $C$ makes the resonant area wider and the attenuation level lower. When investigating resonant effects, it is wise to start with a high value of $C$. I used 440 nF to 2000 nF.

In any Series Resonant LC-circuit the frequency response has a notch at the resonant frequency. The frequency response is the opposite of that in a Parallel LC-circuit.

To get maximum effect it is therefore best to have high attenuation level at a primary Parallel LC-circuit (low $C$) and a high amplification level at a secondary LC-circuit (also low $C$).

The “Q-factor” is the inductive reactance of a coil divided by its DC resistance. The Q-factor determines the resonant rise in a resonant circuit and so the higher the Q factor is, the higher the power output will be. In a coil,
the DC resistance can be minimised using thicker wire and fewer turns. Inductive reactance can be maximised using a higher resonant frequency which is controlled by the L and C components of the circuit. Smaller L and C values produce an increased resonant frequency.

There is plenty of information about the Q-factor on the web. I just wanted to put a short introduction to Q-Factor here so that you will understand that a high Q resonant LC-circuit can be dangerous.

2. Two Kinds of inductances
Any simple helical coil wound on a core affects only another helical coil which has been wound underneath it or on top of it. If two coils are placed beside each other there is little interaction between them. Let's call this the 'local inductance field'.

A coil wound on a closed-loop core affects any coil on that same core and the coil also has a much higher inductance than an air-core coil. Does this mean that the local field disappears? No, it doesn't. This effect can be used to make a simple over unity device.

3. Testing of closed-loop cores
I used E-shaped parts from low power, laminated iron transformers and put those E parts together. I used a primary coil of very high inductance and fed AC through it. The E plates snapped together and stayed that way even after power was disconnected. I tried several times, sometimes the force was strong and sometimes they did not stick together at all. The strength clearly depended on the input AC waveform. When I separated the E plates they no longer stayed together, so something was interrupted in the core. While the cores were fixed together they did not have any external magnetic effects and another piece of iron would not stick to the core. This demonstrated Ed Leedskalnin's perpetual motion holder effect.

Conclusion: There is something moving inside the core and the core has zero resistance to that flow. Let's call the flow “magnetic current”.

I then put three identical coils on the core, one had a load connected to it and the others were left unconnected. I applied AC to the primary. There was same voltage at both output coils. Short-circuiting one output coil caused power to began to flow in the primary and at the same time voltage dropped to half in the unconnected output coil. The following, seemingly unimportant and obvious conclusion can be made:

Conclusion: A secondary coil also creates magnetic current and different secondary coils affect each other in opposite ways.

Next, I connected various points in the core with iron. Points that I used for testing are shown here:

![Figure 1. E-I core with coils and probe points.](image)

When iron was connected between points 1 and 2 there was no effect. When connected between points 2 and 3 there was a notable effect: a sound and sort of vibration when iron approached the core which seized when both ends touched the core. When connected between points 4 and 5 there was the same effect but stronger. In this
case power output of the core dropped while power input remained the same.

**Conclusion:** Magnetic current inside the core wants to loop back to itself through every possible route it can.

For the next test I used a nanoperm core, and I wound coils of about 50 turns for both the primary and the secondary. The primary was fed with AC from the output of an audio amplifier and the secondary was connected to a loudspeaker. I then played some music from my PC through the audio amplifier. I heard the music and higher frequencies were attenuated while lower frequencies sounded fine. What I had got was a low-pass analogue audio filter.

**Conclusion:** There can be all frequencies active in the output coil at the same time. Hence there can also be magnetic current active at the same time at all frequencies in the core.

Based on these simple tests I then reached the following overall conclusion:

In a closed-loop core there can be a flowing magnetic current which varies with time when the core is energised using AC electric current. The magnetic current has summing/subtracting properties and it also has a perpetual motion property. It can be modelled as a sine wave and sine waves can be manipulated to our advantage.

4. Using two coils in a resonant LC-circuit

Below are pictures of C-I shaped and E-I shaped cores which show how coils should be wound. All coils are wound in the same direction and connected from the ends. When coils are used like this their closed loop magnetic currents cancel each other and only a local inductance field remains. This is why there is a resonant frequency but much higher than otherwise possible. For example, I used two 160 turn coils and resonant frequency was between 12-13 kHz. One coil of 20 turns in my nanoperm core blocks everything above 1.5 kHz. And I can push 260 watts from my audio amplifier.
Now you may think that this is of no use. If there is a power collection coil then it will not collect anything as magnetic currents inside the core are cancelled. But if these two coils are used as outputs and they are driven by a primary coil which is wound over both of them then the result is that power is generated. Both outputs will then be in exactly the same phase and when connected correctly they amplify each other while the primary circuit does not see a thing as the opposing phase magnetic currents cancel each other out - see Figure 3.
The primary coil is in fact a solenoid, it has no magnetic loops and it has low inductance. Secondary coils form closed loops and they have higher inductance. The more secondary coils which are used, the more magnetic current (in correct phase) will be circulating inside the core. Don Smith called this ‘resonant magnetic flux’.

Thick multi strand wire (not Litz type!) should work best, few turns and a capacitor. But any thickness of wire will do.

Warning: Begin using small diameter wires, something below 0.5mm. I haven't tested thick wires but resonant rise will occur. Also, you had better start with low-Q resonant circuits as you don't want kilovolts generated near you.

Tuning is now easy. First you make a parallel LC-circuit using secondary coils, see Figure 2. For the core you can use a toroid shape, C-I or E-I core pieces. The E-I shape pieces should be the most efficient. Next find the resonant frequency of the L-C circuit which you have just created. Now disconnect the secondary coils and do the same for your primary coil. Adjust the number of turns in the primary coil or amount of capacitance until you get a close enough resonant frequency in the primary matching with the secondary coil’s resonant frequency which you have just found.

Now connect the load and feed the primary coil with a pure AC sine wave. Pulses do not work because a square wave pulse contains all frequencies which in turn creates magnetic currents at all frequencies resulting in a total mess of magnetic flow inside the core. The input definitely has to be a pure sine wave.

There has got to be amps running in the primary LC-circuit so that the primary capacitor is filled. If you get resonance but see no power then try using a higher frequency.

If you use E-I or C-I type cores, make sure that there are no air gaps between the pieces forming the core. There has to be a closed magnetic circuit in the core. Using an LED as a load obviously does not work because it prevents resonant rise in the output LC-circuit. I suspect that E-I works best when core dimensions are such that the core area in the middle leg is twice that of the outer legs. Magnetic currents created by the secondary coils should be equal so that their sum is always zero.

Permeability of the core does not matter and you can use iron or ferrite. You need to use a frequency that is within the limits of what the core material can handle. The Nanoperm material which I used can handle frequencies up to 1 MHz.

5. My results
My input source was an audio amplifier, I expect that it outputs power at 5 volts but I really don't know. I cannot measure it as I have no meters. I used the GoldWave audio editor to create a sine wave input. It has a nice expression evaluator that allows you to do frequency sweeps easily. GoldWave is a free software download
I used a M-088 Nanoperm core from Magnetec (µ was 80,000) with 0.3 mm wire. First I had about 160 turns in each secondary and 20 meters wrapped in the primary, about 120 turns or so (far too much but that was my initial guess). I had to use high number of turns because my input was limited below 20 kHz. I was lucky to find suitable L and C combinations so I could see a glimpse of the resonant action.

Since I don’t have any meters I used halogen bulbs. I put a 5-watt 12 volt bulb in the primary and 10-watt and 8-watt 12 volt bulbs in the output. I did a sweep and as the frequency went through the sweet spot output power increased. At resonant frequency somewhere between 12 - 13 kHz there was no light at all in the primary halogen but both of the output bulbs were lit to about half brightness.

Now that I got it, I reduced the number of turns in the secondary coils to half and changed the capacitance from 440nF to 1000nF. The resonant frequency at the output changed a bit but since the resonant area was wide it did not make a notable difference. Now I got more light, almost full brightness and halogens were way too hot to touch. Again no light visible in the primary side bulb.

So what did I just do? DC resistance dropped to half in the output coils so their Q factor was doubled giving double the resonant rise in the output LC-circuit. Cool!

I observed the same action in the primary LC-circuit. There I used 40 meters of wire in the primary and I got much less power output. In that case the Q-factor dropped to half which explains the results nicely.

6. Things to try after a successful replication
Bi-filar windings should lower the total value of L and so a higher resonant frequency can be used. At the output there could be bi-filar windings without capacitors because high voltage capacitors are expensive and dangerous when loaded. Then place a correct capacitor in primary LC-circuit to tune in.

David Klingelhofer

David Klingelhofer was impressed with the Thane Heins transformer designs and so he started experimenting with variations and improvements to the design while Thane moved on to motor design. David’s design is called the “Gabriel Device” and it uses a ‘Nanoperm’ M-416 toroid size 150 x 130 x 30 mm available from Magnetec GmbH: [http://www.magnetec.us/shop/details.php?id=73&kategorie=5&main_kat=&start=50&nr](http://www.magnetec.us/shop/details.php?id=73&kategorie=5&main_kat=&start=50&nr) which is wound with 300 feet (92 metres) of AWG #16 enamelled copper wire which is 1.29 mm in diameter. That wire was used primarily because it was to hand at the time. The coil wound directly on the toroid forms the secondary coil and it is wound in the way generally known as CCW for Counter-Clock-Wise. For this, the wire passes over the toroid, down through the hole, up the outside and continues on the right hand side of the first turn. The toroid looks like this:
The highly unusual feature of the design is that this high-permeability toroid is now encased in cold-rolled steel half-doughnut shaped pieces:

David places this steel screen between the primary and secondary windings of the transformer. On the surface, it looks impossible for the device to work, but it does work, the best performance being an output of 480 watts for an input of 60 watts which is COP=8. The actual values are an input of 0.5A at 120V and an output of 4A at 120V. Every transformer has a limit and that limit is reached when the magnetic power flowing through the toroid reaches the maximum amount which that toroid can handle.

However, the construction of the toroid is completed by the two half-toroid steel pieces being connected together in a way which does not allow electrical current flow between them, possibly, glued together using epoxy resin. Finally, some 400 feet (122 metres) of the same AWG #16 wire is wound around the steel shell.

The critical part of this arrangement is the thickness of the metal shield. In his patent 433,702, Tesla discusses the use of such a protective shell with the intention of delaying the response of the secondary winding to the magnetic field of the primary winding. For that, the shield needs to saturate in exactly the right length of time and Tesla states that experimentation is needed to determine the thickness of the shield. He used iron wire or insulated thin iron sheets or strips to construct his shield.

In my opinion, iron is needed rather than steel as steel magnetises permanently (unless it is good quality stainless steel) while iron does not become permanently magnetised, but we need to go with the recommendation of those people who have built and tested this design, and they find steel to work well in use, although it is specified as “cold-rolled” steel. In this design it is not the same requirement as that of Tesla in that the objective is to catch the return magnetic field going from the secondary coil back into the primary coil where it opposes the input power.

The High-power Motionless Generator of Clemente Figuera
In 2012 a contributor who uses the ID ‘Wonju-Bajac’ started a forum to investigate the work of Clemente Figuera at http://www.overunity.com/12794/re-inventing-the-wheel-part1-clemente_figuera-the-infinite-energy-achine/#.UXu9gzcQHqU and member ‘hanlon1492’ contributed enormously by producing English translations of Figuera's patents.

Clemente Figuera of the Canary Islands died in 1908. He was a highly respected individual, an Engineer and University Professor. He was granted several patents and was known to Nikola Tesla. Figuera's design is very simple in outline.

In 1902 the Daily Mail announced that Mr. Figuera, a Forestry Engineer in the Canary Islands, and for many years Professor of Physics at St. Augustine’s College, Las Palmas, had invented a generator which required no fuel. Señor Figuera has constructed a rough apparatus by which, in spite of it's small size and it's defects, he obtains 550 volts, which he utilises in his own house for lighting purposes and for driving a 20 horse-power motor.

The Figuera Device looks like a complicated transformer, but in fact, it isn’t. Instead, it is two sets of seven opposing electromagnets with an output coil positioned between each opposing pair of electromagnets. The physical position of the electromagnets and output coils is important as they are positioned very close to each
other and there are induced magnetic fields between adjacent electromagnets and between the output coils due to their close proximity.

The two sets of electromagnets are wound with very low-resistance, high-current wire or possibly, even with thick foil. The information given in the Figuera patent states that the electromagnets will be referred to in the patent by the letters “N” and “S” and it is now thought that those two letters are deliberately misleading as people tend to think of those letters referring to “North magnetic pole” and “South magnetic pole” while in reality, the electromagnets almost certainly oppose each other, that is, with North poles facing each other or possibly, with South poles facing each other. The arrangement is believed to be like this when seen from above:

This arrangement creates a magnetic Bloch wall (or magnetically null point) in the centre of the yellow output coils and the position of that magnetic balance point is very easily moved if the power supply to the two sets of electromagnets is altered slightly and any movement of that magnetic balance point creates a substantial electrical output due to the alteration of the magnetic lines cutting the turns of wire in the yellow output coils. While the sketch shown above indicates a small gap between the electromagnets and the output coils, it is by no means certain that any such gap is needed and while winding the three coils is more convenient if they are separate, when wound and being assembled, their cores may well be pushed together to form one continuous magnetic path.

Another thing which has confused people (including me), is the drawing in the patent which looks like an electrical commutator, but which is not part of the Figuera generator design. It looks like this:
The dotted lines indicate internal electrical connections, so for example, contact 14 is connected to contact 3, but let me stress again that this unit is not part of the design and while it is used to “explain” the actual operation, I would not be surprised if it were not intended to misdirect people from the actual operation.

This point has been stressed and it has been suggested that the actual working device is magnetic in nature and could be constructed like this:

This looks like a very simple device but it is an item of major importance in the Figuera design. First, the core is solid iron (sometimes called “soft iron” but if you were beaten with a bar of it you certainly wouldn’t call it “soft”). The most important characteristic of such a core is its magnetic properties as it is able to store energy. Please remember that this switching device is primarily magnetic in nature. It looks like this:

This core is then wound with thick wire – perhaps AWG #10 or 12 SWG (2.3 x 2.3 mm square wire). The turns of wire should be tight, side by side and sit exactly flat on the top surface as the wire there will be contacted by the sliding brush:
The sliding brass contact or “brush” is dimensioned so that it connects across two adjacent wires so that there is never any sparking as the brush contact slides around the circle of wires. The brush is driven by a small DC motor. In order for the sliding brush to contact the wire, the plastic insulation needs to be removed from the top half of the wire with the remaining insulation keeping the turns from short-circuiting together. The wire is wound half of the way around the iron core and a short length of wire is left to make an electrical connection. An additional winding is then made to cover the remaining half of the core and again, a length for connection is left before cutting the wire. This gives you two windings each covering 180 degrees around the core. The wire turns are strapped tightly with tape or cord wound around the side of the core as that holds the wires securely in place. The two wire ends on each side are connected together, giving a 360 degree winding with good electrical connections 180 degrees apart.

There are many ways to arrange the small DC motor so that it drives the brush slider. The motor could be mounted on a strip passing over the core, or on the baseboard, or to one side using a belt or gearwheel drive link. It does not matter which direction the brush moves around the core. The speed of rotation is not critical either although it does determine the alternating frequency of the output. In most cases, the output will power a heating element or will be converted to DC to give the local mains frequency and voltage.

When we first look at a device like this, we immediately think of the flow of electric current passing through the wire wound around the iron core. It appears as if the current is limited by the overall length of the wire between the brush position and the two outputs, but the reality is that while that is correct to a certain extent, the main control of the current flow is the magnetic field inside the circular iron core, and that field causes reluctance (resistance to current flow) proportional to the number of coil turns between the brush and each output. This alters the current flow to the set of “N” electromagnets compared to the current flow to the set of “S” electromagnets.

As the magnetic intensity generated by the set of “N” electromagnets increases, the magnetic intensity generated by the set of “S” electromagnets decreases. But, as the magnetic power of the set of “N” electromagnets overcomes the magnetic field of the set of “S” electromagnets, that magnetic field gets pushed back into the soft iron core of the commutator device, essentially storing energy in that core. When the system needs to replace the energy lost in heating, it can use that stored magnetic energy in the commutator core, raising the overall efficiency. In this design, the current flowing through the electromagnets is always in the same direction and never drops to zero, merely oscillating in its intensity.

The overall arrangement is like this:

While the sketch above shows a 12-volt battery, there is no great reason why it should not be 24-volt or higher, especially if the wire used to wind the electromagnets is smaller diameter. The amount of power needed to create a magnetic field is not related to strength of the magnetic field and a larger number of turns of thinner wire with a small current flowing through the wire can create a stronger magnetic field than few turns of thick wire with a large current flowing through those turns.
The Alexkor Zero-Back-EMF Coils

Alex in Russia who has shared several of his motionless pulse-charging systems for batteries, now shares his design which does not appear to have any back-EMF effect on the primary coil. If that is the case, then any increase in output current draw does not have a corresponding increase in the current flowing through the primary coil. That is completely different to the way in which a conventional transformer operates.

The arrangement is somewhat like the Transmitter / Receiver arrangement of Don Smith and while it looks to be a simple arrangement, isn’t. Alex draws his coil configuration like this:

![Diagram of the Alexkor Zero-Back-EMF Coils]

Here, his chosen form of construction is a frame of twelve lengths of 20 mm diameter plastic pipes – four at the top, four at the bottom and four verticals. Each pipe is filled with ferrite powder and there is an output coil wound on each of the four vertical pipes. Suspended in the centre is the primary coil which is 15 mm in diameter. All five coils are wound using 0.5 mm diameter enamelled copper wire (swg 25 or AWG #24). While Alex’s drawing shows a single strand of wire, the actual arrangement for the four output coils is that they are wound as a single layer bi-filar coil:

![Diagram of the coil configuration]

For this, the output coils are wound with two strands of wire side by side, in a single layer along the length of the plastic pipe. Then, the start of one wire is connected to the end of the other wire. As the coils are filled with ferrite, they can operate at high frequency, when the 15 mm primary coil is fed with either DC pulses or an AC sine wave. Each output coil can provide a separate output or the output coils can be connected in series to give a higher voltage or connected in parallel to give a higher output current.

Alex also shows how ferrite toroids can be used, even with 220V mains, to give back-EMF-free transformer operation. If the input frequency is as low as the mains, then the toroids may be iron-dust types or they can be constructed from iron shims in the same way that ordinary mains transformers are constructed. However, please
understand clearly that the current flowing through any coil connected across a high voltage source such as 110V or 220V and using any of the following configurations, is limited by the impedance of the coil itself. ‘Impedance’ is effectively ‘AC resistance’ at the frequency of the AC voltage supply. If the coil impedance is low, then the current flowing through the coil will be high and since the power dissipated by the current flow is Voltage x Current, the power dissipation with increased current goes up very quickly when the voltage level is as high as 220 volts. The power dissipation is in the form of heat which means that with excessive power dissipation, the wire in the coil is liable to melt or ‘burn out’ in an impressive flash of flame, smoke and blackened wire. Consequently, the coil winding needs to have many turns and the wire diameter needs to be sufficient to carry the current flow – the wire table on page 1 of the Appendix shows the current which can be carried by each size of wire when wound into a coil. If there is no back-EMF effect with the following configurations, then the current in the primary winding connected across the mains will not be affected by the other coils, so remember that when preparing the primary coil.

The first arrangement uses three toroids to give four separate outputs. The amount of current which can be drawn from any secondary depends on the amount of magnetic flux which can be carried by the magnetic core or cores between the primary coil and that particular secondary coil. Obviously, the output current draw will also be limited by the current-carrying capacity of the wire used in the secondary coil. If that level of current is exceeded for any length of time, then the insulation of the wire will fail, turns will short-circuit together, the coil impedance will drop, the current increase further and the coil will burn out – so, common sense is called for.

Here, the primary coil “1” is wound on a toroid which is horizontal in the picture above, and the secondary coils “2” are wound on toroids which are shown as vertical in the drawing. The important point here is that the toroids with the secondary coils, touch the primary coil toroid at right angles, that is, at 90-degrees. For convenience of winding the coils, any toroid can be assembled from two half toroids which allows the coil to be wound separately and when completed, slid on to one of the C-shaped half toroids before the two halves are placed together to form the complete toroid.

The second arrangement three toroids:

The third arrangement uses four toroids, in a more powerful arrangement where the magnetic flux carrying capacity of the transformer is doubled as the cross sectional area of the toroids inside each coil is doubled. This is a more difficult arrangement to construct and if the coils are to be wound on a separate coil winder, then the toroids each need to be made from one half-toroid plus two quarter toroids so that the coils can be slipped on to two separate quarter-toroid sections which are curving in opposite directions, unless of course, the inside diameter of the coils is a good deal larger than the toroid cross section (which reduces the number of turns for any given length of coil wire):
If these simple transformer arrangements operate as back-EMF-free devices as claimed, then the current draw from any, or all, of the secondary windings does not have any effect on the current flowing through the primary coil. This is quite unlike present day commercial transformers which are wound symmetrically, which in turn causes the current draw in the secondary coil to force an increased current in the primary winding.

Alex (http://www.radiant4you.net/) also shows another arrangement which uses seven toroids. He states that this arrangement is also free from the energy-wasting back-EMF designs used at present in most commercial items of equipment. He specifies that the intended operating frequency is 50 Hz which is the frequency of the mains as the difference between 50 Hz and the 60 Hz used in America is not significant in any way. This frequency suggests that the toroids could readily be made of iron as in commercial transformers. The prototype was wound with 0.5 mm diameter wire and aimed at a power level of 100 watts. The capacitors are high-power oil filled with capacitances up to 40 microfarad and rated at 450V when using 220V mains input. The tuning is very much like that of the RotoVerter shown in chapter 2. The physical layout is:

The central toroid is wound all around its circumference as indicated by the blue colour. This winding is fed directly with the input current source which would normally be from the mains or from a mains transformer, probably at a lower voltage.

There are then twelve output coils, six shown here in green and six shown in red. For best operation, each of these output coils need to be 'tuned' to the central coil and that needs to be done by altering the capacitor size by experiment to get the best performance from each coil. When properly set up, increasing the current draw from any of the output coils does not increase the power flowing into the central input coil. This contradicts what is normally taught in schools and universities as they are only familiar with symmetrically wound transformers and motors where increased output current does indeed oppose the input power, causing increased input current and heat waste. The circuit is:
The blue coil has the power input at “A” and the capacitor in series with each coil is there to get all of the windings to resonate at the same frequency. The items “B” and “C” represent the useful load being powered by each coil, although, obviously, only two of the twelve output coils are shown in the circuit diagram above, and there are an additional five green and five red coils which are not shown in the circuit diagram.

It is probably worth remembering that adding a magnet to a toroid or closed-loop core transformer can boost the output provided that the permanent magnet is not strong enough to saturate the core completely and prevent oscillation of the magnetic flux. This has been shown by Lawrence Tseung, Graham Gunderson and others, and so it might be worth while to experiment further with these configurations along the lines shown in the video at https://www.youtube.com/watch?v=sTb5q9o8F8c&list=UUaKHAdY13gp-un2hn_HJehg&index=1&feature=plcp.

The Easiest Version:
Alexkor has produced a simplified Lenz-law-free design, using commercial toroids already wound as step-down mains transformers. One supplier is http://www.electro-mpo.ru/card8524.html#VXsKl7n7s with transformers of this type on offer:
The technique is to remove the plate covering the central opening and connecting the 220V and 110V windings in series. Two of these transformers are used, each of them connected with their 220V and 110V windings wired in series and then the toroids either placed side by side or alternatively stacked on top of one another with a 1 millimetre thick sheet of plastic between them.

In the configuration where the toroids “A” and “B” are placed side by side, a power extraction winding “D” is wound between them:

In the case where the toroids “A” and “B” are arranged in a stack with 1 mm plastic sheet between them, the power extraction winding “D” is wound around the two toroids, enclosing them both:

While the winding “D” is shown as a narrow strip in the diagram, that is only to make the drawing easier to understand as in reality, the winding “D” is continued all the way around the whole of the circumference of the toroids and it can be many layers deep to suit the desired output voltage.

Toroid “A” has a tuning capacitor “C1” which is adjusted in value to achieve resonance in that circuit as that minimises the current flowing into toroid “A” from the mains.

Toroid “B” has a capacitor “C2” which is adjusted to give the highest output voltage (typically 600 volts) coming from toroid “B”. The purpose of toroid “B” is to divert the reverse magnetic flow in Toroid “A” and so, produce an
efficient working system. The load “L” is in theory, a dummy load, but in reality there is no reason why it should not be considered to be an actual working load if that output is convenient to use.

The output winding “D” is free of the Lenz law effect and the input current from the mains is not affected in any way when the current draw from coil “D” is increased, or even short-circuited. Alexkor stresses the fact that as the toroids are supplied already wound, this is actually a very easy design to replicate.

The Self-Powered Generators of Barbosa and Leal
In July 2013, two Brazilian men, Nilson Barbosa and Cleriston Leal, published a series of patents which appear to be very significant. Their patent WO 2013/104042 published on 18th July 2013, is entitled “Electromagnetic device for Capturing Electrons from the Ground to Generate Electricity” and has some very interesting features. It describes a simple device which they describe as an “electron trap”. Their patents are written in Portuguese.

An unusual feature of this design is the fact that it has a continuous conductive loop, in which it is claimed, current flows continuously, even without the need for an applied voltage. Instead, it is the magnetic fields of electromagnets which keep the current flowing. They state that an insignificant amount of input power produces a substantial power output, and they consider a COP of 100 to be about the minimum performance which can be expected from the design. That is a 1 watt input for a 100 watt output. One version of the electron trap looks like this:

The inventors describe their device like this: “this electromagnetic-field-generating device, powered by a power source, produces an electromagnetic field which induces an electric current in a closed conductive circuit, creating an interaction between the magnetic poles of the equipment and the magnetic poles of the earth – through both electromagnetic attraction and repulsion. An endless supply of electrons is drawn from the earth into the conductive closed loop, which is connected to the ground through a conductive interconnected grid. The attracted electrons add to the current already flowing in the conductive closed loop, making power available for driving high-power loads, although the device itself is supplied with only a small amount of power.”

One very interesting feature is that the continuous-loop coil formed by wire 4 in the diagram above, is literally, only two turns of wire. The power-gaining mechanism, amazingly, is the earth wire (shown in blue) which is merely wrapped around wire 4 and not directly connected to it as the electron-transfer link is by induction. With this arrangement, the current circulating in the closed loop wire 4, attracts more electrons from the ground, flowing through the wrapped connection of wire 5, into wire 4, augmenting the current flow there by a major amount. Wire 3 can have an alternating voltage applied to it in order to get alternating current in wire 4, but please understand
that the current flowing in wire 4 is not the result of the current in wire 3. If the current in wire 3 is DC, then the current in wire 4 will be DC as this is not a conventional transformer, but instead, it is an electron trap, operating in an entirely different way.

The electron trap can be connected in an AC circuit of this type:

Here, the earth wire 5 is wrapped around the continuous loop wire 4, feeding it additional electrons captured from the ground. The ends of wire 4 are connected together to form the loop, and that connection also forms the positive side of the output (where a DC output is being produced). The magnetic field produced by the current flowing in wire 3, acts on the electron flow coming from the earth, but as it does not provide any of the electric power flowing in wire loop 4, the current flowing in wire 3 can be tiny, without affecting the power output.

In their patent WO 2013/104043, also of 18th July 2013, they show several different ways of connecting their electron trap in a useful circuit. For example, like this:

Here, the battery 13, is used to power an ordinary inverter 12, which produces a high alternating voltage, in this case, at very low power. That voltage is applied to the wire 3.1 to 3.2 of the electron trap, creating an oscillating magnetic field, which creates an oscillating inflow of electrons into the closed loop wire (4), which creates an amplified electrical output at the same frequency – typically 50 Hz or 60 Hz as those are the common mains frequencies. That amplified power output from the electron trap 14, is passed along wire 18 to an ordinary diode bridge 10, and the pulsing DC from the bridge is smoothed and used to replace the battery input to inverter 12. The battery is now switched out of the circuit and, as well as making the overall circuit self-powered, the power coming from the electron trap is used to recharge the battery if it needs recharging (and/or, perhaps, to charge the batteries of an electric car). Because the electron trap needs almost no input power at all, the input power to the inverter is very small, and so a good deal of additional AC power can be drawn off through cable 17, and used to drive powerful electrical loads, with no electrical power being needed from the battery. Being self-powered, the COP value for the circuit is infinity.

Just as there are several different ways of using an electron trap in a circuit, there are several ways of constructing and connecting an electron trap. While it is possible to arrange the components so that the power output is 2-phase or 3-phase, here we will just deal with the ordinary, household, single-phase power supply.

The first variation is to use more than one frame. Two frames can be connected like this:
This is the actual drawing from the patent and it presents a slight problem in that it is not physically possible to implement the number 4 wire in the way shown. Each frame will have two complete turns wound on it, although the drawing does not show this. Because of the inaccuracy of the drawing, I am not able to say if the coil turns on frame 2, are in the same direction as those on frame 1. There are four possible ways of winding these 2-turn coils when interconnecting them, so perhaps experimentation can be used to determine which method works best.

With this two-frame arrangement, there is just the one earth wire 5, as before, again, it is wrapped around wire 4 rather than being physically connected to it. The continuous wire loop 4 has two ends as before, but there are now two 3.1 wire ends and two 3.2 wire ends. The Portuguese translation programs produce highly questionable results for this area of the patent, but I gather that the inventors intend the two 3.1 ends to be connected together and the two 3.2 ends to be connected together, and then the joined ends are treated exactly as before, effectively putting the two windings in parallel.

One disadvantage of this design is that it is not portable due to the earth connection. Barbosa and Leal deal with this problem in their patent WO 2013/104041 of the same date where they show a method of constructing an electron trap which collects excess electrons from the air. If you feel that there are no excess electrons in the air, then consider the fact that all of the aerial designs in chapter seven all extract and use those electrons. Also, consider the amount of electricity in a lightning strike, where much of the electrical energy comes from the air, and remember that world wide, there are between 100 and 200 lightning strikes every second.

The free-electrons-in-the-air electron trap is somewhat more complicated than the earth-wire electron trap, with four pairs of coils (3 and 4) being mounted inside two aluminium hemispheres (1):
The methods for using the air-electrons trap are the same as those for the earth-wire electron trap.

An earth-wire video demonstration is here: [http://www.youtube.com/watch?v=iRSP7h73u-Q](http://www.youtube.com/watch?v=iRSP7h73u-Q) with 22 watts producing 6 kilowatts.

An attempted translation of one of the three Barbosa/Leal patents is here:

**WO Patent 2013/104043** 18th July 2013 Inventors: Nilson Barbosa and Cleriston Leal

**ELECTRIC ENERGY GENERATION SYSTEM WITH FEEDBACK**

Note: These three patents are in Portuguese and what is shown here is a low-quality attempt at translation into English using a translation program. **Abstract:**
The present invention relates to electric energy generation equipment comprising a basic circuit formed by a rectifier (10), for example, an AC/DC converter connected in series to an inverter (12), for example, a DC/AC converter, and a bank of batteries (13) connected in series between the rectifier (10) and the inverter (12). An electron-capturing element (14), which can be either a free space electron-capturing element or, alternatively, an earth electron-capturing element, is connected in series to the basic circuit formed by the rectifier (10), the inverter (12) and the battery assembly (13). The bank of batteries (13) powers the basic circuit because it is connected to the system. Consequently, the inverter (12) converts direct current into alternating current and supplies this current to the electron-capturing element (14). After receiving the electric current from the inverter (12), the electron-capturing element (14) starts capturing electrons from the alternating current and powering the rectifier.
(10), which converts the alternating current into a direct current in order to recharge the bank of batteries (13) and power the inverter (12) which powers the electron-capturing element, closing the feedback loop, and also providing electric energy for consumption by external loads.

SELF-POWERED ELECTRICITY GENERATOR.

Technical field
The present invention relates to a device for generating electricity, in particular self-powered equipment for generating electricity.

Description of the Related Art
There are many methods for generating electricity using electromagnetism, but all of these are electromechanical devices using magnets and have limited generating capacity and an ecological impact which makes them unsuited to large scale projects.

Objectives of the Invention
The aim of this invention is the sustainable generation of electricity, using a generator which is able to produce large amounts of electricity from an extremely low input current, which initially is supplied by a bank of batteries, but subsequently is supplied by the output from the generator which is also able to power external loads.

The above objective, and other objectives, are achieved by the present invention through the use of a typical Uninterruptible Power Supply circuit comprising of an AC/DC rectifier feeding a battery bank which powers a DC/AC inverter, which is connected to a device to trap electrons from space (as described in Brazilian patent application No. BR1020120008378 of 13th January 2012) or alternatively, a device which extracts electrons from the Earth (as described in Brazilian patent application No. BR1020120008386 of 13th January 2012), which then passes the extracted electrons to the AC/DC rectifier, charging the battery bank, thus closing the loop as well as providing electricity to power external loads.

The self-powered system for generating electricity from the present invention can be fixed or mobile. It is fixed when using electron capture from the earth due to the ground connection, or mobile when using electron capture from space.

The self-powered electricity generating system of this invention may be configured in several different ways, each using the same inventive concept but using different arrangements of components. Different versions include single-phase, two-phase or three-phase versions, producing outputs of any power and voltage.

Brief Description of the Drawings
The present invention will now be described with the aid of drawings, but this patent is not limited to the versions and details shown in these drawings, although they show additional details and advantages of the present invention.

The drawings:
Figure 1 - shows a basic circuit system for self-powered electricity generation of the present invention.

Figure 2 - shows a first embodiment of the constructive system for self-powered electricity generation of the present invention;

Figure 3 - shows a second embodiment of the self-powered system for generating electricity of the present invention;
Figure 4 - shows a third embodiment of the self-powered system for generating electricity of the present invention;

Figure 5 - shows a fourth embodiment of the self-powered system for generating electricity of the present invention;
Detailed description of the Invention:
There are different ways of closing the self-feeding cycle depending on the circuit configuration chosen. Some of these arrangements are shown in Figures 2 to 6, wherein the main circuitry continues to oscillate, continuously generating instant electricity.

As shown in Fig.1, the self-powered system for generating electricity comprises a basic circuit consisting of a rectifier (AC/DC converter) 10 which is connected in series to an inverter (DC/AC) 12. A bank of batteries 13 is connected between the rectifier 10 and the inverter 12. The output from the DC/AC inverter 12, connects to an electron-trap 14 which can extract electrons from space (as described in Brazilian patent application No. BR1020120008378 of 13th January 2012) or alternatively, extracts electrons from the Earth (as described in Brazilian patent application No. BR1020120008386 of 13th January 2012).

When connected, the battery bank 13 provides power to the DC/AC inverter 12 which converts the direct current into alternating current and provides current to the electron-trap 14. The output of the electron trap 14 is passed through wire 18, to the AC/DC bridge rectifier 10, which keeps the battery bank charged as well as powering the DC/AC inverter 12. Additional power is passed to external equipment through wire 17.
Fig. 2, shows another embodiment of the system of this self-powered electric power generation equipment. It comprises a typical Uninterruptible Power Supply circuit of a battery charger (AC/DC converter) 21 connected to a drive device (a DC/AC inverter) 23 and between them, a battery bank 22 forming the basic circuit. Additional devices are an electron-trap 27 which may collect free electrons from space (as defined in Brazilian patent application No. BR1020120008378 of 13th January 2012) or, alternatively, collects electrons from the Earth (as described in Brazilian patent application No. BR1020120008386 of 13th January 2012). The 3-phase electronic switch 24 normally connects 24.1 to 24.3 connecting the electron trap 27 to inverter 23. Connected in parallel is the surge suppressor 25, which, when activated, via filter 26, causes switch 24 to disconnect the 24.3 to 24.1 link and instead, connect 24.3 to 24.2.

An alternative arrangement for use in emergency situations, is to use the system no longer self-powered. For this, the system is comprised of a power input from an external power source, directly to the interconnection point 29 to provide power to surge suppressor 25, which provides power to feed the power output point 28 in order to power external loads. When the electron-trap 27 is turned off, the electronic transfer switch 24 reverts to its default position which connects point 24.1 to point 24.3 causing the circuit to function, once again, in its self-feeding mode. As soon as the electron sensor 27 provides sufficient power to the over-voltage sensor 25, it operates the transfer switch 24 through filter 26, ending the self-feeding phase and supplying energy directly to the power output point 28, in order to feed external loads.

Fig. 3 shows another embodiment of the self-powered system for generating electricity, comprising a device which includes the basic circuit of a typical Uninterruptible Power Supply, consisting of a battery charger (AC/DC converter) 31 connected to a drive device (inverter DC/AC) 35 and attached to them, a battery bank 32. This basic circuit together with other devices is connected to an electron-trap 37 for collecting free electrons from surrounding space or, alternatively, an Earth-connected electron trap 37. We have then, a bank of batteries 32 connected to the DC/DC converter 33, which is connected to the phase transfer switch 34 / 34.1 which is connected to point 34.3, which connects to the inverter 35, and so, the electron-trap 37.
Fig. 4 shows another embodiment of the system for self-powered electricity generation which is comprised of a basic circuit of a typical uninterruptible power supply, consisting of a battery charger (AC/DC converter) A connected to an inverter (DC/AC) 42 and attached to them, battery bank 41, and this basic circuit together with other devices are connected to a free space electron-capture device 44 or an earth-connection electron-trap 44. Comprising thus, a battery charger A connected to a battery bank 41, which is connected in series with inverter 42 at point B which is in series with point C of inverter 42 which is in series with the electron sensor 44, which is in series with the phase transfer switch 43 via the three-phase load output connection point 45. The phase transfer switch 43 is in series with the inverter 42, which is connected in series the (AC/DC converter) battery charger A feeding the battery bank 41.

An alternative construction for use in emergency situations, in which the system ceases to be self-powered, the system may include power input from an external power source, via the interconnection point 46, thus providing electricity output 45, to power external loads. The battery bank 41 provides power to the inverter 42 which converts the direct current into alternating current and feeds the electron trap 44. The phase transfer switch closes when the batteries need recharging.

Sensor 44 captures electrons, producing alternating current, which feeds the phase transfer switch 43 with alternating current input power. The phase transfer switch 43 feeds the inverter 42 which charges the batteries, closing the self-powering loop which provides power at the output 45, feeding both the power input and any external loads.

Fig. 5 shows another embodiment of the system for self-powered electric power generation equipment comprising a circuit which includes a typical uninterruptible power supply comprising a battery charger (AC/DC converter) 51 connected to a DC/AC inverter 53 and attached to them, a battery bank 52. This basic circuit together with other devices are connected to a space free-electron capture device 56 (as defined in Brazilian patent application No. BR1020120008378 of 13/1/12) or, alternatively, an earthed free-electron collector 56 (as defined in Brazilian
This then comprises a battery charger 51 which is connected in series with a battery bank 52, which is connected in series with the inverter 53, which is connected in series with the transformer 55 at its point C, which is in series with its point B which is in series with the electron collector 56, which is in series with the battery charger 51 which is connected to the load exit point 58, which is also the circuit entry point 59, which is in series with the phase transfer switch 54 section 54.1, which is connected to terminal 54.3, which is in series with point A of the transformer 55 which exits at point B. Points A and 54.3 as well as the parallel points 54.1 and 54.2, are all parallel to the battery charger 51, the battery bank 52, the inverter 53 and to point C of the transformer 55.

An alternative construction for use in emergency situations, in which the system ceases to be self-powered, the system may include an external power input point 59, allowing phase transfer switch 54 to provide power output 58, to feed external loads. Battery bank 52 provides power to the inverter 53, which converts the direct current into alternating current, feeding point C of the transformer, which comes out at points B and A of the transformer 55. Point B of the transformer feeds the electron-trap 56 producing alternating current which feeds the battery charger 51, recharging the battery bank 52.

The battery charger 51 is connected in parallel with the transfer switch 54 via connection points 54.1 and 54.3, feeding point A of the transformer, which comes out at point B. Point A of the transformer and the switch transfer points 54.3 and 54.1 are in parallel to the battery charger 51, the battery 52, the inverter 53 and point C of the transformer 55.

Battery bank 62 provides power to the inverter 63, which converts the direct current into alternating current, powering the free-electron collector 64. The captured electrons from collector 64 form an alternating current which feeds the delta converter 61 via an output power load wire 67.

The alternating part of the three-phase delta converter 61 is fed with alternating current from inverter 63 via connecting wire 65, which is connected in parallel to the continuous DC delta converter 61 with the battery bank 62 and the DC part of inverter 63. An alternative construction for use in emergency situations, in which the system ceases to be self-powered, the system may comprise a power input from an external power source, via the interconnection point 66 connected to the delta converter 61, the output 67 supplying power, to the external loads.
A very important part of the above patent is the device described as a "collector of free-electrons", either from the earth or from space. We have to go to the patent applications mentioned above to find the details of these designs:

**ELECTROMAGNETIC ELECTRON TRAP FOR ELECTRIC POWER GENERATION**

**Technical Field**
The present invention refers to electromagnetic equipment for electric power generation or alternatively for thermal power generation. More specifically equipment capable of producing abundant electricity and thermal energy from a tiny amount of input electrical energy

**Description of the Related Art**
According to Lenz’s law, any induced current has a direction such that the magnetic field it generates opposes the change in magnetic flux which produced it. Mathematically, Lenz’s Law is expressed by the negative sign (−) that appears in the formula of Faraday’s Law, as follows.

The magnitude of the induced emf (ε) in a conducting loop is equal to the rate of change of magnetic flux (Φ_B) with time:

\[ \varepsilon = -\frac{d\Phi_B}{dt} \]  

Equation 1

As an example of application of Faraday’s Law, we can calculate the electromotive force induced in a rectangular loop that moves in or out, with constant speed, a region of uniform magnetic field. The magnetic field flux through the surface limited by the loop is given by:

\[ \Phi = xLB \]  

Equation 2

and its variation in time:

\[ \frac{\Delta \Phi}{\Delta t} = \left( \frac{\Delta x}{\Delta t} \right) LB = vLB \]  

Equation 3

So:

\[ \varepsilon = vLB \]  

Equation 4

and if the coil has a resistance (R) and the induced current:

\[ i = \frac{\varepsilon}{R} = \frac{vLB}{R} \]  

Equation 5

A conductor traversed by an electric current immersed in a magnetic field undergoes the action of a force given by:

\[ F = IL \times B \]  

Equation 6

Thus, the effect of the current induced in the loop appears as forces Ff, and F - FM. The first two cancel each other out and the third is cancelled by an external force F_{EXT} needed to maintain the constant speed loop.

As the force FM must oppose the force F_{EXT}, current (i) induced in the loop by varying the magnetic flux must have the meaning indicated in Fig.3. This fact is a particular example of Lenz’s Law.

Considering the experimental activities discussed with Faraday’s law, when a magnet approaches a coil, the induced current in the coil has a direction as shown in Fig.1. This generates a magnetic field whose north pole is
facing the north pole of the magnet, that is, the field generated by the induced current opposes the motion of the magnet.

When the magnet is moved away from the coil, the current induced in the coil has a direction opposite to that shown in Fig.1, thereby generating a magnetic field whose south pole is facing the north pole of the magnet. The two poles attract each other, that is, the field generated by the induced current opposes the movement of the magnet away from the coil. This behaviour is present in all current power generators, and known as ‘engine brake’ is highly undesirable as it increases the resistance and so, the energy loss.

When two electromagnetic coils are placed facing each other, as shown in Fig.2, there is no current in either of them. At the instant of power-up of one of the coils, the current in the coil, generates an induced current in the second coil. When powered up, the current in the coil goes from zero to its maximum value, and then remains constant.

Thus, when the current is changing, the magnetic field generated by it, (whose north pole faces the second coil) is also changing and so the magnetic flux of this field through the second coil is also changing. Then there is a current induced in the second coil whose sense is such that the magnetic field it generates tends to decrease the flow mentioned above, that is, its north pole confronts the north pole of the first field coil.

When the power switch is opened, the current in the first coil drops from its maximum value to zero, and correspondingly its magnetic field decreases. The flux of the magnetic field in the second coil also decreases, and the induced current now flows in the opposite direction. This current flow direction produces an enhancing magnetic field, that is, it has a south pole facing the north pole of the field of the first coil.

Thus, there is a realisation of the principle of conservation of energy, expressed by Lenz’s law, wherein any induced current has an effect which opposes the cause that produced it. Assuming that the induced current acts to favour the variation of the magnetic flux that produced the magnetic field of the coil, it would have a south pole facing the north pole of the approaching magnet, causing the magnet to be attracted towards the coil.

If the magnet were then released, it would experience an acceleration toward the coil, increasing the intensity of the induced current and thus create an enhanced magnetic field. This field, in turn, would attract the magnet with increasing force, and so on, with a continuing increase in the kinetic energy of the magnet.

If energy were to be withdrawn from the magnet-coil system at the same rate at which the kinetic energy of the magnet increases, then there would be an endless supply of energy. So it would be a perpetually operating motor, which would violate the principle of conservation of energy. Therefore, it can be concluded that current generators feature a large energy loss during the generation of electricity.

Objectives of the Invention
An objective of the present invention is to contribute to the generation of sustainable energy, proposing an electromagnetic machine capable of producing abundant electricity from an extremely low input of electrical energy.

The above objective and other objectives are achieved by the present invention by a device comprised of at least one electromagnetic field-generating device (without a core or with at least one core) powered by an electrical power source (without a core or with at least one core) having their coils, or sets of coils, wound on at least one common conductive member in a closed circuit which itself has a polarised voltage which is connected to at least one conductive interconnection element which is connected to a grounding grid, these interconnections creating a new technical effect, namely, the appearance of an electric current which keeps circulating in a closed conductive loop, and which can therefore be used to power external loads.

The device which is the object of the present invention operates as follows: the electromagnetic field generating device, powered by a power source, produces an electromagnetic field which induces an electric current in a closed conductive circuit, creating an interaction between the magnetic poles of the equipment and the magnetic poles of the earth - through both electromagnetic attraction and repulsion. An endless supply of electrons is drawn from the earth into the conductive closed loop, which is connected to the ground through a conductive interconnected grid. Attracted electrons add to the current already flowing in the conductive closed loop, making power available for driving high-power loads, although the device itself is only supplied with a small amount of power. Thus, advantageously, the device which is the object of the present invention, acts as a trap for electrons from the earth and this allows the generation of electricity.

Advantageously, the present electromagnetic equipment generates either electricity or thermal energy, providing access to this new source of energy is through an electromagnetic field. The interconnections of the components
of the electron-trap of the present invention, cause an advantageous new technical effect, namely, the appearance of an electric current which keeps circling in the conductive closed circuit, with or without voltage being applied and even without a load being connected to the loop - provided that the electron-trap is connected.

The proposed sensor can also be used to generate thermal power, depending on the form in which you want to use the effect of the flow of electrical current produced in this electromagnetic equipment.

For the generation of thermal energy in amounts proportional to the power of the electron-trap, through the movement of electrons in the conductive closed loop itself, the resistance should be increased by increasing the number of turns around the cores in the conductive element of the closed circuit, and in that instance, the coils of the electromagnetic field generating device, will then be made of heat-insulated electrical circuit components, bearing in mind the required temperature which is to be produced. The thermal energy generated by the electron-trap can be used in any application from domestic to industrial applications.

This technology can also be used for various technical purposes in electric machines. By "electrical machines", it should be understood to include: static electrical machines, transformers, ballasts, rotating electrical machines, synchronous machines, dual power supply machines, current rectifiers in synchronous cascade, external pole machines, synchronous current machines alternating current machines and/or direct current machines, electronic equipment and electrical resistances. The capture of electrons can provide single-phase, two-phase or three-phase supplies, operating at low, medium or high voltage.

The capture of electrons by induction, does not impact on the environment. The fact is that we use as the capturing force, only a negligible amount of electricity relative to the current captured by the sensor. The relationship between power input and the quantity of electricity generated by the electron-trap is at least 1 to 100, that is, for each 1 watt provided to the sensor, there is at least 100 watts of power available for external loads. This relationship, however, is not limited, as it depends on the mounting of the electron-trap and the objectives of the circuit, and so, the generated power can be greater than 100 times the input power.

Another advantage of the earthed electron-trap proposed in the present invention is that the electron-trap can transport electrons from point "A" to point "B" without a voltage drop across the closed-loop conductive element - if it is biased with a voltage - regardless of the distance between the points depending on the strength and quantity of the electromagnetic field generating devices. It is also possible to transport electrons when the conductive element in a closed circuit is itself not polarised. Thus, the electric current is transported without voltage, just by the magnetic field formed between the device and the generator of the electromagnetic field.

**Brief description of the Drawings**

The present invention will now be described with the aid of drawings, but the design is not limited to the implementations shown in these drawings, although they show other details and advantages of the present invention.

**The figures show:**

**Detailed Description of the Drawings**

Fig. 4 shows one of several types of electron-trap proposed by the present invention, where the electron-trap is single-phase and consists of at least one electromagnetic field-generating device with at least one set of coils, in this case it happens to be an electromagnetic type coil with one common magnetic core, but it could alternatively have any number of windings of any kind and shape. However, the electron-trap proposed by the present invention can be constructed with a different type of electromagnetic field generating device, such as an electromagnetic inductor or magnet of any type or shape, or any combination of them, and in unlimited numbers for each phase of the electron trap.
When winding these coils, for example, coil 4-4, each coil must have at least one complete turn, preferably two turns if the objective is to generate electricity, and preferably four turns if the objective is provide thermal energy. The number of turns in the coils wound around the common core, is directly related to the amount of current to be generated.

At least one conductive interconnection element, in this case the driving member 5 - which can be copper or any other suitable conductive, material whether insulated or not insulated, connects or loop-links wire 4 to the ground grid. The connection between the conductor 5 and wire 4 is by electromagnetic induction. Winding 4 is also the power supply for the loads which are to be powered by the captured electrons.

Also in Fig.4, the power wires 3.1 and 3.2 (live phase and neutral) have an input from an external power coil 1 which can be energised from any external source of electricity such as a power grid. The trapped electrons can be configured to supply DC or AC current. Thus, if the coil 1 power source is alternating electrical current - AC, then the electron-trap provides alternating electrical current. If the power source is continuous electrical current - DC, then the electron-trap provides continuous electrical current - DC. The electrical supply provided by the trapped electrons can be single-phase, two-phase or three-phase, and at low, medium or high voltage.

Fig.5 shows an electron-trap with two single-core phase coils: 1 and 2, although these coils may be of any type and shape. However, the electron-trap proposed by the present invention can be constructed with other types of electromagnetic field generating device, with at least one electromagnetic inductor or electromagnet which can be of any type and shape, with any combination of them, and in unlimited quantities in each phase of the electron-trap.

The coils on frames 1 and 2 may have other shapes, but they must each have at least one complete turn, particularly in coil 4. The number of turns in this winding are directly related to the amount of current to be generated. This coil also makes the interconnection between the coils 1 and 2 forming the link between their two cores.

At least one conductive interconnection element, in this case the driving member 5 - which can be copper or any other suitable conductive, material whether insulated or not insulated, connects or loop-links wire 4 to the ground grid. The connection between the conductor 5 and wire 4 is by electromagnetic induction.

In electron-traps which have numerous sets of coils 1 and 2, the ends of all of the power-supply conductors 3.1 can all be connected to each other, and all of the 3.2 conductor ends may be connected together. Thus, all of the coils 1 and 2 can be fed exactly the same voltage. The power to energise coils 1 and 2 can be provided from any external source of supply of electricity such as a power grid.
In electron-traps which have numerous coils 1 and 2, a single coil winding 4 connects the cores of all of the coils 1 and 2.

The diagram shown in Fig. 6, illustrates the magnetic induction 6 around the core "X" of the coil 1. This induction causes electrical current flow in the conductor coil link 7/4, attracting electrons from the earth, through the conductive member 5, to the magnetic field of the electron-trap, where those electrons are added to the current generated by induction in the link coil 4 conductor loop circulating between north and south magnetic poles.

Fig. 7 shows how the connections should be made in one version of the electrical circuit of the electron-trap proposed in this invention. The diagram shows the electrical circuit of an electron-trap where the link/coil driver 4 is polarised with a voltage. This is one form of construction for an electron-trap which has two coils 1 and 2, where a link/coil loop conductor 4 is biased with a voltage, that is, there is a link connecting the coil conductors 4 of a power supply 3.1 or 3.2, whatever the stage.

In this way, earth electron-traps, by adopting this circuit, that is, with the link/conductor loop 4 and polarised voltage on coils 1 and 2, besides being used as a power source for external loads, can also be used for thermal power generation.
Fig. 8 shows how connections should be made in another electric circuit electron-trap proposed in this invention. The circuit illustrates a circuit of an electron-trap with a non-polarised link / coil driver 4. This is one form of construction of the electron-trap where a link / coil conductor 4 of the spiral conductor coils 1 and 2 is not polarised, that is, there is no such link connecting conductor / conductor coil conductors 4 of a coil 3.1 or 3.2.

Thus, earth electron-traps adopting this circuit, that is, with the link coil not polarised, the current flows without there being voltage in the link/coil conductor 4 joining the first and second coils by electromagnetic induction. They can also be used for generating thermal energy.

The structure of the circuit - in the open or closed coils 1 and 2, and always in the closed link / loop lead 4 - makes it possible to generate current by induction and electron capture by electromagnetism on the link conductor 4 - where current is generated and stays in motion with or without voltage, as the coils 1 and 2 are being fed. Thus, the present invention provides a new concept for electrical energy generation, since it is obtained from an electric current circling without consumption and even without an output load being attached to it.

Additionally, because the induced electrical current flows regardless of the voltage present, it can be used as a current stabiliser for electrical networks whether they be single-phase, two-phase or three-phase, with low, medium or high voltage.

The First Barbosa and Leal Replication
While many people have tried to replicate the Barbosa and Leal power generator design which draws power from the Earth, and failed. One man whose forum ID is “Clarence” read the relevant patents and knew immediately how the design works and what items in the patents are misdirection by Barbosa and Leal. He has built his own implementation of the circuit and it works perfectly. He has generously shared the relevant details. Please understand that what follows is not a description of where to start experimenting, but instead it is an actual working design. Build it as described and it will work. Build it differently and it won’t work. Clarence has this to say:

In the Barbosa and Leal patent they make a vague reference to the Lenz Law. It just so happens that this is the key to the whole device. On the overunity forum, a circuit diagram posted by member “ZeroZero” showed the exact and complete method of defeating the Lenz Law, although most forum members did not seem to understand the importance of the circuit. However, I knew immediately that Lenz’s Law was just another name for back-EMF. The Lenz Law effect is overcome by winding the single primary coil in a clockwise direction and the
AWG #4 2.5 turn windings are wound on the bare core in an anti-clockwise direction and that totally negates the Lenz Law.

What does this achieve? It gets rid of the voltage component in the secondary windings, leaving only the amperage component! When you wind two toroids exactly the same using this method and connect them as shown below, you create a loop similar to a horseshoe magnet with a keeper on it and the amperage in the loop just goes on circulating round and round as shown by Ed Leedskalin. This is the same principle. The loop has the ability within itself to add unlimited amperage, instantaneously to the neutral green Ground Return wire accordingly as the load requires. The only limit to the available amperage is the current-handling capacity of the looped black wire.

You can touch the black wire loop connections with bare hands because as there is no voltage, there is no resulting shock. The connecting of the AWG #10 phase wire to the bottom loop wire only serves to orient the polarisation of the amperage.

The oriented spinning of the amperage in the loop induces the amperage needed by the load, into the Captor output. This little toroid can allow the loop to load an AWG #4 wire enough to melt it!!

The toroid primary wires Live to Live and Neutral to Neutral should be powered from the inverter by a separate circuit.

Another separate circuit should be used with the Live connected to the bottom black looped wire in order to polarise it. The Neutral powers the input to ground.

The return ground rods are linked in a series loop and then, from a convenient ground rod to the green 2.5-turn loop around the black captor loop and then on to serve as the captor Neutral to the load.

You will know that you have enough ground rods when the Captor rms output voltage matches the rms voltage of the inverter, and then, you will probably have to add about another ten ground rods in order to keep the rms voltage of the Captor output from dropping. If the Captor rms output voltage drops – simple – add more ground rods. Please understand clearly that without sufficient ground rods, the apparatus just will not work. Here is a connection pattern where many 6-foot (1.8 m) long earthing rods are used:

The circuit diagram from ZeroZero shows this arrangement:
The direction of winding is vitally important as are the wire sizes. You will notice that the windings on the two magnetic frames are in opposite directions, and the thick wire loop windings are both in opposite directions, and, the thick wire winds also oppose the thin wire winding on the same frame. Looking from above, the thick wire forms the shape of the numeral 8. The thick wire is AWG #4 with a diameter of 5.19 mm and the other core windings are AWG #10 with a diameter of 2.59 mm. The “polarising loop” is produced by taking a few turns of the AWG #10 wire around the insulation of the AWG #4 wire – the wires inside the cables are not actually joined together. The input and output are marked as “mains” as either 110V or 220V can be used, however, not actually fed from the mains as that would create a ground loop, but instead, the input is from an inverter. The earth wire is AWG #6 with a core diameter of 4.11 mm.

While the magnetic frames above are shown as rectangular, they are actually circular toroids (which was what Barbosa and Leal used but failed to mention). The ones used by Clarence are type TD300 1120 toroids with a diameter of 5.2 inches (132 mm) and a thickness of 2.3 inches (58 mm) each weighing 6.2 pounds (2.8 Kg) and available from http://www.tortran.com/standard_isolation_transformers.html. Clarence remarks that building this power generator replication is not cheap and he has spent more than US $2000 on his replication. Mind you, with an output power of 3 kW, this unit meets all of his household electrical requirements.

It is said that all builders should get a global or national Geomagnetic Map of their area before building, but Clarence says that he is in a “dead” area anyway, so there is probably little point in this as the number of earthing rods needed in your area is found by trial anyway, and knowing in advance does not change that number.
Here are some pictures of Clarence’s successful build:
Components used were:

**Toroids:**

Bridgeport Magnetics:

*In Stock Standard Design Toroidal Isolation Transformers - Bridgeport Magnetics Group*

Contact: Michael Kharaz  E-mail: sales@bridgeportmagnetics.com

Custom ordered toroid (2 required):

TD300-1120-P, 300VA, 60Hz, Primary 120V, 160 degrees winding on toroid surface, no secondary winding - $125 USD each

**Smart Battery Charger:**

*Xantrex TrueCharge2 Battery Charger - 20Amp model*

Website: Truecharge Battery Charger | Truecharge2 20A, 40A, 60A | Xantrex

Xantrex Dealers list: Where to Buy - N. America

Available from Amazon.com:

Amazon.com: Xantrex 804-1220-02 TRUECharge2 12V 20A Parallel Stackable Battery Charger: GPS & Navigation

Looks like the price is around $260 to $300 USD - depending where you order from.

Minimum recommended battery bank size for use with the 20Amp Charger model is 40 Ah

**12V Pure Sinewave Power Inverter**

AIMS POWER 3000 Watt 12VDC Pure Sine Wave Power Inverter - Model: PWRIG300012120S

Amazon - $799 USD  http://www.amazon.com/AIMS-Power-PWR...+wave+inverter

Forum moderator “Level” who has done an excellent job of retrieving and displaying Clarence’s material here:
says:

Stick to the battery and inverter method as the power source, as that is the only way you can avoid a ground loop to the mains electrical power system. The one exception is you might be able to avoid such a problem when powering from the mains if you use an isolation transformer, but isolation transformers can be expensive and have a limited capacity as well.

Caution: Also beware that an inverter with an output of 120 volts or 240 Volts can kill you if you touch live wires, so don't build such a setup if you don't understand such things. You need to take necessary safety precautions.

Free energy from Lorrie Matchett

The style of operation used by Barbosa and Leal looks as if it is related to the developments of Lorrie Matchett. On 16th June 2008, Lorrie Matchett published his very simple design for a device which captures usable free-energy (video: http://youtu.be/eGD9o7D4To8). His device is based on a very simple and well-know principle of static electricity. This is a principle which is taught in schools all around the world but is generally considered to be of no importance as static electricity is considered too low-power to be of any use. I seriously doubt that anyone who has been struck by lightning would consider static electricity to be "low-power" and suggesting that to them is likely to expand your vocabulary with some words which are seldom heard.

Important Note: the following details mention the use of mains voltages and so let me stress that this presentation is for information purposes only and must not be construed as being a recommendation that you construct or use any such device. Should you choose to ignore this and construct and use Lorrie Matchett’s device, then please be fully aware that you do so entirely at your own risk and nobody else is in any way responsible for the results of what you do.

The principle which is being used here is that an electrically charged object causes the migration of opposite charges on the surface of any object brought close to it. For example if a charged surface if brought close to a metal sphere, then this happens:

The ordinary metal sphere “B” which has no particular charge on it is very much affected by being close to a charged surface “A” and the closer it gets, the greater the effect. The surface of the sphere had an even distribution of positive and negative charges on its surface, giving it an overall charge of about zero, but the charged surface changes all that. The positive charges on surface “A” attract the negative charges on the surface of the sphere causing them to migrate towards surface “A”. While the positive charges on surface “A” do repel the existing positive charges on the surface of the sphere, the migrated negative charges of the sphere itself have an even greater effect, causing the segregation of electrical charges shown above. The situation returns to normal if the sphere is moved away again.
However, the situation changes considerably if the metal sphere “B” is connected to the ground:

The movement of charges on the surface of the sphere is the same as before, but the Earth has millions of spare charges of both kinds and so, immediately siphons off the excess positive charges on the side of the sphere away from charged surface “A”. You will notice that charged surface “A” is not directly involved in any way and no charge moves from “A” to “B”.

The same effect is seen if the surface “A” is negatively charged (except for the fact that the sphere has positive charges rather than the negative charges shown above. The only current flow is along the wire connecting the sphere to the earth connection.

Lorrie Matchett uses this principle, and for the charged surface he connects one end of a brass rod to the ‘Live’ side of a 100V 60 Hz mains electricity supply. The other end of the brass rod is not connected to anything else. This produces this situation for 8.3 milliseconds:

And then for the following 8.3 milliseconds the mains reverses and you get this situation:
The result of this is that there is a backwards and forwards flow of static electricity along the earth connecting wire, a flow which reverses direction sixty times per second. This is not conventional electricity but is the same form of electricity which is collected by an aerial. Nikola Tesla’s patents show many different ways of utilising this static electricity, as does Herman Plauson in his patent (www.free-energy-info.com/Chapter7.pdf). Thomas Henry Moray produced fifty kilowatts of continuous power from quite a small aerial. Paul Baumann of the Swiss commune produced several kilowatts from static electricity. Lorrie Matchett settles for just a few watts and he does it like this:

He connects the live wire of a 110V (RMS) AC mains supply to a brass rod 28-inches (710 mm) long and 3/16 inches (4.76 mm) in diameter. The rod is not directly connected to anything else and so does not form part of a closed loop circuit and so, no current flows from the mains. It must be stressed that the rod and connecting wire are potentially very dangerous and need to be insulated very carefully to ensure that touching them will not cause an electric shock. Please understand very clearly that as no current of any kind is drawn from the mains that this circuit is not “stealing electricity from the mains”.

For convenience, and only for convenience, Lorrie uses the earthing system of the house mains supply by connecting a green earthing wire to the earth pin of his mains plug. It needs to be clearly understood that this has nothing directly to do with the mains supply and any good quality separate earth would be at least as good as the earthing point inside the mains plug. Effectively, there is only one mains connection.

Instead of using a metal sphere as shown in the illustrations above, Lorrie uses a coil of wire wound around the insulation layer on his brass rod, and he passes the alternating flow of static electricity, drawn from the earth, through a standard diode bridge as shown here:

Lorrie covers the brass rod with insulation which is as thin as possible. He suggest heat-shrink tubing for the insulation and on top of it he winds 0.405 mm diameter, solid-core enamelled copper wire, covering a 24-inch (610 mm) length of the rod, placing the turns closely side by side and leaving 2-inches (50 mm) clear at each end of the rod. Thicker wire should not be used.

He also shows a 500 milliamp fuse in the mains supply line. I am not at all happy about that as that fuse can power five incandescent 100-watt mains bulbs connected in parallel, and do you really want that amount of power flowing through you if your insulation is not good enough and you touch it? If you use a fuse in that position I would suggest a 20 mm glass quick-blow 100 mA fuse (mainly because no smaller one is readily available). The fuse is not needed for the circuit and is there in an attempt to protect careless humans.

The coil wound on the insulated brass rod is only connected at one end and that end goes to one of the two “Alternating Current” tags on a 3A diode bridge. Lorrie does not specify the voltage rating for the diode bridge, but it needs to be a minimum of 170-volts if the mains is a 110V (RMS) type, and double that for a 220V (RMS) mains connection. I have no idea why he specifies a 3-amp rating, but the minimum bridge available locally at 3-amps which I would recommend is a 400V rated unit which is supplied at trivial cost.

We need to understand the effect of the diode bridge. It halves the available voltage and doubles the frequency as illustrated here:
A 110V supply is supposed to swing from Minus 155V to Plus 155V and back again sixty times per second, which is an overall voltage swing of 310V. When passed through a diode bridge that changes to a voltage waveform which swings from Zero volts to Plus 154V and back again 120 times per second, which is an overall voltage swing of 154V which is an average or “RMS” voltage of 109V due to the sine wave shape.

In the rest of the world, the mains voltage is 220V (RMS) nominal, alternating fifty times per second and the Live mains wire is colour coded brown in the UK and the earth wire yellow/green stripes. In passing, the Neutral wire is white for the American 110V system and blue for the 220V system used in the UK.

This design has been brought to my attention by Jes Ascanius of Denmark who is a very able developer of all kinds of free-energy designs. He has replicated this design of Lorrie Matchett and confirms that it works. He has also taken the design further and shares some of the practical details which he has discovered through his own experimentation:

For greater power, additional rods can be used:

While brass is considered to be the best material for the rod, the diameter is not critical in any way and any size from 5 mm to 20 mm can be used and instead of a rod, a length of brass pipe should be quite suitable. It is also possible to use other materials for the rod but doing that reduces the output power available.

Jes has checked the output of his implementation with the mains fuse removed. The result was an output voltage of 2.6V picked up from the many 220V 50Hz signals generated by the mains wiring all around the place for lighting and sockets. When the fuse is inserted, the voltage rises immediately to 129V with two rods or 162V with five rods. When that voltage is loaded with a 7-watt LED lighting array, the voltage gets pulled down to 61V, but good lighting is being produced for zero current draw from the mains. I would expect that putting a reasonably large capacitor across the load, that the reservoir effect of the capacitor would improve the LED output. Jes initially used two long rods wound with coils:
And later, five rods. His AC ammeter is sensitive enough to show that due to inefficiencies caused by the tiny stray capacitance between the rods and the coils, there is a very slight current draw from the mains. The mains wattage is far less than the output wattage of the system.

An improvement implemented by Jes is adding four high-speed BYV27 diodes to the ordinary diode bridge like this:

This has the effect of improving the action of the diode bridge and allows more power to be extracted from each cycle of the energy flow. When using two brass rods, Jes gets his 5-watt LED array to light up like this:
Lorrie also extended his development to a remarkable 48 rods:

Video link: http://youtu.be/hJyZK6t9gcA The electrical output could be used to charge batteries. Adding extra turns does not increase the output voltage. If the number of turns in each coil matches the output load, then the output power will be greater.

Alexkor in Russia, who is expert in recharging batteries has experimented with this concept and he uses ten coils connected in parallel. He does not use brass, but instead uses the much shorter 300 mm long, 3 mm diameter welding rods with their chemical coating removed. Also, these rods are only used to raise the effectiveness of two separate coils wound on each rod. Each coil is 700 to 750 turns of 0.4 mm diameter wire and the connections are made to the coils and not the rods, as shown here for a single coil pair:
Alex isolates his set of 10 coil-pairs inside a short length of plastic piping:

and uses them to power his battery-charging circuit:

Some people claim that these Matchette style circuits just draw power from the mains. I do not believe that that is the case (although there is a very small leakage caused by the slight capacitance between the coils and the rods, and that is indeed, charged for by the electricity supply company. For drawing power from the mains, a circuit like this is used:

Here, the output voltage is determined by the number of turns in the coils and the available current is controlled by the number of rods involved:
You will notice that these circuits have connections only to the mains and nowhere else. These are not circuits which I use, nor do I recommend that you use it either. The green bars are iron welding rods with the chemical coating removed. These are then wound with a single layer of 0.5 mm diameter enamelled copper wire – that is swg 25 or AWG 24 size wire (a power hand screwdriver is said to be good for coil winding like that). The side-by-side wire coil is then coated with shellac or high-voltage varnish. I am told that with 220V mains power and a 1A diode bridge, that power can be drawn from the circuit without anything being recorded on the electricity supply meter. This is a seriously dangerous circuit as it can produce high voltage at the output of the bridge and that power could kill you. No power drain is recorded, presumably because the coils are wound in opposing directions. Now that is a circuit which could be considered to “steal” power from the mains.

The Matchett style circuit is different in that the power flows through the circuit from the ground. Barbosa and Leal demonstrated 169 kilowatts of power flowing from the ground, and as they powered their circuit from a battery-driven inverter and not the mains, there was definitely no question of ‘stealing’ mains power. The battery input also allowed them to establish the actual performance as 104 times more energy flowing out of their circuit than the energy flowing into it.

Actually, I’m not at all convinced that the circuit shown above does actually draw net power from the mains. The mains meter charges you for power assessed by multiplying the average voltage by the average current, even when those two are out of step and you receive less power than you are charged for. In this instance, if no current draw is registered on the meter, then perhaps as a result of the opposing direction coils, the power drawn is matched by an equal amount being returned to the mains and there may not be any real net current draw. Either way, I do not recommend the use of these circuits.

**The Solid-State Magnetostrictive System of Annis and Eberly.**

Theodore Annis & Patrick Eberly have produced a variation on this multiple-magnetic-path method which is shown in their US Patent Application 20090096219. They have opted to use a motionless reluctance switch which is a solid-state device which can block magnetic flow when energised. They have arranged one of their devices like this:
The ring shown in grey is a magnet which connects to the ring shown in yellow through two diagonal ‘reluctance’ (magnetic flow) switches. The yellow ring can carry magnetic flux and the control box marked 118 switches the diagonal strips on and off in turn, causing the magnetic flux to reverse its direction through the yellow ring. The coils wound on the yellow ring pick up this reversing magnetic flux and pass it out as an electric current. While only one pair of rings are shown here, the design allows for as many rings as are needed to be connected together as shown here:

![Diagram of magnetic flux control device]

The patent says: “The currently preferred motionless reluctance switch is described by Toshiyuki Ueno & Toshiro Higuchi, in their paper entitled ‘Investigation of the Dynamic Properties of a Magnetic Flux Control Device composed of Laminations of Magnetostrictive Piezoelectric Materials’ – University of Tokyo 2004. As shown in Fig.4, this switch is made of a laminate of a Giant Magnetostrictive Material 42, a TbDyFe alloy, bonded on both sides to a Piezoelectric material 44, 46 to which electricity is applied. The application of electricity causes the reluctance of the piezoelectric material to increase.

Fig - 10

The patent says: "The currently preferred motionless reluctance switch is described by Toshiyuki Ueno & Toshiro Higuchi, in their paper entitled ‘Investigation of the Dynamic Properties of a Magnetic Flux Control Device composed of Laminations of Magnetostrictive Piezoelectric Materials’ – University of Tokyo 2004. As shown in Fig.4, this switch is made of a laminate of a Giant Magnetostrictive Material 42, a TbDyFe alloy, bonded on both sides to a Piezoelectric material 44, 46 to which electricity is applied. The application of electricity causes the reluctance of the piezoelectric material to increase."
ENERGY GENERATION APPARATUS AND METHODS
BASED UPON MAGNETIC FLUX SWITCHING

Abstract
In an electrical energy generator, at least one permanent magnet generates flux and a magnetisable member forms the single flux path. An electrically conductive coil is wound around the magnetisable member, and a plurality of flux switches are operative to sequentially reverse the flux from the magnet through the member, thereby inducing electrical current in the coil. A “Figure of Eight” construction comprises two continuous loops of magnetisable material sharing a magnetisable member common to both loops. An alternative configuration uses stacked loops and a separate piece of material acting as the magnetisable member. One end of the magnet is coupled to one of the loops, with the other end being coupled to the other loop. Each loop further includes two flux switches operated in a $2 \times 2$ sequence to sequentially reverse the flux through the magnetisable member. A relatively small amount of electrical power is used to control the magnetic flux of a permanent magnet by switching the flux between alternate paths. The resulting power from the switched magnetic flux yields substantially more power than the power required for the input switching.

Description

FIELD OF THE INVENTION
This invention relates generally to energy generation and, in particular, to methods and apparatus wherein magnetic flux is switched through a flux path to produce electricity.

BACKGROUND OF THE INVENTION
Magnetic flux may exist in “free-space,” in materials that have the magnetic characteristics of free-space, and in materials with magnetically conductive characteristics. The degree of magnetic conduction in magnetically conductive materials is typically indicated with a B-H hysteresis curve, by a magnetisation curve, or both.

Permanent magnets may now be composed of materials which have a high coercively (Hc), a high magnetic flux density (Br), a high magneto motive force (mmf), a high maximum energy product (BHmax), with no significant deterioration of magnetic strength over time. An example is the NdFeB permanent magnet from VAC of Germany, which has an Hc of 1,079,000 Amperes/meter, a Br of 1.427 Tesla, an mmf ranging up to 575,000 Ampere-turns, and a BHmax of 392,000 Joules/meter$^3$.

According to Moskowitz, “Permanent Magnet Design and Application Handbook” 1995, page 52, magnetic flux may be thought of as flux lines which always leave and enter the surfaces of ferromagnetic materials at right angles, which never can make true right-angle turns, which travel only in straight or curved paths, which follow the shortest distance, and which follow the path of lowest reluctance (resistance to magneto motive force).
Free space presents a high reluctance path to magnetic flux. There are many materials which have magnetic characteristics similar to those of free space. There are other materials which offer a low or lower reluctance path for magnetic flux, and it is these materials that typically comprise a defined and controllable magnetic path.

High-performance magnetic materials for use as magnetic paths within a magnetic circuit are now available and are well suited for the (rapid) switching of magnetic flux with a minimum of eddy currents. Certain of these materials are highly non-linear and respond to a “small” applied magneto motive force (mmf) with a robust generation of magnetic flux (B) within the material. The magnetisation curves of such materials show a high relative permeability (ur) until the “knee of the curve” is reached, at which point ur decreases rapidly approaching unity as magnetic saturation (Bs) is reached.

Some of these non-linear, high-performance magnetic materials are referred to as “square” due to the shape of their B-H hysteresis curves. An example is the FINEMET® FT-3H nanocrystalline core material made by Hitachi of Japan. Other examples include Superperm49, Superperm80, SuperMalloy, SuperSquare80, Square50, and Supermendur, which are available from Magnetic Metals in the USA.

A “reluctance switch” is a device or means that can significantly increase or decrease (typically increase) the reluctance of a magnetic path. This is ideally done in a direct and rapid manner, while allowing a subsequent restoration to the previous (typically lower) reluctance, also in a direct and rapid manner. A reluctance switch typically has analogue characteristics. By way of contrast, an off/on electric switch typically has a digital characteristic, as there is no electricity “bleed-through.” With the current state of the art, however, reluctance switches exhibit some magnetic flux bleed-through. Reluctance switches may be implemented mechanically, such as to cause keeper movement to create an air gap, or electrically by various other means.

One electrical reluctance switch implementation uses a control coil or coils wound around a magnetic path or a sub-member that affects the path. U.S. Navy publication, “Navy Electricity and Electronics Series, Module 8 - Introduction to Amplifiers” September 1998, page 3-64 to 3-66 describes how to modulate alternating current by changing the reluctance of the entire primary magnetic path by these means, one of which is used in a saturable-core reactor and the other in a magnetic amplifier. Flynn, U.S. Pat. No. 6,246,561; Patrick et al., U.S. Pat. No. 6,362,718; Pedersen, U.S. Pat. No. 6,946,938; Marshall, and US Patent Application 2005/01256702-A1 all disclose methods and apparatus that employ this type of reluctance switch for switching magnetic flux from a stationary permanent magnet or magnets for the purpose of generating electricity (and/or motive force).

Another electrical means of implementing a reluctance switch is the placement within the primary magnetic path of certain classes of materials that change (typically increase) their reluctance upon the application of electricity. Another electrical means of implementing a reluctance switch is to saturate a sub-region of a primary magnetic path by inserting conducting electrical wires into the material comprising the primary magnetic path. Such a technique is described by Konrad and Brudny in “An Improved Method for Virtual Air Gap Length Computation,” in IEEE Transactions on Magnetics, Vol. 41, No. 10, October 2005.

Another electrical means of implementing a reluctance switch is described by Valeri Ivanov of Bulgaria on the web site www.inkomp-delta.com, shown in Fig.1. An electric toroid 110 is inserted into a primary magnetic path (100), so that the primary magnetic path is divided into two sub-paths 110A and 110B. A net magnetic flux reduction
effect in the primary magnetic path 100 results from the combination of the effects in the two sub-paths 110A and 110B, each of which results from different physics principles. In the first sub-path 110A, the magnetic flux generated by applying electrical current to the windings 110 around toroidal path 110 opposes and subtracts from its portion of the magnetic flux 103 received from the primary magnetic path 100 yielding a reduced magnetic flux, which is also further reduced by a decrease in the sub-path 110A's relative permeability thereby increasing the reluctance of the sub-path. In the second sub-path 110B, the magnetic flux generated by applying electrical current to the toroid windings 111 adds to its portion of the magnetic flux 103 received from primary magnetic path 100 yielding an increased net magnetic flux that approaches or exceeds the knee of the material's magnetisation curve thereby reducing its relative permeability and increasing its reluctance.

**SUMMARY OF THE INVENTION**

This invention is directed to methods and apparatus where magnetic flux is switched in both direction and intensity through a flux path to produce electricity. The apparatus broadly comprises at least one permanent magnet generating flux, a magnetisable member forming the flux path, an electrical conductor wound around the magnetisable member, and a plurality of flux switches operating to reverse sequentially, the flux from the magnet flowing through the member, thereby inducing electrical current in the coil.

The preferred embodiment includes first and second loops of magnetisable material. The first loop has four segments in order A, 1, B, 2, and the second loop has four segments in order C, 3, D, 4. The magnetisable member couples segments 2 and 4, and the permanent magnet couples segments 1 and 3, such that the flux from the magnet flows through segments A, B, C, D and the magnetisable member. Four magnetic flux switches are provided, each controlling the flux through a respective one of the segments A, B, C, D. A controller is operative to activate switches A-D and B-C in an alternating sequence, thereby reversing the flux through the segment and inducing electricity in the electrical conductor. The flux flowing through each segment A, B, C, D is substantially half of that flowing through the magnetisable member prior to switch activation.
The loops and magnetisable member are preferably composed of a nanocrystalline material exhibiting a substantially square BH intrinsic curve. Each magnetic flux switch adds flux to the segment it controls, thereby magnetically saturating that segment when activated. To implement the switches, each segment may have an aperture formed through it and a coil of wire wound around a portion of that segment and through the aperture. The controller may be at least initially operative to drive the switch coils with electrical current spikes.

The first and second loops may be toroidal in shape, and the loops may be spaced apart from one another, with A opposing C, and 1 opposing 3, and with B opposing D and 2 opposing 4. The magnetisable member in this case is preferably a separate piece of material. Alternatively, the first and second loops may form a “Figure of eight” shape, with the two loops intersecting to form the magnetisable member.

The permanent magnet(s) and the material comprising the magnetic paths are preferably proportioned such that the material through the common segment is at or slightly below its maximum relative permeability before the electrically conducting output coil is energized. In the preferred embodiments, the power resulting from the switched magnetic flux yields substantially more power than the power required for the input switching.

BRIEF DESCRIPTION OF THE DRAWINGS

DETAILED DESCRIPTION OF THE INVENTION

Fig.2 is a detail drawing of a reluctance switch according to the invention. The reluctance switch includes the following components: a closed magnetic path 110 comprised of a high performance magnetic material (preferably a non-linear material exhibiting a “sharp knee” as saturation is approached), around which is wound a coil 111. The closed magnetic path 110 shares a common segment 101 with a primary magnetic path 100, in which magnetic flux 103 is induced by a permanent magnet (shown in subsequent drawings). Electric current is applied to windings 111 having a polarity and sufficient amperage so that the magnetic flux generated in the path...
of switch 110 is additive to the magnetic flux 103 from the permanent magnet, such that the primary path 110 approaches or reaches magnetic saturation.

Fig.3A and Fig.3B are detail drawings of an apparatus which employs four reluctance switches according to the invention in a manner similar to that disclosed in U.S. patent application Ser. No. 11/735,746 entitled “Electricity Generating Apparatus Utilising a Single Magnetic Flux Path”, the entire content of which is incorporated herein by reference. In this and in all embodiments described herein, the geometry of the closed magnetic paths may be circular (toroidal), rectangular, or any other closed-path shapes. A primary path 304 carries the flux from permanent magnet 302 unidirectionally. Flux switch pairs 310 A/E and 310 B/D are activated in alternating fashion to reverse the flux in magnetisable member 304C, thereby inducing electrical current in winding 330. Fig.3A shows the flux flow in one direction, and Fig.3B shows it reversed.

In Fig.3A, switches 310A and 310E are activated by controller 320 in electrical communication with the windings on the switches such as through conductor 322 to winding 324. The additional flux in switches 310A and 310E are additive with the flux that would otherwise be present in segments 304A and 304E, thereby saturating these paths, causing the flux through segment 304C to be in the direction shown. In Fig.3B, switches 310B and 310D are activated, saturating segments 304B and 304D, and reversing the flow.

Fig.4 is a drawing that depicts an embodiment of the invention using circular toroids 400, 401 and multiple permanent magnets 402, 403 disposed in the primary path 404. The two toroids 400, 401 intersect, forming magnetisable member 404E. A coil 430 is wound around the member 404E, as shown.

The primary magnetic path 404 interconnects the upper end of loop 400 and the lower end of loop 401. One of the magnets, 402, couples one end of the primary magnetic path 404 to the first loop 400, and another, 403, couples the other end of the primary magnetic path 404 to the second loop 401.

In this, and all of the embodiments described here, the permanent magnets are strong, rare-earth magnets, and multiple magnets of any length (thickness) may be used in each case. Further, in all embodiments, the loops, primary magnetic path and/or magnetisable member are preferably constructed from a high magnetic permeability.
material such as the FINEMET FT-3H nanocrystalline soft magnetic material available from Hitachi. The invention is not limited in this regard, however, as alternative materials, including laminated materials, may be used.

The connections of the primary magnetic path 404 to the two loops 400, 401 create four segments apart from the magnetisable member 404E, the four segments including two opposing segments A, B in the first loop on either side of magnet 402, and the two opposing segments C, D in the second loop on either side of magnet 403.

Four magnetic flux switches are provided, each being operative to control the flux through a respective one of the four segments. A controller 420 is operative to activate the switches associated with segments A and D, and then B and C, alternately, thereby reversing the flux through the member 404E, and so, inducing electrical current in coil 430.

![Fig - 5](image)

Apertures may be formed through each of the four segments, with the switches being implemented by coils 410A to 410D which pass through the apertures and around an outer (or inner) portion of each segment. As shown in Fig.5, if the loops are fabricated with laminated material 502, the laminations may be split at 506 to accommodate coil 504. The percentage of the segment surrounded by the coil may vary in accordance with the material used, the waveforms presented to the coils, and other factors, with the goal being to magnetically saturate each segment through activation of the associated switch, thereby reversing the flux through path 404E.

![Fig - 6A](image) ![Fig - 6B](image)

Fig.6A and Fig.6B show the operation of the apparatus of Fig.4. The primary path 404 carries the flux from permanent magnets 402 and 403 unidirectionally. Reluctance switches 410A to 410D are activated alternately to reverse the flux in segment 404E which, in turn, induces electrical current in winding 430. Fig.6A shows the flux flow in one direction, and Fig.6B shows it flowing in the opposite direction.

In Fig.6A, switches 410A and 410D are activated by controller 420 in electrical communication with the windings on the switches, such as through conductors 422 to switch 410B. The flux provided by switches 410A and 410D, thereby saturating these paths, causing the flux through segment 404C to be in the direction shown. In Fig.6B, switches 410B and 410C are activated, saturating segments 404B and 404D, thereby reversing the flux through path 404E.
Fig. 7A depicts a preferred construction of the apparatus depicted in Fig. 4, Fig. 6A and Fig. 6B. Loops 400 and 401 are implemented as complete toroids 700, 701. This is important, since preferred high-performance magnetic materials are currently available in regular shapes of this kind. Note that, in this case, curved slots such as 770 are formed through the sides of each toroid to implement flux switches A to D. The magnetisable member in this embodiment is implemented with a block of material 704, preferably the same high-performance magnetic material used to construct loops 400, 401. Permanent magnet 702, shown at 702, preferably has the same length as block 704, enabling the various constituent parts to be held together with compression, shown in Fig. 7B.

The following sections summarise some of the important characteristics of the preferred embodiments:

In terms of materials, the apparatus benefits from the use of nanocrystalline material with a "Square" BH intrinsic curve, a high Br (remanence) which is about 80% of its Bs (saturation), a low Hc (coercivity), and a fast magnetic response time to saturation. An example is FineMet FT-3H from Hitachi of Japan, which has a Br of 1.0 Tesla, a Bs (saturation) of 1.21 Tesla, a time to saturation (Bs) of 2 usec, and an Hc of −0.6 amp-turns/meter.

Modern permanent magnets are used with a square BH intrinsic curve, a Br in the range of 1.0 Tesla or more, and high Hc in the range of −800,000 amp-turns/meter or more. An example is the NdFeB magnet from the German company VAC, which has a Br of 1.427 Tesla and an Hc of −1,079,000 amp-turns/meter.

An important consideration is the matching of the magnet to the nanocrystalline material, both in Tesla rating and in cross-sectional area. The magnet's Br should be below the Bs of the nanocrystalline material. If the magnet is too "strong" for the nanocrystalline material, this may cause the nanocrystalline material to saturate at the area of contact with the magnet.

The current driving the reluctance switches in the prescribed 2 × 2 sequence should have a sharp rise in the leading edge (Tr) of each pulse with a pulse width (Pw) and Amperage value that are sustained until released at the end of the pulse width (Tf). The table below shows the effects of input current pulse rise times (Tr) on the output. There exists a narrow band of Tr, before which there is small power output, at which there are excellent power output and COPs in the range of 200 to 400 or greater, and after which there is no major increase in power output. The COP of this device without the coupling circuit is defined as “Output power/Drive Power” for the switches.
The Motionless Generators of Heinrich Kunel

While Richard Willis of Magnacoaster in Canada, has gone commercial with his generators, making each of the generator outputs multiples of 12V 100A, a lot of very interesting earlier information can be found in the 1982 patent of Heinrich Kunel. The patent describes four separate configurations of his basic design, a design which looks very much like that used by Richard Willis. Here is an attempted translation of the Kunel patent which is in German:

**PROCEDURES AND DEVICES FOR ENERGY PRODUCTION**

Application Number: DE19803024814 19800701
Priority Number(s): DE19803024814 19800701
IPC Classification: H02N11/00 EC Classification: H02K53/00

DESCRIPTION

The invention concerns procedures and devices for energy production, which convert the magnetic flux from permanent magnets, without the need for rotary, or any other form of motion, into temporally variable induced flux and produce large fluctuations of the induced magnetic flux into electric current, without the need for a thermal circuit, or torque or chemical process, and in such a manner that the electric current is amplified.

The energy problems of our time are sufficiently well-known in the professional world. The transformation of conventional primary energy forms into technically usable energy is relatively cost-intensive. Additionally, by doing this, precious and ever scarcer raw materials are being destroyed and pollutants are accumulated, pollutants which are able to cause the end of mankind.

In order to reduce or avoid these and other disadvantages during power production, it is suggested according to this invention, that for the production of electric current by induction, no torque is used, but instead, the magnetic flux from permanent magnets is converted into an induced flux with large rapid variations, e.g. into a rapidly changing or pulsating induced flux, which can generate an electric current.

In accordance with this invention, one proceeds from the basic arrangement where a permanent magnet is connected to an iron core via one or both of its poles, the core consisting of, for example, dynamo iron, pure iron or amorphous iron or any similar suitable material which has little or no core losses.

Following the procedure of this invention if, for example, one pole of a bar magnet touches such an iron core and is aligned with the longitudinal axis of that core, then both the magnet and the core act as a magnet.

During this initial magnetisation process of the core a magnetic flux flows in the core, which induces a current in a conducting circuit surrounding the core.

If, in addition to the permanent magnet, a coil is wound around the core, and arranged in such a way that a current flowing in that coil wholly or partially interrupts the magnetic flux flowing through the core, then this causes another modification of the magnetic flux passing through a coil wound around the core.
If this interruption of the flux flowing from the permanent magnet is large, and has the waveform of a Alternating Current, then a pulsating Direct Current is induced in the coil wound around the core.

With an AC input to the magnetic flux modifier coil wound on the core beside the magnet, the coil receives two current flow direction changes per AC cycle, and so the magnetic flux coming from the permanent magnet is interrupted once and released once during each input power cycle. In this way, a pulsating induced Direct Current is generated in the output coil caused by the pulsating magnetic flux in the core.

It was found that the induced flux from a permanent magnet achieves its full initial value of the magnetic flux density in the core also at the free end of the soft-iron magnetic core, even if there are several induction windings each with the same number of turns and the conductor cross section are appropriate as in a magnetic flux modification coil wound on the core, without changing the strength of the magnetic flux density or the remanence of the permanent magnet.

The permanent magnet is not demagnetised when used to provide the flux in the core, no energy is extracted from it, unlike an electromagnetic core, whose windings require more operating current than that produced as an output. With an electromagnetic core, as much input current is required, as is induced in the output winding, corresponding to the relationships of the well-known transformer. Therefore it is important to produce the induction flux by using a permanent magnet.

After the basic primary system, one can build e.g. energy linear generators or energy circle generators or other arising or suitable types and forms of energy generators, without the necessity of a rotor or a stator or any such mobile sections or providing torque in the generator.

The invention is so designed as to make only frequency control governed by electrical means so that the internal induction flux in the generator core is essentially caused by the magnetic field of the permanent magnet.

In the drawings constructional examples are schematically represented according to the invention:

**Fig.1** shows a linear energy generator in longitudinal cross-section.

![Fig.1](image1.jpg)

**Fig.2** shows a linear energy generator in the instantaneous state of the transmission of the induction flux of the permanent magnet to the generator core and

![Fig.2](image2.jpg)

**Fig.3** represents a linear energy generator at the moment of the interruption by the induced flux;

![Fig.3](image3.jpg)
Fig. 4 explains a static energy pulse generator with a closed magnetic circuit at the moment the transmission of the induction flux of the permanent magnet to the generator core block.

Fig. 5 is a schematic diagram of the functional way in which the feedback process operates in a system according to the present invention.

Fig. 6 shows a double linear energy generator with some of its sub-elements and

Fig. 7 shows an energy generator, according to the present invention, with cyclic pulsing operation and with some of its sub-elements in and at the energy circuit.
The linear energy generator shown in cross-section in Fig.1, consists of a permanent bar magnet ı with a soft-iron magnetic generator core 2, which can be a single piece, or, as shown here, divided into two sections. The magnetic flux modification coil is not directly attached to the permanent magnet ı, so that the permanent magnet ı is not subjected to the alternating fields produced by the magnetic flux modification coil 3.

On the generator core 2, following the magnetic flux modification coil 3, there are several output coils 4. An air gap 6 serves as a gate or circuit-breaker for the magnetic flux coming from the permanent magnet ı and the magnetic induction flux for the induction windings 4.

With this arrangement, an alternating current applied to the magnetic flux modification coil 3 is used to produce an alternating magnetic field in the air-gap 6, so that, as shown clearly in Fig.2, with each phase of the alternating current the induced magnetic flux 5 is directed first to the core 2 and then against the permanent magnet ı, as shown in Fig.3, causing the magnetic flux 5 induced in core 2 by the permanent magnet ı, is interrupted totally or partially, and thus experiences a modification which varies with time.

If an alternating current is supplied to the magnetic flux modification coil 3 e.g. with a frequency by 50 Hz, then the induced flux 5 in core 2 experiences one hundred modifications per second, inducing in the induction windings 4 a pulsating direct current 14 which has 50 positive maximum values per second.
Fig. 2 illustrates that on the generator core 2 several induction windings 4 are wound, which correspond to the number of turns with same wire diameter as used in the magnetic flux modification coil 3.

The permanent magnet 1 requires no electric current to produce its magnetic flux and nevertheless has at its North Pole end N of the core 2 the same magnetic saturation, as produced by the multiple number of turns of induction coil 4 of Fig. 2 or in a continuous coil 4 as shown in Fig. 3, receives a multiple version of the input current which is needed for the excitation of the magnetic flux modification coil 3.

From the power source 9 the energising current flows to the pulse generator 10, the 1-amp ammeter 20 displays the intensity of the electric current. The induced current 7 or the pulsating direct current 14 is added via connections 11,1 and is measured by the 10-amp ammeter 20,2. The rectifier 15 (not shown) produces pulsating Direct Current which is smoothed and supplied as the DC output 18, through wire 21 to the battery charger 25, which provides the input for the power source 9.

The interruption of the magnetic flux by the direction change of the Alternating Current, necessary for the repeated modification of the induction flux 5, is shown in Fig. 3. When the induction flux 5 is interrupted, the wire coil(s) 11.2 is negative in that instant. Wire 21 provides the connection to the output power (not shown) and the input power source 9.

Fig. 4 shows an embodiment of the above design which uses a U-shaped permanent magnet 1 and a U-shaped generator core 2 which has its two ends facing towards the poles of the permanent magnet 1. Wound around two narrow air gaps 6 and its own narrow core, is a magnetic flux modification coil 6.6.

Fig. 4 shows the instantaneous state, when the magnetic flux 5 is transferred from the magnetic flux modification coil 3 into the generator core 2 forming a closed magnetic circuit 24. The magnetic flux modification coil 3 here has a core 6.6, which alternately makes and interrupts the passage of the magnetic flux 5 between two narrow air gaps 6 from the permanent magnet 1 to the generator core 2 which has the induction windings 4, so that each
pulse of the induction flux 5 induces a current in the induction windings 4. Thus a pulsating Direct Current results which is several times larger than the input energising current.

When the direction of current flow in the soft-iron magnetic core 6,6 of the magnetic flux modification coil 3 is changed, then at that time, the magnetic flux 5 of the permanent magnet 1 flows over into the iron guidance block 1,1 and flows along the paths 5,5 and 5,1 to the South-pole of the permanent magnet 1 or to the equilibrium in the air gaps between the North-pole of iron guidance block 1,1 and the South-pole of the permanent magnet 1. The dashed line 5,5 from North-pole to South-pole through the iron guidance block 1,1 depict the magnetic flow when it is prevented from travelling through the generator core 2.

This steering of the magnetic flux 5 prevents leakage flux entering the generator core 2 and so the maximum RMS of the induced current is achieved, as the generator core 2 is without magnetic excitation.

PJK note: I have difficulty in accepting this as the excitation coil would appear to produce an equivalent magnetic flux into the U-shaped frame 2 as it blocks the permanent magnet flux passing across the air gaps between magnet 1 and electromagnets 3, and to make things worse, magnetic flux flows about a thousand times more easily through soft iron than through air. However, we do know that modulating the flux from a permanent magnet with the magnetic field from a coil is very effective in producing COP>1 as has been shown by the independent replication of Lawrence Tseung’s magnetic frame covered earlier in this chapter.

The following schematic diagram Fig.5, shows the sequence in the cyclic process e.g. in an energy generator according to Fig.4.

The pulsating current from the power source 9 or Alternating Current 12 from the power-grid 23 flows through wire 13 to the magnetic flux modification coil 3 and produces a pulsating induction current 7 or pulsating direct current 14, which is converted by the rectifier 15 to smooth Direct Current 16 which is passed to the voltage regulator 17, and then on as Direct Current 16 now at the desired voltage, on to the DC output 18 and to the current transformer 10, by which the received Alternating Current 12 is led to the AC output 19 and coupled by AC link 22 with the power-grid input 23, whereby the AC output 19 can be supplied with current from the power-grid or from the electric output of the energy generator.

Fig.6 shows a double linear generator in accordance with the invention. On a preferably straight-line permanent magnet are fitted generator cores 2 of dynamo iron to its two poles. The magnetic flux modification coil 3 gets its working current from the power source 9 through a current transformer or from pulse generators 10 fed by the
excitation circuit 13. Through appropriate windings 4 an output of either Direct Current or Alternating Current can be obtained.

Pulsating Direct Current 14 from the induction current circuit 11 is smoothed and passed to the DC output 18 and to the input power source 9.

A further version of the system in accordance with the invention is shown in Fig. 7. This is also a motionless energy producer, although it has a cyclic arrangement and function. In this generator there are no mobile sections such as a rotor and the induction flux 5, like the induction current 7, develops from a cyclically pulsating induction flux.

The permanent magnet 1 is inserted into a circular generator core 2. The magnetic flux modification coils 3 can be operated with pulsating Direct Current 14 or as here with Alternating Current 12. For example, the Direct Current 16 from the power source 9 is led into a current transformer 10 converted into Alternating Current and fed into the exciter circuit 13.

The magnetic flux modification coils are created so that the positive maximum value of the Alternating Current 12 opens and supports the natural flow of the permanent magnet flux 5 passing from the North-pole to the South-pole through the circular generator core 2 to form a closed magnetic circuit 24.

If the magnetic flux modification coils 3 on both sides of the permanent magnet 1 carry the maximum negative value of the Alternating Current 12, then the natural magnetic flux in the generator core 2 is constricted by induction flux moving in the opposing direction in the magnetic flux modification coils 3 and this interrupts the magnetic flux 5 either totally or partially.

In the case of temporally large modification of this sequence in the coil 4 a pulsating direct current 14 is caused, which is led by the induction circuit 11 to the electric rectifier 15, in which the pulsating direct current 14 is reduced to a smooth DC current. The Direct Current 16 can be passed to the DC output 18 and the input power supply 9 and the current transformer 10 which supplies the AC output 19 and AC to the magnetic flux modification coils 3.

If the induction flux 5 is restricted in the core 2 by the magnetic flux modification coils 3, then an Alternating Current with a smaller negative maximum value is produced and the arithmetic average value during one period shifts down to zero.

According to this invention in a cyclic process an energy circle is created, with considerable energy surplus for the supply of the various outputs as well as for the maintenance of the operation of this system.

According to this invention, by avoiding the need for torque, the same induction effect is obtained by the magnetic flux modification coils and the use of permanent magnets in energy generation, as with the conventional
generators which use the transformation of torque into electricity, whereby however, the energy value of the input torque is greater than the energy value of the electricity this generated.

It was found that from each pole of the permanent magnet to the two ends of a U-shaped generator core one of the magnetic flux modification or guidance coils with or without core for transmission of the magnetic induction flux has to be designated in such a manner that by alternating induction flux, which is caused by the permanent magnet e.g. in the rhythm of the phase change of an alternating current frequency of the energising current the generator core is constantly commutated, as the North-pole will be transferred alternating to one and the other open end of the core and the coils likewise leading to the core to s-pole of the permanent magnet close the reversible magnetic circuit in the core with each current pulse, which is caused by a permanent magnet.

In this way the induction flux in the core experiences its desired flux direction change and produces in the output windings of the generator an Alternating Current of the same frequency as those of the energising current, however with identical frequency to that of the input energising current.

Since the pulsating or reversible induction flux is caused by a permanent magnet, no electric current is necessary for its production also for the whole length of the generator core and its output windings, because the reversible magnetic excitation of the core takes place indirectly in each case or directly via a permanent magnet, whose remanence is changed by the magnetic excitation of the generator core in accordance with the invention.

The system according to invention for energy production and energy producer can be extremely efficient e.g. in high frequency operation with electronically controlled direct current pulse operation and it can output a multiple of the necessary input current and electricity be produced in this way, is produced without material being used up and without a thermal circuit or a torque being necessary.

If several of these generators are cascaded in graduated increasing size e.g. in a series where the second generator receives the full output from first and third generator receives the full output of the second, then with a power multiplier of 10 for each generator, the sixth generator in the chain will have a 1000 MW performance if there is a 1000 W power input to the first (and smallest) generator at the start of the series.

Thus it is possible to replace all well-known primary energies and procedures of the energy conversion with the systems and energy generators according to invention, for all future on economical into electricity because of their high costs, since these cannot operate in any way remotely as economically, as it is possible with the devices of this invention.

Valeri Ivanov's Motionless Generator.

There are other devices which have what appears to be a very important air-gap in a magnetic frame. One of these was displayed on a Bulgarian website and is on the web page which is located at http://www.inkomp-delta.com/page3.html, put up by Valeri Ivanov in 2007. Valeri lives in Elin Pelin, Bulgaria and his motionless generator has COP=2.4 performance. Videos:
http://www.youtube.com/watch?v=7IP-buFHKKU and http://www.youtube.com/watch?v=npFVaeSbk1Q are for his design, and it appears that he is about to go commercial: http://www.inkomp-delta.com/index.html in May 2014.

It is shown that an effective device can be constructed from a permanent magnet, a toroid and a laminated iron yoke. The arrangement is displayed like this:
When the input coil is pulsed with an input voltage, it causes a flux reversal in the frame around which the output coil is wound, generating an electrical output.

There is another forum related to this and the better known MEG of Tom Bearden’s which can be found at http://tech.groups.yahoo.com/group/MEG_builders/message/1355 where that particular message states that Valeri’s device can be made to work at frequencies as low as 50 Hz and can use standard laminated iron frame components and produces Coefficient Of Performance figures up to 5.4 (that is, the output power is more than five times the input power). A demo video is at http://inkomp-delta.com/page10.html but not in English. It may well be that in order to work well, the MEG needs a very narrow input coil with an air-gap on each side of it and the same may well apply to Lawrence Tseung’s magnetic frame shown earlier in this chapter.

The Motionless Generators of Kelichiro Asaoka

Kelichiro Asaoka received US patent 5,926,083 some two years before the well-known MEG patent of Tom Bearden and his associates. Personally, I find it hard to understand how the MEG patent (in the Appendix) could have been awarded when the Asaoka patent was already in place. However, here is most of the content of the Asaoka patent:

US Patent 5,926,083 20 July 1999 Inventor: Kelichiro Asaoka

Static magnet dynamo for generating electromotive force based on changing flux density of an open magnetic path

ABSTRACT

A static magnet dynamo including at least one permanent magnet having different poles; a first core comprising a soft magnetic material and which couples the different poles of the permanent magnet to form a closed magnetic path; a second core comprising a soft magnetic material which couples to the closed magnetic path via a paramagnetic material to form an open magnetic path; a magnetised coil wound around a portion of the first core where the closed magnetic path is formed; and an induction coil wound around a portion of the second core. A direction of a flux of the closed magnetic path is changed by applying an alternating voltage to the magnetised coil, generating an electromotive force in the induction coil by electromagnetic induction due changes in a flux of the open magnetic path induced by the change in direction of the flux of the closed magnetic path.

FIELD OF THE INVENTION
This invention relates to a dynamo which generates electromotive force by electromagnetic induction by changing the flux passing through an induction coil. More particularly, this invention relates to a static magnet dynamo that changes magnets that pass through an induction coil without turning the armature or electromagnet.

DISCUSSION OF BACKGROUND
Dynamos currently in practical use are so designed as to generate electromotive force by electromagnetic induction by changing the flux passing through an induction coil. Dynamos that generate power this way come in a wide variety, ranging from large models used in hydroelectric, thermal or atomic power plants to small models such as small dynamos with a diesel engine.

In all dynamo models mentioned above, the armature and electromagnet are turned, to change the flux passing through the induction coil, thus generating electromotive force in the induction coil by electromagnetic induction. For examples, the armature and electromagnet are turned by the torque of a water turbine in hydroelectric power generation, by the torque of the steam turbine in thermal and atomic power generation, and by the torque of the diesel engine in small dynamos.

Disadvantages: Dynamos that generate electromotive force by electromagnetic induction as mentioned above are so designed that, regardless of the size of the dynamo, the armature and electromagnet are turned in order to change the flux passing the induction coil. These dynamos are disadvantageous in that the said turning of the armature and electromagnet generates vibrations and noise.

OBJECTS OF THE INVENTION
The purpose of this invention is to provide a static magnet dynamo devoid of any torque-giving means or other moving part to eliminate vibrations and noise, in order to resolve the various problems mentioned above.

To resolve the above problems, this invention is composed as described below.

The static magnet dynamo involved in this invention consists of at least one permanent magnet, a first core consisting of a soft magnetic material forming a closed magnetic path by coupling the different poles of the said permanent magnet, a second core consisting of a soft magnetic material forming an open magnetic path by being coupled to the closed magnetic path via a paramagnetic material, a magnetised coil wound around a part consisting only of the closed magnetic path of the first core, and an induction coil wound around the second core. The point of this invention is to generate electromotive force in the induction coil by electromagnetic induction by changing the direction of the flux of the closed magnetic path by applying an alternating voltage to the magnetised coil and by changing the flux of the open magnetic path induced by changes in the direction of the flux in the closed magnetic path.

Effects: In the above configuration, the static magnet dynamo involved in this invention consists of a first core consisting of a permanent magnet and a closed magnetic path, a second core consisting of an open magnetic path via a paramagnetic material, a magnetised coil wound around the part consisting only of the closed magnetic path of the first core, and an induction coil wound around the second core. The dynamo is so designed as to generate electromotive force in the induction coil by electromagnetic force by changing the direction of the flux of the first core by applying an alternating voltage to the magnetised coil, and by changing the flux of the second core induced by changes in the direction of the flux of the first core.

This makes it possible to change the flux passing through the induction coil without a torque-giving means or other moving part and to generate electromotive force in the induction coil by electromagnetic induction, thus enabling power generation without causing vibrations or noise. This dynamo can also be downsized and made available at low prices.

Other characteristics and benefits of this invention will be made clear by the description given below with diagrams attached.

BRIEF DESCRIPTION OF THE DRAWINGS
A more complete appreciation of the invention and many of the attendant advantages thereof will be readily obtained as the same becomes better understood by reference to the following detailed description when considered in connection with the accompanying drawings, wherein:
**Fig. 1**

Fig. 1 represents a basic configuration of a static magnet dynamo with an open magnetic path involved in this invention.

**Fig. 2**

Fig. 2 represents how a flux in the direction opposed to that of a permanent magnet typically occurs in the magnetised coil.
Fig. 3 represents how a flux in the direction opposed to that of a permanent magnet typically disappears from the magnetised coil.

Fig. 4 represents how a flux in the same direction as that of the permanent magnet typically occurs in the magnetised coil.

Fig. 11 is a first embodiment of the static magnet dynamo with a closed magnetic path involved in this invention.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

Referring now to the drawings, wherein like reference numerals designate identical or corresponding parts throughout the several views, and more particularly to Fig. 1 where there is illustrated a basic configuration of the static magnet dynamo with one permanent magnet. Figs. 2, 3, and 4 describe how the static magnet dynamo represented in Fig. 1 generates power.

![Diagram of Fig. 11]

As indicated in the figures, the first core 2 formed to couple the permanent magnet 1 and the different poles of the permanent magnet 1 in an annular manner, forms a closed magnetic path. This closed magnetic path is then equipped with a second core 3 via a paramagnetic material 10 μm to 5 mm thick. This results in the formation of an open magnetic path consisting of a permanent magnet 1, part of a first core 2, a paramagnetic material, and a second core 3. The part consisting only of the closed magnetic path of the first core 2 is wound around with a magnetised coil 4. The second core 3 is then wound around with an induction coil 5 designed to generate electromotive force by electromagnetic induction.

Here, the permanent magnet 1 is a magnet with a high residual flux density, a great coercive force, and a large maximum energy product for higher power generation efficiency. Typical materials used here are neodymium iron boride magnet (Nd₂Fe₁₄B), samarium cobalt magnet (Sm₂Co₁₇), or samarium iron nitride (Sm₂Fe₁₇N₂).
The first core 2 and the second core 3 are made of a soft magnetic material having a high permeability, with high initial, maximum, and other permeability levels, high residual flux density and saturation magnetisation, and small coercive force, thus making effective use of the flux of the magnetic path for power generation. Examples include Permalloy-based alloys.

Applicable paramagnetic materials are those with a specific permeability comparable to that of a vacuum, such as air, copper, and aluminium. When air is used as a paramagnetic material, that is, when a gap $G$ is secured between the first core 2 and the second core 3, the second core 3 is retained with a solid paramagnetic material. The figures represent embodiments with a gap $G$, without a solid paramagnetic material designed to retain the second core 3.

Following is a description of how a static magnet dynamo of the above configuration generates power. First, when no voltage is applied to the magnetised coil 4 of the static magnet dynamo, a first flux 11 is formed in the first core 2 in the direction going from the N pole to the S pole of the permanent magnet 1. In this state, no flux has been formed in the second core 3 coupled via the gap $G$.

![FIG. 2](image)

A voltage can be applied to the magnetised coil 4 in three manners described below. In the first voltage application, as indicated in Fig.2, a DC voltage $V_S$ is applied to the magnetised coil 4 in the direction that the voltage repels the first flux 11 of the first core 2 generated by the permanent magnet 1, and vice versa, that is, in such a manner that the second flux 12 occurs in the reverse direction of the first flux 11. As a result, the first flux 11 repels the second flux 12 and vice versa, so that the flux more easily leaks from the closed magnetic path. The first flux 11 and the second flux 12, which more easily leak from the closed magnetic path, jump across the gap $G$ and enter the second core 3, so that a third flux 13 is induced in the second core 3. Furthermore, the induction of this third flux 13 changes the flux passing through the induction coil 5, so that electromotive force $V_1$ occurs in the induction coil 5, resulting in power being generated.

![FIG. 3](image)
Next, removing the DC voltage applied to the magnetised coil 4 prompts the first core 2 to try going back to a state where only the first flux 11 is formed as indicated in Fig.1. At that time, the second core 3 has a flux in the reverse direction of the third flux 13, that is, the fourth flux 14 indicated in Fig.3, in order to kill the third flux 13. Then, the induction of the fourth flux 14 changes the flux passing the induction coil 5, so that electromotive force V2 occurs in the induction coil 5, resulting in power being generated.

Power generation in this first voltage application can be realised by a static magnet dynamo involved in this invention, a DC power supply to apply a DC voltage VS to the magnetised coil 4, and a switching circuit that turns the DC power supply on and off. A contact-less switching circuit can be made if a semiconductor switching device, such as a thyristor, is available.

The second voltage application is the same as the first voltage application up to the point where the third flux 13 is induced in the second core 3 by applying a DC voltage VS to the magnetised coil 4 so as to generate the second flux 12 in the reverse direction of the first flux 11 and where the third flux 13 is induced to generate electromotive force V1 in the induction coil 5, thus generating power.

Next, changing the polarity of the DC voltage applied to the magnetised coil 4 generates in the first core 2 the first flux 11 caused by the permanent magnet 1, as well as the fifth flux 15 in the same direction as the first flux, caused by the magnetised coil 4. Here, the first flux 11 is given the fifth flux 15, so that the second core 3 is given the fourth flux 14 as indicated in Fig.4, as well as the sixth flux 16 in the same direction as the fourth flux 14. Furthermore, inducing the fourth flux 14 and the sixth flux 16 changes the flux passing through the induction coil 5, so that an electromotive force V3 larger than the electromotive force V2 is generated in the rotary coil to produce power.

This second voltage application requires a polarity switching circuit PSC that changes the polarity of DO voltage instead of a switching circuit that turns on and off the DC voltage applied to the magnetised coil 4 in the first voltage application. This polarity switching circuit can be made of a semiconductor switching device, similarly to the switching circuit in the first voltage application.

In the third voltage application, AC voltage VS is applied to the magnetised coil 4 instead of applying DC voltage to the magnetised coil 4 in the second voltage application with the polarity changed. The flux generated by applying AC voltage to the magnetised coil 4 becomes an alternating flux that alternates between the second flux 12 in Fig.2 and the fifth flux 15 in Fig.4. Then, the flux induced in the second core 3 is the third flux 13 in Fig.2 when the second flux 12 is generated, and is the fourth flux 14 trying to kill the sixth flux 16 and the third flux 19 in Fig.4 when the fifth flux 15 is generated. That is, the flux induced in the second core 3 naturally also becomes an alternating flux.

In power generation of this third voltage application, AC voltage is applied to the magnetised coil 4, which overcomes the need for a switching circuit or polarity switching circuit PSC, which was needed in the first and the second voltage application, so that the device becomes simplified. Furthermore, the flux induced in the first core 2 and the second core 3 becomes an alternating flux induced by AC voltage, so that the dynamo functions also as a transformer having a gap G between the first core 2 and the second core 3. It is therefore possible to increase further the electromotive force V generated by electromagnetic induction in the induction coil 5.
Next, the power generation efficiency of a static magnet dynamo involved in this invention is described. The static magnet dynamo can be considered as a transformer if its permanent magnet 1 is removed and there is a gap G.

A transformer entails an eddy current loss $W_e$ and hysteresis loss $W_h$ of the core, and a loss $W_r$ due to the electric resistance of the coil. These factors are in a relation formulated below.

$$W_1 = W_e + W_h + W_r \ldots \ldots \ldots (1)$$

Let the input be $W_{in}$ and the output $W_o$, and the $W_{in}$ becomes equal to the total loss, so that the conversion efficiency of the transformer is

$$\text{Eff} = \frac{W_o}{W_{in}} = \frac{W_o(W_e + W_h + W_r)}{W_{in}} < 1 \ldots \ldots (2)$$

In reality, in Fig.1, the closed magnetic path consisting of the first core 2 contains a permanent magnet 1. The flux of this permanent magnet 1 therefore contributes to power generation. Therefore, in Fig.1, let the input be $W_{in2}$ and the output $W_{o2}$, then

$$W_{o2} = W_p + \alpha W_{in2} \ldots \ldots (3)$$

Where $W_p$ represents power resulting from the flux of the permanent magnet 1 contributing to power generation, and $\alpha$ represents a conversion efficiency obtained when the device is considered as a transformer with a gap G.

Therefore, power generation efficiency is:

$$\text{Eff} = \frac{W_{o2}}{W_{in2}} \text{ or } \frac{W_p}{W_{in2}} + \alpha \ldots \ldots (4)$$

Here, since $\alpha < 1$, if $W_p / W_{in2} > 1$, that is, if power obtained resulting from the flux of the permanent magnet 1 contributing to power generation is larger than dynamo power supplied to the magnetised coil 4, power generation efficiency becomes no less than 1, so that the device can display its performance as a dynamo.

Thus, the inventor examined as described below how much the flux of the permanent magnet 1 contributes to the induction of the third flux 13 in Fig.2. First, the inventor provided static magnet dynamos of the basic configuration indicated in Fig.1, one with a permanent magnet 1 and another without a permanent magnet 1. The inventor then compared the power levels needed to induce fluxes of equal flux densities to the second core 3 of each embodiment, that is, the power levels supplied to the magnetised coil 4. As a result, an embodiment with a permanent magnet 1 required only a very low power level to be supplied to the magnetised coil 4. It was observed that the power level required was no more than one fortieth of that of the embodiment without a permanent magnet 1, depending on the test condition.

In a static magnet dynamo involved in this invention, therefore, $W_{in2}$ can be made sufficiently smaller than $W_p$, so that the inventor considers it possible to make $W_p / W_{in2} > 1$.

**Embodiment 1**

Next, as the first embodiment, a static magnet dynamo system composed of two static magnet dynamos of the basic configuration is described based on Fig.5.
In Fig. 5A, in a static magnet dynamo, a closed magnetic path is made of two permanent magnets 1 and two first cores 2 formed so as to couple the different poles of one permanent magnet 1 with the other permanent magnet 1 in an annular manner. This closed magnetic path is then equipped with a second core 3 via a gap G. This forms an open magnetic path consisting of a permanent magnet 1, part of a first core 2, a paramagnetic material, and a second core 3.

This open magnetic path can be arranged in two different ways. In one configuration, as indicated in Fig. 5A, one open magnetic path can be made of two permanent magnets 1 and two second cores 3. In the other configuration, as indicated in Fig. 5B, one open magnetic path can be made of one permanent magnet 1 and another can be made of one first core 2. The static magnet dynamos in Fig. 5A and Fig. 5B do not differ substantially in terms of effect results, except that their patterns forming such an open magnetic path differ.

The part forming only a closed magnetic path of each first core 2 is wound around with a magnetised coil 4. Each second core 3 is then wound around with an induction coil 5 which generates electromotive force by electromagnetic induction.

This static magnet dynamo forms a first flux 11 in the first core 2 in the direction going from the N pole to the S pole of the permanent magnet 1, with no voltage applied to the magnetised coil 4. Furthermore, the action of this dynamo applying voltage to the magnetised coil 4 and generating electromotive force in the induction coil 5 by electromagnetic induction to generate power is similar to static magnet dynamos of the basic configuration. The static magnet dynamo with two permanent magnets 1 as mentioned above has well-balanced magnetic paths. Since the flux of the permanent magnets 1 can be effectively used, this embodiment achieves higher power generation efficiency than static magnet dynamos of the basic configuration.

The first embodiment is a static magnet dynamo system composed of two static magnet dynamos of the basic configuration. Similarly, a static magnet dynamo system can be made as a combination of three or more static magnet dynamos of the basic configuration (Figs. 1-4). In that case, similarly to the first embodiment, an open
magnetic path can be formed in two manners. One configuration is the formation of one open magnetic path by coupling all permanent magnets 1 with a second core 3. The other is the formation of as many open magnetic paths as permanent magnets by coupling the N pole of each permanent magnet 1 to the S pole with a second core 3.

**Embodiment 2**

Next, the second embodiment of the present invention is represented in Fig.6,

![Fig.6](image)

the third embodiment in Fig.7,

![Fig.7](image)

and the fourth embodiment in Fig.8.
In these embodiments, the action of applying voltage to the magnetised coil 4 and generating electromotive force in the induction coil 5 by electromagnetic induction is similar to that of a static magnet dynamo of the basic configuration (Figs. 1-4).

The second and the third embodiments represented in Fig.6 and Fig.7 have the same basic configuration as the first embodiment, except that the first core 2 in each embodiment is shaped quite differently.

In the second embodiment, the part opposed to the end of the second core 3 sticks out toward the end of the second core 3. Thus, the leakage flux due to the repulsion of the first flux 11 and the second flux 12 generated in the first core 2 jumps across the gap G and enters the second core 3 with greater ease.

**Embodiment 3**
The third embodiment is so designed that the part coupling the second core 3 is that part of the first core 2 which is nearest to the permanent magnet 1 and, to shorten the open magnetic path even further, the two permanent magnets 1 are close to each other. Since a flux tends to form a closed magnetic path with the shortest distance, the leakage flux due to the repulsion of the first flux 11 and the second flux 12 generated in the first core 2 jumps across the gap G and enters the second core 3 with greater ease.

**Embodiment 4**
The fourth embodiment indicated in Fig.8, as opposed to a static magnet dynamo of the basic configuration, consists of a first loop where permanent magnets 1 with multiple closed magnetic paths are arranged circularly with the fluxes oriented in the same direction, and of a second loop which is wound around with a magnetised coil 4 and installed inside the first loop. Furthermore, the parts with their first cores 2 coupling the first loop to the second one stick out toward each other across a specified gap. The parts where this first core 2 stick out are coupled together with a second core 3 via a gap G to form an open magnetic path. This reinforces the flux of the permanent magnets 1 and makes it easier for the leakage flux due to the repulsion of the first flux 11 and the second flux 12 generated in the first core 2 to jump across the gap G and enter the second core 3.

**Embodiment 5**
The configuration of a static magnet dynamo involved in this invention has so far been described in terms of embodiments where an open magnetic path is connected to the first core 2 at both ends of the second core 3 via a paramagnetic material. However, this invention is not limited to these embodiments.
That is, as indicated in Fig.9, the open magnetic path may be embodied by extending any two parts of the first core 2 in the direction that they approach each other, thus defining them as core extensions 6, and coupling these core extensions 6 via a paramagnetic material 6'. This embodiment can be applied to all embodiments mentioned above.

**Embodiment 6**

As indicated in Fig.10, a closed magnetic path consists of a permanent magnet 1 and a first core 2 formed so as to couple the different poles of the said permanent magnet 1 in an annular manner. This closed magnetic path is then equipped with a second core 3 so that it comes magnetically in parallel with the permanent magnet 1, so that a bypass closed magnetic path is composed of a permanent magnet 1, part of a first core 2, and a second core 3.

The part consisting only of the closed magnetic path of the first core 2 is wound around with a magnetised coil 4. The second core 3 is then wound around with an induction coil 5 designed to generate electromotive force by electromagnetic induction.

The action of a static magnet dynamo of the above configuration generating power is described below. First, when no voltage is applied to the magnetised coil 4 of a static magnet dynamo, the first core 2 forms a first flux 11 in the direction going from the N pole to the S pole of the permanent magnet 1. In this state, a flux similar to that of the first core 2 is generated in the second core 3 as well.

**Embodiment 7**
The seventh embodiment is described below based on Fig. 11, in terms of a static magnet dynamo system composed of two static magnet dynamos of the basic configuration and with the relative position of the permanent magnets changed.

In a static magnet dynamo, a closed magnetic path is composed of two permanent magnets 1 and two first cores 2 so designed as to couple the different poles of one of the permanent magnets 1 with the other permanent magnet 1 in an annular manner. This closed magnetic path is then equipped with a second core 3. This results in the formation of a bypass closed magnetic path consisting of a permanent magnet 1, part of a first core 2, a paramagnetic material, and a second core 3.

The parts where a closed magnetic path of each first core 2 alone is formed are wound around with a magnetised coil 4. Each second core 3 is then wound around with an induction coil 5 designed to generate electromotive force by electromagnetic induction.

In this static magnet dynamo, where no voltage is applied to the magnetised coil 4, a first flux 11 is formed in the first core 2 in the direction going from the N pole to the S pole of the permanent magnet 1. The action of applying voltage to the magnetised coil 4 and generating electromotive force in the induction coil 5 by electromagnetic induction to generate power is similar to that of a static magnet dynamo of the basic configuration.

In the aforementioned static magnet dynamo incorporating two permanent magnets 1, magnetic paths are arranged in a well-balanced manner. This makes it possible to make effective use of the flux of the permanent magnets 1, so that power generation efficiency is higher than that of a static magnet dynamo of the basic configuration.

This invention has so far been described somewhat in detail in terms of the most favourable embodiments. Since it is clear that a wide variety of embodiments can be realised without opposing the philosophy and scope of this invention, this invention will not be limited to any particular embodiment, except for the limitations described in the attached claim.

**Stephan Leben's Circuits.**
There is an interesting video posted on YouTube at [http://www.youtube.com/watch?v=9zh_C3yvJH0](http://www.youtube.com/watch?v=9zh_C3yvJH0) where Stephan W. Leben whose ID is "TheGuru2You" posts some really interesting information. He starts with a circuit produced by Alexander Meissner in 1913 and shown here:
Stephan states that he has built this circuit and can confirm that it is a self-resonating powering circuit. Once a twelve volt supply is connected to the input terminals, the transistor switches on powering the transformer which feeds repeating pulses to the base of the transistor, sustaining the oscillations. The rate of oscillation is governed by the capacitor marked “C” in the circuit diagram above and the coil across which it is connected.

Stephan suggests combining Alexander Meissner’s circuit with Charles Flynn’s magnetic amplification circuit. Here the transformer is switched to become the Charles Flynn oscillator winding plus a second winding placed alongside for magnetic coupling as shown here:

The transistor stage is self-oscillating as before, the transformer now being made up of the red and blue coil windings. This oscillation also oscillates the Flynn magnetic frame, producing an electrical output via the black coils at each end of the magnetic frame. This is, of course, an oscillating, or AC output, so the four diodes produce a full-wave rectified (pulsating) DC current which is smoothed by the capacitor connected to the diodes.

This circuit would be started by touching a 12 volt source very briefly to the output terminals on the right. An alternative would be to wave a permanent magnet close to the red and blue coils as that generates a voltage in the coils, quite sufficient to start the system oscillating and so, becoming self-sustaining. Stephan suggests using the piezo crystal from a lighter and connecting it to an extra coil to produce the necessary voltage spike when the coil is held close to the blue coil and the lighter mechanism clicked.

A surprising problem would be how to switch the device off since it runs itself. To manage this, Stephan suggests a two-pole On/Off switch to disconnect the output and prevent it supplying the input section of the circuit. To show whether or not the circuit is running, a Light-Emitting Diode (“LED”) is connected across the output and the current flowing through it limited by a resistor of about 820 ohms.
Anyone wanting to try replicating this device will need to experiment with the number of turns in each coil and the wire diameter needed to carry the desired current. Stephan states that you need to have at least twice the weight of copper in the (black) output coils as there is in the (blue) input coils in order to allow the device produce excess power. The first page of the Appendix shows the current carrying capacity for each of the standard wire diameters commonly offered for sale. As this is a fairly recently released circuit, I am not aware of any replications of it at this time.

Floyd Sweet’s “VTA” Generator.
Another device in the same category of permanent magnets in conjunction with oscillating coils, was produced by Floyd Sweet. The device was dubbed “Vacuum Triode Amplifier” or “VTA” by Tom Bearden.

The device was capable of producing more than 500 watts of output power at 120 Volts, 60 Hz requiring less than one third of one milliwatt as input power. The output power can operate AC motors, lights, heaters and when rectified, DC motors.

Thanks is due to Horst Weyrich who has recently provided me with links to useful material which I had not seen before. This link: http://www.youtube.com/watch?v=0gM9natKlyY is to a video in which Floyd shows most of the magnet conditioning process.

Recently, some additional information on Floyd Sweet's device, has been released publicly by an associate of Floyd's who goes just by his first name of "Maurice" and who, having reached the age of seventy has decided that it is time to release this additional information. That information can be found in the Appendix. I am not aware of anybody who has succeeded in replicating Floyd’s VTA, but here is as much information as I have at this time.

In the above video, Floyd talks about separating two of his conditioned permanent magnets with an “air gap” which is astonishing as he is putting them on opposite sides of a length of aluminium channel with thick walls and aluminium has a major damping effect on magnetic fields:

This arrangement which seems quite mad, is confirmed by a picture from Floyd's lab. As shown here:
This shows clearly that the open ends of the channel are not between the two magnets allowing an unrestricted magnetic field to flow between them, but instead, two channel thicknesses of aluminium are between the two magnets, obstructing the magnetic flow – quite remarkable!!

Floyd shows two coils being used to condition the magnets. The first is the large vertical coil shown here in front of Floyd:

The second coil is not seen as it is inside the vertical coil, sitting flat on the base, and consisting of an entire reel of AWG #17 (1.15 mm diameter) wire, something like this:
This coil operates effectively as an air-core solenoid, producing a strong axial magnetic field inside the larger coil which surrounds it. This inside coil is driven by a sine wave signal in the 10Hz to 15Hz range, boosted through a 100-watt audio amplifier which provides the current needed to impose the sine wave on this low impedance coil without distorting the waveform.

The first step is to determine the resonant frequency of each of the two permanent magnets to be used. The ferrite magnets used appear to be about 6 x 4 x 1 inch (150 x 100 x 25 mm). As they will eventually be used as a pair, one end of each is marked so that they can be aligned in the correct orientation after conditioning. That size of magnet appears to have a resonant frequency of about 12Hz, but each magnet will be slightly different.

The inside, low frequency coil is powered up at around 12Hz, the length of the magnet aligned with the Earth's magnetic field (that is, North/South), and placed on top of the vertical coil. An iron shim as used in transformer core construction is placed vertically on top of the magnet as an indication of resonating:

As shown in the video, the sine wave frequency feeding the AWG #17 coil is adjusted slowly to find the point at which the iron shim vibrates most strongly. That frequency is noted, and the same is done for the second magnet. It is not likely that the two resonant frequencies will be the same, and so the average frequency for the pair is used.

Next, the two magnets are placed in attraction mode, one on each side of the aluminium channel, with their marked ends at the same end of the channel. That is, the North pole face of one will touch the aluminium and the South pole face of the other will touch the aluminium. The two magnets and their separating aluminium channel are then placed inside the main coil and aligned so that the outer North pole faces southwards and the opposite external South pole faces Northwards. The large coil dimensions are arranged so that the centre of the magnets is at the centre of the outer coil:

While the inner coil continues to be powered up with a powerful sine wave, the outer coil is now fed a 60Hz stream of sharp voltage pulses. These are generated by charging up a 16,000 microfarad 250V capacitor and then discharging it through an SCR (Thyristor) connected to the outer coil. It is important that the spikes be sharp as they are imposing that frequency on the internal magnetic structure of the magnets. Presumably, if aiming for a European 240V version, then the outer coil would be pulsed at 50Hz rather than the American 60Hz and the capacitor would be a 450V rated type.
The working pictures of Floyd’s prototype powering a load, seem to indicate that the one input coil and one output coil as described by Ashley Gray below, are the same as used by Floyd as we see wires coming out of the open end of the channel.

Horst wishes to emphasise that it is not easy to make a working replication of Floyd’s design as the people at www.hyiq.org have tried to replicate it for a number of years now, without any success.

**Ashley Gray of New Zealand.**

In April 2014, I was sent some information about a colleague of Floyd Sweet’s – Ashley Gray of Nelson, New Zealand. The version described by Ashley appears to be understandable.

On 20th June 1994, Ashley says:

> After a trip to America in 1985 when I was first introduced to Floyd Sweet, I was invited to go back and work with him. At that time he was being funded by Mark Goldes of the Aesop Institute, and Darryl Roberts was working as co-coordinator for the Institute in L.A. After working with Floyd for some time we left America for England. At that stage the “politics” had become difficult. While we were in England, we were contacted by Mark Goldes and told that Floyd had obtained some results which they would like us to verify for them.

On our return to New Zealand, Darryl Roberts sent us the Lab Notes which he had recorded during the first tests of the “Space Quanta Modulator” and it’s construction details. We were asked to repeat the experiments to verify the results. We constructed the device but were unable to get any results at that time. In the light of the new information which had been released, I conducted some further experiments and managed to obtain some interesting results without magnet ‘conditioning’ which, as far as I was aware, was not used in the original device.

The initial device which I constructed when in America, consisted of two 1-inch x 1-inch (25 x 25 mm) neodymium magnets mounted in a steel frame. There were two ‘modulating’ windings and one output winding. It was driven by a specially built sine-wave oscillator which was adjustable from 1 kHz to 2 kHz. We did not get any output or significant result from this device. Floyd felt that this was due to the high field strength of the neodymium magnets and the closed magnetic path. Floyd did not mention anything about magnet conditioning being necessary.

A second prototype was then built, using Barium Ferrite magnets size 6-inches x 4-inches x 1-inch (150 x 100 x 25 mm): 

![Diagram of prototype](image)

Ashley appears to be using magnets which are not ‘conditioned’. Ashley has had what I consider to be very significant results from his prototype with an output power of 111 watts for an input of just 0.001 watts (a COP of 111,000). Ashley’s successful build has an aluminium housing. People get the very mistaken idea that aluminium is not magnetic because magnets do not stick to it. The reality is that aluminium has a really major effect on magnetic fields and can be used as magnetic shielding if thick enough. Ashley’s design uses two coils at right-angles to each other and that style of operation can be seen in other free-energy designs. Anyway, take a look at the version built by Ashley:
The aluminium enclosure is shallow. The ends are 4" x 2.5" which is 100 x 63 mm. The diameter of the input coil is 1.5 inches or 38 mm. Similarly, the output coil length has to be less than 63 mm.

The diagram below may give a slightly better idea of the dimensions involved in the construction. At the present time, magnets of that size are available for £14 each in the UK. They each have an 8 Kg pull and are very heavy.

The magnetic lines of force flow through the length of the output coil and through the width of the input coil. As you can see from the diagram, the unit is compact in spite of the very large magnets. The input needed is a good-quality sine wave. Ashley also says:

**Details From Lab Notes of First Successful Tests**

**Original Test Setup:**
A Signal Generator made by Wavetek, USA, was used to drive the input coil.

- **Input coil**: 1.5" diameter 120 turns #20 gauge (0.812 mm diameter, overall resistance about 1 ohm)
- **Input**: 7.5 volts at 3.1 microamps = 23 micro watts
- **Output Coil**: 1.5" diameter 12 turns #12 gauge (2.05 mm diameter)
- **Output**: 10.4 volts sine wave at 1.84 amps = 19.15 watts at approx 400 Hz

**Comments:**
Frequency generally affected resistive 1.8 amp 20 watt bulb load proportionally - brightness increased with frequency, decreased with frequency except at certain points when it appeared inversely related, increasing as frequency decreased etc.

**First Modifications:**
The Signal generator was replaced with a purpose-built Sine Wave Oscillator of 9 volt output. The input coil was increased to 250 turns of #18 gauge (1.024mm) and the output coil was increased to 24 turns of #18 gauge(1.024 mm diameter) wire. Magnets, spacing, etc. all remained the same.

**Input:** 7.2 volts at 143 micro amps (0.001 watts)

**Output:** 24.2 volts at 4.6 amps = 111watts. Frequency 388 and 402 Hz

**Comments:**
By increasing the area of the wire exposed to/or occupying the fluctuating magnetic field the output was doubled. The exact proportions /ratios of the space filling volume of winding to output had not been determined at the time of writing. Magnet size seems to be less important than the volume of the windings, wire diameter, input voltage and current.

The current is only limited by the impedance of the wire which rises dramatically in the magnetic field to several hundred thousand ohms, while the impedance when outside the magnetic the field is only 2 or 3ohms @ 400 Hz. (250 turns #18 (1 mm diameter) wire).

The AC excitation current is only required to support $I^2R$ losses as the magnetic field requires no additional power, as it is not loaded by the wires passing through the field.

The unit ran for 10 to 12 hours with no heating occurring but no longer duration tests were performed. The tests were witnessed by three people.

**Technical Notes:**
The quality of the oscillator is important - there should be no harmonic distortion i.e. it needs to be a pure sine wave.

The signal diode divides the current into the circuit, and being parallel - puts a small microamp current into the power coil as well as the excitation coil. This works with the magnets in such a way that there is produced a vector complementation.

When in close proximity to the magnets, the output load bulbs vibrate.

**The Optical Generator of Pavel Imris.**
Pavel was awarded a US patent in the 1970’s. The patent is most interesting in that it describes a device which can have an output power which is more than nine times greater than the input power. He achieves this with a device which has two pointed electrodes enclosed in a quartz glass envelope which contains xenon gas under pressure (the higher the pressure, the greater the gain of the device) and a dielectric material.
Here, the power supply to one or more standard fluorescent lamps is passed through the device. This produces a power gain which can be spectacular when the gas pressure in the area marked '24' and '25' in the above diagram is high. The patent is included in this set of documents and it contains the following table of experimental measurements:

**Table 1** shows the data to be obtained relating to the optical electrostatic generator. **Table 2** shows the lamp performance and efficiency for each of the tests shown in **Table 1**. The following is a description of the data in each of the columns of **Tables 1 and 2**.

</table>

The results from Test No. 24 where the gas pressure is a very high 5,000 Torr, show that the input power for each 40-watt standard fluorescent tubes is 0.9 watts for full lamp output. In other words, each lamp is working to its full specification on less than one fortieth of its rated input power. However, the power taken by the device in that test was 333.4 watts which with the 90 watts needed to run the 100 lamps, gives a total input electrical power of 423.4 watts instead of the 4,000 watts which would have been needed without the device. That is an output power of more than nine times the input power.

From the point of view of any individual lamp, without using this device, it requires 40 watts of electrical input power to give 8.8 watts of light output which is an efficiency of about 22% (the rest of the input power being converted to heat). In test 24, the input power per lamp is 0.9 watts for the 8.8 watts of light produced, which is a lamp efficiency of more than 900%. The lamp used to need 40 watts of input power to perform correctly. With this device in the circuit, each lamp only needs 0.9 watts of input power which is only 2.25% of the original power. Quite an impressive performance for so simple a device!

The Michel Meyer and Yves Mace Isotopic Generator.

There is a French patent application number FR 2,680,613 dated 19th August 1991 entitled “Activateur pour Mutation Isotopique” which provides some very interesting information. The system described is a self-contained solid-state energy converter which abstracts large amounts of energy from an ordinary iron bar. This is also shown in Michel’s Czechoslovakia Patent No.284,333.

The inventors describes the technique as an “isotopic mutation effect” as it converts ordinary iron (isotope 56) to isotope 54 iron, releasing large amounts of electrical energy in the process. This excess energy can, they say, be used to drive inverters, motors or generators.

The description of the mechanism which is being used by the device is: “the present invention uses a physical phenomenon to which we draw attention and which we will call ‘Isotopic Change’. The physical principle applies to isotope 56 iron which contains 26 protons, 26 electrons and 30 neutrons, giving a total mass of 56.52 Mev, although its actual mass is 55.80 Mev. The difference between the total mass and the actual mass is therefore
0.72 Mev this which corresponds to an energy of cohesion per nucleon of 0.012857 Mev.

So, if one introduces an additional 105 ev of energy to the iron core isotope 56, that core isotope will have a cohesion energy level of 0.012962 Mev per nucleon corresponding to iron isotope 54. The instability created by this contribution of energy will transfer the isotope 56 iron to isotope 54 causing a release of 2 neutrons.

This process generates an excess energy of 20,000 ev since the iron isotope 54 is only 0.70 Mev while isotope 56 has 0.72 Mev. To bring about this iron isotope 56 conversion, we use the principle of Nuclear Magnetic Resonance.

The practical method for doing this is by using three coils of wire and a magnetic-path-closing support frame of iron as shown in this diagram:

In this arrangement,

- **Coil 1**: Produces 0.5 Tesla when fed with DC, converting the iron bar into an electromagnet
- **Coil 2**: Produces 10 milli-Tesla when fed with a 21 MHz AC sinewave signal
- **Coil 3**: Is the output coil, providing 110, 220 or 380 volts AC at about 400 Hz depending on the number of turns in the coil

This simple and cheap system has the potential for producing substantial energy output for a very long time. The inventors claim that this device can be wired to be self-powered, while still powering external devices. Coil 1 turns the iron rod into an electromagnet with its flux channelled in a loop by the iron yoke. Coil 2 then oscillates that magnetic field in resonance with the isotope 56 iron atoms in the rod, and this produces the isotope conversion and release of excess energy. Coil 3 is wound to produce a convenient output voltage.

**The Colman / Seddon-Gilliespie Generator.**

This device, patented by Harold Colman and Ronald Seddon-Gillespie on 5th December 1956, is quite remarkable. It is a tiny lightweight device which can produce electricity using a self-powered electromagnet and chemical salts. The working life of the device before needing refurbishment is estimated at some seventy years with an output of about one kilowatt.

The operation is controlled by a transmitter which bombards the chemical sample with 300 MHz radio waves. This produces radioactive emissions from the chemical mixture for a period of one hour maximum, so the transmitter needs to be run for fifteen to thirty seconds once every hour. The chemical mixture is shielded by a lead screen to prevent harmful radiation reaching the user. The patent, GB 763,062 is included in the Appendix.
This generator unit includes a magnet, a tube containing a chemical mixture of elements whose nuclei becomes unstable as a result of bombardment by short waves so that the elements become radio-active and release electrical energy, the mixture being mounted between, and in contact with, a pair of different metals such as copper and zinc, and a capacitor mounted between those metals.

The mixture is preferably composed of the elements Cadmium, Phosphorus and Cobalt having Atomic Weights of 112, 31 and 59 respectively. The mixture, which may be of powdered form, is mounted in a tube of non-conducting, high heat resistivity material and is compressed between granulated zinc at one end of the tube and granulated copper at the other end, the ends of the tube being closed by brass caps and the tube being carried in a suitable cradle so that it is located between the poles of a magnet. The magnet is preferably an electro-magnet and is energised by the current produced by the unit. The transmitter unit which is used for activating the generator unit may be of any conventional type operating on ultra-shortwave and is preferably crystal controlled at the desired frequency.

The transmitter unit is of any suitable conventional type for producing ultra shortwaves and may be crystal controlled to ensure that it operates at the desired frequency without needing tuning. The quartz tube containing the chemical mixture, works best if made up of a number of small cells in series. In other words, considering the cartridge from one end to the other, at one end and in contact with the brass cap, there would be a layer of powdered copper, then a layer of the chemical mixture, then a layer of powdered zinc, a layer of powdered copper, etc. with a layer of powdered zinc in contact with the brass cap at the other end of the cartridge. With a cartridge some forty five millimetres long and five millimetres diameter, some fourteen cells may be included.

The Devices of Don Smith.

One free-energy developer who had most impressive claims for his devices is the late Don Smith who produced many spectacular devices, generally with major power output. Don says that his understanding comes from the work of Nikola Tesla as recorded in Thomas C. Martin's book “The Inventions, Researches, and Writings of Nikola Tesla” ISBN 0-7873-0582-0 available from http://www.healthresearchbooks.com and various other book companies. This book can be downloaded from http://www.free-energy-info.tuks.nl/ as a pdf file, but a paper copy is much better quality and easier to work from.

Many experimenters have spent considerable time and effort in attempts to replicate the work which Don reports and while COP>1 has definitely been achieved, high power has not yet been reached. If you want more detail then it can be found here: http://www.free-energy-info.tuks.nl/DonSmith.pdf as a free download – or a Russian translation here: http://www.free-energy-info.tuks.nl/Don_Smith_Russian.pdf. Tom Swift attempts to explain the science behind Don’s designs here: http://www.free-energy-info.tuks.nl/Radiant1.pdf. Being a very patient and determined developer Tom has been working on understanding Don Smith’s circuitry for some time now. He has succeeded in replicating the self-powered front end of Don’s most popular circuit:

![Image of circuit diagram]

and he invites you to see if you can replicate the circuit too.

In broad outline, the circuit is driven by a 12V battery which powers a high-voltage high-frequency circuit. That part of the circuit can be a 12V Neon Tube Transformer, or it could be a PVM12 high-voltage high-frequency Plasma Driver power supply running at 70 kHz (although that frequency is not particularly important) or it could be an inverter followed by a mains Neon Tube Transformer. The key point here is that connecting wire lengths are critical. It is essential that the wires between the battery and the oscillator are equal in length to the length of wire in the output coil. He draws the circuit like this:
The output passes through a UX-FOB diode to a spark gap which is set to a very short spark length and then to a coil connected to ground. It is suggested that the wire in the coil is 1 to 2 metres long and the battery connection leads are exactly the same length. The prototype coil looks like this:

![Prototype coil](image)

and it is placed close to the battery. When started operating, the battery voltage drops slightly for a few minutes and then starts to climb due to the feedback to the battery from the circuit. Each of the 70,000 pulses per second produces this result:

![Graph](image)

The yellow line indicates the feedback to the battery. The prototype uses a PVM12 power supply from [http://www.amazing1.com/](http://www.amazing1.com/) which is intended to drive a plasma globe.
This circuitry confirms what Don said about the front end of his circuit. If you build a self-sustaining front end, then please let us know. Development work continues on the rear end of the circuit.

Mohamed assesses Don Smith's Devices
Late in 2014, Mohamed released the following document after two years of examining and testing Don Smith’s main design. If preferred, his document can be downloaded as a separate pdf file: http://www.free-energy-info.com/Mohamed.pdf

The Resonance Energy Device Explained

Preface

This presentation is the result of more than two years of deep thinking about the resonance energy device invented by Donald Lee Smith. I was interested in this device due to the huge amount of power which it is able to provide. The device has no moving parts and is small in size. This presentation is an attempt to explain two important sources of information about the resonance energy device; they are a document and a video:

The document is located here: http://www.free-energy-info.com/Smith.pdf

The video can be seen here: http://www.youtube.com/watch?v=cQkYAh8Qgb4

The information contained in the document is free and open to the public. I think that it is time for such information to become widely known - free energy is free because it's for everyone. Energy is everywhere in an unlimited quantity, ready to be taken with minimum effort, the resonance energy device described here is one of the most attractive free energy devices, it depends on a multidimensional transformer which makes possible a harmonic exchange between the positive energy reality and the unseen negative sea of energy. This is possible using a spark-gap arrangement, the energetic symmetry between the positive and negative energy oceans make it preferable to use the term ambient background energy rather than the name zero point energy. The video pointed to above, is an excellent source that can be viewed in parallel with this work, and when considered together, the reader will understand both the video and this presentation.

At the start of the above video, the inventor explains the importance of the magnetic field in generating electricity. The magnetic energy upsets the background energy and that results in a separation of electrons between the two ends of a coil, this separation of electrons is a source of electric power.

The resonance energy device is based on a very important idea, namely, that magnetism and electricity are two sides of a single entity!

Matter and energy are two aspects of the same thing as Oliver Heaviside expressed in his famous energy equation $E = MC^2$. The electrical equivalent of this in our Resonance Energy Device is:

$$E = (\text{Volts} \times \text{Amperes}) \times (\text{Cycles per Second})^2$$

In this presentation, we will learn together how the device works but before any attempt to use this information, please pay attention to the following caution:
You need to read this document again and again to understand the power behind this device; this device is a power producer! You are near a power production factory but in a small size, this special coil only needs voltage and when we oscillate that voltage, the voltage turns into real current‼

This means that even a short-circuit isn’t permitted in the collection system if you plan to use HV capacitors. This is not the place for amateurs, please do not attempt to implement or use the information shown here unless you are experienced and skilled. Neither the publisher nor the author makes any representations as for the completeness or the accuracy of the information contained here and disclaims any liability for damages or injuries resulting from your actions.

Algeria, August 2014
hopehope3012 (at) gmail (dot)com

Let’s examine how a magnetic field generates a voltage in an ordinary coil and why our coils lack the energy key that Donald Smith has found!

When a magnetic field penetrates a coil, the induced rotating electric field generates additive elementary voltages along the coil. Every turn in the coil receives the same voltage, we extract the power along the length of the coil, but we miss the power available in the area inside the coil‼ To understand this, let’s examine the induced electric field:
If we examine Fig.2, which represents a single turn of the coil shown in Fig.1, we see that the magnetic field penetrates all of the area inside that ring. This magnetic field will be transformed to a voltage because it will drive a rotating electric field, this field is able to induce a voltage and this induced voltage will cause the current to flow due to the different of voltage between the two points A and B in Fig.1.

The important, generally forgotten thing about the induced electric field, is its availability inside our coil as shown in Fig.3:

![Fig.3](image)

The induced electric field exists independent of the conducting loop. In other words, an induced electric field permeates all of the space within the region of the changing magnetic field, as indicated by the red field lines in Fig 3. What about this field? It is wasted power. It is wasted power at point A, as well as all of the distance between the two points A and B.

If we want to achieve power amplification we have to combine the magnetic field with the induced electric field in such a way as to conserve the non-conservative electric field! The induced rotating electric field will remain non-conservative but we could play with the induced voltage created by that field using a Tesla Bi-filar Coil (“TBC”).

**We need to extend the capacitive side of a Tesla bi-filar coil** in order to benefit from the induced E field to a reasonable degree, if we try to use a flat TBC we will face the same problem in our solenoid coils where we concentrate between two points… The heart of the Resonance Energy device is based on an extended Tesla bi-filar coil (Fig.4)

![Fig.4](image)
During my search for the specification of Tesla bi-filar coil I wasn't able to find a lot of information such as the resonance frequency of this special coil as if it has been forgotten, although it has been known since 1894!

I felt it’s without advantage; fortunately at that time I successfully built a new type of asymmetrical capacitor that has four plates rather than three plates, I was able to replicate my source voltage, I gave it the name C1/C2 system, when I fed C1 with high voltage I was able to take the voltage from C2 without direct contact, the device is based on the electric field interaction between C1 and C2.

The C1/C2 system opened my mind to the possibility of charging a capacitor without the need of direct contact; with the device. I began thinking in a different way, wondering how I could combine the two side of electricity in just one device. The device shown in Fig.4 can be simplified as shown in Fig.5:

The magnetic side is the path from A to B, it is the path which the current will follow, and then the magnetic energy will be formed and concentrated inside our coil, the magnetic side is the hidden side of electricity because we can't conserve this state for a long time as we do in the capacitors. This side is directly related to the ambient background energy or zero point energy. (Later we will see why Donald Smith prefers the name of ambient background energy as opposed to ZPE)

To make things easier we could take the permanent magnet as an example, the permanent magnet appears to create the magnetic field all the time without requiring us to provide any visible power for which we have to pay.

The electric side of this amazing coil is the most difficult thing to understand. The capacitor in our extended Tesla bi-filar coil is just one point! It's the point 'X' but from a static perspective, we say that it is between points C and D. The path from C to D is the way to conserve the direction of current needed to build the coil and ensure the maximum voltage is generated between the two plates of the capacitor. This capacitor is a dynamic capacitor and not a static capacitor. In this capacitor the displacement current is absent... because it gathers the two polarities of electricity in one device. The magnetic side is the current side where the current starts from point A and flows to point B. The electric side is the point at which the maximum voltage between the two plates exists. I think that this is the most difficult point to understand in the Tesla Bi-filar Coil, because we see it as just a coil and not a coil with a built-in capacitor!

Back to 1894 and take a look at what Mr. Nikola Tesla said about his bi-filar coil:

> My present invention has for its object to avoid the employment of condensers which are expensive, cumbersome and difficult to maintain in perfect condition, and to so construct the coils themselves as to accomplish the same ultimate object.

Let us start by analysing how the extended Tesla bi-filar coil works. Imagine that the following drawing is a charged, extended Tesla coil with the positive and negative parts, shown as red and black plates respectively.
When we connect these two plates by their points C and D, an electric current will flow from point A to point B as shown by the red arrows. When the induced electric field finds a coil which is wound counter-clockwise ("CCW") – the red plate – versus another coil wound clockwise ("CW") – the black plate – this electric field will generate an induced voltage which will tend to recharge the capacitor again!

The rotating electric field will start to build an induced electric voltage from point B which will be 0V in this case because the induced electric fields rotate in a clockwise direction. When the magnetic field increases, the electric current will flow counter-clockwise and so the direction of the magnetic field will be out the screen as indicated in Fig.6.

In this case we achieve a cost-free voltage difference between adjacent plates. This situation attracts electrons which were not previously available, to become incorporated and produce a very large net gain in potential, this gain is real!!

The induced rotating electric field flows in closed loops but this design causes it to build a voltage difference between adjacent plates. This fact prevents the voltage difference between the adjacent plates from dropping and it makes the replication of electric power with radio frequency a practical operation.

Because of this, we can understand why resonance can't produce the power but it replicates the power with radio frequency and this is the secret of the huge power which this device is able to give with the equation which Don Smith gave us:

\[
\text{Power in one second} = \frac{1}{2} CV^2 F^2
\]

The induced rotating electric field will build induced elementary voltages; B is the starting point for that field, so it will have 0V but when we arrive at point D it will have V volts, which same voltage will be available at point C. The induced rotating electric field will continue it's rotation producing a value of 2V at point A!! (Fig.7).
A question arises: where is the capacitor if C and D both have the same voltage?

The capacitor in our extended Tesla bi-filar coil (TBC) is a dynamic capacitor, it will be formed only when the coil oscillates. When that happens, the induced electric field will give C and D the same value of voltage but every adjacent turn will receive the same difference of voltage needed for attracting ambient electrons which weren’t originally in the system but now are incorporated in large numbers, providing the excess power. This capacitor appears due to the junction CD, and from a dynamic point of view, it is the point X.

This device treats the magnetism and electricity as if they are the same thing. When this happens both sides help the other side. The displacement current is absent here because it appears when we separate electricity and magnetism. When we do that, we fill the gap by introducing something isn’t real. The displacement current does not exist!!

When you move a permanent magnet in the air, an induced electric field will appear regardless of the presence of a coil. The electricity is there, it comes from the background energy and returns to its background level, both electricity and magnetism have the same origin, the magnetism is the energy side (magnetic field), the electricity is the physical side (electrons).

The physical side appears when we place a conducting coil in an area where there is a changing magnetic field. The magnetic field causes the electrons to rotate CCW and produce voltage and rotate CW and produce current, voltage electrons appear to be more negative because they are more active, current electrons appear to be less negative. We seek the number of electrons separated by the changing magnetic field. The current (I) is the energy killer because it absorbs the power of the voltage electrons!

In this system, the magnetic field penetrates inside a special capacitor coil where both sides of electric power are found in a unified state. We discussed the phase when the capacitor discharges across itself, and now it is time to see how the coil will charge the capacitor with a reversed polarity.

It’s important to review the resonance in a normal L/C circuit to understand the work of the extended TBC. Imagine that you have a charged capacitor, when connected to a coil a current starts to flow, when the current reaches its maximum value, this means that the capacitor was totally discharged, the magnetic field will have the greater value and start to decrease and induce a voltage which will charge the capacitor again with the opposite polarity.

The same will happen in our extended TBC, when the magnetic field reaches its maximum value it will then decrease and induce a voltage which will charge the capacitor again, the complexity here is to understand the positions of coil and capacitor.

![Diagram](image)

Fig.8

In a dynamic perspective the coil sees the capacitor in the X position, the coil situated between A and B, comparing this to what happens in a normal L/C circuit at this phase the coil has to drive a current outside its region, the outside region between A and B has to be position X. when the magnetic field induces a current to recharge the capacitor between C and D, the induced electric field will do this job because it will change the
direction of rotation to be CCW (Fig.8), and this behaviour will tend to keep the current at a high value while the voltage increases! The position of the capacitor in this device has to be the position of a spark gap. A spark gap in this position will improve the performance dramatically and amplify the power gain.

The Resonance Energy device works with radio speeds above 20 kHz. The ambient background electrons are usually found in a dormant or inactive state and this makes the drawing-in of ambient electrons a difficult operation. For this reason, we need an earth connection to improve the performance of this system, later in the video, Don Smith talks about something new, the earth connection isn’t needed because there is something called air grounding.

To activate air electrons effectively we need another source of power, actually this source of power exists as a negative energy but before we go further, we have to see the symmetry between the electric and magnetic sides. When we start from A to C we have half coil-capacitor while from D to B we have capacitor-half coil.

To understand how our extended TBC receives negative energy, it is better to see the way in which the device oscillates. There are two methods of feeding this coil:

**The direct method**
Here we have to know the resonant frequency of this coil or alternatively, we need to have the resonant frequency covered by our feeding circuit. This method is the best because we don’t need lots of power, because when we achieve resonance our extended TBC will have a very high impedance, and so, a maximum voltage will be available between A and B, and fewer turns will be needed in the reactant coil L2.

**The indirect method**
Here we don’t have to know the resonant frequency, if we feed this coil from A and B the capacitor will charge. The spark gap has a very high resistance and it will not fire until there is a voltage difference between points C and D, at that moment a spark will occur, and when that happens, the resistance of the spark gap drops from a very high value to very low value and that short-circuits any power coming from the power source until the natural coil resonance finishes!

When the capacitor is fully charged, the maximum voltage appears between points A and B which is the coil side, when the spark occurs the capacitor will transform into a coil which has a capacitor built into it! This operation provides the natural resonance needed without causing any problems.

**Caution!**
When we feed this coil from point A to point B and then disconnect it from the power source, you would then expect to discharge it by short-circuiting point C to point D (usually from the location of spark gap). If you do this and then touch the coil you will definitely receive a substantial high voltage shock! Even if you see the spark, the spark will not discharge this capacitor immediately but it will cause the coil to oscillate again and recharge itself. This device isn’t a simple capacitor because when you short-circuit the spark gap it will transform the electrical energy into electromagnetic energy capable of recharging the capacitor again.
If you try to short-circuit points A and B in an attempt to discharge the extended TBC, then these two points will transform into electric points (due to the symmetry). From a static perspective, the capacitor can take an AB position as well!

**The solution** is to short circuit C to D permanently and then short circuit A to B at the same time.

As I mentioned before, there is a need for extra energy in order to activate air electrons effectively. In reality, this is not exactly what will happen as the arrangement is complicated. The negative energy enters this device in an unusual way. The extended Tesla Bi-filar Coil will supply reactive energy in enormous amounts because there are common characteristics between reactive energy and negative energy. Reactive power is a kind of electrical power, measured in volts-amps-reactive (“vars”) which cannot do work in its present form. For sinusoidal waveforms, the formula for reactive power is

\[
\text{Reactive power} = V \times I \times \sin(\theta)
\]

The reactor coil in our system is a shortened version of a normal parallel L/C circuit. The output energy received in the reactant coil has to be a reactive energy because of the presence a coil in parallel with a capacitor. The phase angle between current and voltage is 90 degrees, and so, the active energy in this case will be zero.

\[
\text{Active power} = V \times I \times \cos(90 \text{ degrees}) = 0
\]

The system acts like a negative resistor, it’s a non-dissipative system because it’s an energy absorbing system:

Fig.10

The reactive energy in this system is an advantage. The energy is ordered and so we can easily achieve superconductivity at room temperature!

As shown in Fig.10, active energy is a chaotic energy and so it is not easy to get rid of resistance. The important point where we need to focus our attention is where the voltage has a maximum value the current will be totally absent. Negative energy is a kind of electric power obtained when sparking (on-off) from a high voltage direct current (Fig.11).
This is why we need a high-voltage diode in our power supply circuit. The resonance in a normal parallel L/C circuit does not require this.

If we connect a spark-gap between point C and point D, then the negative energy will be drawn into our system with the same speed as positive energy! The symmetry between the magnetic and electric sides in our positive energy reality will open the correct door for the undetectable negative energy reality!

Initially, when the capacitor starts to discharge, the current increases but the induced rotating electric field will tend to keep the voltage at a high value. The capacitor discharge through the spark-gap (which requires a large amount of voltage), the current flow does not start immediately. Initially, the current increases but the spark does not occur. This pushes the voltage up higher (behaviour which is known in parallel L/C circuits), then the current increases to a high value very quickly, while the voltage is drawn down to a level which cannot sustain the spark. When the capacitor is totally discharged the current flow through the spark-gap is at its maximum value. Consequently, the extended Tesla Bi-filar Coil produces a square wave rather than the expected sine-wave which is produced by an ordinary parallel LC circuit. The square wave produced when the spark occurs, contains waves of all frequencies and so, even if the time during the spark is short, there will still be thousands of oscillations in that time. I know that it is not easy to visualise this, but it is what actually happens.

This special genius design solves the most difficult problems in cold electricity, due to it's reversed behaviour compared to hot electricity. Cold electricity prefers to flow along materials which we consider to be insulators while hot electricity prefers to flow along materials which we consider to be conductors.

According Tom Bearden, with negative electricity the capacitor performs in the way that a coil does with hot electricity, and the coil will perform like a hot electricity capacitor (Fig.12).
the above illustration is an attempt to understand how cold electricity work but it's better to take a look at Floyd sweet explanation of his VTA device in the Appendix (page A-1209):

it is important to note that so long as positive energy is present in a positively-flowing time regime, then unity and over-unity power gains are not possible. The summation of the losses due to resistance, impedance, friction, magnetic hysteresis, eddy currents and windage losses of rotating machinery will always reduce overall efficiency below unity for a closed system. The laws of conservation of energy always apply to all systems. However, the induced motional E-field changes the system upon which those laws need to be applied. Since the vacuum triode operates in more than four dimensions and provides a link between the multi-dimensional reality of the quantum state and the Dirac Sea, we are now dealing with an open-ended system and not the "closed system" within which all conservation and thermodynamic laws were developed. To achieve unity, the summation of all magnetic and ohmic losses must equal zero. To achieve this state, negative energy and negative time need to be created. When this is achieved, all ohmic resistance becomes zero and all energy then flows along the outside of conductors in the form of a special space field.

**Fig.12** (the capacitor is discharging across itself)
The above explanation describes the VTA device but also demonstrates the work of the Resonance Energy device of Don Smith!!

The correct model of capacitor is the extended Tesla Bi-filar Coil because it provides a link between the multi-dimensional reality of the quantum state and the Dirac Sea of negative energy. From a positive energy perspective, \(AB\) describes the coil while \(CD\) describes the capacitor, but the coil will transform into capacitor \(AB\) in the region of negative energy; and in the same area the capacitor will transform into the coil!!

**How can we explain this physically!?**

The energy equation and Dirac's equation call for both positive and negative energy. Thus they are symmetrical with respect to energy, as are the forces of physics positive repulsive forces increase positive energy, while negative attractive forces increase negative energy. According to the modern kinetic theory of mass-energy, negative energy would merely be a vibration of charges at right angles to our ordinary dimensions in an “imaginary” direction. (Fig.13).

![Fig.13 (shows the relationship between positive and negative energy in just one phase)](image)

To understand Fig.13 correctly, we need to remember that we are confined by our positive energy reality; in our extended Tesla Bi-filar Coil we need the negative energy in our positive side, the spark gap in CD position is the flexible place for both positive and negative energy to be combined.

Tom Bearden has an important book entitled “Energy from the Vacuum”. The following text is on page 236 where he explains the specification of a true negative resistor:

The true negative resistor is an open dissipative system *a priori*, and equilibrium thermodynamics therefore does not apply. Instead, the thermodynamics of open systems far from equilibrium applies. The negative resistor freely receives energy from outside the system (from the environment), and “dissipates” it in interception and collection actions inside the system, to freely increase the available potential energy in the system.

In circuits, the main characteristic of a negative resistor is that the environment freely furnishes some excess energy to (i) power the load, and/or (ii) move the current back against the voltage, particularly when shunted across the back emf region of the source dipole. The operator does not have to furnish this excess energy dissipated to propel the current backwards or dissipated to power the load!
The true negative resistor in our system is the blue extended TBC where negative energy moves the current back against the voltage; this power will charge the coil electrically if it’s acting as a capacitor!

The electric current in the negative energy region (past light cone) works in a reverse manner compared to the electric current in positive energy region (future light cone), the symmetry between the magnetic energetic side and the physical electrical side will curve space for the negative energy power to enter our device through our flexible spark-gap zone which represent a one dimensional capacitor $X$, the negative energy which can be represented by attraction forces will find its way through the spark-gap to increase the electric energy through $AB$, the system will continue its divergence and the clockwise rotation of the hot electric current (potential energy), this tends to amplify the power between point $A$ and point $B$ which represents the voltage gained by this virtual current!

We are examining the first instant when the capacitor discharges across itself (transform into coil), the curved $AB$ space will transform into one point in the negative energy sea which is the capacitor in our imaginary extended TBC.

Similarly, when the magnetic field collapses and charges the capacitor across $CD$, the magnetic field returns to its background level, the space-time continuum is reversed by the fields which are produced in the presence of excited coherent space flux. These quanta have been attracted from, and ultimately extracted from, the virtual vacuum, the infinitely inexhaustible Diac Sea (from Floyd Sweet papers in the Appendix)

Like charges have repulsion behaviour on the positive energy side, while they attract each other in the negative energy region. This information is essential for an understanding of the nature of the negative energy sea.

When the turn comes (second time period) for our capacitor to be charged again with opposite polarity, the system will diverge toward negative energy space to close the loop in that space!! The current passes from $C$ to $D$ to charge the capacitor but in the virtual dimension it starts from $D$ and finishes in $C$. This power will charge the capacitor magnetically if it’s a coil.

As you see there is positive real energy and undetectable negative real energy. I think that Don Smith preferred the name ambient background energy as opposed to Zero Point Energy because there are two regions from which we can take power, namely, over ambient background energy and below ambient background energy.

At this point, we can understand why cold electricity prefers insulators rather than conductors. This kind of power is capable of running in an imaginary dimension parallel and reversed relative to our ordinary, familiar dimension. But... according to Floyd Sweet; when run in parallel with positive energy however, cancellation (annihilation) of opposing power types occurs. This has been fully tested in the laboratory.

This applies to the chaotic positive energy flowing regime time when voltage electrons (ccw rotation) and current electrons (cw rotation) run together at the same time, our Reactive Energy resonance system works in harmony with negative energy, our previous study allows us to draw us some important conclusions:

For the first time period, we have (C discharging across L);
+ energy increase magnetic energy ---- $I$
- energy increase electric energy ---- $V$

For the second time period we have (L charging C);
+ energy increase electric energy ---- $V$
- energy increase magnetic energy ---- $I$

since magnetic energy is the current and electrical energy is the voltage and because they are out of phase (reactive energy), positive energy will work in harmony with negative energy and no cancellation will appear.

Our extended TBC is a very important device not only because it can supply unlimited electric power but it give us an exceptional opportunity to understand the way that energy flows inside our universe!

When the device oscillates it produces cold electricity and hot electricity, this means that the device is able to relate to both positive and negative energy. The flow of energy has two directions; from positive to negative and vice versa. Let’s think about the physical way in which things work.

In this analysis I’m trying to explain some deep physical aspects about positive and negative energy. As illustrated in Fig.12 and Fig’13, it is important to consider energy flow in relation to time. These two pictures just
Cold electricity has the ability to produce an electric response when it interacts with metal surfaces. This can also be seen in the Casimir Effect where two non-magnetic metal plates, which are not carrying an electrostatic charge, are suspended very close to each other. The plates do not hang straight down but move towards each other.

Cold electricity has the ability to produce an electric response when contacting metal surfaces because it’s able to ionise empty space. In our extended TBC, when the spark occurs, we are actually colliding the space-time field through one point (the spark-gap).

The space-time field is, in my opinion, the space where negative and positive energy exist together, they exist together but cancel each other out due to a constant ratio. If we take a mass with a gravity field around it, and we move the mass and create a mass current, a new field is also created. It is a different kind of gravity field with no source and no sink, when the speed of the mass increases, then the created gravity field increases also. If the mass reaches the speed of light, then this means that it has the value $E = mC^2$ as a positive energy. $mC^2$ is the maximum value exchange between positive and negative energy admissible by zero point fluctuation (ZPF) for that mass to exist the way it does in its time-space field, the mass has two options to reach the speed of light:

1. It will transform into exotic matter.
2. It will break the time-space structure.

The only places which provide these two conditions are black holes. Black holes exist in the centre of galaxies which provide the rotational energetic symmetry between the mass and gravity field - see Fig.14, Fig.15 and Fig.16.
For a spiral galaxy to maintain its shape with cosmic dimensions (the diameter of galaxy may exceed 100,000 light years) there is a need for a negative energy to be the underlying energy for space-time throughout all of that galaxy. That negative energy has to transport virtual particle instantly! The transformed physical matter (including space-time!) provided by black holes furnishes an excess of positive energy in the galaxy, providing stability and symmetry. Black holes are not a fracture in space-time but they are essential.
The above explanation will help to clear the way for a better understanding of the nature of electric energy. This explains why a sharp positive-going DC electric pulse interacts with negative energy to produce cold electricity which is an instant response from the negative energy sea. This response does not start from the spark-gap, but it ends in it!

The negative energy will rotate to finish in the spark gap, this will squeeze the space-time to provide excited coherent virtual particles which in turn produce electronic responses when contacting a metal surface. From my point of view, the electronic responses created in metal surfaces have a magnetic angular momentum. Cold electricity is able to charge a capacitor to a much higher voltage than the capacitor's voltage rating, even if the capacitor's rated voltage is low. The question which springs to mind is; do electric fields inside a capacitor charged with cold electricity really exist?

If the answer is yes, then why isn't the capacitor destroyed? In my opinion, it is because the electronic responses caused by cold electricity have magnetic angular momentum instead of electric field lines. I suggest that the presence of magnetic field lines between the positive and negative plates of a capacitor charged with cold electricity are actually as shown in Fig.17.

![Fig.17](image)

When the spark gap impacts on space-time (that is, when the spark occurs) the response from the negative energy sea looks as if it should neutralise the excitation created in the positive energy side (Fig.18). We can't detect the movement of negative energy, and so we only see the impact which it has in our positive energy reality.

![Fig.18](image)

The small red ball in the above drawing, is the spark gap which is the door for negative energy to enter our positive energy reality; the negative energy sea will react both before and after the spark occurs.

Referring back to Fig.14, before the spark-gap fires the negative energy will rotate starting from the spark-gap to neutralise the excitation created in the positive energy side (Fig.19a) and when the spark-gap finishes firing, the negative energy will end in the position of the spark gap (Fig.19b).
The Bloch wall area in an ordinary permanent magnet, is the area of electron separation. Let's see how this happens in our extended Tesla Bi-filar Coil. During the first time period, when the capacitor starts discharging across itself to become a parallel L/C circuit, point A will provide a maximum voltage while point B is the maximum current. The current flow starts from point A and finishes at point B. The system is now producing magnetic energy and because of the magnetic field increase, the electrons will start from point B and flow to point A which causes clockwise rotation to neutralise the counter clockwise spin of the voltage electrons, and cold electricity will charge the coil electrically if it is acting as a capacitor, and it will push the current to go back against the voltage by providing a magnetic angular momentum (the clockwise rotation shown in Fig.19a) at point X the result is to turn back the voltage electrons, causing strong initial potential electrical energy which increases the electrical energy. Current in cold electricity is the equivalent of voltage in hot electricity. The Bloch wall is the place where negative energy interacts with our E-TBC, in other words when the spark-gap fires, the current will not start immediately because the negative energy will supply a virtual current by providing a CW rotation in the Bloch wall area X. This virtual current is a compensator of the real current but it will not absorb the power from the voltage electrons which increase the available potential electrical energy. All this happens before the real current increases to provide the magnetic energy.

**Caution:** Please be aware that high voltage capacitors have dielectric recovery which stores the electric field for a long time. High voltage capacitors need 5 minutes or more to discharge completely.

Energy is everywhere and in enormous amounts ready to be taken for free. When we do that, we do not reduce the available power because the universe is full of energy, the energy in our universe is the source, physical matter is the energy in a visible form and the energy is in invisible matter form.

The presence of the negative energy sea beside our positive energy reality, raises an important question, namely, why they are separated when they could be united? They are separated to let our universe exist in the way that it does. Negative energy serves our existence because it's designed to be the under background energy level for our foreground positive energy reality. Our existence is a thin part between those two energetic oceans. Negative energy is extremely active until the point when it appear to be nothing!

We now need to explain another important behaviour of our extended Tesla bifilar coil, namely, it’s super conductivity at room temperature.

One of the puzzles in this device is its capability to equal the voltage with the current. The wire of the coil AB can receive ambient electrons because it’s the surface for the capacitor CD; let’s examine this surface in Fig.20:
When the capacitor discharges across itself to become a parallel L/C circuit, the induced rotating electric field (with the help of negative energy) creates a difference of voltage between adjacent plates, this voltage according the Gauss law causes new electrons to be present in the system.

\[ \oint E \cdot d\vec{A} = \frac{Q_{enclosed}}{\varepsilon_0} \]

When ambient electrons enter our system (Fig. 21), they increase the power gain across the Y axis (Fig. 20). When the current flows inside the extended TBC, parallel currents will be added while parallel voltage will be the same in the Y axis, while in the X axis serial voltage will be added while serial currents will be the same!!

- On the Y-axis: sum (I) equals (V)
- On the X-axis: sum (V) equals (I)

This system treats the voltages and currents in the same way, the voltages and the currents are physically equal.
When this happens the device squares the electromagnetic flux and becomes a near-unity system in every process which will replicate the electric power according to the working frequency. This is a near-unity system due to the super conductivity at room temperature where the electrons don’t face the usual reduction encountered in an ordinary parallel L/C circuit.

A normal L/C circuit cannot produce the super conductivity at room temperature because the exchange between the electric power and the magnetic power must lower one of them in each process. In our extended TBC they are combined in such a way so as to amplify the power in every process, and so the total available electrical energy in each cycle is twice the power available in a charged capacitor which can be seen from the following relationship:

\[
\text{Power} = 0.5 \times C \times V^2
\]

(consider the similarity between the magnetic and electrical energy in a resonating parallel L/C circuit)

Here, I need to explain the importance of the reactive electric power in the Resonance Energy device, in an alternating electric system where the voltage and current go up and down at the same time (Fig.10). Only active, real power is transmitted and when there is a time shift between current and voltage both reactive and active power are transmitted. When this time shift is 90 degrees (\(\pi/2\) degrees) the transmitted real power will be zero as discussed above. This does not mean that there is no power, but it does mean that we cannot use this power in this alternating form, we have to transform it into Direct Current so that both current and voltage are united.

Reactive power looks like a skipping rope (Fig.22):

\[\text{Fig.22}\]

Imagine the voltage to be the rope and the children's bodies are the current. Reactive power looks like a skipping rope, the active power will not let the kids' bodies move correctly. Reactive power is an essential part of the Resonance Energy device, and a skipping rope is a good example which shows how kids go up and down without any problem. This sort of movement exists in our device.

The separation between voltage and current in the Resonance Energy device is crucial for producing and cloning electric power at radio frequency speed. A proper method of collecting and converting the huge available electric energy is needed.

The example given in Fig.22 is important when planning to collect and convert the available electric power. If we simply use a step-down transformer it is highly likely that we will alter the current which will reduce the gained power. With reactive energy, when the voltage is high the current is low. A step-down transformer will lower the voltage but it can't amplify the current as expected! In a normal transformer we amplify the current depending on the available active power (\(V \times I\)): 
Physically (Fig.23) the electromagnetic flux inside the transformer has two components, the electrical component $V$ and the magnetic component $I$, for successful transfer of electric power from the primary to the secondary, both of them are needed at the same time. In our case, when $V$ is high the product $(V \times I)$ is low due to the time shift, even if the available power could achieve megawatts!

Another factor which we have to take into consideration, is the high-speed needed to replicate the power, using a transformer to lower the voltage imposes the need for a special transformer core which is able to respond at radio frequencies. These facts have to be taken seriously if we want to collect the available energy effectively.

Personally, I prefer to improve on the use of high-voltage diodes as shown in Fig.24. It is better to use a diode bridge constructed with fast recovery high-voltage diodes. Fast recovery diodes have the ability to return to their blocking state very quickly, making it possible for the other half-oscillation to be accumulated in the high-voltage capacitors, each cycle (up and down in Fig.25) will give power similar to the power available in a charged capacitor given by the following equation $\frac{1}{2} CV^2$.

The amazing, energetic behaviour of the extended Tesla Bi-filar Coil make it totally different from an ordinary parallel L/C circuit. Our extended TBC gives twice the frequency of an equivalent parallel L/C circuit. This means that if you form the same inductance with the same capacitance in an ordinary parallel L/C circuit, then that will...
produce only half the frequency that the same combination produces with an extended Tesla bifilar coil form!

I have not been able to verify this because I don’t have an oscilloscope or a frequency meter. That, of course, is no excuse for not thinking about how the device will act, so the following analysis is an attempt to imagine the energy equation given by Mr. Donald Smith as:

\[ \text{Power in one second} = 0.5 \times C \times V^2 \times F^2 \]

To simplify things, let us analyse only the voltage. When the capacitor discharges across itself to become a complete parallel LC circuit, at that instant, the magnetic field reaches its maximum value. What makes this system different, is the induced rotating electric field. This field will instantly charge the capacitor with the opposite polarity before the induced current resulting from the collapsing magnetic field can do it. As we learned before, this is the key to energy amplification.

Resonance is the key for energy multiplication, our extended TBC acts like one device, so the passage from the positive cycle to the negative cycle takes no time. In other words, the device has the ability to change its direction of charge instantly. The yellow zone in Fig.26 is absent (compared to a normal parallel L/C circuit), when the energy cycles up and down (Fig.25) the device gives twice the power available in the capacitive side of the extended TBC.

![Fig.26](image)

The cycle in an ordinary L/C circuit is from the red point to the black point. In our device, that is only half of the time which explains why an E-TBC produces twice the frequency when compared to an ordinary parallel combination.

The power is each cycle will be given by:

\[ \frac{1}{2} C V^2 \times 2 = C V^2 \]

Since the frequency will affect both the voltage and the current we will examine the equation number 1 as follows:

\[ C V , C V \text{ is the quantity of charge available in a charged capacitor, if we divide it by 1 second this will give us the current since } Q/T \text{ is the current in one second. Let us suppose that the frequency is 3 Hz.} \]

![Fig.27](image)

From Fig.27 we can see that the total available power is proportional to 9 which is the square of the given frequency. Each cycle has the power of \( C V^2 \), the number of cycles in one second gives us the frequency; the frequency will replicate \( CV \) which is the current and this will give us \( CV \times F \) and replicate the voltage by the product \( V \times F \), this analysis is the best explanation of why the voltage equals the current in this system, because \( CV \times F \) is the available current and \( V \times F \) is the available voltage! This seems strange; how could the product \( V \times
F be the available voltage since the result is very high since we are working with radio frequencies above 20 KHz?

The example given in Fig.23 will help us understand this. The energy formula gives the available DC power when converted from its alternating state; the electromagnetic flux will be squared causing amplification of both current and voltage. In each second, the available power is $CV \times F \times V \times F$, the power obtained depends on the number of turns in coil $L_2$, and the limiting factor is the product $V \times F$ which is a very high number in practical systems. Below this factor, the current is very high being the product $CV \times F!!$ This explains why a megawatt sized unit can fit quite easily on a breakfast table and it explains why this device is able to give any required level of energy.

The energetic formula of our extended TBC can now be written as follows:

$$\text{Power in one second} = CV^2 \times F^2$$

This equation gives the available power in watts when converted into high-voltage Direct Current. When the device oscillates the power obtained is pure reactive energy, Volt-Ampere-Reactive (VAR) is present while active electric power ($W$) is absent in this dynamic state, Fig.28:

![Fig.28](image)

In practical terms, the extended TBC is just a high-voltage capacitor which has the ability to let the current penetrate inside itself, so it has both magnetic and electric specifications.

**Practical section**

A free-energy device is something which is fascinating, being hasty in wanting to build and test one is common, but that is not good. **High-voltage with high current isn't a game!**, your first mistake may well be your last. If you decide to build this device in your house it is a good idea to use locks and keys and sticking a high-voltage warning symbol on the device is a sensible action.

![DANGER_ HIGH VOLTAGE](image)

I am not encouraging you to actually construct the device described here; the above theoretical information provided is the most important section. When the device is fully understood, then taking care when near it will be automatic. This device is a very special Tesla coil, when increasing the voltage in a normal transformer the current drops, but here the current increases in the same manner as the voltage does! This device has current equal to the voltage. Resonance will impact both the voltage and the current. The special geometrical design of the extended Tesla Bi-filar Coil, including the flexible position of the spark-gap, produces the needed rotational energetic symmetry between positive and negative energy. As we have already seen, the spark gap opens the door for a massive inflow of electrical energy to be present. I personally got shocked indirectly from the L2 coil and I certify the risk of this device.

For construction, the first thing we need is a source of high-voltage. The device can be fed using two different methods as described here. The first is the direct method where the high-voltage power source has the same frequency as the natural resonant frequency of the extended Tesla Bi-filar Coil. The second method is the indirect method; where there is no need to know the frequency of the reactor (active) coil.
The high-voltage power source is needed to feed the extended TBC which is the reactor coil (active coil), Fig.29 shows an easy to build oscillator:

![30kV flyback driver](image)

Fig.29

It’s better to use a flyback transformer which has a high-voltage diode built into it. Flyback transformers are readily available and cheap. The above circuit diagram is for a flyback transformer, where a high-voltage power source enter our reactor coil via points A and B (Fig.30):

![Fig.30](image)

Initially, the capacitor charges up to the value needed by the spark-gap. When the voltage across the electrodes of the spark-gap reaches a high enough value, a spark occurs causing the resistance of the spark-gap to jump from a very high value to a very small value, short-circuiting any power coming from the power source until the natural resonance finishes. The capacitor transforms into a complete coil which has its capacitor built into it. The natural resonance of the TBC is assured when using this method, but it does have some disadvantages. The frequency produced by power supply/spark-gap combination has to be high enough to allow more power to be produced and this calls for a powerful power source. On the other hand, the voltage between the reactor coil AB will be limited by the distance between the electrodes of the spark-gap. This imposes the need for a large number of turns in the L2 coil.

The output current obtained is directly related to the available voltage between the capacitor plates which form the device between A and B. We need to bear in mind that the capacitor incorporated inside our extended TBC operates in a dynamic fashion where no displacement current exists.

The direct method of feeding the reactor coil with its own exact natural frequency is the best way to get the most available power, but this creates a real problem as it is not at all easy to find a high-voltage power supply adjustable over the range of frequencies which we want, especially frequencies above 200 KHz. We may require our extended TBC to work above 200 KHz, and for that, we may need impedance-matching capacitors (Fig.31).
The two yellow capacitors seen above are for impedance matching since the working frequency in Don Smith's device was very high, requiring a neon-tube driver to supply it.

Impedance matching is simply the process of making one impedance look like another; in our situation it is necessary to match the load impedance to the source. For example, if the extended TBC resonates at 2.4 MHz (this is the load), and the neon-tube driver operates at 35.1 KHz (this is the source) we need to add parallel capacitors to our extended TBC in order to make it resonate at 35.1 KHz.

In practice, you need to short-circuit the points C and D and measure the inductance of the E-TBC (L2 has to be in place for this measurement). After that, remove the short-circuit and measure the capacitance of the E-TBC. This gives you two values “C” and “L”.

The resonance of the Extended –Tesla Bi-filar Coil is given by:

$$F^2 = \frac{1}{(\pi^2 \times LC)} \quad \text{(a)}$$

The resonant frequency of an E-TBC is double

When you add a capacitor for impedance matching to the extended TBC, the resonance frequency will decrease with the following relationship

$$F^2 = \frac{1}{(4\pi^2 \times L(c+c^*))} \quad \text{(b)}$$

where F is the frequency of the source

I believe that we can use the above equation to calculate the value of c* which needs to be added in order to achieve resonance. From equation (b) we could write

$$\frac{1}{F^2} = 4\pi^2 LC + 4\pi^2 LC^* \quad \text{and so we have}$$

$$C^* = \frac{1}{4\pi^2 L} \left( \frac{1}{F^2} - 4\pi^2 LC \right) \quad \text{............... (c)}$$
Using equation (c), we will be able to calculate the needed capacitor for impedance matching; the value obtained is in Farads, and that equation the frequency is in Hz and the inductance in Henries.

When you have the correct $C^*$ value and you power your device up (Fig.33), resonance will not be achieved instantly because the spark gap forms the full L/C parallel circuit only when it fires!!

The first thing which happens is the charging of capacitor $C^*$, after that the capacitor “C” of the extended TBC will be charged until it reaches the voltage needed to make the spark-gap fire. When that happens, the spark-gap has a very low resistance value, making the E-TBC fully formed. At this point, the incoming electric energy from the high-voltage power supply will find a load whose impedance matches it’s resonant frequency. This, in turn, produces the maximum possible voltage across inductance $L$ of the E-TBC. Further, the resulting electromagnetic field will increase cycle by cycle causing the device to resonate fully after a very short time.

**Constructing the extended TBC**

The extended Tesla Bi-filar Coil is just a high-voltage capacitor which has a magnetic behaviour. So, it is both a capacitor and coil at the same time. Constructing this device is relatively simple. You need two lengths of aluminium foil, each 1.2 meters long (later I will explain the possibilities of modifying the characteristics of an extended TBC). Because it is a capacitor, you need 3 pieces of polyethylene sheet, each 1.3 meters long.

To construct a high voltage capacitor usually you need 2 pieces of polyethylene sheet but it's better to use 3 pieces since we are working with a high voltage (Fig.35), this will depend on your skills in constructing a high voltage capacitor.

You need welding rods to insure the electrical conductivity of the aluminium foils, Fig.36 indicates how to do that. Actually the best length and width of aluminium foil need some experimentation; you have to establish the
positions of the magnetic and electrical points (Fig.37). A and B are the magnetic points (coil) while C and D are the electric points (capacitor).

**Fig.35**

**Fig.36**

Welding rod fixed using a very small drop of super glue (avoid too much super glue) now wrap the foil around the rod.

**Fig.37**
The E-TBC need a coil former for it to be wound on it (Figure 38)

The following photo shows the dimensions used in the prototype (Fig.39)

Internal arcing is a common problem with high-voltage capacitors (Fig.40)

Notice the cutoff along the plastic tube; this will help in penetration the aluminum foils, the points C and B will be inside the tube but A and D will be outside, now firmly turn the plastic tube to form your E-TBC.

An internal arcing is a common problem in a high voltage capacitor; a good isolation is needed as well as a good insulator.
The best combination between the length and the width of an extended TBC has a major influence on the electric energy obtained at the L2 coil (the reactant coil). For example, the electric arcing experienced at the L2 coil using the E-TBC shown in Fig.41, was very weak, the length shown by the black arrow is very much greater than the width (orange arrow), this give a weak magnetic flux due to the small coil inductance, the coil inductance is very important because it will transform the replicated power into electromagnetic flux.

![Fig.41](image)

The reactant coil (L2):

![Fig.42](image)

The coil length is about 25cm as shown in Figure 42, the diameter is 6 cm, and the thickness of the wire is 1.18 mm (AWG #17 or swg 18) and the number of turns is about 200. Fig.43 shows some nice sparks from L2 coil:

![Fig.43](image)

The spark shown above is very strong but it can't burn through thin paper! This proves that the electric energy obtained is reactive, and so it can't do work as it is. Converting a high-voltage reactive electric power into Direct Current isn't easy to achieve. Working with a voltage over 10KV is really dangerous, in my device I had about 40KV of reactive power which to be converted.

**Ideas:**
To solve this problem let's think again about the energy equation of our extended TBC. The idea is to work with a step-down method rather than using the step-up technique.

The energy equation can be written like this: \[ \text{Power in one second} = CVF \times VF \]

**CVF** is the available current in one second since \( C \) is the capacitance value of the E-TBC, \( V \) is the voltage used, and \( F \) is the resonance frequency.
VF is the limit value when stepping up the voltage across the L2 coil, the gained electric power goes up proportional to the voltage value across L2, when achieving VF the total obtained power will be exactly: $CV^2F^2$ which is a very high power level. I know that this can be confusing, but this system has equal voltage and current. When stepping up the voltage, the current remains constant because it depends on the product $CVF$. We could increase the voltage by adding more turns to the L2 coil, when doing this the current is the same but the available electric energy will be given by: \[ \text{Power in one second} = CVF \times V^* \]

Where $V^*$ is the voltage across L2.

Using this new equation will help us a great deal in determining the voltage needed across the L2 coil in order to achieve the required electric power.

**Example:**
Imagine you have the following working conditions:
- $C = 10 \text{ nF}$
- $V = 30 \text{ KV}$
- $F = 100 \text{ KHz}$
You need a power of 30 kW, what L2 voltage is needed to achieve this power level?

Using the previous relation will give us:

\[
30,000 = CVF \times V^*
\]

\[
30,000 = 10 \times 10^{-9} \times 30 \times 10^3 \times 100 \times 10^3 \times V^*
\]

\[
30,000 = 30 \times V^* \implies V^* = 1,000 \text{ volts}
\]

To obtain 30 KW you only need 1000 volts across the L2 coil. To achieve this power level you need direct resonance, feeding the E-TBC with a high-voltage only, without direct resonance, will not give this result since the voltage across the coil of the E-TBC will be limited by the electrode separation of the spark gap.

The voltage $V$ across the E-TBC is very important here because the product $CVF$ is the current obtained using the reactant coil (L2). The working frequency $F$ is important too. Similar to an ordinary transformer, if we want to use the step-down method effectively, we have to think about using too many turns when winding the E-TBC. When designing an E-TBC, it is important to think about the length of the capacitor plates because the length between B and D will give the total value of the induced voltage between the capacitor plates which increase the electromagnetic flux (Figure 44).

![Figure 44](image)

A simple diagram of the resonance energy device can be like the following drawing (Fig.45):
When converting the reactive electric power from the L2 coil to Direct Current and stepping down the energy obtained to the mains voltage and frequency (for example, 220V, 50Hz), the current will be boosted yet again.

Some applications may not need an inverter. An electric heater can be fed directly from the capacitors banks but we have to prevent the Alternating Current coming from L2 to enter the heater by using another high inductance coil.

Another idea about increasing the capacitive side of the extended TBC is to use etched aluminium foil to increase the surface area. The foil can be treated chemically using high-voltage. The result is shown in Fig.46:

Maybe this is the technique used by Donald Smith to avoid the need for an earth connection. I have already mentioned about using negative energy to avoid the earth connection requirement in the Resonance Energy device but I can't guarantee that this is the method used by Donald Smith.

Any questions, or suggestions are welcome via my e-mail: hopehope3012 (at) gmail (dot) com

Video: https://youtu.be/PyyTv2r1xfY

**Part 2**

This is an update for the above document with some corrections and a lot of new information, after publishing my pdf many people found it very difficult to understand, the concept depends on using the rotating electric component generated from the varied magnetic field to create a kind of excess energy present as a static electric field, instead of using normal wire it's vital to use conducting foils to benefit from this excess of energy.
The extended Tesla bi-filar coil can be understood from another point of view which can explain a very interesting remark made by Don Smith, but before that, let’s start with Professor Konstantin Meyl when he explains Tesla wireless energy transfer using a model of a closed resonating L/C.

**closed resonant circuit**

\[
\text{resonance frequency: } \quad f = \frac{1}{2\pi \sqrt{LC}}
\]

Prof. Konstantin Meyl described wireless energy transfer and at the same time the presence of overunity at the receiver, Fig 48 shows a kind of resonating transformer with excitation coil and a resonance L/C circuit on the secondary side, the circuit above can be modified as follows:
The separation of the resonant circuit takes place in the capacitor plate initially because it's an open device, after that the secondary can be divided into two identical parts the same happens to the excitation coil:

**Fig.49**

**Fig.50**
The final situation is the famous Tesla wireless energy transfer device which composed of a transmitter and a receiver as shown in Fig. 50. The interesting phenomena present in the reception side where overunity can be measured and seeing, the received voltage is much higher a published result by Prof. Konstantin Meyl is the input is 0.5 milliwatt and the output is 6 milliwatts.

The following photo show the used experimental kit:

Fig. 51

On the right, is the transmitter and on the left, the receiver. Some very interesting values of the electric and magnetic fields have been measured as follows:

Fig. 52

The following photo shows the Tesla Monofilar flat spiral coil used:
Fig.52 is from Tesla's patent 787,412 entitled ART OF TRANSMITTING ELECTRICAL ENERGY THROUGH THE NATURAL MEDIUM. Tesla was interested in using stationary waves for special purposes including wireless power transmission. Mutual induction is a weak point, so he decided to use a spiral form of the secondary coil C, this allow his stationary wave oscillator to work as expected. The mutual inductance is neglected in Tesla system but compensated for using a kind of capacitive coupling, something similar in Meyl device shown in Fig.53 where you can see the primary coil nearly surrounding the secondary many-turn coil, this is to cause as much capacitance as possible between the primary and secondary windings. If that is the case then why did Prof. Meyl see the maximum magnetic field but zero electric field in this area?

The answer is the exchange of power when we have a resonance cause for this to happen, in the center of the secondary coil the winding gets smaller and smaller which allows a higher concentration of voltage, as you see there is an inverse relationship between magnetism and electricity in the scalar wave environment, Prof. Meyl explain this as a 90-degree phase shift between the electric field pointer and the magnetic field pointer, the overunity effect in the receiver can be also understood regarding this inverse relationship because the scalar electric field in the receiver is converted to a scalar magnetic field in the secondary few-turn coil, the conversion process in this case can convert voltage to electric current, beyond Ohm’s Law, overunity can be seen since the used current is very low (the used power was half of one milliwatt). The loss is very small, this explains why overunity is small when using higher power in that system. In my opinion, the reason is the increased electric current which cause more loss for example if you send 10 watts you receive only 11watts!

In my opinion, both magnetism and electricity have to be taken into consideration in any such open system, the problem in the Meyl experimental kit is that you have to break the resonating LC circuit to achieve this, Prof. Meyl explains Tesla wireless energy transfer but not the overunity effect involved, if the capacitor is still present in the conducting two spheres the inductance is destroyed - see Fig.54
If the electric field lines are present, because we already have two spheres, the magnetic field lines are absent because the coil is divided as shown in Fig.49 to Fig.54. A divided coil isn’t similar to a single coil since there’s no shared magnetic field.

According to Tesla there are two shapes which are suitable for radiant energy: the sphere shape or a cylinder. The wireless energy system can be divided into transmitter and receiver as follows:

**Transmitter Zone (1)  |  Receiver Zone (2)**
The combination of Tesla Monofilar flat spiral coil with a sphere will give an extended Tesla Monofilar coil:

![Diagram of Tesla Monofilar coil and sphere](image1)

**Fig. 56**

The transmitter in Tesla wireless energy transfer can be made as a single Extended Tesla Monofilar coil ("ETM"). The same can happen to the receiver. The idea in Fig. 55 is understood now but we still have another problem and that is how to combine the two ETMs to make a single device? As explained before, we need to keep the coil unbroken, when combining the two ETMs the coil has to be kept intact at the same time we could place the two ETMs so as to form a kind of capacitive coupling, the capacitive interaction here is strong because we have a wide area covered – see Fig. 57

![Diagram of Extended Tesla Bi-filar Coil (ETBC)](image2)

**Fig. 57**

When combining two ETMs we have an Extended Tesla Bi-filar Coil ("ETBC"), in the first ETM we move from D to B and go to the second ETM starting at point A and finishing at point C. In part 1 of this document I suggested using a spark gap between points A and B, but that kills the correct geometry because the coil is partitioned, all the experiments I did with some friends show there’s no useful power when putting a spark gap between A and B, so the correct configuration is the following:
When moving from point D to point B, the device forms a transmitter but from point A to point C the device forms a receiver. This looks like having a Tesla wireless energy transfer system acting in a single device, upon oscillation we shall have an excess of power in the receiver side, this explains the increased oscillations captured when using this corrected model:

Instead of using one capacitor to excite the ETBC it’s important to use two of them, with this each side is excited in the same manner which allow a better energy balance. Don Smith presented the following device as over unity example! one transmitter and three receivers:
Each receiver gives the same amount of power sent by the emitter, it’s possible to replicate the power according to the receiver we have. In this case, we have three receivers, 3 times more power than the input. In the case of ETBC, each side DB or AC can be either a transmitter or a receiver, so the amount of gained power is proportional to the working frequency. It’s clear the ETBC is superior compared to the example given by Don Smith but as we see the idea remain the same (hint)...

The concept energy balance need a little explanation because it’s related to the special capacitor that exist inside the ETBC.
Because the ETBC form another resonating L/C circuit where everything situated in the same device, I could say that there’s a symmetry between magnetism and electricity in it, I think we need to dig deeper to approach the concept of electron spin given by Don Smith.

If we divide a magnet into small parts, each part will form another magnet, if we continue with it we find that an iron atom acts as small magnet:

![Diagram showing a magnet divided into small parts](image)

**Fig.62**

If we replace a magnet with a coil and we the repeat the subdivision, then we find that an electron acts as a small magnet, the magnetic field in a straight wire forms a circle around it, this suggests that the electrons do spin to make a closed magnetic field as shown in Fig.63.

![Diagram showing electron spin](image)

**Fig.63**

In a solenoid coil the electrons spin in the same direction along the coil. In Fig.63 you see that the coil is divided into two identical parts where the electrons take the same direction of rotation and so the magnetic field flows along the coil. The mistake in part 1 of this document was talking about an electric current that doesn’t exist! The reason is the absence of a closed loop to introduce an electric current, in this case the electron spin takes the lead. To explain this, let’s take another look at the scope graph in Fig.59:
The marked area shows an absence of voltage. In that experiment, no ferromagnetic material was used, only aluminum foil, the voltage is zero so it's expected for the ETBC to stop the oscillation but the device acts once again! This means that there's an accumulation of magnetic flux inside the ETBC, in other words it's a magnetic field without an electric component, the magnetic field in this case is present as electrons spin potential which gives a better picture of the presence of the Bloch wall area in the ETBC. This device looks like a dynamic permanent magnet, this explains the statement given by Don Smith about the similarity of his device with an ordinary permanent magnet power generator.

Now it's absolutely clear the ETBC needs a kind of energy balance to oscillate correctly. As explained in Fig.59, two capacitors are needed to arrange a kind of spin balance inside it, I said the ETBC forms a special capacitor coil but this is not exactly true! In reality, there's no coil nor a capacitor! Both the coil and the capacitor need an electric current but the ETBC needs an energy balanced electron that can be supplied only if the same amount of positive charges meets the same amount of negative charge.

Chinese Developer Ming Cao.
a free-energy developer in mainland China, comments on the designs of Don Smith, and Tariel Kapanadze. He says:

None of these things originate from me, they come from Tesla and God.

1. The most important issue, is resonance. Don Smith said that we should make the wire length of the primary coil to be one quarter of the wire length of the secondary coil in order that they will resonate together. My experiments show that this is not true. In a Tesla Coil, the primary coil and it's capacitor form a tank circuit which is an L/C circuit, which oscillate at it's own resonant frequency, and when it does that, it generates a longitudinal wave at that exact frequency. The frequency of this longitudinal wave is determined by the inductance of the primary coil combined with the capacitance of it's tank circuit capacitor, and not the wire length of the primary coil alone. The secondary coil with it's sphere at the top, together form an antenna, which transmits this longitudinal wave. The secondary coil and it's top sphere together form a quarter-wave resonant antenna for this longitudinal wave. They do not form an L/C circuit and that is why very few people have managed to replicate Don Smith's devices.

2. In the devices of Don Smith and Tariel Kapanadze, there is no sphere. We see a single coil as the secondary. This is no longer a quarter-wave antenna, but a half-wave antenna. The highest voltage shows up at the very centre of this coil, and zero voltage shows up at the two ends of the coil winding. These are where the energising coil and the pick up coil should be positioned.

3. The longitudinal wave which passes through the secondary coil is not a current at all, it is a signal running through it, so if we let the secondary to charge a capacitor, we will get nowhere. All we will get is hot electricity caused by the loose induction coupling. The arc at the top of a typical Tesla coil is lightning voltage, and no capacitor on earth can handle that voltage, so even a very high voltage capacitor will be over stressed and the arc will shock through it.
4. The speed of this wave is well defined. It depends on the total capacitance of the coil, and the sphere if there is one. In a typical Tesla coil, the bigger the sphere, the bigger the capacitance, and the lower the resonant frequency of the secondary coil. People are trying to explain it by L/C circuit theory, but this is not necessarily true. Increased capacitance will slow the wave down. If there is no sphere, as in the devices of Don Smith and Tariel Kapanadze, the total capacitance is quite small, and so, the speed of the wave should approach the value \((\pi/2) \times C\), where \(C\) is the speed of light. This speed of the longitudinal wave is claimed by Tesla himself. I kind of verified this by experiment. I said “kind of”, because in my experiment, I got a speed of \((\pi/2) \times C \times (8/9)\). The wave is slowed down by the copper losses and the capacitance of the coil, mostly the capacitance, but it's definitely faster than the speed of light.

5. So, to tune the secondary, we should not use the speed of light at all, Don was playing a game with us here. Take Don's device as an example. If we position the primary coil at the centre of the secondary coil, then that middle point of the secondary should either be grounded or connected to a large metal sphere, and each half of the secondary coil should act as a half-wave antenna. Also, the pick-up coils should be located at the two far end terminals. The speed of the longitudinal wave along the secondary coil is unpredictable and so we can only predict a general speed range, we cannot tell whether it is already resonating by performing calculations. Like Nick Giannopoulos's arrangement (see below) and Tesla's patent diagram, there are two quarter wave coils, whose inner terminals are connected together and open to the air. Here 'open to the air' means that it is different from the other turns of the coil. The longitudinal wave is climbing the turns rather than passing along the wire. But at the end of each quarter wave coil, there is no other turn to climb any more, only a long wire for it to travel along. This straight long wire is open to the air and provides a capacitance for the whole device, and this additional capacitance will slow down the longitudinal wave which is passing through it, so that the resonant frequency for the combination of these two secondary coils will be lower. But if we eliminate the straight wire, and make it a single half-wave secondary coil, the longitudinal wave can keep climbing the turns, and there's no additional capacitance, so that the speed of the longitudinal wave will be very close to \((\pi/2) \times C\), and the resonant frequency will be higher. We can use the same wire length and same diameter coil former to build different devices, which will work at completely different frequencies. So the resonant frequency is unpredictable and we need to find the exact frequency by equipment measurement, or it won't work. The only correct way of tuning the secondary is shown by Eric Dollard in his video of the 1980s, entitled "Eric Dollard Transverse and Longitudinal Wave" which at the present time can be found on YouTube at [http://www.youtube.com/watch?v=6BnCUBKgmnC](http://www.youtube.com/watch?v=6BnCUBKgmnC).

6. A pick-up coil is always necessary, and it should be positioned near the zero node of a standing wave. This is one of the only two ways of harness the longitudinal wave. This method is the dynamic method, the other way is the static method, which I believe was used by Ed Gray.

7. In Dr. Peter Lindemann's book and video, he says that Tesla is using unidirectional current. I have to disagree with this. When we charge a capacitor and discharge it through a spark gap, the discharge current "bounces" between the two plates of the capacitor, until the energy is all lost at the spark gap. This process repeats itself endlessly in a typical Tesla Coil. We can see this primary waveform with an oscilloscope and it is alternating current. Thousands of Tesla Coils work in this way and generate lightning. I am confident that this is how it operates.

8. It is not like Don Smith said, that doubling the voltage quadruples the output. It does look like that, but it is actually the current flowing through the primary doing the job. Of course we increase the current by increasing the breakdown voltage of the spark gap by widening the gap. But fundamentally, it is the current which is doing the job. Ed Gray's tube uses a short straight copper bar as the energising 'coil', but it's not a coil, it has little inductance to generate voltage, it only has high current passing through it to energise the longitudinal wave. Of course I haven't actually seen this process, it is a conclusion which is not fully based on experiment.

9. The larger the number of turns in the pick-up coil, the higher the output voltage will be. I still cannot understand how the pick-up process works, but it does pick up more energy.

I get all these by low voltage from a signal generator, as I haven't finished building a high voltage device yet, although I'm already working on it. But I think it's safe for me to believe that these results are solid and good enough to share.

Here is a image from Tesla's patent 593,138 Electrical Transformer.
We can see it's exactly the same as Nick Giannopoulos' setup, except that Tesla is using a generator in this diagram, I believe for simplicity. As long as the generator is generating the exact frequency of current, it will work fine. The secondary at the energising side is a quarter-wave coil, and at the pick-up side is another quarter-wave coil. The highest voltage is at the far end of these two secondary coils and their connecting wire, and zero voltage is at the very outside turn of each of the coils. Now if we change the spiral form coil to helical, it becomes Nick's set-up. And let's take this further, we can shorten the connecting wire until the two solenoid secondary coils actually become one big coil, then, when combined it is a half-wave coil, and the highest voltage is at the middle point of it. Now it becomes Don Smith's and Tariel Kapanadze's device, like this:
Because the energy is also coming back from the energising side, Kapanadze adds another pick-up coil right underneath the primary energising coil. This arrangement, I think, is very hard to replicate, because it is so very hard to tune, for several reasons:

1. The Secondary wire length is rather short, and the wave speed is very very close to $((\pi/2) \times C)$, so the frequency should be very high, at least 5-7MHz I would guess, or perhaps even higher.

2. The pick-up coil and the energising primary coil is too close to the centre point of the half wave secondary coil. Because the centre point is the point of highest voltage, if the input is a little high, there would be arc shock between the secondary to the energising coil and the pick-up coil, at lightning voltage levels, and so even the best isolation is useless. Also, the centre point is very very sensitive, any conductor close to it will add to the total capacitance of the coil and of course that will alter the half-wave resonant frequency. This adds more difficulty to the tuning adjustment. Besides, after all, people don't even know it's a half-wave coil if he doesn't tell us.

3. The coupling coefficient $K$ is a little high, this will increase the hot transformer effect by inductive coupling, and that will not help at all.

Don Smith did indeed say something useful. He said that we can make the secondary coil a fixed size, and then slide the primary coil inside it. Well based on experimental results, this sliding process is altering the actual effective length of the secondary coil. In general, we should assess coil size by counting the turns from the turn right underneath the primary energising coil, to the turn right underneath the pick-up coil, this section is the actual secondary, and this section should be a half-wave resonate coil, the rest of the coil just sits there doing nothing.

But it's not that simple, the terminals of the secondary coil should connect to the earth or to a large sphere, or a typical Tesla Coil secondary with the same quarter-wave resonant frequency. Otherwise the signal will bounce backwards and forwards in the coil producing a mess, or generating an arc, and this is bad for performance, and this is why a solid ground connection is desirable. And this is the true meaning when Don says "slide the primary coil to do the fine tuning".

So, returning to the Kapanadze device, the energising coil covers a large area of the secondary coil, making the effective length of the secondary coil very much shorter, again, boosting the working frequency of the device even higher. For such a device, it is impossible to tune it without a 20Mhz signal generator, an oscilloscope and complete understanding of how a longitudinal wave behaves. For a start, I don't even know where to connect the oscilloscope probe or which terminal should connect to the ground, I'm so lucky to be able to watch Eric Dollard's old video, and I recommend everybody to watch that video, watch it over and over again, also many other educational videos from Eric. A lot of fundamental stuff about how a longitudinal wave behaves are explained there, it's like a treasure map covered in dust in a quiet corner of an open library.

Ming’s video http://www.youtube.com/watch?v=1p41KLIOM2E&feature=youtu.be demonstrates what he is saying here. For the video he uses an input coil, a monitoring coil and a secondary coil, each end of which is earthed using separate earth connections:
Ming also remarks:

For the set-up in the video, the secondary coil is wound using 1mm diameter enamelled copper wire, 365 turns around a 160mm diameter PVC pipe. The total coil length is 39.5cm. The total wire length of the secondary is approximately 182m. The white material is several layers of insulating glue to prevent arcing between adjacent turns when working with high voltage. The primary coil and the pick-up coil are wound with audio cable which is more than 4 square millimetres in cross section. The primary coil has 2 strands, 2 turns. The pick-up coil has 4 strands and only one turn. I use this thick wire, because I am going to use these coils for my high voltage project.

For a low voltage experiment like shown in the video, it would be quite adequate to use ordinary copper wire of 1 square millimetre cross section (swg 18 or AWG 17). If the secondary wire length is reduced, then the resonant frequency will be higher, but the principle is the same.

If only low voltage is going to be used - perhaps just to study the nature of longitudinal waves, then the secondary coil can be made using very thin wire of 0.3 to 0.4mm diameter (swg 30 to swg 27) enamelled copper wire, which will cost much less. I made my coils with thick wire because I intend to continue using high voltages.

It's been a long time, but I've got some more understanding about harnessing radiant energy. I have made two additional videos: http://www.youtube.com/watch?v=WJUJf53geBo and http://www.youtube.com/watch?v=BdBjKVyKBZA In these two videos, I explain the method of converting Tesla's 'cold' electricity to normal 'hot' electricity by storing it in a capacitor. I strongly believe that, the method shown in the second video is exactly what Don is doing with his famous device, which has no pick-up coil, just a two-part secondary.

In the first video, I replace the pick-up coil with an uncoated sheet of copper, to show people that, this is not a transformer, and so, is not based on electromagnetic induction. The pick-up coil is fundamentally, a piece of metal which can be electrified by a longitudinal wave. I can remove the diode and the capacitor, and just let the copper sheet discharge to ground through a spark gap and two ordinary 200-watt incandescent light bulbs connected in series, the light bulbs are pretty bright although not fully lit, but pretty bright in spite of this being a non-resonant situation. They look like this:
The copper sheet is electrified, and it’s charge is flowing to ground, and it is this very process which forms the current. So if we consider it as a transformer, and consider the pick-up coil as a inductor, and add a load to this "inductor" to form a closed loop, then we are going in the wrong direction.

Then I re-read about Nick Giannopoulos' device, and I noticed that he said that the light coming from his bulb is blue and white. Following his circuit diagram, I believe that it is like this:

I get this kind of light when I attach the light bulb directly to the sheet copper without an earth connection or any other additional wire. Here at this stage, we have no ‘hot’ electricity. The blue-white light is caused by the high voltage of the metal, to which the bulb is attached. The high voltage is not caused by induction, it is purely static charge on the metal surface, caused by longitudinal wave electrification. If we use Tesla's specially made bulbs as shown in his lectures, we have his single-wire lighting system, and we will have a very bright light suitable for general-purpose lighting instead of this kind of blue-white light. Generally speaking, my bare copper sheet is the equivalent of Nick's pick-up coil plus his step-down transformer, which, of course, is not a transformer at all.

Note: As will be seen in the videos, Ming uses two separate earth connections. One is the earthing wire of his mains electricity and the other is a connection to his cold water pipes.

**A Russian Developer**
A Russian developer has lit a large light bulb with a self-powered Kapandze-style circuit:
‘Salty Citrus’ Chinese Developer.
A Chinese developer whose forum ID is ‘Salty Citrus’, has replicated Don Smith’s main device very successfully. Using an input of 12V at 1A to 2A (24 watts) he is lighting ten 100-watt light bulbs to a high level of brightness. The Chinese language video relating to this can be seen at:
http://www.energysea.net/forum.php?mod=viewthread&tid=1350&extra=&page=1

Here are some of the frames from that video:
The circuitry used is shown here:
Subsequently, a forum post by a Mexican man says:

Hello ‘Salty Citrus’,

I love your video!!!! I can really appreciate the amount of work you and your group have spent to develop and perfect the Don Smith / Tesla free-energy device. Thank you for pursuing such a noble cause.

I am intrigued by your switching network using the CREE CMF20120. How did you wire the MOSFET’s? You used a UCC3825A Pulse-Width Modulator to clock the signal --> MOSFETS --> Gate Drive Transformers (x3) --> push-pull transistor --> CMF20120? Did you run the CMF20120 in series? Sorry about so many questions, but I am totally impressed by your ingenuity, and completely agree that your solid-state solution has undoubted benefits over Tesla’s conventional spark gap.

I would be honoured if you could take the time to answer my questions. I would love to replicate your circuits.

I wish you the best of luck with your endeavours.

Sincerely,

‘Lost_bro’ (half a world away)

--------

Re: ‘Lost_bro’

Thanks for the compliment. The success does credit to my team. Thanks to my team. Yes, the CMF20120 run in series in this solution. The voltage balancing between each MOSFET is critical as is the balancing between RC and DC voltage created by R.

Welcome to our forum for the exchange of information. China is an hospitable country. If you have any information or ideas, please don’t hesitate to share them with us. ‘Half a world away’ is not a great distance.

All the best,

Sincerely

‘Salty Citrus’
An earlier entry on the Chinese forum translates as:

Here is an earlier build. It is simple and has no step-down section and so cannot be self-powered:
Each bulb is 100 watts. The first board has a 12-volt input and an adjustable output which can be varied from 500V to 1600V (any higher voltage would damage the four 450V 20 microfarad capacitors). In the video, the variable resistor is used to set the voltage level of the FBT after boost as the voltage step-up circuit can go up as high as 3,000 volts.

The L2 coil is wound in a single direction and has just one tap at the centre. The idea is from Tesla’s Colorado Springs Notes, in which Tesla disclosed the best method for a resonant driver. The frequency used in this circuit is about 230 kHz.

Question: There is nothing to do with quarter-wavelength, but is there anything with the length of the L1 and L2 coils on quarter-wavelength?
Answer: I think that the phase is more important.

Question: Do you need a Phase-Locked Loop circuit with a certain phase difference?
Answer: Basically, I use a fixed frequency, I have tried a Phase-Locked Loop and the effect is the same.

Question: Do you use direct drive with the spark gap only being used to limit voltage?
Answer: You can use a vacuum tube to drive it.

Question: If you drive it directly, then the loading will be very big and the current will increase, whereas if you use a spark gap, then the spark will become smaller and the current will be steady.
Answer: If the load affects the input, then you cannot drive it even with a spark gap. If you trigger with a spark gap, then the load will not increase the input. The spark gap is just a switch.

Question: Is there any direct Lenz relationship between the load and the primary?
Answer: Once the phase has been adjusted, the primary has no adverse effect on the secondary.

Commenting on his circuitry, ‘Salty Citrus’ states:

The diode symbols with a tick indicate a Zener diode (or bidirectional TVS-Transient Voltage Suppressor or “varistor”). For example, in this circuit, they are used to suppress the Grid voltage of the MOSFET, to maintain the gate voltage within the range of +20V to -20V. The above circuit is just a description of the structure of the MOS series method. Specific components will be needed for your own requirements considering the MOSFETs being used in your construction.

The voltage E0 can be adjusted. The source can be made using a TL494 IC operating at 12V, or alternatively, an adjustable, voltage-stabilised inverter can be used. The voltage setting depends on the numbers of MOSFETs which are being used in series and the parameters of Grid voltage and the turns ratio of the isolation transformer. The circuit is arranged so that each MOSFET has its own separate isolation transformer, and all of the primary windings of those transformers are connected in series to form a single current path. The number of turns in the primary of each isolation transformer is exactly the same. To drive an IGBT (or MOSFET), VT6 provides a high-frequency pulse current to drive the Gates of the MOSFETs, so as to achieve consistent switching.
In my circuit, the frequency used is 220 kHz, for this frequency, I use six MOSFETs type CMF2012 (1200V, 37A, Resistance Drain-to-Source of just 80 milliohms). This MOSFET from CREE has excellent performance, but you have to design the drive circuit carefully, 2V to 22V for the Gate voltage will be best. I particularly stress that it is very important that MOSFETs operated in series, require voltage balancing and an accurate drive. Especially important is having synchronized drive signals and the rise and fall time of the drive signal should be as short as possible, so that the switching time difference between the MOSFETs will be short, and that improves the high frequency operation.

**Another Russian Development**

At [https://www.youtube.com/watch?v=4n22MNKrUsA](https://www.youtube.com/watch?v=4n22MNKrUsA) there is a video which shows a self-powered motionless generator with an output of 105 watts:

![Video still](https://example.com/vid-still.jpg)

Thanks are due to Wesley for his translation of the Russian soundtrack. No circuit details are available that this time, but Wesley’s video has “Part 1” in the title and so further details may be provided at a later time.

**Tesla Coils Back-to-Back**

I have been told of one man who used his common sense and produced an impressive result. He used a Tesla Coil as the driving force, and then used a second Tesla Coil back-to-back with the first one, to step the high voltage back down again. Doing that, he was able to light a series of powerful light bulbs from the “L1” output coils. He also confirmed that doubling the voltage, quadrupled the power output, verifying what Don said. He also found that adding additional coils with bulbs to the output Tesla Coil, did not increase the input power at all, did not cause any of the existing light bulbs to shine any less brightly, and yet lit the additional bulbs. That would appear to be confirmation of Don’s statement that any number of magnetic copies of the original oscillating magnetic field of the first Tesla Coil, can provide a full-power electrical output without requiring any additional input power. I’m no expert, but my understanding of the arrangement is:
As the large diameter coil is exactly one quarter the length of the smaller diameter coil, there is an automatic resonance of both when the applied frequency is just right. As the first narrow coil is identical to the second narrow coil, they are also automatically resonant together. Again, as the large coils which feed the loads are exactly one quarter the wire length of the narrow coils, they also resonate at the common frequency and at that frequency, the input power is at its minimum while the output power is at its maximum. The spike at the top of each of the narrow coils is connected with a wire to channel the generated power from the first Tesla Coil to the second one.

This arrangement may seem too simple to be effective, but with Tesla technology “too simple” just does not apply. This can be seen clearly from the work of Nikanor “Nick” Giannopoulos. Before he ever learned anything about electronics, Nick read and understood Nikola Tesla’s “Colorado Spring Notes” (http://www.free-energy-info.tuks.nl/TeslaCSN.pdf 60Mb) and this helped with his present level of understanding. Interestingly, and perhaps not surprisingly, Nick had difficulty with conventional electronics after becoming familiar with Tesla’s technology.

Nick used a square wave signal generator adjustable from 50 kHz downwards and with a fully adjustable Mark/Space ratio. This was used to drive an oil-filled car ignition coil, which, as he points out is not a Tesla Coil in spite of the frequently held view that it is. Ignition coils only operate at low frequency due to the limitations of their core material. However, John Stone points out that certain coil designs, such as those for the Fiat ‘Punto’ car, are built in such a way that replacing the core with ferrite should be possible, and that would allow high frequency operation.

Anyway, Nick uses a standard car ignition coil at lower frequency and uses it to feed a spark gap like this which is constructed from two chipboard screws:

![Spark gap](image)

His circuit is:
Nick has had very impressive results from his circuit, although it is still very much a work in progress with more development and testing still to be done. The 24 watt input of 12V at 2A is producing two very brightly lit 220V light bulbs. This does not tell us very much about the actual output power as bulbs are notorious for lighting brightly at low power levels, especially if the frequency is high. But, a very important point is the quality of the light which is an unusual, blue-white colour, quite unlike the colour produced when connected to the 220V mains supply. This is generally a sign of the power being ‘cold’ electricity. While he has not yet had the opportunity to test it, Nick believes that the circuit as it stands now is quite capable of powering much higher loads, and considering the colour of the light, I would be inclined to agree with him, although anything like that has to be tested and proven before any solid conclusions can be drawn from what is already known about the performance. The circuit performance is much improved if two separate physical earth ground connections are made.

Please don’t fall into the trap of thinking that because the sparks are occurring at less than 5 kHz, that the Tesla coils also operate at that frequency. If you strike a bell which vibrates at 400 Hz, does that mean that you have to hit it 400 times every second in order to hear it? Actually, no, you don’t, and the same thing applies here where the resonant frequency of the Tesla coils is approximately 650 kHz. The primaries are wound on 100 mm diameter PVC pipe sections and 19 turns of 1.02 mm diameter enamelled copper wire is used for them (19 swg or #18 AWG). The secondary coils are wound on 70 mm diameter PVC pipe using 0.41 mm diameter enamelled copper wire (27 swg or #26 AWG) with a total length of four time the primary winding wire length. As you will see later on in this chapter, resonance in a coil involves a standing wave inside the wire. That standing wave is
created by the signal bouncing off the end of the wire and being reflected back. At frequencies other than the resonant frequency, this results in a constantly changing set of many different waves travelling in both directions and at different intensities (what could reasonably be described as a total mess). When the resonant frequency is fed to the coil, then all of that mess disappears and just one waveform remains, and at any point along the wire, that waveform appears to be stationary although, of course, it is not actually stationary, just the effect of the peaks always occurring at exactly the same spot and the troughs occurring at exactly the same spot, making successive waves look exactly the same as the previous one.

This feature has one very practical aspect, namely that if you run the same wire away from the coil turns to connect to whatever the next circuit component happens to be, then the wave inside the wire will not bounce back at the end of the coil turns but will continue on to the end of the wire before bouncing back. So, the connecting wire length has to be included when reckoning the wire length in the turns of the coil. On the other hand, if the wire in the coil turns is terminated at the ends of the coil and wire of a very different diameter is used for connecting to the next component in the circuit, then the signal inside the wire will bounce back from the sudden change in wire diameter and so the connecting wire length will not be part of the wire length in the turns of the coil. This is an important feature if you are aiming for an exact 4:1 wire length ratio (and 4:1 wire weight) between the Tesla Coil windings in order to impose an automatic resonance between the two windings.

It should be noted that PVC (especially non-white PVC) has a very restrictive effect on high frequency coils. At low frequencies, PVC is ok, but it drags down the coil performance as the frequency rises, lowering the “Q” (for “Quality”) factor of the coil. Using acrylic instead of PVC overcomes this. Alternatively, coating the PVC with a high-voltage insulating material such as shellac or one of the proprietary coating agents, will improve matters considerably. The ideal, of course, is to have no former at all and have the coil standing unaided because of it's own strength.

Making a Solid-state Tesla Coil

As some readers may feel that there is some "black magic" about the neon-driver circuit used by Don to drive the Tesla Coil section of his circuitry and that if a suitable unit could not be purchased then the circuit could not be reproduced or tested, it seems reasonable to show how it operates and how it can be constructed from scratch:

The circuit itself is made up of an oscillator to convert the 12-volt DC supply into a pulsating current which is then stepped up to a high voltage by a transformer. Here is a circuit which has been used for this:

![Tesla Coil Circuit Diagram]

The supply for the 555 timer chip is protected against spikes and dips by the resistor "R" and the capacitor "C". The 555 timer chip acts as an oscillator or "clock" whose speed is governed by the two 10K resistors feeding the 440 nF capacitor. The step-up transformer is an ordinary car coil and the drive power to it is boosted by the IRF9130 FET transistor which is driven by the 555 chip output coming from it's pin 3.

The output from the (Ford Model T) car coil is rectified by the diode, which needs to have a very high voltage rating as the voltage at this point is now very high. The rectified voltage pulses are stored in a very high-voltage
capacitor before being used to drive a Tesla Coil. As a powerful output is wanted, two car coils are used and their outputs combined as shown here:

You will notice that the car coil has only three terminals and the terminal marked "+" is the one with the connection common to both of the coils inside the housing. The coil may look like this:

and the "+" is generally marked on the top beside the terminal with the two internal connections running to it. The circuit described so far is very close to that provided by a neon-tube driver circuit and it is certainly capable of driving a Tesla Coil.

There are several different ways of constructing a Tesla Coil. It is not unusual to have several spark gaps connected in a chain. This arrangement is called a "series spark gap" because the spark gaps are connected "in series" which is just a technical way of saying "connected in a row". In the chapter on aerial systems, you will see that Hermann Plauston uses that style of spark gap with the very high voltages which he gets from his powerful aerial systems. These multiple spark gaps are much quieter in operation than a single spark gap would be. One of the possible Tesla Coil designs uses a pancake coil as the "L1" coil as that gives even higher gain. The circuit is as shown here:
The connection to the pancake coil is by a moveable clamp and the two coils are tuned to resonance by careful and gradual adjustment of that connection. The series spark gap can be constructed in various ways, including using car spark plugs. The one shown here uses nuts and bolts projecting through two strips of a stiff, non-conducting material, as that is much easier to adjust than the gaps of several spark plugs:

Tightening the bolts which compress the springs moves the bolt heads closer together and reduces all of the spark gaps. The electrical connections can be made to the end tags or to any of the intermediate wire connection straps if fewer spark gaps are required in the chain.

Let me remind you again that this is not a toy and very high voltages will be produced. Also, let me stress again that if you decide to construct anything, then you do so entirely on your own responsibility. This document is only provided for information purposes and must not be seen as an encouragement to build any such device nor is any guarantee given that any of the devices described in this eBook will work as described should you decide to attempt to construct a replication prototype of your own. Generally, it takes skill and patience to achieve success with any free-energy device and Don Smith's devices are some of the most difficult, especially since he admits quite freely that he does not disclose all of the details.

The output capacitor marked “C1” in the circuit diagram above has to be able to handle very high voltages. There are various ways of dealing with this. Don dealt with it by getting very expensive capacitors manufactured by a specialist company. Some home-based constructors have had success using glass beer bottles filled with a salt solution. The outside of the bottles are wrapped in aluminium foil to form one of the contacts of the capacitor and bare wires are looped from deep inside each bottle on to the next one, looping from the inside of one bottle to the inside of the next one, and eventually forming the other contact of the capacitor. While that appears to work well, it is not a very convenient thing to carry around. An alternative is just to stand the bare bottles in a container which is lined with foil which forms the second contact of the capacitor.

One method which has been popular in the past is to use two complete rolls of aluminium foil, sometimes called "baking foil", laying them one flat, covering it with one or more layers of plastic cling film and laying the second roll of foil on top of the plastic. The three layers are then rolled up to form the capacitor. Obviously, several of these
can be connected together in parallel in order to increase the capacitance of the set. The thicker the plastic, the lower the capacitance but the higher the voltage which can be handled.

The November 1999 issue of Popular Electronics suggests using 33 sheets of the thin aluminium used as a flashing material by house builders. At that time it was supplied in rolls which were ten inches (250 mm) wide, so their design uses 14" (355 mm) lengths of the aluminium. The plastic chosen to separate the plates was polythene sheet 0.062 inch (1.6 mm) thick which is also available from a builders merchants outlet. The plastic is cut to 11 inch (280 mm) by 13 inch (330 mm) and assembly is as follows:

![Diagram of sandwich stack of sheets clamped together](image)

The sandwich stack of sheets is then clamped together between two rigid timber sheets. The tighter that they are clamped, the closer the plates are to each other and the higher the capacitance. The electrical connections are made by running a bolt through the projecting ends of the plates. With two thicknesses of plastic sheet and one of aluminium, there should be room for a washer between each pair of plates at each end and that would improve the clamping and the electrical connection. An alternative is to cut a corner off each plate and position them alternatively so that almost no plate area is ineffective.

As Don Smith has demonstrated in one of his video presentations, Nikola Tesla was perfectly correct when he stated that directing the discharge from a Tesla Coil on to a metal plate (or in Don's case, one of the two metal plates of a two-plate capacitor where a plastic sheet separates the plates just as shown above), produces a very powerful current flow onwards through a good earth connection. Obviously, if an electrical load is positioned between the plates and the earth connection, then the load can be powered to a high level of current, giving a very considerable power gain.

### The Screened Transformer of Joseph Boyd.

It is not at all clear if the Boyd power system should be located here or in chapter 7 which deals with aerials. Joseph talks about the way that radio circuits operate and why only very limited power appears to be the limit of radio receivers. He explains a method of extracting serious levels of power from a transmitting coil and a receiving coil, but the higher power levels require an input oscillator, and so, while an aerial and earth can be used for lower power levels, input power is needed for optimum performance. Here is part of Joseph's patent application:

5th June 2008  
Joseph Boyd

**ELECTROMAGNETIC ELECTRIC GENERATOR**

**Abstract:**
An electrical generator that uses a high frequency oscillator in a tuned circuit, set to resonate with the transmitter coil of a full-length high frequency transformer unit, to generate electromagnetic energy, to transform this energy to electrical energy and to collect this energy.

1. **Field of the Invention**
The present invention is an electrical generator that uses a high frequency oscillator in a tuned circuit, set to resonate with the transmitter coil of a full-length high frequency transformer unit, to generate electromagnetic energy, to transform this energy to electrical energy and to collect this energy.

2. Description of the Related Art
If an oscillator circuit is properly connected to a tuned antenna so that it resonates, a current will flow between the aerial and the ground, and this produces the high frequency electromagnetic air waves and ground waves of our radios and other electronic equipment.

An oscillator of the same type used in electromagnetic wave transmission equipment is used to generate the electromagnetic energy used in this patent. These electromagnetic transmitters are well developed and are used world wide, and broadcast at frequencies that extend from the longest radio waves to the very short ones. Certain radios send their signals great distances, some even travelling around the world.

Although these high frequency electromagnetic energy waves are all around us, this energy has long been considered impossible to collect on a large scale due to the induction characteristics of the electromagnetic wave as it passes a metallic object. As the wave goes by a wire tuned to resonate at the frequency of the wave, it induces an electrical charge in the wire, but to use this charge, we need another wire to close the circuit and let the charge flow. If we use another wire alongside the first wire and connected to it, the wave induces a charge in it exactly like in the first wire and no current will circulate in the two wires.

This problem of collecting the energy of the wave was solved by the invention of the half-length electromagnetic transformer, but the half-length electromagnetic transformer applies only to the means of collecting the atmospheric energy. The invention of the full-length electromagnetic transformer of this invention, however, allows us to combine the generation of the electromagnetic wave and the electrical converter into one compact unit.

BRIEF SUMMARY OF THE INVENTION
Basically, this unit uses an oscillating electric current to generate an electromagnetic wave, which releases a much greater electric current, and the total electrical energy derived in this manner, is over and above the amount of energy needed to operate the equipment.

It has long been assumed that the only energy involved in high frequency electromagnetic transmission is that supplied by the operator to drive his equipment. The actual energy of the electromagnetic wave is often over a hundred times greater than this since the amount of electromagnetic energy in the earth is practically unlimited, there appears to be no limit to the size of the electromagnetic generators, or to the size of the power plants based on this energy source. This energy is available, world wide, free for the taking.

This energy is related to the light waves and is probably a variation of the light waves, however, the radio type waves are longer than light waves and are vibrating at a lower frequency. Light waves are a source of high energy just for the taking, also. Anything that is brought up to a high heat, will give off light energy. A very small wire in a light bulb, when brought to a high heat will release a light ray of such power that it will go all the way to the moon. This is natural energy, produced by the speed of the earth through space. Using the math of Dynetics, the speed of the earth necessary to give any pound of earth the atomic energy of one pound of uranium, came out exactly the same as the speed of light (186,300 miles per second). The fact that the math came out exactly at this speed leaves little doubt that the speed of the earth through space is the speed of light, and that every pound of material on earth has the energy of one pound of uranium, due to this speed.

The electromagnetic energy in the low frequency range differs from other types of energy, in many ways, but of interest to us is that it is propagated by electrical currents, travels through the air like the light waves, and is detected and may be collected, when it induces an electric charge in a wire.

This is an ideal source of energy. The generators may be hand-held or large enough to replace the biggest power plants. They may be used to drive motor cycles, sleds, autos, trucks, trains, ships and planes. The fact that the output is in the form of electrical energy is, in itself, a great benefit, but the fact that the generating equipment is light and compact is a real plus for all types of mobile equipment.

It is possible that this invention will supply all of the electrical energy needed in the homes making the distribution lines unnecessary, and if used to drive automobiles, our dependence on oil will be a thing of the past. This invention makes possible an abundance of energy, available to mankind anywhere in the world. Even the poorest nations will have an abundance of energy.

The oscillating equipment that generates the electromagnetic wave used in this invention includes an oscillator, of some type driving a tuned transmitter coil that resonates with a tuned collector coil in a full-length electromagnetic transformer. The induced current is collected in the collector coil and may be rectified and stored in a battery or
used to do work. The oscillator circuit is an ordinary oscillator circuit, driven by a tube, crystal or even an electoral arc, and the tuning means and rectification set-up are standard.

The basic element that is novel to this invention is the full-length electromagnetic transformer unit that is made up of two or more metallic pipe-like sheaths side by side. The sheaths are not connected together, electrically. Two or more coils are wound in the sheaths.

The transmitter coil uses an insulated wire, which is threaded up through one sheath, and down through another sheath a number of times forming a long flat continuous circuit of wire inside of the pipe-like sheaths. And then the collector coil is threaded up through the sheaths, and wound the same way. The two coils may have a different number of turns. The coils are tuned to resonate at the oscillator frequency and an electromagnetic wave is generated in the transmission coil. The wave induces a charge in that part of the collector coil that is in the same sheath, and next to it, and if the wave is moving up in the sheath, the charges of all of the collector wires in that sheath are moving up, and if the wave is moving down, the charges of all of the collector wires are moving down. But the transmitter wave in one sheath does not induce a current in the wires of another sheath, nor does it induce a current in a wire outside of that sheath. This allows a current induced in one sheath to freely circulate in the other sheaths or on an outside wire.

When the transmitter coil is brought up to resonance and broadcasts its electromagnetic wave inside of the sheaths, it benefits us in two ways. It keeps the wave inside of the sheaths and prevents it from spreading far and wide, and it concentrates the wave on that part of the collector coil in the same sheath.

Since each of the collector wires are of the same length, say ½ wave length of the electromagnetic wave, and since they are parallel and side by side, a resonant electromagnetic wave induces equal charges in all of the collector wires within the sheath. These induced currents are exactly in phase and are connected in series, so that the voltages add up to an amount proportional to the number of turns.

More than two sheaths may be used with the coils wound inside, or the ff11 length-transformer may be combined with the half-length transformer where the winding is part inside the sheath and part outside of the sheaths. The oscillator may be replaced by an aerial in cases where low power is needed. The inductance coil may be left entirely outside of the transformer, and the coupling made to the transmission coil by magnetic induction. These and other objects, features and advantages of the present invention will become more apparent upon reading the following specification in conjunction with the accompanying drawing figure.

BRIEF DESCRIPTION OF THE FIGURES

Fig. 1 is a view of an electromagnetic wave, due to resonance, passing two side by side wires tuned to the same frequency. The wave generates equal alternating charges in each wire, and no current flows when the wires are connected.
**Fig. 2** is a view of a resonating electromagnetic wave passing two wires, tuned to resonate, where one wire is surrounded by a metal sheath. The outer metal sheath stops the wave and prevents it from inducing a charge in the shielded wire. The charge induced in the outside wire now flows freely through the shielded wire.

**Fig. 3** is a view of a full-length electromagnetic transformer made of two metallic pipe-like sheaths, having two wires threaded up through the inner opening of one sheath and down through the inner opening of the other sheath, a number of times to form two continuous coils. When an electromagnetic wave is fed into the tuned transmitter coil, an alternating current is induced in the tuned collector coil.

**Fig. 4** is a view of a full-length electromagnetic transformer, having two sheaths, insulated from each other, and a cutaway portion shows the coils inside.

**Fig. 5** is a view of a full-length electromagnetic transformer, having four sections insulated from each other.
Fig. 6 is a section view of a full length electromagnetic transformer made of two metallic pipe like sheaths, where an oscillator circuit is fastened to a tuned transmitter coil, which induces a current in the tuned collector coil; and a half-wave rectifier circuit converts the high frequency current to DC current.

Fig. 7 shows a view of a full-length transformer, used as an inductance in a radio receiver or other similar electronic circuit 61. In this case the transmitter coil is between the aerial and ground, and the collector coil acts as the radio frequency inductance.

Fig. 8 shows a number of full-length transformers, connected in series. They all have rectifiers to convert the high frequency AC current to DC current and the voltages at the load add up.

Fig. 9 shows a view of a full-length transformer, connected in parallel. In this case the currents at the load add up.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS
When a circuit is made to resonate at some frequency, it generates an electromagnetic wave. These waves move at the speed of light and travel great distances, and this makes possible our radios, televisions and cell phones. These waves, in passing a wire suspended in the air, set up alternating charges in the wire, varying at the frequency of the wave. If we put an inductance, that is tuned to the frequency of the wave, between the wire and the ground the circuit will resonate and charges will flow back and forth on the wire. This allows us to pick out the wave we are interested in, amplify it and read its message. We have long known that the voltage of the wave we choose to receive is greatly amplified when we make our circuit resonate at that wave's frequency, but we have been unable to accumulate this additional energy from the wave because we are limited to what energy we can pick up by the equipment that we use.

**Fig. 1** shows why this is so. The passing electromagnetic wave 6 generates an alternating electric charge in the wire 10, tuned to the wave frequency to close the circuit so that the induced charge can circulate, we have added a second wire 11, but if we connect the ends of the wires together, the electromagnetic wave 6 induces a charge in the second wire exactly like the one in the first wire, and no current will flow. Any effort to circulate the charge induced in wire 10 is blocked by an equal opposing charge in 11.

**Fig. 2** we have replaced the wire 11 with a metallic, pipe like sheath 13 having an insulated wire 14 inside when an electromagnetic wave 7 passes, the wave is stopped at the sheath 14 and does not induce any charges in the inner wire 14. This allows the inside wire 14 to conduct the charge induced in the wire 12.

**Fig. 3** we see two sheaths 20 and 21, parallel and insulated from each other. Two separate coils 22 and 23 are wound inside the sheaths. The coil 22 is the transmitter coil and it is tuned to resonate at the frequency of the oscillator circuit 24, and this generates an electromagnetic wave that induces a current in the collector coil 23, which is adapted and used in the tuned collector circuit 25.
**Fig. 4** is a view of a full-length electromagnetic electric generator using two separate sheaths 30 and 31, where the electromagnetic wave is almost completely contained within the sheaths. The sheaths are parallel and insulated from each other by insulators 34 and 35. The transmitter coil 32 and the collector coil 33 are shown in the cut-away, and are wound completely inside the sheaths. Additional coils may be added as needed. The transmitter coil 32 is tuned to resonate at the frequency of the oscillator circuit, which connects in at 36. And this generates an electromagnetic wave that is contained within the sheaths and induces a current in the collector coil 33, which is tuned to resonate at the wave frequency and is coupled to the collector circuit at the terminal 37. The insulating separators 34 and 35 are necessary to prevent induced current from flowing in the sheaths 30 and 31.

A number of sheaths may be combined, as is shown in **Fig. 5**. In this case four sheaths 40, 41, 42 and 43 are combined, so that the coils wound inside the sheaths are in series, and the sheaths are electrically separated by the insulators 44, 45, 46 and 47. The tuned circuit for the transmitter coil is hooked up at connectors 48, and the collector circuit connects to the collector coil at 49.

A simple circuit for operating the full-length electromagnetic transformer is shown in **Fig. 6**. The two sheaths 50 and 51 are shown with the transmitter coil 52 and collector coil 53. The transmitter coil is connected to the tuned circuit 55, which is driven by the oscillator 54. The oscillator 54 is tuned to oscillate at some frequency and the transformer circuit 55 and collector circuit 56 are tuned to resonate with it. At resonance the transmitter coil 52 emits an electromagnetic wave which induces a current in the collector coil 53. Shown here is a half-wave rectifier 57 and capacitor 58 connected to the load 59. The rectifier is necessary on each collector unit, because we can add the direct currents of the separate units, but the alternating currents of the units might be out of phase and without the rectifier they would cancel out.
Fig. 7 shows the transmitter coil connected between an aerial and the ground, where the aerial circuit and collector circuit are tuned to resonate at a desired frequency to greatly boost the sensitivity and to amplify the signal. This type application will work equally well with transmitters.

Also, using the half-length transformer as an aerial and the full-length transformer as the radio frequency transformer works the same with both receivers and transmitters. The oscillator circuit can use a high frequency magnetic inductance and the full-length transformer unit to resonate with a half-length transformer which acts as an aerial. A unit such as this would greatly add to the power of a radar system.

The full-length units, when combined with rectifiers, may be connected in series as in Fig. 8, or in parallel as in Fig. 9.

While the invention has been disclosed in its preferred forms, it will be apparent to those skilled in the art that many modifications, additions, and deletions can be made therein without departing from the spirit and scope of the invention and its equivalents as set forth in the following claims.

Claims:

1. An electric generator that uses an oscillating circuit to resonate with inductances enclosed in a full-length electromagnetic transformer unit, comprising: two or more parallel, metallic, pipe-like sheaths, insulated from each other; an electromagnetic transmitter coil, which is wound inside the sheaths, using an insulated wire, threaded up through the inside opening of one of the sheaths and down on the inside of a second sheath, one or more times, to form a continuous coil; a means of tuning the transmitter coil to the frequency of the oscillating circuit, so that the transmitter coil resonates and generates an electromagnetic wave that is contained within the sheaths; a collector coil composed of an insulated wire, threaded up through the inside opening of one of the sheaths and down on the inside of a second sheath, one or more times, to form a continuous coil, wherein the electromagnetic wave of the transmitter coil induces an electric charge in the collector coil; and a means of tuning the collector coil to resonate at the frequency of the oscillating circuit; so that the electromagnetic wave induces a current in the collector coil, and since the coil is contained within the sheaths, the current is free to flow, and the high frequency alternating current, so generated, can be used elsewhere in an electronic circuit, or altered and used as a power source.

2. The full-length electromagnetic transformer unit of claim 1, where the collected current is rectified, and the DC current is stored in capacitors and used to do work.

3. The full-length electromagnetic transformer unit of claim 1, where the transmitter coil acts as a tuned
inductance, in a receiver, between the aerial and the ground, and a tuned collector coil resonates to increase the sensitivity and the amplitude of the signal.

4. The full-length electromagnetic transformer unit of claim 3, where the tuned transmitter coil resonates with an oscillator and an aerial to act as a transmitter for radios, televisions, cell phones, radars and computers.

5. The full-length electromagnetic transformer unit of claim 1, where the lengths of the sheaths are some multiple of the wave length of a particular electromagnetic frequency.

6. The full-length electromagnetic transformer unit of claim 5, where a number of the units are connected in parallel to increase the current.

7. The full-length electromagnetic transformer unit of claim 5, where a number of the units are connected in series to increase the voltage.

8. The full-length electromagnetic transformer unit of claim 5, where the parts are reduced to a size small enough to fit in, and supply power to, a cell phone, a lap-top computer, or other electrical appliance.

9. The full-length electromagnetic transformer unit of claim 1 further comprising three or more, metallic, parallel, side by side, pipe like sheaths, where the sheaths are not electrically connected, and have two or more coils wound inside the sheaths.

***************

Up to the present time (June 2013), I have not heard of anyone attempting to replicate the design shown in this patent, and so it is just being put forward here in case somebody wants to try it. It appears to be a clever technique. The power gain is maximised by tuning the transmitting and receiving coils to the frequency of the oscillator, although in practice, it is highly likely that the oscillator frequency would be adjusted to the transmitter coil as it is so easy to adjust the frequency of an oscillator.

Boyd does not go into great detail about attaining resonance, and that is generally a major difficulty in any design which does not have automatic tuning. It needs to be borne in mind that the length of wire in each coil (and possibly its weight) is a key factor. Boyd talks about the coils possibly having the same number of turns, and that is fine provided that the coils are identical in size, that is, having the same shape when viewed from the top and the same depth of turns when viewed from the side, and exactly the same number of turns with each coil having exactly the same wire length. Resonance in a length of wire, whether it is laid out straight or wound into a coil, tends to confuse many people. Richard Quick’s very clear explanation of resonance in any length of wire, in his US patent 7,973,296 of 5th July 2011 is very helpful. He says:

“Quarter-Wave” Resonance; Standing Electromagnetic Waves”

One of the two main types of electrical resonance is referred to here as quarter-wave resonance. This type of resonance depends almost entirely on the length of a wire element For reasons described below, if a segment or length of wire is one quarter as long as the “voltage waves” which are travelling through the wire, then a set of “reflected” waves will be added to the emitted waves, in a synchronised alignment which creates stronger “superimposed waves”.

Accordingly, an understanding of the “quarter-wave” phenomenon will help a reader understand how a straightforward and easily-controlled factor (i.e., the length of a wire ribbon which will be used to form a spiral coil) can help create a “quarter-wave” resonant response, which will create the types of electromagnetic pulses and fields referred to as “standing waves”.

The speed at which a voltage impulse is transmitted through a metal wire is extremely fast. It is essentially the same as the speed of light, which travels 300 million meters (186,000 miles) in a single second (that distance would circle the earth more than 7 times).

If wavelength (in meters) is multiplied by frequency (cycles per second), the result will be the speed of light, 300 million meters/second. Therefore, the wavelength of an “alternating current” (AC) voltage, at some particular frequency, will be the speed of light, divided by which frequency.

Therefore, using simple division, if an alternating voltage operates at a frequency of 1 megahertz (MHz), which is a million cycles per second, then the “wavelength” at that frequency will be 300 meters. If the frequency halves become 500 kilohertz, the wavelength becomes twice as long (600 meters); and, if the frequency were to increase to 2 megahertz, the wavelength drops to 150 meters.

It should be noted which the term “cycles” is what scientists call “a dimensionless unit”, which drops out and becomes silent when other physical terms are multiplied or divided.
At AC frequencies of 10 kilohertz or greater, the common references to “alternating current” (AC) voltage begin using a different term, which is “radio-frequency” (RF) voltage. Accordingly, RF voltage is a form (or subset) of AC voltage, which operates at frequencies higher than 10 kilohertz. RF power generators are readily available, and are sold by numerous companies which can be easily located by an Internet search, using the term “RF power generator”. For example, Hotek Technologies Inc. (hotektech.com) sells two RF power generators, called the AG 1024 and AG 1012 models, which can provide output power at frequencies ranging from 20 kHz to 1 MHz; the 1012 model has a power output of 1000 watts, while the 1024 model has a power output of 2000 watts. The output frequency of any such RF power supply can be adjusted and “tuned” across the entire range of operating frequencies, merely by turning knobs or manipulating other controls in a power supply of this type.

In a wire having a fixed and unchanging length, the easiest way to create a “standing wave” is to adjust the RF frequency emitted by a power supply with an adjustable frequency, until the “tuned” frequency creates a wavelength which is 4 times as long as the wire. This principle is well-known to physicists, and it is commonly referred to as “quarter-wave” behaviour, since the length of the wire segment must be one quarter as long as the wavelength. Since it is important to this invention, the principles behind it are illustrated in a series of drawings provided in Fig.1 to Fig.4, all of which are well-known prior art.

**Fig.1A** indicates an idealized wavelength of an alternating voltage, depicted by a sine wave which is being sent from an AC power supply (shown by a circle at the left end of a horizontal straight wire) into the “input” end of the wire. The voltage waves travel through the wire towards the right, as indicated by the block arrow in **Fig.1A**. When the waves reach the end of the wire, they cannot leave the wire (at least, not in a simplified and “ideal” system, which is being assumed and used here to explain the principle of how a simple straight wire can create a standing wave). Therefore, the voltage wave will effectively “bounce” or “reflect” back from the tip of the wire, and the “reflected wave” will begin travelling back through the wire, going in the opposite direction, as indicated by the left-pointing block arrow in **Fig.1B**.

Because of the laws of conservation of energy, the reflection and “return travel” of these types of waves, when they bounce off the tip of a wire, is actually quite good, and rather efficient, as discussed below, provided which the wire tip does not emit sparks, arc discharges, or other forms of “escaping” electrical energy. Accordingly, **Fig.1A** depicts a set of “emitted waves” travelling towards the right, while **Fig.1B** depicts an idealised set of “reflected waves” travelling toward the left along the same wire.

**Fig.1C** illustrates what happens when both sets of waves (emitted and reflected) are superimposed on each other. Since the two sets of waves are travelling at exactly the same speed, and since they have exactly the same wavelength, they will create a “standing wave” pattern when they are added together. As can be visualised from **Fig.1C**, there will be a set of locations, along the length of the wire, which can be referred to as “peak nodes”, where the AC voltage reaches it’s maximum.

At a location halfway between a pair of adjacent “peak nodes”, there will be a spot which can be called a “null node”, a “zero node”, a trough or valley node, or similar terms. At each “null node” location, the AC voltage will
appear to be not fluctuating at all. Those are the sites, along the length of the wire, where each “positive” hump (created by a sine wave travelling toward the right) will be counter-balanced and offset by a “negative hump” with exactly the same height, travelling at an identical speed toward the left.

As a result, this type of response within a wire creates a “standing wave”. If the instantaneous voltage is measured at a “null node”, it would appear that nothing is happening, in terms of fluctuating voltage. Furthermore, the “null node” will not be moving, along the length of the wire; instead, it will appear to be standing still.

This can be demonstrated, in a coil, by using a “grounded lead” to test for voltages along the length of a coil. If a “grounded lead” coupled to a voltmeter is used to touch the surfaces of a series of strands in a non-insulated coil (such as a coil made of thin copper tubing, wrapped around a plastic cylindrical shape, as used in the types of large transformers used by hobbyists to create “Tesla coils” which will emit large and visually impressive electrical arcs), the “test lead” will detect no apparent voltage at a null node, which will occur at some particular strand in the coil. At a different strand of the coil, the “test lead” will detect an alternating voltage which has twice the strength and intensity of the voltage being emitted by the power supply.

If voltage is measured at a “peak node”, the voltage will be doing something which can be called, using vernacular or laymen’s terms, “the full-tilt boogie”. The AC voltage levels will be moving back and forth, between: (i) a very high and intense positive voltage, to (ii) an equally intense negative voltage. This is indicated by the “bubble” shapes shown along the wire in Fig.1C.

The “bubbles” which are shown in Fig.1C can help someone understand how standing waves are created, and how they act in a synchronised manner. However, which drawing fails to show another result which is very important in what actually happens in a standing wave. For purposes of description and analysis at this introductory level, the system can be assumed to be “ideal”, which implies a perfect “mirror-image” reflection of each wave from the right end of the wire. An “ideal” system also implies that no reflections occur at the left hand end of the wire where the power supply is located, and all “reflected” wave activity simply ceases. In real circuits and wires of this type, second and third order reflections do in fact occur, and they are used to further increase the strength and power output of these types of systems; however, those additional factors and “harmonics” should be ignored until after the basic principles of this type of system have been grasped and understood.

In an ideal system, when the reflected waves (which are travelling toward the left, in the wire segments illustrated in Fig.1) are “superimposed” on the emitted waves (travelling toward the right), the “peak” positive voltage which will be instantaneously reached, at the highest point of each “bubble” shown in Fig.1C, will occur when the positive peak of an emitted wave crosses a mirror-image positive peak of a reflected wave, travelling in the opposite direction. Accordingly, when those two “positive peak” values are added to each other, the instantaneous positive peak voltage which will occur, in the wire, will actually be twice as intense as the “positive peak” voltage being emitted by the AC power supply.

An instant later, at that exact point on that segment of wire, a negative peak voltage will be created, which will be the sum of (i) the negative peak voltage emitted by the power supply, and (ii) the negative peak voltage of a reflected wave also will pass through, travelling toward the left. At which instant, when those two negative peak voltages are added to each other, the instantaneous negative voltage which will occur, in the wire, will be twice as intense as the “negative peak” voltage being generated by the AC power supply.

A more accurate and representative visual depiction of a “standing wave” in a wire would actually show the heights of the peaks as being twice as tall as the peaks of the emitted voltage waves. However, which depiction might confuse people, so it usually is not shown in drawings of “standing waves”.

Accordingly, the instantaneous response in the wire, at a location halfway between two “null nodes”, is doing something which can fairly and properly be called “the full-tilt double double boogie”. The “double double” phrase (note which it contains not just one but two “doubles”) was added to that phrase, for two reasons:

(i) To emphasise the fact that each and every voltage peak (maximum positive, and maximum negative) will be twice as strong, and twice as intense, as the maximum positive and negative peak voltages emitted by the power supply; and,

(ii) to point out that the frequency of the superimposed “bubbles”, shown in Fig.1C, is actually twice as fast as the frequency of the AC cycle which is emitted by the power supply, as discussed below.

The “twice the intensity” result is directly comparable to what an observer will see, if a large mirror is placed behind a light bulb in an otherwise dark room. The mirror effectively keeps the room dark, everywhere behind the mirror, so there is no “magical doubling” of the light in the room; which would violate the basic law of conservation of energy. Instead, what the mirror does is to shift light away from the backside of the mirror, and keep that light energy on the reflective side of the mirror. Anyone standing in front of the mirror will see two apparent light bulbs. Both of those light bulbs (the original bulb, and the reflected image) will have the same brightness (if the mirror is perfect). Therefore, the mirror will double the intensity of the light energy reaching the observer.

That same effect, in a circuit, will happen if the end of a wire acts like a mirror. If a wire does not have any components which will cause it to become an active “emission source” (which is the behaviour of transmission
antennas and certain other components), in a way which efficiently releases voltage-created energy into the atmosphere, then the basic rules which require conservation of energy will prevent that energy from simply disappearing and ceasing to exist. As a result, even if the end of a wire is not designed to be a perfect reflector, a large portion of the voltage wave will indeed reflect off the wire tip, and travel back through the same wire, in a “second pass”.

To understand adequately, the type and amount of “wave reflection” which occurs at a wire tip, consider what happens if a light bulb is shining in a room which has shiny, glossy white paint on all the walls and ceilings; then, consider how it would look if the same light bulb were located in a room with all of the walls and ceilings painted “matt black”. The total amount of light which would be available, to carry out a task such as reading a newspaper, clearly would be much greater in the white room, because light reflects off white paint, even though white paint does not even begin to approach the type of “reflection quality or clarity” which a mirror creates. The difference in what happens, when light intensity in a room painted matt black is compared to a room painted a glossy white, does not arise from the presence or absence of “reflection quality or clarity”; instead, it is governed by the laws of conservation of energy. When light shines on to a surface which is painted matt black, the light energy is absorbed by the paint, and it literally warms the paint up. In contrast to that, glossy white paint will not absorb light energy, so it reflects the light back out, for a “second pass” through the air which fills a room.

Because of the laws of conservation of energy, and without depending on any “quality of reflectance” characteristic of wire tips, electrical energy cannot simply disappear, when it reaches the end of a wire. Instead, there are only two things which can happen to that energy:

(i) the electrical energy can be emitted into the surroundings, such as by emitting sparks, arcs, or radio-frequency signals which will carry energy; or

(ii) if the energy is not emitted by the tip of the wire, then, by simple necessity and because of the basic law of conservation of energy, it must be reflected back into the wire, and it will be forced to travel back through the wire again.

If a wire has a long and tapered tip, then the reflected wave might become somewhat diffused, and it might lose some portion of the “clarity” of the wave. However, since wavelengths in the frequencies of interest here are hundreds of meters long, the type of tip created by a conventional wire cutter will not create any significant diffusion, in a reflected wave. And, unlike the white-painted walls of a room, there is not a large area which is available, at the tip of a wire, which can create scatter, spread, or diffusion. As a result, the tip of a wire will be a relatively efficient mirror-type reflector, when an AC voltage is “pumped” into one end of the wire.

The second factor mentioned above, when the “double-double” boogie phrase was mentioned, relates to a doubling of the frequency of a standing wave. When a standing wave is created in a wire by reflection of an emitted AC voltage wave, the frequency of the standing wave is, quite literally, double the frequency of the emitted wave.

This can be seen, visually, by noting that in the emitted AC voltage, shown in Fig.1A, a single complete wavelength contains both a “positive hump” and a “negative hump”. Accordingly, three complete sine waves, divided into three segments by the imaginary vertical lines, are shown in Fig.1A.

By contrast, each and every “bubble” shown in Fig.1C depicts a complete and total “wavelength”, in a standing wave. Six of those standing wave “bubbles” fit into exactly the same length of wire which holds only 3 emitted wavelengths from the power supply.

The “frequency doubling” effect of standing waves is important, because AC systems can convey and release energy in a manner which increases, as the frequency of the AC voltage supply increases. To some extent, this is analogous to saying that, if a motor can be run at twice the speed (while still generating the same torque), then the work output of that motor can be twice as great, at the higher speed. That analogy is not entirely accurate, since work output from an electric device which uses AC power depends on “area of the curve” functions which occur when sine waves are involved. Nevertheless, as a general principle, if the frequency of the voltage peaks increases, then power output will also increase, in many types of electric circuit components.

In the three panels of Fig.1, the wire length is three times as long as the wavelength of the voltage from the power supply. However, to create standing waves, a wire length does not need to be any particular multiple of the wavelength of an AC voltage. As can be seen by considering Fig.1C, the same types of “bubbles” would be created: (i) if the wire length were exactly twice as long as the wavelength; or, (ii) if the wire length were the same length as the wavelength.
Accordingly, Fig. 2 (which includes Fig. 2A showing an emitted wave, Fig. 2B showing a reflected wave, and Fig. 2C showing the superimposed “bubbles”) shows what happens in a wire segment which has a length which is equal to a single wavelength from an AC voltage at a fixed frequency. A resonant standing wave will be formed, with a frequency which is double the frequency of the input AC voltage. The same result will apply, in a wire having any length which is an exact (integer) multiple (such as 1x, 2x, 3x, etc.) of the wavelength of the AC voltage being pushed (or forced, driven, pumped, etc.) into the wire segment.

Moving to still shorter wires, the same principle also applies to any wire with a length equal to one half of an AC voltage wavelength. As shown in Fig. 3 (which includes Fig. 3A showing an emitted wave, Fig. 3B showing a reflected wave, and Fig. 3C showing the superimposed “bubbles”), if the wire length is one half of the wavelength, a natural and resonant standing wave will still form, with a frequency which is double the frequency of the input AC voltage.
Finally, moving to a still shorter wire, the same principle also applies to any wire which has a length equal to one quarter of an AC voltage wavelength, as shown in Fig.4A, Fig.4B, and Fig.4C. Even though it does not stretch across or cover a complete “bubble”, the standing wave shown in Fig.4C is nevertheless a stable, natural, and resonant “standing wave”, with a frequency which is exactly twice the frequency of the input AC voltage.

It is possible to create partially stable and semi-resonant responses, using one eighth, one sixteenth, or shorter lengths of wire, by using additional devices which can remove electrical power from the system, or which can generate effects which are usually called “harmonics”. However, those are not the types of natural and stable responses which can be created by a simple, basic system consisting of nothing more than: (i) a wire having a fixed length and a “reflective” tip; and (ii) an AC power source with a frequency which can be “tuned” until it creates a resonant response in any wire segment having a suitable length.

Therefore, since quarter-wave wire lengths are the shortest lengths which can create natural and stable standing waves, the conventional term which is commonly used, to describe what happens when a wire creates a resonant standing-wave response, is a “quarter-wave” response.

In some devices, telescoping components (or other elements which can alter the effective length of a wire-type element) can be used to alter the ability of the element to respond to a fixed wavelength. Many types of antennas use this approach, if they need to process signals which are being transmitted on fixed and known frequencies. However, those examples are not relevant to spiral coil reactors, which will use an approach which involves tuning and adjusting the frequency of the voltage which is being supplied to a reactor, until a resonant response is observed in coils with fixed and unchanging lengths.

It should also be noted that certain types of “tuning” elements (such as capacitors, which can have either fixed or adjustable capacitance levels) can also be coupled electrically to a wire, in a manner which “emulates” adding more length to that wire. This approach can be used to alter (or increase the range of) the frequencies to which a wire circuit will respond resonantly.

The ‘Gegene’ Magnetic Arrangement.
As we have seen from what Don Smith has said, a very effective method of gaining additional power is to make a high frequency magnetic transmitter that allows several outputs to be taken from the transmitter without increasing the input power in any way. Recently, a clever idea for a simplified version of this has been shared on the web. As far as I am aware, this device was first presented by the Lithuanian ‘FreeEnergyLT’ whose website is at http://freeenergylt.narod2.ru/dynatron/
and the information then replicated and documented by J L Naudin on his website http://jnaudin.free.fr/gegene/indexen.htm and named ‘Gegene’ being short for ‘Great Efficiency Generator’. The clever idea is to use a commercial induction hot-plate as the transmitter. These have recently become available at low cost, this one:

Sold in the UK by Maplin, has power levels adjustable from 300 watts to 2000 watts, and at time of writing, costs only £30 delivered to your address. These devices operate by generating a powerful high frequency oscillating magnetic field which induces eddy currents in any magnetic material placed on the surface of the cooker. That is, cookware which is made of cast iron or steel (not stainless steel which is supposedly non-magnetic). The heating is very rapid and completely uniform across the item of cookware which is very helpful when cooking. The hot plate is controlled by sophisticated electronics which will not switch on unless there is an iron object on the plate and which varies the frequency and current in a way chosen by the designer.

The circuitry produces the magnetic field by pulsing current through a large, flat coil in the centre of the case as can be seen in this photograph of a typical induction plate with the case opened:
The brown coil gets hot, and so there are spacers on it to prevent the cool outer casing from picking up the heat of the coil. There is also a fan which draws air in from underneath the case and blows it across the coil in order to keep the heat down.

In order to use this magnetic transmitter, we need to place a suitable output coil on the plate, and power a load from the energy collected by that coil. This is a fairly recent idea and so there is still a good deal of experimentation going on, testing different coils, and various loads. It is generally agreed that the best load is a non-inductive load with halogen lamps and ordinary filament light bulbs being recommended. Halogen lamps are used in some low-cost commercial heaters, and they are very effective method of radiant heating. In his video at http://www.youtube.com/watch?v=LbAhUwHvJCE, Laurent powers seven separate 400-watt halogen lamps using a small 800-watt maximum plate which has a small 120 mm diameter transmitter coil:

No particular power output is claimed by Laurent, but as you can see, the 2800 watts of halogen lamps are brightly lit while a wattmeter on the input to the plate reads just 758 watts. It seems to be fairly clear that there is a significant power gain with this arrangement. Then, Laurent places an additional coil on top of the first one and shows it lighting a 100-watt filament light bulb very brightly:
It is actually quite difficult to see the brightness of lamps shown in a video as the video camera automatically turns down the brightness of the recording. The important point here is that there is significant power output from a second coil, without there being any increase in the power input to the transmitter coil in the induction plate.

There are many different designs of electronics in commercial induction plates. Most will not start operating until a magnetic object is placed on top of the plate. If that is done, then the object needs to be removed very promptly as it heats up very rapidly. Fortunately, most plate designs keep operating as soon as the induction process is started and so there is no problem with removing the metal cookware (or whatever is used to start the process). Laurent’s very small induction plate does not have that protection circuitry and so starts up as soon as it is switched on.

Jean-Louis Naudin uses a 2000-watt induction plate turned down to its 1000-watt setting. It has a 180 mm diameter pick-up coil. He says that for him, it is essential to have at least 1500-watts of load or else the induction plate will shut down with an error code indicating that no cookware is present.

The coils used are Tesla bi-filar pancake types, typically, attached to a thin sheet of MDF or plywood, say 2 mm thick, with superglue. Laurent’s 120 mm coil has ten turns and Jean-Louis’ 160 mm coil has sixteen turns, needing about 5 metres of twin-core wire, and Laurent’s about 2.5 metres of wire. I suggest that the wire should be rated for mains voltage and have, perhaps 1 sq. mm cross-sectional area of copper wire in each conductor. A Tesla pancake coil is wound like this:

Please remember that this arrangement involves high voltages and so is not suitable for newcomers to electronics. This presentation is strictly for information purposes only and it is not a recommendation that you attempt to implement anything shown here, and if you choose to do so, then the responsibility is yours and yours alone.

An interesting video is here: http://www.youtube.com/watch?v=SJ1MG1Q7LQ&feature=em-uploademail.

Tariel Kapanadze’s Self-Powered Generators
Tariel Kapanadze, like Don Smith, appears to have based his work on that of Nikola Tesla. There has been a video on the web, of one of his devices in operation, but it appears that the video has been removed. However, part of it can be seen here: http://www.youtube.com/watch?v=l3akywcvb9g. The video commentary was not in English and so the information gathered from it is not as complete as it might be. However, in spite of that, a number of useful things can be learned from it. Unfortunately, Tariel refuses to share the details of his designs.
The video shows a demonstration being staged in a back garden, I believe, in Turkey. Strong sunshine was casting dense shadows which made video detail less than perfect. Essentially, Tariel demonstrated one of his builds of a Tesla-style free-energy device, powering both itself and a row of five light bulbs.

One of the most encouraging things about this video is that the construction and operation was of the most basic kind, with not the slightest suggestion of expensive laboratory work or anything high-precision. This is most definitely a backyard construction within the scope of any knowledgeable person.

Electrical connections were made by twisting bare wires together:

and where necessary, tightening the twist with a pair of pliers:

This shows clearly that a high-power and very useful free-energy device can be made with the most simple of construction methods - no expensive connectors here, just a zero-cost twisted connection.
The device being displayed is a Tesla Coil powered, earth-connected system of the type already described. You will notice that the thick primary winding is not placed at one end of the central secondary winding but is much closer to the centre of the coil. Remember that Don Smith states that if the primary coil is placed centrally, then the amount of current which the coil can deliver is very large, in spite of the fact that most people think that a Tesla Coil can only produce trivial currents. Notice also that this Tesla Coil appears to be mounted on a cheap kitchen-roll holder. I have seen it said that Tariel makes a new device for each demonstration and takes it apart afterwards, so if that is correct, then it is likely that there is no great effort or expense involved in making one of these systems.

The main operational components are shown here, placed on one small table. There is a lead-acid battery (which is removed later in the demonstration), what appears to be an inverter to produce mains AC voltage from the battery, a high-voltage step-up system housed in a green box for safety reasons, a Tesla Coil, a spark gap mounted on the box and a fan-cooled component, probably a solid-state oscillator system driving the Tesla Coil. Not seen in this picture, is an item contained in a small box which might well be a high-voltage capacitor.

Two earth connections are organised. The first one is an old car radiator buried in the ground:

and the second is a bare wire wrapped around a garden tap’s metal pipe and twisted tight as shown above. It is distinctly possible that the circuit is based on this circuit of Tesla's:
Perhaps, the battery powers the inverter which produces mains voltage, which is then stepped up to a high voltage level by the enclosed electronics. This then drives the Tesla Coil, producing both very high voltage and current with the capacitor storing the energy as a reservoir. The spark gap then pulses this energy, driving the primary winding of the isolation transformer which produces a lower voltage at substantial current (depending on the current-handling capacity of the transformer itself) powering the load, which in this case, is a row of light bulbs.

The load is a row of five light bulbs hung from a brush handle placed across the backs of two chairs:

![Image of light bulbs](image)

As you can see, this is not exactly high-tech, high-cost construction here, with all of the materials being used for other things afterwards.

Initially, the battery is used to power the inverter and it is demonstrated that the current being drawn from the inverter is substantially less than the power entering the load. In conventional terms, this appears impossible, which is an indication that the conventional terms are out of date and need to be updated to include the observed facts from demonstrations such as this.

As the system is putting out a good deal more power than is required to drive it, might it not be possible to use part of the output power to provide the input power. This is often called "closing the loop" and it is demonstrated in this video as the next step.

First, the circuit is altered so that the input power connection to the inverter is taken from the output. Then the circuit is powered up using the battery as before. The battery is then disconnected and removed altogether, and the people helping with the demonstration pick up all of the active items and hold them up in the air so as to show that there are no hidden wires providing the extra power from some hidden source. The items on the table are not part of the circuit:
There is some additional information on Tariel including videos of some of his more powerful, newer designs at 
http://peswiki.com/index.php/Directory:Kapanadze_Free_Energy_Generator#Official_Website although it has to 
be said that there does not appear to be very much on him or his work available at this time.

In December 2009 an anonymous contributor e-mailed to say that Kapanadze returned to the ex-USSR republic 
of Georgia and that the video soundtrack is in the Georgian language and after the demonstration, the interview is in 
Russian. He has kindly translated the parts which relate to the device, as follows:

**Question:** What are you showing us today?  
**Answer:** This is a device which draws energy from the environment. It draws 40 watts as it starts up, but then it can power itself and provide an output of 5 kilowatts. We don't know how much energy can be drawn from the environment, but in an earlier test, we drew 200 kilowatts of power.

**Question:** Is it possible to solve the energy problems of Georgia?  
**Answer:** We consider that they have already been solved.

**Question:** Please tell us in simple terms, how your device works.  
**Answer:** (1) Power is drawn from the battery to get the device running  
(2) If we want, we can use part of the output power to drive a charger and charge the battery  
(3) When the device is running, we can remove the battery and it then operates self-powered. This particular unit can deliver 5 kilowatts of power which is enough for a family. We can easily make a version which supplies 10 kilowatts. We don't know what the practical power limit is for a unit like this. With this particular device we have here, we do not draw more than 5 kilowatts as we don't want to burn out the components which we used in this build.

**Question:** Does your invention pick up current from mains wires?  
**Answer:** The mains has nothing to do with this device. The energy produced comes directly from the environment.

**Question:** What do you call your device and do you dedicate it to anyone?  
**Answer:** I would not dream of claiming this device to be my invention, I just found something which works. This is an invention of Nikola Tesla and all the credit is his. Tesla has done so much for mankind but today he is just forgotten. This device is his invention, his work.

**Question:** Why are you so sure that this is a design of Nikola Tesla's?  
**Answer:** Because I worked from his invention - his design. I discovered how to get automatic resonance between the primary and secondary windings. The most important thing is to achieve resonance. Melnichenko came close to solving this problem. The government of Georgia refuses to take this invention seriously.

**Question:** You said that resonance must be maintained. Which parts resonate?
Answer: Here (pointing to the green box) and here (pointing to the Tesla Coil mounted on the top of the green box). The resonator is inside the green box and at present, it is secret until patented.

Question: How much would one of these units cost?
Answer: When mass produced, it would cost between 300 and 400 US dollars for a unit which has an output of 5 or 6 kilowatts.

Question: How much did it cost you to build this demonstration device?
Answer: About eight thousand (currency not specified). Parts had to be got in from twenty different places.

Question: Is this your house?
Answer: No. I rent this place because we have sold all that we have to make these devices. And, having done it, the government and many scientists say "We are not interested because a device like that is impossible and can't possibly exist!". I have not been allowed to make a presentation to them, but people who understand the Tesla Coil understand how this device works.

Kapanadze is an architect by profession and has not had any training in either physics or Electrical Engineering. The information on which this design was based was downloaded free from the internet.

One of the most important aspects of this video is the confirmation it gives for the work of Tesla and of Don Smith, in that it shows clearly, yet again, that large amounts of energy can be drawn from the local environment, without the need to burn a fuel. Another video: http://www.youtube.com/watch?v=gErefbcTz-U

People frequently ask for construction drawings or alternatively, outlets where they can buy one of his devices. Unfortunately, Tariel is not willing to share the details of his designs and so they will probably never be manufactured. Many people have tried to analyse and replicate his design.

Kapanadze Analysis by William McFreey
Shown below are two analysis papers on Tariel Kapanadze’s designs. These papers by William McFreey are written primarily for physicist, and so they may not be easily understood by you if you are not familiar with scientific symbols and notation, so please feel free to move past this section..

While William McFreey's paper is highly technical, the designs disclosed in it have been prototyped and proved to be fully functional. However, it needs to be understood that there are several ways of extracting free-energy from our local environment. For example:

1. Thomas Henry Moray demonstrated that it is possible to draw kilowatts of energy directly from the local environment, using an aerial of relatively minor dimensions.
2. Stanley Meyer demonstrated that water can be separated into a hydrogen and oxygen gas mix using tiny power levels. This allows an ordinary petrol generator to be run self-powered on water alone.
3. Bob Boyce has produced a pulsed toroidal circuit which allows a battery to recharge itself.
4. Robert Adams produced a motor/generator design where permanent magnets generate an electrical output far in excess of the power needed to operate it.
5. Carlos Benitez designed a system which is self-powered and which provides kilowatts of excess power using just simple, standard electronic components.
6. Thane Heins has built and demonstrated simple asymmetrical transformers where the output power is more than thirty times greater than the input power.
7. Clemente Figuera produced a split-transformer design where the Lenz “Law” effect does not apply and so it produces far greater output power than input power.
8. John Bedini designed a pulsed flywheel motor/generator system which ran self-powered for years. Jim Watson built a large version which had many kilowatts of excess power.
9. Dr Oleg Gritskevitch built a self-powered motionless toroidal generator which produced 1.5 megawatts for two years.
10. James Hardy has demonstrated how the jet of water from a powerful water-pump can spin a generator fast enough to self-power the pump and supply additional electrical power for other equipment.
11. Mikhail Dmitriev has produced a gravity-powered generator which uses a small electrical motor to deflect weights on a rotor and that system produces kilowatts of excess power drawn from the gravitational field.
12. Lawrence Tseung has shown how a magnet embedded in an iron frame produces a greater output than the input power when it is powered with DC pulses.

13. Lawrence Tseung has also demonstrated that a heavy rotor powered by electromagnet pulses can have a substantially greater output power than the power needed to drive it.

14. Veljko Milkovic has demonstrated how combining a pendulum with a lever produces a system which has far greater mechanical output power than the mechanical power needed to operate it.

15. Richard Willis has shown how pulsing a magnetic material can produce kilowatts of excess power.

16. James Kwok has shown that introducing air into the bottom of a tank of water can generate tens of kilowatts of excess power through buoyancy.

17. Dietmar Hohl has published his design where permanent magnets cause permanent rotation of a cylinder without the need for any external source of power.

18. Mummar Yildiz has demonstrated a 300 watt permanent magnet only motor and then taken the motor completely apart to prove that there is no other source of power.

19. Lawrence Tseung has produced a variation on the Joule Thief circuit which has greater output power than the input power (something which I personally have built and can confirm).

20. Floyd Sweet produced a system where a tiny amount of power is used to wobble the magnetic poles of a specially conditioned magnet, producing thousands of times greater output power than the input power needed to power the system.

There are many other proven systems. The two papers from William McFreey can be freely downloaded from: http://www.free-energy-info.tuks.nl/McFreey.pdf.

### The Cold Electricity Coil of ‘UFOpolitics’

A man who uses the forum ID of ‘UFOpolitics’ has been sharing his insights and experiences on various different forums, such as the one dealing directly with the production and use of cold electricity in solid-state circuits: http://www.energeticforum.com/renewable-energy/10529-my-motors-got-me-tap-into-radiant-energy-1.html. His insights are unusual and very important. His basic statement is that if a coil is pulsed, using a circuit like this:

![Circuit Diagram](image)

then conventional hot electricity pulses the coil when the transistor is switched ON, but if that current is switched OFF rapidly, then there is an inflow of cold electricity into the coil from the surrounding environment. That inflow of energy can be collected and diverted to power a load through the use of two high-speed diodes which can carry considerable current as the power inflow is substantial. The inflow of energy occurs when the transistor is switched OFF and so it is desirable to have the transistor switched off for most of the time, in other words, a low percentage Duty Cycle for the transistor. There must be a significant load on the cold electricity output. If there is not, then the cold electricity will flow back into the hot electricity section of the circuit and it may damage the transistors. Tom Bearden states that resistors boost cold electricity rather than hindering it’s flow, so the load should be a coil, a DC motor with brushes or a fluorescent light bulb.

It has been observed that the incoming energy tends to flow inwards towards the centre of the coil, so an additional method of collecting this extra energy is to place a second coil inside the main coil, and wound in the same direction as it, like this:
This provides two separate, independent cold electricity power outputs. Diodes are not needed for the inner ‘secondary’ coil. This inner coil is a pick-up coil and is not related in any way to the number of turns in the hot electricity pulsing coil. Instead, this coil collects inflowing cold electricity during the period when the pulsing coil is switched OFF. The hot electricity pulsing coil can be wound directly on top of the extra pick-up coil or the extra coil can be wound separately and placed inside the main coil spool.

Very surprisingly, it is recommended that the powerful high-speed diode used to channel the cold electricity out of the circuit, be followed by a small 1N4148 silicon epitaxial planar high-speed diode (75V 0.45A) as this is said to clean up the cold electricity output even more. It is important that the cold electricity has to encounter the more powerful silicon diodes before reaching the 1N4148 diodes, so the order of the diodes is very important, and should be as shown here:

Alternative diodes for the NTE576 (6A, 35nS, 400V) are the NTE577 (5A, 70nS, 1000V) and the HFA16PB (16A, 19nS, 600V). The main requirement is high-speed operation, voltage rating of at least 400V and current rating of at least 5 amps.

There is one additional thing to be done with this circuit when a DC output is required and that is to apply filtering to the output. First, when the energy has passed through the NTE576 (or equivalent) power diodes, it encounters a high-frequency (low capacity) high quality film capacitor placed across the output in order to siphon off any high-frequency voltage ripple before it is passed through the small 1N4148 diodes and into a smoothing and storage electrolytic capacitor. Storing the cold electricity in the electrolytic capacitor converts it into conventional hot electricity.
While this circuit looks like something which you just switch on and it works, that is not the case as there is an essential start-up procedure where the signal applied to the transistor is started at just a few cycles per second and 50% duty cycle and that input is then adjusted carefully and slowly while monitoring the voltages and currents produced by the circuit. This is a seriously powerful system with the capability of producing a major power output.

It is very important that the circuit is not powered up without a suitable load on the cold electricity output. A suitable load is a self-ballasted 230-volt fluorescent light. It must be understood that just flipping the power switch to its ON position is not sufficient to get an inflow of cold electricity. Instead, it is necessary to progress the start-up sequence carefully, and a fluorescent light is particularly helpful for doing this although a neon bulb is also a popular choice of temporary load, because these devices allow the current flow in the load to be assessed visually.

Before switch-on, the input oscillator is set to 50% duty cycle and minimum frequency. Then the frequency is raised very slowly, causing the lamp to start flashing. As the frequency is raised, the current drawn from the battery needs to be monitored as it is the current flowing through the transistor, and the current is kept down by lowering the duty cycle progressively. This process is continued carefully and if successful, the colour of the light produced will initially be purple or green before reaching continuous bright white light. Videos showing the light produced and the fact that it is not dangerous to life or affected by water can be seen at http://www.youtube.com/watch?v=W1KALMgFscg&list=UUdmFG5BeS0YnD2b5zasXXng&index=1&feature=plcp.

The driving force is a series of powerful magnetic pulses, and implementing the physical circuit to achieve that requires careful construction. The battery driving the circuit is a 36 volt combination of cells. The coil is wound as an air-core construction on a 2-inch (50 mm) diameter spool and the DC resistance is arranged to be about 1.4 or 1.5 ohms. This, in turn, requires a substantial drive from the transistor and so it is normal to connect six powerful output transistors in parallel in order to spread the current flow between them as well as dissipating the heat generated across several transistors bolted to a common heat-sink of generous area.

How the coil is wound is something to consider. The objective is to have a coil of about 1.5 ohm resistance and which has the maximum magnetic effect for the current passed through it. Copper wire has become very expensive and so it would be very costly to wind the coil with vast lengths of thick wire, not to mention the very large size and great weight which would be produced by doing that. The copper wire options in Europe are typically to work with half-kilogram reels of wire. The details of some of these are as follows:
We can see from this that a 500 gram reel of 14 swg wire has a total resistance of just 0.09 ohms and so it would take sixteen reels (weighing 8 kilograms and costing a lot of money) to wind just a one-strand coil using that wire, producing a coil which could carry a current of 9.3 amps. As opposed to that, a single reel of 28 swg could provide 52 separate windings, which when connected in parallel, could carry 15 amps as well as costing and weighing far less. It would be tedious, but not impossible, to wind a 52-strand coil, so a more reasonable number of strands connected in parallel might be used. We are aiming at a DC resistance of about 1.45 ohms in any coil arrangement which we select.

The magnetic field produced by a single strand is generally less than the magnetic field produced by two strands carrying the same total current. So, if we were to pick 22 swg wire, then we could measure out four 133.5 metre lengths, join them at the start, and wind the four strands simultaneously, side-by-side to form a coil with a DC resistance of 1.45 ohms. It is important that the strands are exactly the same length so that they carry exactly the same current and no one strand gets overloaded with current due to it having a lower resistance than the other strands. It should be realised that as the maximum current which the wire can carry is 4.8 amps and the resistance is only 1.45 ohms, the maximum continuous DC voltage which can be sustained by the coil is only 7 volts, and so as a 36-volt battery is being used, we must adjust the frequency and duty cycle very carefully, especially since we are starting at very low frequencies. If the full battery voltage is applied continuously to the coil, then the coil will be destroyed.

Various members of the forum have suggested, built and tested different circuits for feeding a variable-frequency variable-duty-cycle drive signal to the output transistor. However, 'UFOpolitics' recommends a simple 555 timer circuit. If you are not familiar with electronic circuits, then read chapter 12 which explains them in some detail, including the 555 timer family of circuits. The point stressed by 'UFOpolitics' is that the output taken from pin 3 of the 555 chip passes first through a 100 ohm resistor and then, every transistor gets a separate feed via a two resistor voltage divider pair. The 47K Gate-to-Ground resistor is to ensure that the FET turns off properly. It may be possible to increase the value of these resistors but they should never be less than 47K.

The thick lines in this diagram indicate heavy-duty wiring which can carry high currents without generating any real heat when doing so. It is also recommended that although the FET has an internal diode, an extra external high-speed diode (NTE576 or similar), be connected across each FET in order to boost the switching speed:
A FET has a gate capacitance of about 1 nF. The faster it can be charged / discharged the faster the FET will switch (and stay cool). What determines the speed of charge / discharge for the gate capacitance is the length of wire from driver to gate or gates is inductance (where one metre of wire produces 0.05µH). In addition to that, different lengths of Gate connection wire will create different switching delays and the different inductances can then initiate High Frequency oscillations with repetitive ON/OFF/ON/OFF switching actions. The result might be burned FETS and lack of cold electricity activities.

Another point made by ‘UFOpolitics’ is that the physical layout should have the connecting wires or tracks kept as short as possible and he suggests this layout:

There are two things to note here. Firstly, the 100 ohm resistor coming from pin 3 of the 555 timer IC is positioned centrally between the six FET transistors mounted on the aluminium heat-sink, and that point is carried closer to each FET with a low-resistance conductor to give a good-quality link for the resistors feeding the Gate of each FET. Secondly, the heat-sink itself is also used to provide a low-resistance electrical connection to the coil which the FETs are driving. The connection to the heat-sink is via a nut and bolt clamping a solder tag firmly to a cleaned area of the heat-sink. Each FET is electrically connected to the heat sink through it’s mounting tag which forms it’s heat-sink connection as well as connecting to the Drain of the Transistor. However, if the aluminium heat sink is a black anodised type, then, apart from cleaning between each FET and the heat-sink contact area, it is worth running a thick wire also linking the central FET pins to the output wire connection point.

The transistors used in the prototype, and recommended for replications are the NTE2397. This is not a very common transistor in Europe at this time and so the popular IRF740 might perhaps be used as it appears to have all of the main characteristics of the NTE2397 transistor. ‘UFOpolitics’ suggests the 2SK2837 (500V, 20A, 80A pulsed), or the IRFP460 (500V, 0.27 Ohm, 20A and 80A pulsed).
As the 555 timer has a maximum supply voltage of 15 volts, an LM317N voltage-stabiliser chip is used to create a 12-volt supply from the 36-volt battery (a 24V battery could be used):

![Diagram of 555 timer circuit](image)

The LM317N integrated circuit should be attached to a good heat sink as it is dropping off 24 of the 36 volts powering the circuit, and so, has to dissipate twice the power that the NE555 chip uses:

![Diagram of LM317N](image)

There are various pulsing circuits which have been used successfully with this system. 'UFOpolitics' considers the NE555 chip to be the most straightforward, so perhaps my suggestion for this arrangement might be a suitable choice:

![Diagram of pulsing circuit](image)

This gives fine control of the frequency and independent adjustment of the Mark/Space ratio or 'Duty Cycle' and it needs only three very cheap components other than the controls. If the expensive multi-turn high quality variable resistors are available, then the 4.7K 'fine-tune' variable resistor can be omitted as those variable resistors make the adjustments easier to control. The 'Lin.' in the diagram stands for 'Linear' which means that the resistance varies steadily at a constant rate as the shaft of the variable resistor is rotated.
In the ‘UFOpolitics’ circuit, it is important to turn the frequency down to its minimum value and set the Mark/Space ratio to 50%, before powering the circuit down. Otherwise it would be easy to power the circuit up with a much higher frequency than is advisable and so, causing damage to some of the circuit components.

There are ways to boost the performance over what has already been described. One way is to insert a stainless steel core inside the coil. Stainless steel is supposed to be non-magnetic but in practice, that is not always the case. However, ideally, this steel core is improved by altering its crystalline structure by heating it up and then quenching it by submerging it in cold water.

Another improvement is to isolate the coil better at switch-off through the use of a second transistor. Having a ‘switched-off’ transistor at each end of the coil certainly blocks the flow of hot electricity, but if Tom Bearden is correct, the resistance of the transistors in their OFF state will actually boost the flow of cold electricity as it reacts in the reverse way to how hot electricity reacts. The arrangement is like this:

While this looks like a very simple circuit to implement, that is not the case. The upper transistor is switched ON by the voltage difference between it’s Gate “G” and it’s Source “S”. But, the voltage at it’s Source is not fixed but varies rapidly due to the changing current in the coil, and that does not help when solid and reliable switching of the upper transistor is needed. A P-channel FET could be used instead and that would have it’s Source connected to the fixed voltage of the Plus of the 36V battery. That would help the switching enormously, but there would still be timing issues between the two transistors switching ON and OFF at exactly the same time. Other circuits have been suggested for doing that type of switching, but in the early stages, ‘UFOpolitics’ recommends that things be kept as simple as possible, so using just one transistor is the best option.

Switching speed is an item of major importance, even to the extent that the reduction in the speed of switching caused by using more than one transistor in parallel has caused the suggestion to be made that it might actually be a better option to use just one FET since these high-performance FETs are capable of carrying the whole of the switching current, and it is mainly to lower the FET operating temperature that multiple FET use is suggested. Every extra FET used in parallel, slows the switching down. However, it should be realised that there is a somewhat greater risk of burning the FET out if just one is used.

The coil dimensions recommended are two-inch (50 mm) diameter and 2-inch length. The wound coil is likely to be about three-inches (75 mm) so making the flange diameter 4-inches (100 mm) is realistic:
The recommended material is fibreglass which has high heat-resisting properties as well as being easy to work, the personal choice of ‘UFOPolitics’ is Polyester Resin with Methyl Ethyl Kethol (MEK) Hardener. A suggested alternative is acrylic, which is not as heat resistant. Acrylic is excellent for high-frequency applications but this circuitry does not operate at high frequencies. Whatever spool material is chosen, it needs to be non-magnetic.

When connected in the circuit, the start of the coil winding wire goes to the battery positive.

Here is another coil wound on acrylic tube and with all four diodes connected to the ends of the coil:

It should be understood that cold electricity provides almost unlimited power and it has uses which are not readily understood by many people.

‘UFOPolitics’ suggests that the hot electricity drive circuitry be tested initially using just a resistive load. If everything checks out correctly, then test with a lesser value resistor in series with the coil, and if that checks out satisfactorily, then testing cautiously with the coil on it's own.

Cold electricity can charge batteries rapidly and after a series of charge and discharge cycles, batteries become “conditioned” to cold electricity and the experiences of Electrodyne Corp. staff show that large conditioned batteries which are fully discharged, can be recharged in under one minute. A member of the present forum has tried this with the ‘UFOPolitics’ circuit and he reports:

Yesterday a friend and I took 6 identical, old, 12V, 115Ah batteries and made two 36V banks. We set up bank “A” (the better three) to power the device to charge bank “B”. Bank A was 37.00v at rest and Bank B was 34.94V.
My lowest frequency was 133Hz (I need to change my cap and add another 100k pot with the one which is controlling the frequency) and the duty cycle was at 13%. We started at 2A draw on the Primary circuit.

As I raised the frequency, the batteries on charge jumped up to 38.4V then dropped evenly to 36.27V and started up again (at about 0.01V every 2 seconds). After two and a half hours, they were up to 39.94V. At this point we stopped the charging and let everything rest for 10 minutes. So far everything seems very normal for this kind of charging, except that the device appears to be very stable and powerful...pushing the batteries right on up continuously. The Primary battery voltage dropped initially to 36.20V and stayed there the whole time, then recovered to 36.98V during the 10 minute rest.

Then we switched battery banks A and B and charged the opposite way for about 20 minutes. We stopped and rested things again, swapped the banks back and started charging bank B again for another 20 minutes and stopped. After letting the batteries rest for a few hours in order to get truer readings, bank A was at 37.07V and bank B was at 38.32V. Both battery banks had gained power. These were not very good batteries, either. One of the bank B batteries was at 10.69V at the start. Another interesting note: The amp draw on the Primary dropped from 2A to 1.5A as the frequency was raised from 133Hz to about 550Hz.

This was with the very first use of cold electricity with these low-grade batteries and a major improvement can be expected after many additional charge/discharge cycles. This completely overcomes the factors which make a battery bank unsuitable for household power. If an entire battery bank can be recharged in just minutes, then it opens the way for serious household power using a battery bank.

Cold electricity can also run motors very powerfully. Forum member ‘Netica’ found that putting a capacitor across the motor terminals improved the running very substantially, giving impressive performance. His video of this is at http://www.youtube.com/watch?v=7uAYKhrPDPc and the motor, running off an air-core coil with no steel insert. His set-up looks like this:

![Motor set-up](image)

It is also possible to submerge cold electricity circuits in water without causing any harm:
A video of this is located here: http://www.youtube.com/watch?v=W1KALMgFscg&feature=channel&list=UL including demonstrating the use of very powerful light bulbs. A general running demonstration is here: http://www.youtube.com/watch?v=yVzhKpEqUgc&feature=player_embedded.

Stanley Meyer's Electrical Particle Generator.
Stan, who is famous for his water-splitting and related automotive achievements, actually held about forty patents on a wide range of inventions. Here is one of his patents which circulates magnetic particles in a fluid, and while the fluid does move, none of the other components in the device move and a high level of constructional skills is not called for. This is a highly efficient generator of electricity.

This is a slightly re-worded excerpt from this Stan Meyer patent. Although it does not state it in the patent, Stan appears to make it understood that this system produces a significant power gain – something with Patent Offices find very difficult to accept.

Patent CA 1,213,671 4th February 1983 Inventor: Stanley A. Meyer

ELECTRICAL PARTICLE GENERATOR

ABSTRACT
An electrical particle generator comprising a non-magnetic pipe in a closed loop having a substantial amount of magnetised particles encapsulated inside it. A magnetic accelerator assembly is positioned on the pipe, which has an inductive primary winding and a low-voltage input to the winding. A secondary winding is positioned on the pipe opposite to the primary winding. Upon voltage being applied to the primary winding, the magnetised particles are passed through the magnetic accelerator assembly with increased velocity. These accelerated particles passing through the pipe, induce an electrical voltage/current potential as they pass through the secondary winding. The increased secondary voltage is utilised in an amplifier arrangement.

BACKGROUND AND PRIOR ART
The prior art teachings expound the fundamental principle that a magnetic field passing through inductive windings will generate a voltage/current or enhance the voltage across it if the winding is a secondary winding.
It is also taught by the prior art, that a magnetic element in a primary inductive field will be attracted at one end of the coil and repelled at the other end. That is, a moving magnetic element will be accelerated in motion by the attraction and repulsion of the magnetic field of the primary inductive winding.

In the conventional step-up transfer, the voltage across the secondary is a function of the number of turns in the secondary relative to the number of turns in the primary winding. Other factors are the diameter of the wire and whether the core is air or a magnetic material.

**SUMMARY OF THE INVENTION**
The present invention utilises the basic principle of the particle accelerator and the principle of inducing a voltage in a secondary winding by passing a magnetic element through it.

The structure comprises a primary voltage inductive winding having a magnetic core, plus a low-voltage input. There is a secondary winding with a greater number of turns than the turns in the primary winding, plus an output for using the voltage induced in that winding.

The primary winding and core are positioned on one side of an endless, closed-loop, non-magnetic pipe. The secondary windings are positioned on the opposite side of the endless pipe. The pipe is filled with discrete magnetic particles, preferably of a gas, and each particle has a magnetic polarised charge placed on it.

Due to their magnetic polarisation charges, the particles will sustain some motion. As the particles approach the accelerator assembly, which is the primary coil, the magnetic field generated by the coil attracts the particles and accelerates them through the coil. As each particles passes through the coil, the repulsion end of the coil boosts the particle on it’s way. This causes each particle to exit from the coil with an increased velocity.

As the magnetic particles pass through the secondary coil winding, they induce a voltage across the ends of that coil. Due to the larger number of turns, this induced voltage is much higher than the voltage across the primary coil.

The main objective of this invention is to provide an electrical generator which is capable of producing a voltage/current of much greater magnitude than has been possible previously. Another objective is to provide a generator which uses magnetic particles and a magnetic accelerator. Another object is to provide a generator which can control the amplitude of the output. Another objective is to provide a generator which can be used with DC, AC, pulsed or other configurations of waveforms. Another objective is to provide a generator which can be used in either a single-phase or a 3-phase electrical system. Another objective is to provide a generator for developing magnetised particles for use in an electrical particle generator. Another objective is to provide an electrical generator which uses readily available components to construct a simple embodiment of this invention.

**BRIEF DESCRIPTION OF THE DRAWINGS**

![Diagram](image)

**Fig.1** is a simplified illustration of the principles of the invention, shown partially in cross-section and partially pictorially.
Fig. 2 is an electrical schematic illustration of the embodiment shown in Fig. 1.

Fig. 3 is an illustration similar to Fig. 2 but which is adaptable to 3-phase use.

Fig. 4 is a first alternative arrangement of a preferred implementation of the invention.
Fig. 5 is another alternative arrangement of a preferred embodiment of the invention.

Fig. 6 is another alternative arrangement of a preferred embodiment of this invention.
Fig. 7 is another alternative arrangement of a preferred embodiment of this invention.

![Diagram of Fig. 7](image)

Fig. 8 is another alternative arrangement of a preferred embodiment of this invention.

![Diagram of Fig. 8](image)

Fig. 9 is an alternative arrangement for a magnetic drive particle accelerator assembly.

![Diagram of Fig. 9](image)
Fig. 10 is an illustration of an alternative method of producing the magnetised particles used in this invention.

DETAILED DESCRIPTION

Fig. 1 and Fig. 2 show the invention in its most simplified schematic form:

It comprises a primary coil magnetic accelerator assembly 10, a closed-loop non-magnetic pipe 30, and a secondary winding 20. The magnetic accelerator assembly is comprised of primary windings 12, a magnetic core 14, and voltage taps 16. The primary windings are positioned around end 32 of the closed-loop pipe 30 which is made from non-magnetic tubing.
At the opposite end 34 of the closed-loop pipe 30, are the secondary windings 20. The end terminals 22 of the secondary winding 20, allow the voltage generated in the winding to be used. Contained inside pipe 30, there is a substantial number of magnetic particles 40 as shown in Fig.2. The particles 40 must be light enough to be freely mobile and so may be particles suspended in a fluid medium such as gas, liquid or light-weight movable solid particles. Of these options, the use of a gas is preferred. If solid particles are used as the transporting medium, then it may be desirable to remove all air from inside the pipe in order to reduce the resistance to the flowing particles. Each of the particles 40 is magnetised and the following description refers to one individual particle and not to the mass of particles as a whole.

The voltage applied to terminals 16 of primary winding 12, is a low voltage, and it’s magnitude may be used as an input signal control. By varying the input voltage, the accelerator will vary the speed of the circulating particles, which will, in turn, vary the magnitude of the voltage/current output of the secondary winding 20. The output 22 of the secondary transformer winding 20, is a high voltage/current output.

It can be appreciated that the system shown in Fig.1 and Fig.2 where there is just one closed loop, provides a single-phase output in the secondary winding 20. Fig.3 shows a closed-loop arrangement with three parallel non-magnetic tubes 31, 33 and 35, each with its own output winding 21, 23 and 25. Each of these three windings are a single-phase output, and as their three pipes share a common input junction and a common output junction, these three output windings provide a balanced 3-phase electrical system.

Fig.4 shows an electrical power generator which operates exactly the same as those shown in Fig.1 and Fig.2. Here, the arrangement is for use in an environment where there is a high moisture content. An insulating coating 45, completely covers pipe 30 as well as all of the electrical windings. Fig.4 also illustrates the fact that increasing the number of turns for any given wire diameter increases the voltage/current output of the device. In this physical configuration, both vertical and horizontal directions are used which allows a large-diameter pipe to be used with a substantial number of turns of heavy-gauge high-current wire.
**Fig. 5** shows a coil arrangement 49, which uses the entire magnetic flux in the closed-loop tubing 47. This is a coaxial arrangement with the primary winding 43 as a central core.

**Fig. 6** illustrates a concentric spiral configuration of the tubing 50, with the secondary windings 53 covering it completely.
Fig. 7 shows an arrangement where the particle accelerator 10 is wound over the tubing 30 in much the same way as in Fig. 1 and Fig. 2. However, in this arrangement, the tubing 30 is a continuous closed loop arranged in a series-parallel configuration where there are three secondary windings providing three separate outputs while the tubing 30 runs in series through those three windings.

Fig. 8 shows a configuration which is the reverse of that shown in Fig. 7. Here, there are several pick-up coils wound in series and unlike the earlier configurations, the tubing 80 is not continuous. In this arrangement, there is an input manifold 82, and an output manifold 84, and several separate tubes 60a, 60b, 60c, ..., 60n interconnecting those two manifolds. Each of those separate tubes has its own separate secondary coil 70a, 70b, 70c, ..., 70n wound on it.
The magnetic particle accelerator 10, can be different in design to that shown in Fig.1. Fig.9 shows a mechanical particle accelerator 100. In this arrangement, the magnetic particles 102 are permanently magnetised prior to being encapsulated in the non-magnetic pipe 110. The particles 102 are accelerated by fan blade or pump 104 rotated by mechanical drive assembly 106. The mechanical drive for assembly 106 may be a belt-drive pulley 112, or similar device driven by an electric motor. A sealing bearing 114 keeps the particles 102 inside the pipe 110.

It has been stated that the magnetic particles traversing the secondary coils, generate a voltage/current in them. It must be understood, however, that that the particles are actually traversing the magnetic field of those coils.

Also, the pipe 30 has been described as a non-magnetic pipe. There are certain non-magnetic pipes which would not work with this invention. Pipe 30 must be capable of passing magnetic lines of force.

A significant feature of each of the various embodiments already described, is the generation of the magnetic particles which are encapsulated within the tubing.

Fig.10 shows an apparatus for carrying out the process of vaporising material to produce suitable particles which are then magnetised by being subjected to a magnetic field. The chamber 155 is an evacuated chamber having
electrodes, made from magnetisable metal, 160 and 162. A voltage is applied between terminals 150 and 152, and this drives a current through terminals 154 and 156, to spark-gap electrodes 160 and 162, generating an arc which vaporises the tip material of the electrodes, producing particles 180. These particles rise and enter tube 190, passing through a magnetic field generator 175. This gives each particle a magnetic charge and they continue on their way as magnetically-charged particles 185, passing through port 190 to reach the electrical particle generator described above.

In the simplified embodiment shown in Fig.1 and Fig.2, as well as the other preferred embodiments mentioned, it was indicated that a low voltage was applied to the particle accelerator 10. Upon acceleration, a high voltage/current would be induced in the secondary pick-up coil 20. A most significant advantage of the present invention is that the voltage amplification is not related to the shape of the waveform of the input voltage. Specifically, if the input is DC a DC voltage will be output. An AC input will produce an AC output. A pulsed voltage input will produce a pulsed voltage output and an input voltage of any other configuration will produce an output having that same configuration.

The Work of Russ Gries.
Russ Gries has produced a video presentation and analysis of the above Stan Meyer patent. http://www.youtube.com/watch?v=OnAmTmxBpAQ.

The very experienced Alex Petty is joining with Russ in working on replicating Stan’s system and Alex’s web site is at www.alexpetty.com. A discussion forum linked to this is at http://open-source-energy.org/forum/ and there is information at http://www.overunity.com/index.php?topic=5805.285 and high-resolution pictures can also be seen in Russ’ video at http://www.youtube.com/watch?v=JOarpi6sDD4. Russ’ own website is at http://rwgresearch.com/ and an additional video of the most recent developmental work being undertaken at: http://www.youtube.com/watch?v=adzVQRsS1KY&feature=youtu.be.

There are various important things which are commented on and Russ is to be commended for drawing attention to them. For the moment, please forget about HHO as that is a separate issue. As far as I can see, the patent does not claim that the device is COP>1 but instead that the device is a power transformer which potentially has a greater power output than conventional transformers since there is no Lenz Law reverse magnetic path from the output coil winding to affect the input power.

Having said that, Stan in his video points out ways to boost the power of the device, namely:

1. Increase the strength of the magnetic particles
2. Increase the speed of the magnetic particles
3. Lower the distance between the magnetic particles and the output winding.

The magnetic particles can be produced in various ways, but the most effective appears to be by filling the arcing chamber with argon gas and using iron, nickel or cobalt electrodes. The reason for this is that the electric arc does not only generate minute particles of the electrode material, but it also interacts with the argon, stripping off electrons and causing some of the metal particles to combine with the modified argon gas molecules to form a magnetic gas. That gas will always remain a magnetic gas due to the atomic bonding as it is not just minute particles of metal physically suspended in a gas due to their tiny size.

You will recall from chapter 1, that the very successful ShenHe Wang magnet motor/generator has a magnetic liquid as a key component. Here, Stan is producing a much lighter magnetic gas and the advantage of that lightness is that it can be boosted to very high speeds without any danger. The larger the number of modified argon molecules, the greater the magnetic effect when they pass through a coil of wire. The argon gas can be passed through the arc chamber over and over again so that a very high percentage of the gas is magnetic. Alternatively, if you are sophisticated in the design of the particle generator, you can arrange for the molecules which have become magnetic, to be pulled off into storage by a magnetic field.

Stan talks about pumping the magnetic gas through whatever pipe loop arrangement you decide to use, by a pump, but he promptly moves on to using a magnetic coil to boost the gas forward as the coil has no moving parts and so, no mechanical wear. This is only one reason. The main reason is that with magnetic acceleration, the gas speed can become very high indeed and in his video he talks about the speed of light. However, I personally do not believe that anything remotely like a speed that great could be achieved inside a pipe loop of small diameter. Nevertheless, speeds well in excess of what a mechanical pump can achieve are likely to be produced by magnetic acceleration.
Russ, in his discussion, points out that on most of Stan’s surviving prototypes, the coil which is used for the acceleration is constructed using several apparently separate coils, and he speculates that each coil section is powered sequentially, causing a rippling magnetic field. While that is definitely possible, I don’t see that a style of coil powering would have any advantage as opposed to powering all of the coils continuously. However, if sequential powering is believed to be an advantage, then the ‘Divide-by-N’ circuitry of chapter 12 can be used to provide the sequential powering or any more complex sequence.

Stan then points out that the output voltage can be increased by increasing the number of turns on the output coil and/or having additional output coils. This is easily understood conventional electrics. But, he then goes on to point out that the output will also be increased if the electrons of the modified argon molecules are raised to a high orbital level. This places the electromagnetic electrons (as described in chapter 11) closer to the output coils and presumably also allows the gas to be accelerated to a greater speed by the driving magnetic field.

This power boosting of the gas is achieved using Stan’s “Gas Processor” described in chapter 10. The Gas Processor pumps electromagnetic energy into the gas through the use of banks of Light-Emitting Diodes which produce light of the correct wavelength to add energy to that particular gas.

If you check on the internet for the wavelength of argon, you find conflicting information, with some sites saying that the wavelength is 1090 nanometres ("nm") and most others saying both 488 nm and 514.5 nm. Most LEDs produce a band of frequencies, so it would be a case of picking LEDs whose band of frequencies include the wanted wavelength.

The Gas Processor itself, consists of a central tube which is polished to a mirror finish on the outside, surrounded by a larger tube which is highly polished on the inside. The LED light is then bounced between these polished surfaces until it is absorbed by the gas which is passed through the gap between the two tubes. This is not easy to illustrate, but it might be shown like this:

In Stan’s design, he uses six columns of sixteen LEDs, with each column of LEDs spaced out evenly around the outer tube. So, to boost the Magnetic Particle Generator to greater power levels, a Gas Processor is placed in the loop of tubing:
The Gas Processor normally has a coil mounted at each end and it may be convenient to use coils in those positions as accelerator coils. It may also be an advantage to apply a pulsed high-voltage between the inner and outer tubes of the Gas Processor. As it stands, this looks as if it has a high possibility of being a COP>1 electrical device.

The E-Stress Power Generation System

On the seventh of September 2013 a man with the ID of 'harisingh' published the following information. I have tried to contact him to ask his permission to publish his work, but without any success. I have no information on it other than what is shown here. What he says is:

The E-Stress Power Generating System is a most intriguing over-unity power generating project. It is extremely versatile while being relatively easy to construct and it is readily upgradable.

The Golden Key or Golden Mean is the principle which allows this device to draw power directly from the e-field's relative vacuum energy density using induction-less coils. What makes this design so unique can be seen from the following illustrations. What makes this dual induction-less coil so special is that it nullifies the effects of electrostatic induction using only a fraction of the power required to sustain the charge-displacement which creates the affecting E-field. In conventional electronic circuits, coils and capacitors are generally kept away from each other, but in this circuit, their interaction is the key to success!

The E-Stress Amplifier consists of three cylindrical capacitors and two induction-less coils with external circuitry designed to start-up and maintain the entire system and load. The interior and exterior capacitors, CDI and CDE, are charged up and kept charged by a voltage source $V_c$ which is in the range of 50 to 90 volts DC. The charge on these capacitors remains for a long time, governed by the resistance of the dielectric, (provided that there are no accidental short circuits) so, the energy required to maintain the charge on these capacitors is minimal.

The third capacitor $C_r$, is sandwiched between the interior and exterior capacitors and is independent of $V_c$. When the other two capacitors, CDI and CDE, become charged, capacitor $C_r$ becomes charged as well but at a slightly lower voltage due to dielectric voltage drop. This charging effect is a result of electrostatic induction. Separating the concentric capacitors are two special induction-less coils. When current passes through these coils, the electrostatic induction forces are temporarily neutralised, allowing the charged capacitor $C_r$ to discharge and oscillate with an exterior power coil or transformer as shown in Fig.7. The induction-less coils $L_o$ are pulsed with DC at the same rate as the natural resonant frequency of the tank circuit ($C_rL_r$). Keeping the pulsing rate within 10% of the tank circuit's resonant frequency will maintain maximum output power. Because of the flexibility in the construction parameters, determining the resonant frequency and power capabilities will be difficult without advanced analysing equipment. So to overcome these difficulties, a variable-frequency oscillator can be used as it allows ready determination of the appropriate frequency range needed. A steady constant load will make this determination easier as well. When the maximum output power is reached, you can measure the resistance of the oscillator's variable resistor to aid in determining, and finally setting, oscillation at the natural resonant frequency of the tank circuit. An additional 1K ohm variable resistor can be connected in series with the 100K variable resistor shown, to allow easy "fine" tuning.
Fig. 1 shows the general layout of the entire E-Stress Power System. This diagram illustrates the driver core and the variable frequency oscillator which determines the tank circuit resonance. Fig. 1 also shows the DC power source of around 50 to 90 volts, which initially charges the "core" capacitor CDI / CDE. Also shown in this diagram is the resonant coil and power output or "pickup" coil.

Fig. 2 shows the "driver core" in a cutaway, perspective diagram. The PVC plastic "core" material can be a 6 inch (150 mm) diameter foot long (300 mm) piece of PVC pipe in this scaled-down model system. In this diagram, please note the inner and outer one-layer capacitor capacitors CDE and CDI. Also note that the middle capacitor
(Cr) is a three-layer capacitor made from heavy aluminium foil or stainless steel. The induction-less coils can be seen in two places on either side of capacitor CR. The induction-less coils are made from solid gauge #20 to #30 magnet wire (0.812 mm to 0.255 mm diameter enamelled copper wire).

Fig.3 above, illustrates how the centre driver "core" is constructed. There are six basic steps to constructing the driver "core" assembly. First begin with the PVC pipe as shown and begin wrapping the first capacitor CDI. Step two shows the first induction-less coil L1. Note that for the induction-less coil, the wire is "folded" back and the two conductors are wound together as shown. This coil is single-wound with #18 to #22 gauge wire (1.024 mm to 0.644 mm diameter). Step three shows the centre capacitor Cr. This capacitor is created in the same manner as the previous capacitor except that it has three layers of turns. Step four illustrates the second induction-less coil which is wound in the same direction as the first coil. This second coil Lo is single-layer. Step five is the final capacitor CDE, which consists of a single wrap, and is wrapped in the same direction as the two previous capacitors. The final step, six, is to wrap the entire assembly with strapping tape to form an outer jacket when finished.
Fig. 4 above, is an electrical diagram of the main capacitor "core" and the coil hookups of the E-Stress Power System. Note the parallel connections of the inner and outer capacitors $C_{EI} / C_{DE}$, which connect to the 90 volt DC power source. Also note the parallel connections of the induction-less coils which connect to the variable frequency oscillator circuit. The centre capacitor $C_r$ is shown connected to the resonant power coil $L_r$. 

\[ \text{Resonant Frequency of Oscillator Tank} \quad f \approx \frac{1}{2\pi \sqrt{L_r C_r}} \quad \text{(Hz)} \]
Fig. 5 above, displays the two different types of variable frequency oscillators which are used to drive the induction-less coils. The first oscillator displayed consists of an LM324 Op-amp configured to produce feedback and thus oscillate. The second example oscillator consists of an LM555 timer IC. Either example oscillator can be used to drive the induction-less coils.

Fig. 6 above, shows the DC voltage source $V_c$ which is applied to the CDE / CDI capacitors which are connected in parallel to form the electrostatic field. The DC voltage source could be one of the three types of voltages sources as shown. A battery could be used, which consists of six nine volt batteries. You could also fabricate an AC to DC power source or you could elect to create your own antenna DC source as shown. The battery method affords a quick means to test the circuitry and is safe as well.
Fig. 7 above, illustrates the options for the two different types of resonant coil $L_r$. Basically, there are two coil options: the standard iron core power transformer and the high frequency Tesla type coil such as the ignition type coil. You will need to determine the type of output you wish to have in the overall design. For conventional designs you would most likely construct the standard transformer shown at the bottom of the diagram, which consists of a core filled with powdered iron or Metglass.

![Diagram A](image1)

![Diagram B](image2)

![Diagram C](image3)

Fig. 8 above, discusses the charge displacement dynamics involved in the E-Stress Amplifier power system. Diagram A illustrates the induction-less coil $L_o$ waveform. Diagram B depicts the displaced charge spins when the voltage and current rise as the induction-less coils are pulsed, while diagram C shows the waveform during the return to the previous charge patterns, starting the cyclic over again.

Chapter 4: Gravity-Powered Systems

**Note:** If you are not at all familiar with basic electronics, you might find it easier to follow parts of this chapter if you read chapter 12 first.

**Lawrence Tseung's COP=3.4 Pulsed-Flywheel Generator.**
It is generally not realised that excess energy can be obtained from pulsing a flywheel or other gravitational device.

This fact has recently been stressed by Lawrence Tseung who refers to the extra energy obtained in this way as being “Lead-out” energy. This gravitational feature has been part of university Engineering courses for decades, where it has been taught that the loading stress on a bridge caused by a load rolling across the bridge is far less than the stress caused if that same load were suddenly dropped on to the bridge.

This impulse technology has been known for some time and it is demonstrated driving a canoe in the video at [http://www.youtube.com/watch?v=aKWPht3fU-o](http://www.youtube.com/watch?v=aKWPht3fU-o) but Lawrence points out the potential for using it as a method for gaining excess energy for practical use. In October 2009, Lawrence and his band of helpers ran public demonstrations of an early prototype electrical pulsing system which produces excess output energy of COP = 3.3, that is, with 3.3 times more output energy than the user has to put into it to make it work:
Lawrence is busy developing this device further as he intends to construct one with a power output excess of several kilowatts. Behind this device is Lawrence's "Lead-out" theory and for this he suggests a simple arrangement to demonstrate the principle. He presents the case of a rotor which has two substantial weights contained in two cylinders attached to the rotor:

As the disc rotates, the ball falls down the length of the tube. At one end, the tube has a rigid cap which causes a significant impact when the ball hits it. The other end of the tube is padded and that cushions the impact which causes a net imbalance in the impacts and that maintains the rotation.

There is a prototype implementation on YouTube but the implementation is not adequate and the disc stops rotating after five minutes. The YouTube video slot is located at: http://www.youtube.com/watch?v=zykJg2Kc22U&feature=related and there are two significant problems with that particular build. Firstly, the tube rotation is too slow to be effective and instead of the weight falling under gravity and accelerating to a good speed before the impact, the weight just rolls gently down a minor slope and does not make a major impact.

Secondly, the weights are far too small for the size of the wheel and there are only two weights providing impacts very widely spaced apart as the wheel rotates only slowly. One man made a ten-foot version and it rotated steadily for ten months after which time his wife insisted that it be taken apart as it was too noisy.

I would suggest some modifications to the wheel as Lawrence is far too busy with developing his COP>1 pulse implementation. Firstly, the movement of each weight should be delayed until the tube is much nearer the vertical. This can be achieved by curving part of the tube like this:

This way, the ball does not start rolling until the main part of the tube is near vertical. This allows a much greater acceleration and impact. The weighted ball should be much larger, say 2" (50 mm) in diameter and made of lead, in order to generate a significant thrust. Also, the cushioned ends of the tubes should be aligned with the pivot of the wheel so that any residual impact does not generate a turning force in the wrong direction. There is a negative turning effect due to the lever arm of the bottom weight. This turning force is only there for a small arc of rotation as the weight will roll inwards as soon as the tube section rises above the horizontal and as the tube then transitions into a circular curve, the movement inwards is gentle. It probably would be better if the tubes were angled slightly more in the clockwise direction, rather than exactly as shown in the diagram.

Secondly, there should be eight tubes on the disc, four on each side and one side staggered by 45 degrees so that there is a driving impact every 45 degrees instead of the 180 degrees of the version shown in the YouTube video. With that arrangement of four times as many impacts, each substantially greater, and no significant reverse impacts, the wheel has a much better chance of successful rotation without needing to be particularly
large. The wheel itself should not be light as it acts as a flywheel and a pulsed flywheel has already been shown to produce excess power. The wheel bearings should be ball races and not the closed variety because those ones are packed with grease and have a serious resistance to rotation. Instead, the open-sided variety of ball bearing should be used as they rotate very freely.

Using straight tubes for illustration, each tube could be like this:

![Tube Diagram]

Here, a wood disc is fitted to each end of a piece of plastic tube and held securely in place with screws or bolts which pass through small holes drilled in the plastic pipe and screw into the wooden disc. A piece of thick sponge is glued to the disc at one end and the heavy weight inside the tube is not a tight fit so that it can move very freely inside the tube. Four of these tubes are fitted to each side of each disc used in the device as shown here:

![Disc Diagram]

The four tubes attached to the back of the disc are 45 degrees away from the tubes mounted on the front of the disc. Each tube is attached securely in place with straps which pass through the disc and are secured on the far side. The tubes can also be glued in place to further strengthen the attachment. These eight tubes give an unbalanced impact for every 45 degrees of rotation. If two of these discs are attached to a common rotor shaft, then the second disc can be positioned 22.5 degrees around from the first one. That arrangement gives an unbalanced impact for every 22.5 degrees of rotation. If three discs were placed on a common rotor shaft and evenly positioned, then there would be an unbalanced impact every 15 degrees of rotation, which is 24 impacts per rotation. A two-disc arrangement might look like this:
If the rotor spins well, then it would be worth while attaching a series of magnets to the discs, being careful to keep each disc perfectly balanced. One or more air-core coils can then be used to determine if current can be drawn from the device without stopping the rotation. The coils should not have a magnetic core as that would cause a major drag on the rotation whether current was being drawn or not.

Chas Campbell's Flywheel System.
Recently, Mr. Chas Campbell of Australia demonstrated electrical power gain with a flywheel system which he developed:
But what this diagram does not show, is that a couple of the drive belts are left with excessive slack. This causes a rapid series of jerks in the drive between the mains motor and the flywheel. These occur so rapidly that they do not appear noticeable when looking at the system operating. However, this stream of very short pulses in the drive chain, generates a considerable amount of excess energy drawn from the gravitational field. Chas has now confirmed the excess energy by getting the flywheel up to speed and then switching the drive motor input to the output generator. The result is a self-powered system capable of running extra loads.

Let me explain the overall system. A mains motor of 750 watt capacity (1 horsepower) is used to drive a series of belts and pulleys which form a gear-train which produces over twice the rotational speed at the shaft of an electrical generator. The intriguing thing about this system is that greater electrical power can be drawn from the output generator than appears to be drawn from the input drive to the motor. How can that be? Well, Mr Tseung’s gravity theory explains that if a energy pulse is applied to a flywheel, then during the instant of that pulse, excess energy equal to $2mgr$ is fed into the flywheel, where “$m$” is the mass (weight) of the flywheel, “$g$” is the gravitational constant and “$r$” is the radius of the centre of mass of the flywheel, that is, the distance from the axle to the point at which the weight of the wheel appears to act. If all of the flywheel weight is at the rim of the wheel, the “$r$” would be the radius of the wheel itself.

This means that if the flywheel (which is red in the following photographs) is driven smoothly at constant speed, then there is no energy gain. However, if the drive is not smooth, then excess energy is drawn from the gravitational field. That energy increases as the diameter of the flywheel increases. It also increases as the weight of the flywheel increases. It also increases if the flywheel weight is concentrated as far out towards the rim of the flywheel as is possible. It also increases, the faster the impulses are applied to the system.

However, Jacob Bitsadze points out that another mechanism comes into play even if all of the belts are correctly tensioned. The effect is caused by the perpetual inward acceleration of the material of the flywheel due to the fact that it rotates in a fixed position. He refers to it as being ‘the rule of shoulder of Archimedes’ which is not something with which I am familiar. The important point is that Chas Campbell’s system is self-powered and can power other equipment.

Now take a look at the construction which Chas has used:

You notice that not only does he have a heavy flywheel of a fair size, but that there are three or four other large diameter discs mounted where they also rotate at the intermediate speeds of rotation. While these discs may well not have been placed there as flywheels, nevertheless, they do act as flywheels, and each one of them will be contributing to the free-energy gain of the system as a whole. A replication video with 750 watts input and 2340 watts output is here: http://www.youtube.com/watch?v=98aIISB2DNw and this implementation does not appear to have a heavy flywheel as you can see from this picture, although the largest pulley wheel looks as if it contains considerable weight:
Jacob Byzehr's Analysis.
In 1998, Jacob lodged a patent application for a design of the type shown by Chas Campbell. Jacob has analysed the operation and he draws attention to a key design factor:

Jacob states that a very important feature for high performance with a system of this kind is the ratio of the diameters of the driving and take-off pulleys on the shaft which contains the flywheel, especially with systems where the flywheel rotates at high speed. The driving pulley needs to be three or four times larger than the power take-off pulley. Using Chas’ 1430 rpm motor and a commonly available 1500 rpm generator, the 12:9 step-up to the shaft of the flywheel gives a satisfactory generator speed while providing a 3.27 ratio between the 9-inch diameter driving pulley and the 2.75" diameter power take-off pulley. If a generator which has been designed for wind-generator use and which has it’s peak output power at just 600 rpm is used, then an even better pulley diameter ratio can be achieved.
The Self-powered Generator of José Luis García del Castillo

In 1998, Spanish patent ES 2,119,690 was granted to José Luis García del Castillo. I suspect that the auxiliary generators shown in the patent are only there to get the patent accepted by the patent examiner, rather than because they are actually needed. If that is correct, then the design is almost the same as Chas Campbell’s design, although built in a more compact form:

---

As Jacob Byzehr points out, an energy gain is achieved through inertial acceleration caused by having the pulley wheel “A” attached to the flywheel shaft, larger than the pulley wheel “B” attached to the shaft of the generator. As drawn, there is a major difference in those diameters. Here is an attempted translation of the patent:

**Patent: ES 2119690**  
**Date: 1 Oct 1998**  
**Inventor: José Luis García del Castillo**

**AUTONOMOUS ENERGY REGENERATION SYSTEM**

---

**Abstract**

The system comprises an electric motor drive (1), a main generator (2), auxiliary generators (3), a battery (4), a charging regulator (5), and a speed regulator (6). The system is intended to generate its own operating power, and provide an extra supply for other purposes.

**DESCRIPTION**

**Field of the invention**

The present invention refers to a self-contained system of energy regeneration, which in addition has several advantages set out below.

**Background of the invention**

It has been known for many years, how to construct machines which can generate electric current. These are known by the generic name of "electric power generators", consisting of rotating machine that transforms mechanical power into electrical power as a result of alternative action between a magnetic field and a moving conductor.
However, the various types of generator which make up the current state of the art, require the help of a motor, which transforms mechanical power into electrical energy, and that motor requires an independent power source which must be supplied continuously.

Thus, a system capable of generating its own power supply as well as providing an extra power supply for other purposes, is not known in the current state of the art.

Summary of the invention

The applicant for the present patent has designed a self-contained energy regeneration system, capable of producing its own operating energy in addition to generating a surplus which can be used in electrical networks using voltage converters required for any electrical installation, whether in homes, offices, warehouses etc., with it is possible to reach places where it is difficult to install the power grid, allowing its use as an alternative source of energy other than solar or wind power.

Other applications would be in the automotive field, as a power source for motorcycles, cars, etc. by connecting the system to the propelling motor, and thus achieving the necessary motion of the vehicle.

Overall, the system is comprised of the following basic components:
1. An electric traction motor.
2. A main generator.
3. Various auxiliary generators.
4. A battery or accumulator.
5. A load and output-power controller.
6. A speed controller.

The electric drive motor supplies the necessary electromotive force needed for the system to operate, the generator supplies power to the system, charging the battery and providing direct power to the traction motor when needed, or if the battery is fully charged, then just to power the motor. It can go provide direct mechanical power by using pulleys and belts, gears or any other means.

The auxiliary generators are responsible for supplying backup power and can use propellers or be in the form of a turbine operating by the action of the wind or by gears attached to a flywheel placed in the traction motor.

The function of the battery is to provide the power needed to start the motor and in addition, to supply any extra power that the engine may need during operation. The battery is recharged by the main generator which is driven directly by the motor. The function of the charge controller is to prevent the battery becoming overcharged. The function of the speed controller is to control the speed of the drive motor.

The present invention offers the advantages described above, as well as others which will be understood from the example embodiment of the system described in detail below, to facilitate understanding of the features stated above, and introducing at the same time, various in addition to the present specification. It should be understood that the drawings are only by way of example and they do not limit the scope of the present invention in any respect, being just an example of one form of construction.

Brief description of the drawings

In the drawings:
Fig.1, is a diagram of the system as one example of a practical embodiment of the invention.
Fig.2 shows an alternative embodiment of this invention.

Description of a preferred embodiment of this invention
As shown in the drawing, the self-contained system of energy regeneration, in accordance with an embodiment of the present patent, comprises an electric traction motor (1), a main generator (2), several auxiliary generators (3), a battery or accumulator (4), a charge controller and power supply (5), and a motor speed controller (6).
The electric drive motor (1) provides the necessary electromotive force for operating the system, and its voltage and power are selected in accordance with whatever size of system you wish to construct.

The main generator (2) supplies power to the system, firstly, to recharge the battery (4), and secondly, direct power to the motor (1) if it requires it. When the battery (4) is fully charged, its charge is maintained by power from the motor, supplied by suitable pulleys or other method of transmission of mechanical power.

The speed of revolution of the generator must be arranged through choice of the gearing between the motor and the generator, so that when the motor is operating at its maximum speed and drawing its maximum current, that the generator is spinning fast enough to supply that current. The main generator (2) will be therefore connected electrically to the battery (4) and mechanically to the motor (1). The auxiliary generators (3), are in the form of a turbine, operating by wind action or by gears attached to a flywheel (7), driven by motor (1), as shown in Fig.2. These auxiliary generators (3) provide reserve power for the system.

The battery (4), must have a capacity which exceeds the maximum power of the motor (1), and its role in the system is to provide the power needed to start the motor (1), and to supply any extra energy which the motor (1), may need during operation. The battery is recharged directly by the main generator (2) which is driven by the motor (1).

The charge controller and power distributor (5) is positioned between the main generator (2), the auxiliary generators (3) and the battery (4). Its job is to regulate the current draw from the battery (4), to prevent excessive current draw. It also distributes any surplus power as a direct feed to the generator (2) and the drive motor (1) when it needs additional current. The auxiliary generators (3) can either provide additional power to the motor (1), or their power output may be used for any other power needs.

The speed regulator (6), is intended to regulate the speed of the motor (1), this adjustment is gradual, and is adjusted to match the intended use of the system.

System applications can be many and diverse, noteworthy among which are uses in the automotive field, where it can be used as a means for propelling cars and other motor vehicles, with the motor (1) connected to a drive wheel which propels the vehicle. In these applications, the auxiliary generators (3), can be fitted with propellers or be turbine-shaped, so that the passing wind provides extra energy to the electrical system. With electric vehicles, only the main generator is connected to a drive wheel.
Other applications for this system are in the field of energy supply, i.e., use in electrical networks. The advantage of using this patented system is that the power supply is practically inexhaustible and clean, and subject only to component wear and tear during operation.

Its operation is as follows:
Battery (4) provides the energy needed to start the motor (1), and allows for the possibility of increased electrical input being needed at certain times during operation of the system. The battery (4) is electrically connected to the motor (1) through the speed controller (6), which is fed from the main generator (2) by the load distribution controller (5). The generator (2), is driven directly by the drive motor (1), and the transmission of motion from one component to another is through gears, belts and pulleys, or any other conventional means.

The auxiliary generators (3) are electrically connected to the charge controller (5), and the battery (4), and their movement by the wind generates their own energy, having turbine blades or propellers, or through being spun by the flywheel (7) which is connected directly to the motor (1). The energy produced by these auxiliary generators (3) may be used for charging other batteries for later use, or used directly to power other electrical equipment or electrical installation networks. Through voltage converters it is possible to convert the voltage produced by the system to a voltage which is suitable for use in other equipment.

The Wilson Self-Powered DC Generator
Mr. Wilson of Texas built a self-powered generator system using an old table and some car parts. His construction was shaky, but in spite of that, it powered itself and other equipment. The table which he used was five feet (1.5 m) in diameter and 2-inches (50 mm) thick which means that it will have weighed at least 130 pounds or 60 Kilograms which is a substantial amount, well in excess of that used by Chas Campbell with his AC self-powered system. In this DC construction the system was driven by a standard, unmodified, off-the-shelf DC motor powered by two car batteries wired in parallel to give a larger current capacity. These batteries were kept charged up by two ‘generators’ from pre-1964 American cars (the closest available today are permanent magnet alternators). These generators also powered additional equipment and Mr Wilson pointed out that three or more generators could be run by the system, giving a substantial level of excess electrical power.

The machine has to be described as ‘shaky’ because he chose to convert the table top into a V-pulley belt drive flywheel by driving a series of nails into the edge of the wooden disc, with those nails angled to form a V shaped gap through which he ran a pulley belt. After three days of continuous running, those nails started to come out, causing him to power the system down. This unit was built around 1990, and if anyone decides to attempt a replication, then I suggest that the rim of the wooden disc is grooved to take the belt rather than relying on nails. The arrangement was like this:

There was also a belt-tensioning roller which is not shown in the diagram above which assumes that the flywheel has been grooved to take the drive belt. Schematically, the arrangement was like this:
Here, the additional output can be used directly for powering 12-volt equipment or an inverter can be used to provide mains voltage and frequency. A typical inverter looks like this:

The battery power is connected to one end using thick cables to carry the heavy current, and one or more mains sockets are provided at the other end of the case, along with an On/Off switch and power indicators. Inverters come in many sizes and power ratings, generally ranging from 150 watts to 3,000 watts (3 kW). The more expensive ones are specified as “True Sine-Wave Output” but very few present day items of equipment will not run well on the cheaper versions which do not produce a true sine-wave output.

Mr Wilson decided not to patent his design and instead wanted it to be open-source information for anybody to use freely. However, the Jesse McQueen patent shown in chapter 13 looks to be Mr Wilson’s design although the flywheel does not appear to be mentioned there. It should be stressed that the generator output needs to be high and so permanent magnet types are considered to be essential for this application. The specialised motor (and consequently, generator) winding methods of ‘UFOpolitics’ shown in chapter 2, raise efficiencies by a factor of typically 300% or more, and so would raise the output of this system very substantially if they were applied to the motor, or the generators, or both.

**John Bedini’s Battery Pulsing System.**

The Chas Campbell system is not an isolated case. On page 19 of the book “Free Energy Generation - Circuits and Schematics” John Bedini shows a diagram of a motor/generator which he has had running for three years continuously while keeping it’s own battery fully charged. At John’s web site [http://www.icehouse.net/john1/index11.html](http://www.icehouse.net/john1/index11.html) about half way down the page, there is a black and white picture of a very large construction version of this motor built by Jim Watson and which had an excess power output of twelve kilowatts. However, in spite of the flywheel in John’s design, it is not used directly to extract energy from gravity although it could readily do that. Instead, the design uses a very tricky method of trying to pulse the acid inside the battery with resonant pulses. That is a dangerous thing to do and if the pulsing is not exactly correct, it can make the battery explode. Strictly speaking, John’s dangerous design should not really be in this chapter on gravitational systems.

John’s design has a motor which spins the flywheel and the flywheel shaft spins an aluminium disc with six permanent magnets embedded in it. The magnets have their South poles facing six helically wound coils of 200 turns each of 0.8 mm diameter wire. The coils are connected in series, so effectively it is a 1200 turn coil which is energised by six magnets simultaneously.

John shows his switching mechanism as a mechanical attachment mounted on, but insulated from the motor shaft. The disc has just one conducting sector of about 100 degrees of arc. This would gives equal duration pulses except for the fact that his commutator brushes have adjustable positions allowing the pulse duration to be altered.
Let me stress again that the purpose of this system is not gravitational but instead is an attempt to shock the ions in the battery acid into self-charging through resonant pulses. In my opinion this is a highly dangerous idea and while it can be successful through nearly random adjustment of sliding contact positions, and a tuning capacitor across the generator, I certainly would not advise anyone to try doing that. John issues what he calls “stern warnings” against inexperienced people attempting to do this. It must be mentioned that perfectly safe motor-generators can be built – systems which have significant excess electrical output.

James Hardy’s Self-Powered Water-Jet Generator.
As described in more detail in Chapter 2 and Chapter 8, there is a very simple device based on a high-power water pump. In this system, a small quantity of water is pumped around continuously, in the same general style as an ornamental fountain. The difference here is that a high speed jet of water is produced and directed at a turbine wheel. The turbine wheel can be of any type as indicated in the patent which James has been awarded for this design. In the video at present on the web, the water wheel is of very simple design and yet works well – it is shown here:

Small discs are attached to the wheel at widely spaced intervals around it’s rim. The water jet hits these and applies an impulse to the wheel, driving it around, but also adding extra energy through those impulses.

The waterwheel is coupled to a standard electrical generator via pulleys and V-belts. The system is started using the mains supply and then when it is running at full speed, the electrical supply for the pump is switched over from the mains to the output of it’s own generator. This is exactly the same as Chas Campbell does with his pulsed flywheel and both systems are capable of powering additional standard electrical equipment intended for mains use.

Chas Campbell’s flywheel, John Bedini’s flywheel and this water-jet generator all demonstrate very clearly that environmental energy is readily available for us to use any time we choose to do so. All that is necessary is for us to construct one of these devices.
The Centrifugal Energy Amplification Conversion Unit (“CEACU”) of Donnie Watts.

James Hardy’s unit relies on the output power of the water pump. The Clem Engine described in chapter 8 is self-powered, becomes very hot in use causing the working liquid to be oil rather than water, and it gives the impression that the very difficult-to-make tapering spiral is an essential feature. However, it is perfectly possible to make a very effective, house-powering, self-powered generator using simple principles. Quite a number of people have been involved in the development which I only became aware of in July 2016.

The design is based on well known principles and is not anything like pumping a great deal of power into the device. Based on sheer input power, you get a very impressive system like this:

Powered by a Fire Service pump and hose, this arrangement supports both the hose and 350 kilograms of weight – usually three people, and while this is spectacular and eye-catching, it is not the sort of device in which we are interested.

Instead, we are looking at a simplified and improved version of the Clem Engine which is just a single cylinder. This engine runs cold and is simple enough for many people to be able to build one. With a rotating cylinder of just 250 mm (10-inch) diameter, a self-powered output of ten horsepower can be achieved and ten horsepower is 7.5 kilowatts, so driving a generator with it would power a household. The output power increases with rotor diameter and with rate of spin and so in order to stop the device accelerating until it destroys itself, an inflow valve to limit the water entering the rotating cylinder is an important control requirement.

What needs to be understood very clearly is that this is an exponential power engine. The output power is proportional to the square of the rotation speed, so double the revolution speed and you quadruple the output power. Also, the output power is proportional to the square of the rotor diameter, so double the diameter and that quadruples the output power. So, if you double the rotor cylinder diameter and you double the rotation speed, the output power goes up by a factor of sixteen. The basic Coefficient Of Performance for the design is four.

Initially, it is necessary to start the device with a 500-watt water pump, but when the rotation reaches 60 rpm the device no longer needs the water pump although it can be left running if desired. At 60 rpm, the pressure inside the rotor drum reaches the point where the suction caused by the water passing through the rotor jets creates sufficient suction to maintain the operation. But, remember that this is a positive feedback system, with an increase in speed causing an increase in power, an increase in water flow, an increase in speed of rotation, ... and consequently, the engine will runaway self-powered and if you are not ready for that with a throttle on the rate of water flow into the cylinder, then the engine is perfectly liable to accelerate to the point where internal pressure destroys the engine.

In principle, the design is like this:
Most generators require to be spun at 3000 rpm or slightly faster. That speed can be achieved by the belt gearing between the output shaft and the generator’s input shaft. A generator of that general type could look like this 6.5 KVA unit costing £325 in 2016:

However, the output power of this design can be further increased by the inclusion of stainless steel thrust baffles on the inside of the housing. The idea is to have the jets of water strike a fixed surface at right angles to the jet and as close to the jet nozzle as possible:

The curved plate version is theoretically more efficient but the difference is so slight that flat plates are generally used. Let me stress that this device is effectively a fuel-less engine with a substantial output and it can power moving vehicles or run an electrical generator. It can be built in various different configurations.
The 25th September 1989 patent application by Donnie C. Watts describes the operation of the device:

**DESCRIPTION AND WORKING DETAILS OF THE CENTRIFUGAL ENERGY AMPLIFICATION AND CONVERSION UNIT**

**Description of Unit**
The unit consists of two circular steel plates one eighth of an inch thick and four feet or larger in diameter, forming the exterior of a wheel. These plates are placed six inches apart on a hollow axle three inches in diameter. Between these two plates are four V-shaped pieces of sheet metal spaced precisely to form six-inch spokes which will direct water from holes in the central axle to the outer rim, while the inside of the V will form air pockets between the spokes. The ends of the V must not be closer than two inches to the outer rim of the wheel. All four V-shaped units must be precisely placed in balance with each other and securely welded to keep the air pockets and the water pockets separated. The outer rim of the wheel is made of a piece of one eighth inch thick sheet metal six inches wide, formed in a perfect circle and welded securely to the edge of the circular plates so that the area inside is completely enclosed. On this outer rim, directly in the centre, are placed between four and fifty water jets about the size of a football needle, slanted sharply to one side to give the wheel a turning motion. (The optimum number of water jets on the outer rim depends on the application, but the volume of water being expelled
through the jets must not exceed sixty-six percent of the volume of water which can pass through the openings at the centre axle. The reasons for this are:

1. The water going out of the jets would be going out faster than the water entering the wheel which would result in no pressure near the outer rim, pressure which is essential for the running of the motor.

2. The water entering the wheel must go immediately into a puddle of water. The longer it remains a stream of water instead of a puddle of water, the more energy is wasted.

Because the water being ejected through the exterior jets is always less then the amount of water available to the jets, a pressure build-up will occur near the outer rim. A spring-loaded pressure release jet (not shown) must be built into the exterior rim along with the other jets, but facing in the opposite direction to keep the wheel from over-spinning if the load (generator) is dropped or does not take enough power off to keep the wheel speed constant. There are several other ways to control the speed.

The central axle is designed to have water going into one end of it, and an electrical generator attached to the other end of it. Between the water entry and the generator, very close to the wheel itself, would be very sturdy roller or ball bearings resting on, and attached securely to, a framework which will hold the wheel one foot off the floor. Water is forced into the axle via a high-volume low-power centrifugal force pump, approximately one half horsepower motor, at approximately 20 (US) gallons per minute depending on speed and power requirements. This motor and water pump is primarily to start the CEACU wheel and since the power from this is all added to the power output of the big wheel, I prefer to leave the pump running during operation.

The entire unit (depending on application) can be put into a containment shell which can be pressurised or evacuated of air. If the unit is to be operated in an open field, the outer shell can be pressurised and the starting pump removed or turned off once the motor is running by itself. If the unit is to be operated in a garage or near a house, it would be operated at atmospheric pressure or in a vacuum, in which case it is necessary to leave the pump attached and running so that air bubbles do not form near the central axle.

Also, the containment shell must be able to collect about ten inches of fluid in the bottom, waiting to be recycled through the wheel.

Important Notes Regarding The CEACU:

1. The speed and horsepower curve of a self-energised motor is exactly the opposite of that of a normal motor. A normal motor reaches a power peak and then starts downwards. The CEACU power curve starts with a slow upward climb and then accelerates rapidly until the power line curve is almost vertical (just prior to disintegration if speed control is not being used).

   The CEACU motor will not generate more energy than is put into it before it reaches 60 to 100 rpm, depending on design and size.

2. As speed increases, air bubbles which occur in the working fluid will accumulate in the air pockets. The air pockets serve only to hold the pressure steady and give a gentle persuasive pressure that is multi-directional instead of just centrifugal, resulting in a steady pressure to the jets. It is not just possible or probable that the unit would blow itself apart by its own power (if the pressure were not released at some point or power taken off); it happens to be a fact. Air pressure will accumulate in the air pockets inside the wheel only after the wheel is going 60 rpm or faster.

3. The pressurised air in the outer rim of the wheel is essential because it pushes in all directions at once, while the water pushes in only one direction. In other words, centrifugally forced water is not interested in finding its way through the jets, it is only interested in pressing directly against the outer rim. The water holds the air in place at the same time that the air is forcing the water through the jets, and the water coming down from the axle keeps replacing the expelled water. This is why I keep saying over and over again, “Make it big enough, make it big enough”. Otherwise it would be no more workable than a small dam.

4. In order for this motor to work properly, the water coming down the spokes must not be restricted in any way until it reaches the outer rim. This is why we have six-inch spokes. The water resting against the outer rim cannot be moving about rapidly; we want the water sitting as still as possible under as much pressure as possible.

5. There are two primary factors which must not be altered in the design of this wheel, otherwise it will not work:
   
   1. The spokes must be very large and free of restrictions, because liquid in general tends to cling to anything it gets near.
2. The speed of the wheel turning is essential to the centrifugal force required to build up the pressure near the outer rim, and for this reason the jets in the outer rim must be small in diameter and in large numbers so that the concentration is on speed instead of on volume (but not to exceed 66% of the water which can enter at the central axle).

6. Regarding the working fluid: Although it has been referred to here as “water”, the working fluid can be any kind of transmission fluid, oil, hydraulic fluid, etc., keeping in mind that the working fluid must also act as a lubricant for the bearings which are expected to last for ten to twenty years. I recommend regular off-the-shelf transmission fluid, which I have seen used alone in a car engine with lubrication results quite comparable to oil.

7. To the reader who would scoff at the energy which can be derived from pressurised systems, I offer the following facts:

1. Six months ago, it was demonstrated on a TV programme that a highly pressurised stream of water about the size of a football needle (with no additives, but just pure water), would cut through a one-inch thick steel plate. That same stream was used to cut through a two-inch thick phone book, and it cut so fast that no matter how quickly the person holding the book moved it, the stream made a totally clean cut through it.

2. Also, currently on the market is a turbine air motor made by Tech Development Inc. of Ohio and it has an output horsepower of 730, with an input air pressure of 321 psig, at 8400 rpm. This motor is only 7-inches in diameter and 14-inches long. This is not an over-unity motor, nor is it related to the CEACU motor in any way. I mention it only to illustrate what can be done with pressurised systems. So let's accept the fact that we are talking plenty of potential, which will be found factual and workable in the CEACU motor.

8. The primary functional differences between, CEACU and damming up a river are: We create our own “gravity” and pre-determine the amount of that gravity by two methods instead of just one. The gravity in a dam can only be increased by building the dam larger; the CEACU motor can also increase the working gravity by increasing the rpm. This is done by adding more jets, right up to the point where 66% of the incoming water is being ejected. To use more of the available water than this would cause too much turbulence of the water inside the wheel. But keep in mind that there is always plenty of pressure inside the wheel to do the work it is designed for, providing that it is let run at a high enough speed to keep the pressure in the outer rim very high – in exactly the same sense that you don’t try to take off in your car until the engine is going at high enough rpm to handle the load application.
The only difficult part of this design appears to be the Slip Coupling where a stationary water pipe is joined to a rotating water pipe. While we are familiar with rotating lawn sprinklers which rotate using exactly the same principles as this Donnie Watts motor, namely impulse jet action, as shown here:

the key point is that the rate of rotation is low. That is entirely intentional as the manufacturer is considering the way that the various streams of water reach the ground. If you consider the rate of rotation, the fastest sprinkler is likely to be rotating at under 300 rpm which may be very much slower than our motor requirement.

Researching the various couplings on the market, the rate of rotation quoted is typically 400 rpm or less, which may be why Donnie quotes such a large rotor drum size and 3-inch diameter supply pipe (axle). Suitable couplings could be https://www.alibaba.com/product-detail/50A-npt-male-thread-brass-water_2009800594.html or
The Permanent Magnet Pendulum.
At the present time, there is a short video clip on YouTube, showing a pendulum which has been running unaided for two years: [http://www.youtube.com/watch?v=SZjNbhxg4](http://www.youtube.com/watch?v=SZjNbhxg4) and which uses both gravity and magnetism to keep going. The device is installed in a case with transparent sides:

The pendulum itself looks rather like a sledgehammer due to its rigid shaft and the additional magnets mounted on the weight. The above picture shows the pendulum at the end of its swing to the right and the picture below, in its extreme left hand swing position:
Which indicates the swing covers a fairly short distance. Mounted near the top of the pendulum, there are two pivoted arms which look quite like microphones, due to having large magnets mounted on their innermost ends:

The device operates like this: The pendulum swings to the right and as it does so, it raises a magnet attached to the pendulum shaft by a curved silver arm:
Presumably, the arm is curved to avoid the constructional complications at the pendulum pivot which would be caused by a straight mounting arm attached to the pendulum shaft. The rising magnet attached to the pendulum pushes the magnet end of the rocker arm upwards even though it does not come close to it.

The rocker arm is used to raise and lower a plate which has a magnet mounted in it. The raising and lowering is achieved by having two cords attached to the end of the rocker arm and their other ends attached to the two upper corners of the moving plate:

The plate slides in two slots in the support housing and the plate movement is relatively small:
The tipping up of the lever arm drops the plate down as the pendulum approaches the plate. This introduces a magnetic braking effect where some of the momentum of the pendulum weight is stored in the opposing magnetic fields of the pendulum magnets and the plate magnet. This brakes the pendulum movement and gives it a magnetic push on its opposite swing, sustaining it's swinging day after day after day.

This is a clever arrangement and the device on display has been built to a very high standard of construction. It does not appear to have any additional energy take off, but seems quite likely that air-core coils could be used along the swing path to generate electrical power. The arrangement appears so close to John Bedini's pendulum battery charger that it may well be possible to use a pendulum of this type to charge batteries just as John does. While this looks like a very simple device, it is highly likely that it requires exact adjustment of the length of the lever arms, the magnetic gap sizes in relation to the strength of the magnets, etc. etc. Repeated small adjustments are probably needed to get the device operating smoothly and sustaining the pendulum swing. All in all though, it is a very interesting device.

Jerzy Zbikowski’s Mechanical Power Amplifier.

We come now to a device which I would love to describe as “impossible” but reluctantly, I can’t actually do that. On the surface, this device has every appearance of being impossible, and yet it has been measured in a laboratory as being 147% efficient. Perhaps the laboratory measurements are wrong, however, there seems to be very little scope for measurement error as the device is so basically simple. My problem is that if the results are 100% genuine, which is distinctly possible, then a series of these arranged in a circle, each driving the next one, it would create a self-powered device and I can’t explain where the driving power would come from. I can understand pretty much every other device in this eBook, but this one has me stumped. As I don’t have any basis for claiming to be a genius, I am sharing the information here and I will let you decide if it can work as the patent claims that it does.

The patent in question is the very innocent looking US 7,780,559 entitled “Chain Transmission” which innocently states that it is a single-chain system for rotating a large gearwheel at the same rate as a smaller, driving gearwheel, and without question, that is exactly what it does. At this point, my Engineering training jumps in and says “sure, but the overall mechanical efficiency will be less than 100% and while the larger gearwheel does rotate at the same rate, it will do so far less powerfully, and you have exactly the same effect as driving the second shaft with a small gearwheel which has a large gearwheel bolted to it.

The only problem with this is that testing appears to show that this is not the case and in fact, (probably due to the larger lever arm of the larger gearwheel radius) the arrangement has an output power which was measured in the prototype as being 47% greater than the input power. OK, so how does it work?

In the diagram shown here, a small-diameter driving wheel marked “1” has exactly the same number of teeth as the much larger driven wheel marked “2”. As they are linked by a chain, these two wheels rotate at exactly the same rate, that is, the revolutions per minute are exactly the same for each of those two wheels.
The way that the chain manages to push the larger teeth of the large wheel is by having the driving roller “5” raised by a triangular link “4” so that it has the same rotational pitch as the teeth on the larger wheel.

My immediate reaction to this is to say that as the triangular links in the drive chain have a somewhat narrower base than their height, that this will cause driving roller “5” to have a less powerful drive than the driving wheel “1”. But if lab measurements made on the prototype are correct, then that increased level arm effect is not sufficient to overcome the gains caused by the increased radius of the larger wheel. The lab measurements were made at certified laboratory of the Institute of Electrical Machines and Drives of the Technical University of Wroclaw, Poland. A video presentation in Polish can be seen at http://www.focus.pl/video/film/perpetuum-mobile/. It is difficult to see how this chain drive could be COP>1 but it has the advantage that anyone with good mechanical construction skills can test it without the need for any knowledge of electronics.

Gravitational Effects.
We are all familiar with the effects of gravity. If you drop something, it falls downwards. Engineers and scientists are usually of the opinion that useful work cannot be performed on a continuous basis from gravity, as, they point out, when a weight falls and converts it’s “potential energy” into useful work, you then have to put in just as much work to raise the weight up again to its starting point. While this appears to be a sound analysis of the situation, it is not actually true.

Some people claim that a gravity-powered device is impossible because, they say that it would be a “perpetual motion” machine, and they say, perpetual motion is impossible. In actual fact, perpetual motion is not impossible as the argument on it being impossible is based on calculations which assume that the object in question is part of a “closed” system, while in reality, it is most unlikely that any system in the universe is actually a “closed” system, since everything is immersed in a massive sea of energy called the “zero-point energy field”. But that aside, let us examine the actual situation.
Johann Bessler made a fully working gravity wheel in 1712. A 300 pound (136 Kg) wheel which he demonstrated lifting a 70 pound weight through a distance of 80 feet, demonstrating an excess power of 5,600 foot-pounds. Considering the low level of technology at that time, there would appear to be very little scope for that demonstration to be a fake. If it were a fake, then the fake itself would have been a most impressive achievement.

However, Bessler acted in the same way as most inventors, and demanded that somebody would have to pay him a very large amount of money for the secret of how his gravity wheel worked. In common with the present day, there were no takers and Bessler took the details of his design to the grave with him. Not exactly an ideal situation for the rest of us.

However, the main argument against the possibility of a working gravity wheel is the idea that as gravity appears to exert a direct force in the direction of the earth, it therefore cannot be used to perform any useful work, especially since the efficiency of any device will be less than 100%.

While it is certainly agreed that the efficiency of any wheel will be less than 100% as friction will definitely be a factor, it does not necessarily follow that a successful gravity wheel cannot be constructed. Let us apply a little common sense to the problem and see what results.

If we have a see-saw arrangement, where the device is exactly balanced, with the same length of a strong plank on each side of the pivot point, like this:

![Diagram of a balanced see-saw](image)

It balances because the weight of the plank ("W") to the left of the support point tries to make the plank tip over in a counter-clockwise direction, while exactly the same weight ("W") tries to tip it over in a clockwise direction. Both turning forces are d times W and as they match exactly, the plank does not move.

The turning force (d times W) is called the “torque”, and if we alter the arrangement by placing unequal weights on the plank, then the beam will tip over in the direction of the heavier side:

![Diagram of an unbalanced see-saw](image)

With this unequal loading, the beam will tip down on the left hand side, as indicated by the red arrow. This seems like a very simple thing, but it is a very important fact. Let me point out what happens here. As soon as the weight on one side of the pivot is bigger than the weight on the other side (both weights being an equal distance from the pivot point), then the heavy plank starts to move. Why does it move? Because gravity is pushing the weights downwards.

One other point is that the distance from the pivot point is also important. If the added weights "m" are equal but placed at different distances from the pivot point, then the plank will also tip over:
This is because the larger lever arm “x” makes the left hand weight “m” have more influence than the identical weight “m” on the right hand side.

Do you feel that these facts are just too simple for anyone to really bother with? Well, they form the basis of devices which can provide real power to do real work, with no need for electronics or batteries.

The following suggestions for practical systems are put forward for you to consider, and if you are interested enough test out. However, if you decide to attempt to build anything shown here, please understand that you do so entirely at your own risk. In simple terms, if you drop a heavy weight on your toe, while other people may well be sympathetic, nobody else is liable or responsible for your injury - you need to be more careful in the future! Let me stress it again, this document is for information purposes only.

The Deflected-Weight Generator of Mikhail Dmitriev.
Mikhail is a Russian experimenter who has worked for many years developing and testing gravity-powered devices. His persistence has paid off and he has been very successful. His work is shown on Sterling Allan’s web site http://peswiki.com/index.php/Directory:Mikhail_Dmitriev_Gravity_Wheel where there are videos and photographs of several of his prototypes. It is envisaged that large versions which generate 6 to 12 kilowatts of excess power will become available for purchase in 2011. Each of his various designs is based on the principle of having weights attached to a wheel and arranging for those weights to be offset outwards when falling and offset inwards when rising. Because of the different lever arms involved, that gives a force imbalance which causes the wheel to rotate continuously and if the weights are of a considerable size, then the rotation is powerful and can be used to generate electrical energy.

In order to arrange for the weights to be offset as the wheel goes around, each weight is suspended on a pivoted arm:

For the device to operate as required, that suspension arm needs to be moved to (say) the right when falling and be centred or deflected to the right when rising. Mikhail has chosen to use a small amount of electrical power to make this happen, because the energy provided by gravity in turning the wheel far outweighs the small electrical input needed to make the wheel rotate.

Several mechanisms for making this happen have been tested as you can see from Sterling’s presentation. One method is to push the lever arms to the right with a simple rotating disc which has deflector arms attached to it:
After being given the sideways push, each weight stays off centre until it reaches the bottom of its travel. Please remember that while the weights show here are tiny, a full-size working device will have weights which weigh a total of perhaps 130 kilograms and the forces involved are then large. The picture above is a little difficult to make out as the rotating disc is transparent and the support for the rotating arms is also transparent. The horizontal metal arm is there to support the transparent panel on which the 'arms wheel' bearing is mounted.

An alternative method is to use a small motor which drives the arms directly as shown here:

Each weight is held rigidly and so when the motor arm presses against it, the lever arm is pushed out sideways without the weight twisting away from the motor arm. These prototype weights are not heavy, but when a working unit is being built they will have considerable weight, so to get a well balanced arrangement, it might be advisable to have weights on both sides of the wheel so that there is no offset axial load placed on the shaft which supports the wheel:

Mikhail's arrangement works well when it relies on the swinging movement of the weights to keep them off centre during the time when they are falling and you can watch a video of that happening. However, it makes one wonder if it would not be possible to arrange for this movement without the need for a motor, although using a motor is a very clever and sensible method of ensuring rotational power. Perhaps if two stationary deflectors were used, one to keep the weights out to the right when falling and one to keep them out to the right when rising, a viable system might be created. Perhaps something like this:
Admittedly, the deflector pieces would have a smoother shape than drawn here, but the principle is shown in spite of the poor quality of the diagram. Where heavy weights are involved, each could have a roller bearing pressing between the weight and the deflector shield in order to minimise friction as the weight slides past. Alternatively, the deflector shield could be faced with powerful magnets opposing similar magnets attached to the weights which would give a no-contact, very low friction movement. A fairly similar idea is part of the next entry from Dale Simpson.

Dale Simpson’s Gravity Wheel Suggestion.
The design of gravity-operated machines is an area which has been of considerable interest to a number of people for quite some time now. The design shown here comes from Dale Simpson of the USA. It should be stressed that the following information is published as open-source, gifted to the world and so it cannot be patented by any individual or organisation. Dale’s prototype wheel has a diameter of about five feet, utilising weights of a substantial value. The overall strategy is to create excess torque by having the weights slide along metal rods radiating from a central hub somewhat like the spokes of a cart wheel. The objective is to create an asymmetrical situation where the weights are closer to the hub when rising, than they are when falling.

The difficulty with designing a system of this type is to devise a successful and practical mechanism for moving the weights in towards the hub when they are near the lowest point in their elliptical path of movement. Dale’s design uses a spring and a latch to assist control the movement of each weight. The key to any mechanical system of this type is the careful choice of components and the precise adjustment of the final mechanism to ensure that operation is exactly as intended. This is a common problem with many free-energy devices as careless replication attempts frequently result in failure, not because the design is at fault, but because the necessary level of skill and care in construction were not met by the person attempting the replication. Here is a sketch of Dale’s design:
The wheel has an outer rim shown in blue and a central hub shown in grey. Metal spokes shown in black run out radially from the hub to the rim. Eight spokes are shown in this diagram as that number allows greater clarity, but a larger number would probably be beneficial when constructing a wheel of this type.

The wheel as shown, rotates in a counter-clockwise direction. Each weight, shown in dark grey, has a pair of low-friction roller bearings attached to it. There is also a spring, shown in red, between the weight and the hub. When a weight reaches the 8-o’clock position, the roller bearings contact a spring compression ramp, shown in purple. This ramp is formed of two parts, one on each side of the spokes, providing a rolling ramp for each of the two roller bearings. The ramp is formed in a curve which has a constant rate of approach towards the hub of the wheel.

The ramp is positioned so that the spring is fully compressed when the weight has just passed the lowest point in its travel. When the spring is fully compressed, a latch holds it in that position. This holds the weight in close to the hub during its upward movement. The springs are not particularly powerful, and should be just strong enough to be able to push the weight back towards the rim of the wheel when the spoke is at forty five degrees above the horizontal. The “centrifugal force” caused by the rotation assists the spring move the weight outwards at this point. The push from the spring is initiated by the latch being tripped open by the latch release component shown in pink.

The weights have an inward motion towards the hub when they are pushed by the wheel’s turning motion which forces the roller bearings upwards along the spring-compression ramp. They have an outward motion along the spokes when the catch holding the spring compressed is released at about the 11-o’clock position. The latch and the release mechanism are both mechanical - no electronics or electrical power supply is needed in this design.

These details are shown in the diagram below:
The question, of course is, will there be enough excess power to make the wheel rotate properly? The quality of construction is definitely a factor as things like the friction between the weights and their spokes needs to be very low. Let us consider the forces involved here:

Take any one weight for this calculation. Any excess rotational energy will be created by the difference between the forces attempting to turn the wheel in a clockwise direction and those forces trying to turn the wheel in a counter-clockwise direction. For the purpose of this discussion, let us assume that we have built the wheel so that the compressed-spring position is one third of the spring-uncompressed position.

As the weights are all of the same value "W", the see-saw turning effect in a clockwise direction is the weight ("W") multiplied by it's distance from the centre of the axle ("L"). That is, W x L.

The turning effect in the counter clockwise direction is the weight ("W") multiplied by it's distance from the centre of the axle ("3W"). That is, W x 3 x L.
So, with WL pushing it clockwise, and 3WL pushing it counter-clockwise, there is a net force of (3WL - WL), i.e. a net force of 2WL driving the wheel in a counter-clockwise direction. If that force is able to push the weight in towards the hub, compressing the spring and operating the spring latch, then the wheel will be fully operational. There is actually, some additional turning power provided by the weights on the left hand side of the diagram, both above and below the horizontal, as they are a good deal further out from the axle than those with fully compressed and latched springs.

The only way of determining if this design will work correctly is to build one and test it. It would, of course, be possible to have several of these wheels mounted on a single axle shaft to increase the excess output power available from the drive shaft. This design idea has probably the lowest excess power level of all those in this document. The following designs are higher powered and not particularly difficult to construct.

**Veljko Milkovic’s Pendulum/Lever System.**

The concept that it is not possible to have excess power from a purely mechanical device is clearly wrong as has recently been shown by Veljko Milkovic at [http://www.veljkomilkovic.com/OscilacijeEng.html](http://www.veljkomilkovic.com/OscilacijeEng.html) where his two-stage pendulum/lever system shows a COP = 12 output of excess energy. COP stands for “Coefficient Of Performance” which is a quantity calculated by dividing the output power by the input power which the operator has to provide to make the system work. Please note that we are talking about power levels and not efficiency. It is not possible to have a system efficiency greater than 100% and it is almost impossible to achieve that 100% level.

Here is Veljko’s diagram of his very successful lever / pendulum system:

![Veljko Milkovic’s Pendulum/Lever System Diagram](image)

Here, the beam 2 is very much heavier than the pendulum weight 4. But, when the pendulum is set swinging by a slight push, the beam 2 pounds down on anvil 1 with considerable force, certainly much greater force than was needed to make the pendulum swing.

As there is excess energy, there appears to be no reason why it should not be made self-sustaining by feeding back some of the excess energy to maintain the movement. A very simple modification to do this could be:

![Diagram of Modified Pendulum/Lever System](image)

Here, the main beam A, is exactly balanced when weight B is hanging motionless in it’s “at-rest” position. When weight B is set swinging, it causes beam A to oscillate, providing much greater power at point C due to the much
greater mass of beam A. If an additional, lightweight beam D is provided and counterbalanced by weight E, so that it has a very light upward pressure on its movement stop F, then the operation should be self-sustaining.

For this, the positions are adjusted so that when point C moves to its lowest point, it just nudges beam D slightly downwards. At this moment in time, weight B is at its closest to point C and about to start swinging away to the left again. Beam D being nudged downwards causes its tip to push weight B just enough to maintain its swinging. If weight B has a mass of "W" then point C of beam A has a downward thrust of 12W on Veljko’s working model. As the energy required to move beam D slightly is quite small, the majority of the 12W thrust remains for doing additional useful work such as operating a pump.

**Amr Al-Hossary’s Patent.**

If that is the case, then the design should perhaps be modified along the lines of the patent application of Amr Al-Hossary where the hinged plates are attached directly to the rotor. That way, the plate lever arm definitely comes into play:

Here, the hinged arms or plates will also give an impact impulse when they open out to their full extent and that provides additional turning power. However, the imbalance between the two side is not a major amount and so this design is not likely to provide a large amount of torque for driving external loads.
Murilo Luciano’s Gravity Chain Suggestion.
Murilo Luciano of Brazil, has devised a very clever, gravity-operated power device which he has named the “Avalanche-drive”. Again, this design cannot be patented as Murilo has gifted it to the world as a royalty-free design which anybody can make. This device continuously places more weights on one side of a drive shaft to give an unbalanced arrangement. This is done by placing expandable links between the weights. The links operate in a scissors-like mode which open up when the weights are rising, and contract when the weights are falling:

In the arrangement shown here, the weights are shown as steel bars. The design is scaleable in both height, width and the mass and number of weights. In the rough sketch above, the practical details of controlling the position of the bars and co-ordinating the rotation of the two support shafts are not shown in order to clarify the movement. In practice, the two shafts are linked with a pair of toothed sprockets and a chain. Two sets of vertical guides are also needed to control the position of the bars when they are in-between the four sprockets which connect them to the drive shafts, and as they go around the sprocket wheels.

In the sketch, there are 79 bar weights. This arrangement controls these so that there are always 21 on the rising side and 56 on the falling side (two being dead-centre). The resulting weight imbalance is substantial. If we take the situation where each of the linking bars weighs one tenth as much as one of the bar weights, then if we call the weight of one link “W”, the rising side has 252 of these “W” units trying to turn the sprockets in a clockwise direction while 588 of the “W” units are trying to turn the sprockets in an counter-clockwise direction. This is a continuous imbalance of 336 of the “W” units in the counter-clockwise direction, and that is a substantial amount.

If an arrangement can be implemented where the links open up fully, then the imbalance would be 558 of the “W” units (a 66% improvement) and the level arm difference would be substantial.

There is one other feature, which has not been taken into account in this calculation, and that is the lever arm at which these weights operate. On the falling side, the centre of the weights is further out from the axis of the drive shafts because the link arms are nearly horizontal. On the rising side, the links are spread out over a lesser horizontal distance, so their centre is not as far out from their supporting sprocket. This difference in distance, increases the turning power of the output shafts. In the sketch above, an electrical generator is shown attached directly to one output shaft. That is to make the diagram easier to understand, as in practice, the generator link is
likely to be a geared one so that the generator shaft spins much faster than the output shaft rotates. This is not certain as Murilo envisages that this device will operate so rapidly that some form of braking may be needed. The generator will provide braking, especially when supplying a heavy electrical load.

This diagram shows how the two side of the device have the unbalanced loading which causes a counterclockwise rotation:

![Diagram showing the principles of device operation](image)

The diagrams shown above are intended to show the principles of how this device operates and so for clarity, the practical control mechanisms have not been shown. There are of course, many different ways of controlling the operation and ensuring that it works as required. One of the easiest building methods is to link the two shafts together using a chain and sprocket wheels. It is essential to have the same number of bar weights passing over the upper sprocket wheels as pass under the lower sprocket wheels. On the upper sprocket wheels, the bars are spread out, say, three times as far apart than they are on the lower sprocket wheels, so the upper sprockets need to rotate three times as fast as the lower ones. This is arranged by using a lower drive-chain sprocket wheel which has three times the diameter of the upper one.

The driving force provided by the weight imbalance of the two columns of rod weights needs to be applied to the lower sprocket wheels at point “A” in the diagram above. For this to happen, there has to be a mechanical connection between the stack of bar weights and the sprocket wheel. This can be done in different ways. In the above concept diagrams, this link has been shown as a sprocket tooth or alternatively, a simple pin projection from the sprocket wheel. This is not a good choice as it involves a considerable amount of machining and there would need to be some method to prevent the bar rotating slightly and getting out of alignment with the sprocket wheel. A much better option is to put spacers between the bar weights and have the sprocket teeth insert between the bars so that no bar slots are needed and accurate bar positioning is no longer essential. This arrangement is shown below:
The description up to here has not mentioned the most important practical aspects of the design. It is now time to consider the rising side of the device. To control the expanded section of the chain, and to ensure that it feeds correctly on to the upper sprocket wheels, the gap between successive bar weights must be controlled.

A guiding channel can be used, as shown here, and standard ball-bearings or roller-bearings can be attached to the ends of the weights by using threaded rod (or a bolt with the head inside the weight) and locking nuts.

In the example shown here, which is of course, just one option out of hundreds of different implementations, the bars on the rising side are three times as far apart as those on the falling side. This means that on the upper sprocket wheels, only every third tooth will connect with a bar weight. This is shown in the following diagram.
However, if the linked weights were left to their own devices, then the rising side bars would hang down in one straight line. While that would be optimum for drive power, Murilo does not envisage that as a practical option, presumably due to the movement of the links as the bar weights move over their highest point. In my opinion, that arrangement is quite possible to implement reliably provided that the length of the links is selected to match the sprocket distance exactly, however, Murilo’s method is shown here.

Murilo’s method is to use additional restraining links between the weights. The objective here is to make sure that when the weights spread out on their upward journey, that they take up positions exactly three bar widths apart, and so feed correctly onto the teeth of the upper sprocket wheel. These links need to close up on the falling side and open up on the rising side. They could be fabricated from short lengths of chain or from slotted metal strips with a pin sliding along the slot.

Whichever method is chosen, it is important that the links stay clear of the bars and do not prevent the bars stacking closely together on the falling side as that would prevent them seating correctly on the teeth of the lower sprocket wheels. The easiest precision option for the home constructor is using chain, where two bar weights are positioned on the upper sprocket wheel to give the exact spacing, and the tensioned chain is welded in position, as shown below. Placing the chain inside a plastic tube causes it to take up an “A” shape standing outwards from the links when they move into their closed position. This keeps the chains from getting between the link bars. In addition, the chains are staggered from one pair of link bars to the next, as shown below, as an additional measure to keep the operation both reliable and quiet.

In the diagram below, only a few of these restraining links are shown in order to keep the diagram as simple as possible. It is not a good choice to make the upper bar sprocket wheels three times larger than the lower sprocket wheels as this would force both the rising and falling sections of chain out of the vertical, which in turn introduces friction against the guides. The central 1:3 gearing is needed to make sure that the chains on the rising side are fully stretched and the spacing of the bar weights matches the upper sprocket spacing exactly.

The diagrams have not shown the supporting framework which holds the axles in place and maintains the unit in a vertical position, as this framing is not specialised in any way, and there are many acceptable variations. A sensible precaution is to enclose the device in an upright box cabinet to make sure that there is no chance of anything getting caught in the rapidly moving mechanism. This is an impressive design of Murilo’s, who recommends that in the implementation shown above, that the links shown in blue are made 5% longer than those shown in yellow, as this improves the weight distribution and drive of the lower sprocket wheel.
A washing machine has a maximum power requirement of 2.25 kW and in the UK a suitable 3.5 kW alternator costs £225 and needs to be spun at 3,000 rpm for full output.

While the above description covers Murilo’s main design, it is possible to advance the design further, raising its efficiency in the process as well as reducing the construction effort needed to build it. For this version, the main components remain the same, with the upper axle geared to the lower axle as before and the upper axle rotating faster than the lower one. The main difference is that on the rising side, the chain opens up completely. This does away with the need for the chain links, moves the rising weights much closer in and reduces the number of rising weights:

With a reduced number of weights in the diagram above, the weight imbalance is a very substantial 40:11 ratio with the massive advantage of a substantially reduced lever arm “d” which is much smaller than the lever arm “x” of the falling weights. This is a major imbalance, giving 40x pulling the axle in a counter-clockwise direction and only 11d opposing that movement.

In the description so far, it has been assumed that all components will be made of metal. This is not necessarily the best choice. Firstly, metal moving against metal does make a noise, so guides made robustly of thick plastic or other similar material would be a good choice for the guides for the weights.

The weights themselves could equally well be made from strong plastic piping filled with sand, lead pellets, concrete or any other convenient heavy material. The pipes would then have strong end caps capable of holding the pivots for the links. The sprocket wheels themselves could well be made from thick plastic material which would give a quieter operation and which could be bolted to the power take-off shaft with a bolt placed right through the axle.

Most of the dimensions are not critical. Increasing the diameter of the lower sprocket wheel will increase the power of the output axle but will lower its speed. Adding more weights will increase both the output power and to a lesser degree, the speed, but will increase the overall size of the unit and its overall weight and cost. Making each weight heavier will raise the output power, or reduce the overall size if the weight is contained in fewer weights. Increasing the length of the links means fewer weights on the rising side but will require larger sprocket wheels.

It is not necessary to have all the links the same size. If the lengths are chosen carefully and the indentations in the upper sprocket wheel cover the entire circumference, then every second link can be one indentation shorter which tips the weights into a more compact and effective column on the falling side:
With this arrangement, the outer weights, shown here on the left, press down very firmly on the inside column of weights, making a compact group. If using plastic pipes with concrete then the hinge arrangement for the rods can be very simple, with a bolt set in the concrete as shown below.

The rods, washers and bolt can be supported on a thin, rigid strip placed across the top of the pipe. When the concrete has gone solid, the strip is removed and the gap produced by its removal then allows free movement of the rods. If this technique is used, then the bar weights are cast in two steps, with a tightly fitting disc pushed part way up inside the pipe so that one end can be filled while the other end remains open and ready for the completion of the other end.

One advantage of using plastic pipes is that if the sprocket wheels are made from a tough high-density plastic material, such as is used for food chopping boards, and the weight guides are also made from tough plastic, then there should be no metal-upon-metal noise produced during operation, if the bolt holes in the connecting rods are a good fit for the bolts used.
The concrete or mortar used as a filling can be made wet and pliable, since mechanical strength is not an issue here, and a filling with no voids in it is desirable. Even low quality concrete (caused by more water than absolutely necessary) would be more than adequate for this purpose.

The arrangement at the ends of a concrete-filled plastic pipe bar weight could be constructed like this:

![Diagram of a concrete-filled plastic pipe bar weight arrangement](image)

There is a very strong inclination when building a device to make it operate smoothly. Where excess energy is being drawn from the gravity field, the reverse is necessary, with a jerky operation being the optimum. Remember that the extra energy only occurs during the duration of the impulses causing the jerks. It follows then, that in an ideal situation, any device of this type should be driven by a rapid series of strong impulses. In practice, using a heavy flywheel or any similar component which has a high inertial mass, although a rapid series of sharp pulses is being applied to the component and jerky operation is not visible to the human eye, excess energy is still being "led-out" and made available to do useful work.

One other observation which may be of interest, and that it the feedback from builders of gravity wheels which says that the power output from a gravity wheel is greater if the axle is horizontal and the rotating wheel is aligned exactly with magnetic East-West.

**A Practical Construction Query**

I have just been asked about the practical issues of mounting the guiding components for the weights. I must apologise for not making it clear that the diagrams in this description are intended to show the overall methods of operation, rather than being a direct construction arrangement. There will be several ways of constructing an implementation of each device. Here is one suggestion for a practical construction method for the gravity chain device.

The query was as follows:
It is pointed out that the lower guide as shown, can't be supported from inside as the weights sweep through the area which would be used for that support. Also, it can't be supported from outside as the connecting rods have to move through the area where that support would be positioned. A solution has been suggested where the lower guide is supported by a strap from the upper guide, the strap running between the inner and outer weights. That is a solution which could work, but it introduces significant unnecessary friction. An alternative method is to place the guides outside the moving weights as shown here:
This method provides a low-friction channel for the roller-bearings to move along. This controls the position of the weights very accurately and the end walls also provide the supports for the axles which synchronise the positions of the weights and provide gearing between the axles if that is required. For clarity, just two of the many weights are shown and the overall proportions distorted so that the diagram will fit on the page.

With the axles, it might look like this:

![Diagram of gravity-powered design with axles and weights]

Here, the axle shafts are geared together outside the end wall and either a chain or a belt drive used. The lower shaft allows a power take-off. The ratio of the diameters of the pulley wheels or sprocket wheels dictates the relative rates of rotation of the two shafts.

**Other Gravity-Powered Designs.**
Sterling Allan reports on Bobby Amarasingam’s design which has 12 kilowatts of excess power: [http://pesn.com/2010/12/04/9501738_British_gravity_motor_generates_12_kilowatts/](http://pesn.com/2010/12/04/9501738_British_gravity_motor_generates_12_kilowatts/)

Another of Sterling’s reports is on the Chalkalis Gravity Wheel which can be seen at: [http://peswiki.com/index.php/OS:_F._M._Chalkalis_Gravity_Wheel](http://peswiki.com/index.php/OS:_F._M._Chalkalis_Gravity_Wheel)

**Buoyancy**
While we are aware of buoyancy being used to convert wave power into electricity, we seem to neglect the idea of using the very powerful buoyancy forces (caused by gravity) as a direct tool at locations away from the sea. This is definitely a mistake because serious levels of power can be generated from such a system. One such system is:

**The “Hidro” Self-Powered Generator of James Kwok.**
This design demonstrates yet again, the practical nature of drawing large quantities of energy from the local environment. Commercial versions are offered in three standard sizes: 50 kilowatt, 250 kilowatt and 1 megawatt and licensing partners are being sought. This generator which James has designed can be seen at the Panacea-bocaf.org web site at [http://panacea-bocaf.org/hidrofreeenergysystem.htm](http://panacea-bocaf.org/hidrofreeenergysystem.htm) and on James’ own web site at [http://www.hidroonline.com/](http://www.hidroonline.com/) both of which have video clips explaining how the design works. The method is based on different pressures at different depths of water, gravity, and on the buoyancy of air-filled containers. The
system does not rely on wind, weather, sunlight, fuel of any type, and it can operate all the time, day or night, without causing any kind of pollution or hazard. This particular design calls for a water-filled structure of some height, a source of compressed air and a pulley system, and without wishing to be in any way critical, it seems rather more complicated than it needs to be. If, unlike James, you have not done the mathematics for the system, you would assume that the amount of power generated by a system like this would be less than the amount of power needed to make it operate. However, that is definitely very far from reality as considerable excess power is gained through the natural forces of the local environment which make the system operate. Part of the patent application which James made is shown here:

US 2010/0307149 A1                          Date: 9th Dec. 2010                            Inventor: James Kwok

HYDRODYNAMIC ENERGY GENERATION SYSTEM

Fig. 1 is a cross-sectional view of an embodiment of the energy generation system of the present invention. Here, the energy generation system 10 comprises a vessel 11 in the form of a water tank and a shaft 12 which can rotate about it’s longitudinal axis. The shaft 12 is provided with a helical screw groove 13 and is connected at it’s lower end to a bearing 16 which allows it to rotate freely about its longitudinal axis.

The upper end of the shaft is connected to a generator 17 which is a flywheel system. The rotational energy of shaft 12 may be transferred to the generator through a ratchet-cog system 20. A buoyant inflatable capsule 14 is provided along with its guiding mechanism 15 which is in the form of a wire or pole to assist in the smooth vertical movement of buoy 14.

There is a first air reservoir 18 located in a lower portion of the vessel 11 and a second air reservoir 19 located in an upper portion of the vessel 11. The first reservoir 18 draws air from the atmosphere, in through air intake port 21. Once the pressure in the first reservoir has reached a predetermined value, a piston 22 is actuated, forcing air through hose 23 into the buoyant capsule 14, which, when inflated, begins to move upwards through water tank 11, as the buoy 14 has become less dense than the fluid 25 (such as fresh water or saltwater) in tank 11. This in turn causes rotation of shaft 12, and activation of the power generator 17, thereby generating power.
When buoy 14 reaches the upper limit of its travel, the air in the buoy may be forced to flow through a second hose 24 and into the second air reservoir 19. When air is removed from the buoy it moves downwards through vessel 11 under gravity and with the assistance of ballast (not shown). The downward movement of buoy 14, causes rotation of the shaft 12, which drives the generator 17, thereby generating power.

Air stored in the second reservoir 19 may be vented to the atmosphere through a vent 26 if the pressure in the second reservoir 19 becomes too high. Alternatively, air may flow from the second reservoir 19 into the first reservoir 18 through a third hose 27 so that less air must be drawn into the first reservoir 18 when buoy 14 reaches the lower limit of its travel and must once again be inflated with air from the first reservoir 18.

The hoses 23, 24 and 27 are provided with non-return valves 28 to ensure that air will flow in only one direction through the system 10. Vessel 11 may be provided with ventilation 29 as required and it may also be provided with access stairs 30 and an access platform 31 so that maintenance may be carried out as required. The system may also be provided with a solar energy collection device 32 to generate at least a portion of the energy required to drive piston 22 and the non-return valves 28. Energy produced by the solar energy collection device 32 may also be used to power a light or beacon 33 to indicate the location of the system 10.

Fig.2 shows one arrangement for buoy 14 comprising an inflatable capsule 34. This figure illustrates the shape of the walls of the inflatable capsule 34 when inflated 35 and when deflated 36. Air passes into capsule 34 through hose 23 and exits from the capsule through hose 24.

The buoy 14 also has a sleeve 37 attached to it. This sleeve has projections which engage with the helical groove 13 of shaft 12, thereby causing rotation of the shaft when the buoy moves relative to shaft 12. Sleeve 37 is provided with ballast 38, such as stainless steel weights that assist in the downward movement of the buoy when it is deflated.

Buoy 14 is attached to a guide pole 15 and the buoy has a pair of arms 39 which slide on the guiding pole 15 and assist in the smooth vertical movement of the buoy.
Fig. 3 shows one version of the first air reservoir 18. Air is drawn into reservoir 18 through air intake 21. The reservoir includes a piston 22 associated with a spring 40, the piston 22 being provided with seals 41 to prevent leakage of air.

When pressure, such as hydrostatic pressure, is applied in the direction of arrow 42, the piston moves to the left of the reservoir 18 compressing spring 40 and forcing air out through outlet 43. A motor 44 is provided to reverse the movement of the piston 22. Reservoir 18 may be fixed to the floor of the vessel.

An alternative construction of the first air reservoir 18 is shown in Fig. 4. In this embodiment, reservoir 18 is housed within a vessel 11 containing a fluid 25. Air enters reservoir 18 through air intake 21 and is held in a chamber 46. The reservoir has a piston 22 and the movement of the piston 22 towards the left of the reservoir 18 forces air in the chamber 46 out through air outlet 43.

Piston 22 is driven by motor 47 which rotates the helically-grooved shaft 48. The motor is linked to the shaft by a ratchet and cog mechanism 49, which is provided with a spring loaded seal 50 on the inner surface of vessel 11. An actuator 51, may be used to control the opening and closing of non-return valves 28 as well as the actuation of motor 47.

Fig. 5 illustrates a cross-sectional view of an energy generation system according to one of the embodiments of the present invention:
Fig. 5 shows an embodiment where a pair of buoys 14 are present. Each buoy is associated with its own shaft 12 and may move up and down inside vessel 11 independent of one another.

In Fig. 6, an alternative embodiment of the present invention is illustrated, where the buoy 60 has a connecting method 61 in the form of a cylindrical sleeve through which a guide chain 62 passes. Chain 62 is provided in an endless loop and is located on an upper tracking device 63 and a lower tracking device 64, both of which are pulleys. The upper pulley 63 may be fixed to an upper wall (not shown) of a vessel (not shown) via a bracket 65, while the lower pulley 64 may be fixed to a lower wall (not shown) of a vessel (not shown) via a bracket 66.

The connection mechanism 61 contains ratchets which engage with the links of the chain 62 when buoy 60 moves downwards. Thus, as buoy 60 moves downwards, chain 62 also moves, thereby causing both the upper and lower pulleys to rotate in a clockwise direction. The upper and lower 64 pulleys have a series of indentations 67 corresponding to the shape of the links of the chain 62. In this way, the chain 62 sits in the indentations 67 and grips the tracking device (63, 64), thereby ensuring that the tracking device (63, 64) rotates.

In the embodiment of the invention illustrated in Fig. 6, a work shaft 68 is associated with the upper pulley 63 such that rotation of the upper pulley results in rotation of the work shaft 68. The work shaft 68 is located substantially perpendicular to the direction of travel of the buoy 60. The work shaft drives a generator to produce power.
Fig. 9 shows an alternative embodiment of this energy generation system 74. The system is comprised of a vessel 75 having a fluid-filled “wet” compartment 76 and one or more “dry” compartments (in this case, a pair of dry compartments 77, 78) with no liquid in them. These dry compartments may be fabricated from any suitable material, such as, concrete, steel, fibreglass, plastic or any combination of materials.

The system also has a pair of buoys 79 each with a deflatable bladder-like construction. The buoys have guide rails 89 which ensure that the buoys move smoothly up and down inside the vessel 75.

In this embodiment of the invention, air reservoirs 86 are located in the base of the vessel 75. Air enters the reservoirs 86 through inlet 87, while air exiting from the buoy 79 is vented through valves 88. The vented air may either be expelled to the atmosphere or recycled to the reservoirs 86.

Each of the buoys is designed to be connected to one end of a chain or rope 80. A weight 82 is connected to the other end of the chain or rope 80. The chain or rope 80 has a series of pulleys 81 such that when the buoy is inflated and filled with air, the buoyancy is greater than the weight 82 and so the buoy rises in the vessel.

When the buoy 79 is deflated, weight 82 is heavier than the buoyancy and so the buoy sinks in vessel 75. In the embodiment illustrated here, the weights 82 are located in the dry compartments 77, 78. There are several reasons for this, including that, by locating the weights 82 in the dry compartments 77, 78, the velocity of the weights 82 in the downward direction is increased, and therefore an increase in the energy produced by the system 74 is experienced.

The weights 82 are associated with second ropes or chains 83, such that vertical movement of the weights 82 results in the rotation of the second ropes or chains 83 around a pair of sprockets 84. Rotational energy generated by the rotation of the second ropes or chains 83 is transferred to a power generation device 85 (such as a turbine or the like) in order to generate power (e.g. electrical power)

***

In spite of its mechanical complexity, the Hidro design is offered as a commercial generator with tens of kilowatts of excess power, indicating that buoyancy is a significant method of generating power, based on the fact that water is hundreds of times heavier than air. Due to its weight, movement in water is slow but can be very
powerful. The helical groove method of converting the vertical movement of the floats into rotational power is used because of this as it has a very high ratio between shaft turns and movement along the shaft. This can be understood when you consider the fact that a complete revolution of the shaft is caused by the float moving up just one step to the next thread position directly above. The turns ratio for the complete float movement is determined by the angle of the groove cut into the drive shaft.

One other thing which needs to be considered for such a project is the weight of the overall structure when filled with water. The overall weight is liable to be many tons and so the footing underneath the generator needs to be very robust. Also, while compressed air is mentioned, giving the impression of cylinders of compressed air or gas, For continuous operation one would expect an air pump to be used. Whether or not an air pump is used, the diameter of the air hoses needs to be considered. Most people think that a gas can flow along a pipe or tube very easily. That is not the case. If you want to get a feel for the constriction caused by a pipe, then take a one metre length of 6 mm diameter plastic tube and try blowing through it. No significant amount of air will pass through the tube even if you blow very hard. The web site http://www.engineeringtoolbox.com/natural-gas-pipe-sizing-d_826.html shows this table:

Notice the major difference in carrying capacity of any of these pipes with just the change from a 10-foot (3 metre) length to a modest 20-foot (6 Metre) length, and those lengths are the sort of lengths needed for many applications. Also, look at the figures for, say, the 0.5 inch (nominal) diameter pipe. With just a 10-foot length, it would take a full two minutes to pump just one cubic foot of air through it. It follows then, that pipes of considerably larger diameter are needed for a project like the ‘Hidro’.

It is possible to construct a much more simple version of the ‘Hidro’, perhaps like this:
A simple hydraulic, buoyancy-powered generator can be constructed, with two or more horizontal, rotating shafts submerged in water in such a way that they are effectively positioned one above the other. Each shaft has one, and preferably two or more sprocket wheels mounted on it. Each of these sprocket wheels engages with a continuous chain loop which also engages with the sprocket wheel which is positioned vertically above it. These vertical chain loops form a belt-style support for a series of identical buckets. On one side of the vertical belt the buckets have their open face upwards and on the other side the bucket openings are facing downwards. An air pump is positioned directly underneath the set of buckets which have the bucket openings facing downwards. The air pump generates an upward-moving stream of air which collects in the rising buckets, displacing the water filling the bucket. This results in a powerful upward thrust caused by the buoyancy of that bucket, and the thrust causes the bucket to move upwards, rotating both horizontal shafts and bringing another water-filled bucket into position above the air pump. A gearing system transfers the rotation torque thus produced, to a generator which produces electricity for general purpose uses.

This is a generator whose input shaft is rotated through buoyancy caused by air-filled containers submerged in a tank of water or some other suitable heavy liquid. Continuous, powerful rotation of the generator shaft is produced through the use of one or more conventional, commercially available air pumps. An air pump is used to fill a series of containers which are open at one end and which are attached to what is effectively a belt arrangement created by two strong chain-link loops which mesh with sprocket wheels mounted on two shafts,
either, or both of which can be utilised for the extraction of useful power, preferably for driving an electricity generator but not necessarily limited to that function as any powerful torque has many useful applications.

Objectives are to provide a power generation system which is very simple in form and which can be understood, operated and maintained by people with minimal training. Also, a system which uses components which are already readily available, thus avoiding significant manufacturing costs, and one which operates without the need for any kind of complex mechanism or high-precision equipment and which can operate with a wide range of commercially available products.

![Diagram](image)

**Fig.1** is a simplified partial schematic cross-sectional view showing the main components of the generator as seen from one end.
Fig. 2 is a cross-sectional conceptual schematic view showing the front view of the generator in its most simple form.
Fig. 3 is a cross-sectional conceptual schematic view showing the front view of the generator where more than one set of buckets is used.
**Fig.4.** is a perspective conceptual view showing arrangements for a simplified air-feed system which operates from above the tank.

**Fig.1.** illustrates the overall concept of the generator in its most simple form where lightweight rigid buckets are used to capture the rising air from the air pump. In this Figure, a water tank 1, holds water or other suitable liquid 2. The surface of the liquid 3, is indicated to illustrate the fact that a bucket 10, which is in the process of turning over at the top of its orbital motion, is positioned so that one edge of the bucket is clear of the surface of the water, which allows the air which was trapped inside the bucket to escape into the atmosphere and the water fill the entire bucket causing only a very minor turbulence when doing so. This is a desirable, but not essential feature as the air trapped in any bucket will escape upwards as soon as the bucket starts its downward movement, positioning its open end upwards, although this causes unnecessary turbulence inside the tank. One possible bucket shape is shown in perspective view, but many different bucket shapes may be used, including flexible membrane types or alternatively, hinged-plate types which have very much reduced resistance to moving through the water when in their collapsed state during their downward movement.

The buckets 8, 9 and 10, are attached to two strong chains 30, which mesh with the upper sprocket wheel 6, mounted on the upper axle 4, and the lower sprocket wheel 7, which is mounted on the lower axle 5. Although it is not visible in **Fig.1**, there are two upper sprocket wheels 6, two lower sprocket wheels 7, and two chain loops 30, although these can be seen in **Fig.2**.

The tank is supported on a robust plate 14, which itself is supported by a series of pillars 15 which rest on a secure footing 16, providing operating space underneath the tank for the installation and maintenance of the air pumping equipment. As fresh water weighs 1000 Kg per cubic metre, the weight of the operational generator system is substantial and so this must be allowed for when assessing the footing needed to support the tank and it’s contents. While a thin-wall tank is shown in **Fig.1**, many different forms of tank may be utilised, including earth bank and plastic membrane styles, or resurfaced abandoned well shafts. The tank of **Fig.1** presumes that the lower axle 5 is taken out through the wall of tank 1, using an arrangement similar to that used for the drive shafts which power the screws of ships and other power vessels. While an arrangement of that type provides a drive shaft which is conveniently close to the ground, the much more simple arrangement shown in **Fig.2** where the output power is taken off using the very simple chain and sprocket wheel method utilised for the bucket supports (chain 30, and sprocket wheels 6 and 7). In general, the more simple and straightforward any design is, the better it works in practice and the lower any maintenance costs become.

Referring again to **Fig.1**, when activated, air pump 11 produces a stream of air 12, which flows rapidly upwards. This stream of air 12, once established, does not have to push against the head of water as immediately above the nozzle of the pump is a rapidly rising column of air, sustained both by the exit velocity from pump 11 and the natural upward movement caused by the relative weights of water and air (as water is several hundred times heavier than air). This column of air would normally flow straight upwards in calm water, but should it be found that turbulence in the water tends to push the rising air away from its vertical path, baffles can be placed around
the pump and positioned so that the air stream is forced to stay within the same section of water taken up by the rising buckets.

The rising air enters the lowest of the rising buckets and collects in it, forcing the water out of the open bottom of the bucket. If the rising bucket is not completely filled with air before the next bucket moves between it and the air pump, the trapped air will expand as the bucket rises and the water pressure reduces due to the lesser depth. Any one bucket with a substantial amount of air in it will create a very significant upward force due to buoyancy, air being about one thousand times lighter than water.

Each bucket on the rising side adds to that upward force and consequently, the chains 30 need considerable strength. The weight of the buckets on each side of the chain match and so the main advantage of light buckets is to lower the inertial mass of the moving parts. Movement through the water is relatively slow but this is offset by gearing between the output drive shaft and the generator's input shaft. The power of the system can be increased by adding more buckets in the vertical chain, increasing the water depth accordingly. Other ways of increasing the power include increasing the volume inside each bucket and/or increasing the flow rate produced by the air pump or pumps used. Another simple method is shown in Fig.3 and discussed below. An alternative to air pumps is to use tanks of a compressed, non-polluting gas, possibly air.

The buckets shown in the various Figures are rigid, very simple shapes, possibly made by a plastic moulding process in order to be cheap, strong, lightweight and permanently water-resistant. There are, of course, many possible variations on this including using rigid hinged plates sealed with a strong flexible membrane, allowing the buckets to fold and become streamlined on their downward path, and opening as soon as they turn to start their upward movement. There are many mechanisms which can provide this movement, but it is a matter of opinion as to whether or not the extreme simplicity of rigid buckets is worth sacrificing.

Fig.2 shows a schematic layout of the generator when seen from the side. The same numbers apply to the components already seen in Fig.1. The arrangement seen in Fig.2 is the most simple, basic, single bucket set. The near-side rising buckets 8 obscure the view of the far-side falling buckets 9 and only the lowest part of the falling buckets 9 can be seen in this view. Fig.1 shows buckets which are some two and a half times longer than they are wide, but this, of course, is just one option among literally thousands of possible proportions. The size and shape of buckets is related to the performance and number of air pumps being used for any one set of buckets and that choice depends on what is available locally at a reasonable price. It would not be unusual for two or three air pumps to be used side by side along the length of the bucket 8 although Fig.2 only shows a single pump.

Fig.2 also shows a simple method for power take off where a large diameter sprocket wheel 16 is mounted on the upper axle 4, and driving a much smaller diameter sprocket wheel 18 which is mounted on the drive shaft of the electricity generator 19 which is mounted on plate 20 which is attached securely to the top of tank 1.

Fig.3 shows one of the possible arrangements for increasing the system power without increasing the depth of water used. Here, the axes 4 and 5 extend far enough to allow another set of buckets to drive them, increasing the torque very substantially. While Fig.3 shows one extra set of buckets, there is, of course, no reason why there should not be three or more sets of buckets side by side. It should be noted however, that the partitions shown between the bucket sets are not there just to reduce the water swirling but are needed to support the bearings which are essential for the extended axles, since without those, the diameter of the bars used for the axles would have to increase very markedly to avoid unwanted flexing along their length. While the second set of buckets has been shown aligned exactly with the first set, there is an advantage in offsetting them relative to each other so that the output torque is more even with buckets emptying and filling at different points in the bucket cycle.

Fig.4 shows a method for further simplification, where the air is pumped from above the water surface. It is a matter of concern to most people, that the pressure of the head of water above the air pump is a major obstacle to overcome and will be a continuous opposing force during operation of the generator. If air is being injected from underneath the tank, then initially, that pressure head has to be overcome. However, once the air flow is established, a vertical cigar-shaped area of water vortex is established by the rising air stream. This three-dimensional annular vortex negates the water head in the small area immediately above the air nozzle, and almost sucks the air out of the pump, after the initial introduction of the air has been accomplished.

There is another way of achieving this desirable effect without ever having to pump against the total head of water, and that is to use a mobile air pipe as shown in Fig.4. Initially, the air pump is started and lowered a short distance into the water. The opposing head of water is not large and the water vortex can be established quite easily. The pipe is then lowered very slowly, so as to maintain the vortex at a progressively lower depth, where, in spite of the increased head of water, the pump does not have to overcome that head. When the pipe outlet reaches the operational depth, it is then rotated to bring it under the set of rising buckets. The major advantage of
this arrangement is that the tank is as simple as possible, with no possibility of leaking, and so abandoned wells can be modified to become energy generators. Alternatively, an earth bank can be erected to form an above-ground tank, possibly sealed with a plastic membrane. This method also avoids needing to support the weight of tank and water above a work-area where the air pump or compressed-air cylinders are located and maintained. The creation of the water vortex can be assisted by the addition of a cowl around the pipe exit as shown in this figure, but that is an optional feature.

**The Ribero Buoyancy Patent.**

While internal combustion engine demonstrate that considerable power can be had from motion which moves backwards and forwards continuously, that sort of action is not very efficient as there is continuous reversal of the oscillating drive components. The floats in the (very successful) ‘Hidro’ design shown above. A different design is shown in the 2011 patent of Renato Bastos Ribero of Brazil. Here is an excerpt from that patent:

**Apparatus and associated methods to generate useable energy**

The present disclosure relates to an apparatus and associated methods for generating energy by capturing and taking benefit of the energy generated by any quantity of air surfacing inside water. In exemplary embodiments, the apparatus comprises compressing a lower density gas in a liquid medium, allowing the gas to naturally rise to the surface of the liquid medium and then capturing the energy generated by the surfacing gas.
**Fig. 2** is a perspective upper view of a rotor disc for compressing a gas into a liquid medium. This disclosure is in two stages which, in this case, work together. The first stage consists of the creation of energy with the introduction of air at the bottom part of a water column. Once introduced, the air creates energy when moving towards the surface. The introduction of air into the water is the main point of this first part of the disclosure. A method was created in order to use a very small quantity of energy when doing this.

The teeth on the disc, when rotated in water, water to flow away from the area between the teeth, lowering the pressure there and allowing the easy introduction of air in that area. Without air introduction, water would not move away and the pressure would not be reduced. The purpose of the cone is to spread the incoming air.

The second section of the present disclosure refers to a system with the objective of capturing the air which is inserted at the bottom of a water column or tank, while moving towards the water surface.

As shown in **Fig.16**, buckets 2030 descend on a continuous chain 2020 which passes around a lower and an upper wheel or pulley. On reaching the lower pulley, the buckets turn around the bottom pulley 2014 and line up
again on the ascending side of the chain. Immediately after turning around the bottom pulley, each bucket receives the rising airflow.

Fig. 17 shows the arrangement at the top of the water tank 2010. Buckets 2030 rising due to being filled with air, turn over as they pass around the top pulley 2018, releasing the air inside them and start descending again towards the bottom pulley. The upper axle 2018 has an estimated rotational speed of 120 rpm.

In Fig. 17 I (Ribero) am showing the transmission of this energy to an axle at the top of the water column where we have a generator 2050 requiring a rotation of 300 rpm plus an engine connected to another generator with rotation of 600 rpm. This part of Fig. 17 is only illustrative to show that we shall generate energy at the primary axle at 120 rpm, or use any kind of transmission to more convenient rotational speeds.

***

I think that the words marked in red indicate that although this patent has been granted, the generator has never been built and is only an idea. Personally, I am highly dubious about the mechanisms which are supposed to give reduced water pressure at the air intake, as I don’t think that they would work, or if they do, certainly not for the reasons stated. What he wants to do can certainly be done, but not in the way that he suggests. If the axles are rotating at the 120 rpm which he suggests, then that would allow less than one eighth of a second to fill each bucket and while the notion of reduced water turbulence through the buckets touching each other is attractive, I don’t think that the method described is feasible.

So, while we can be sure that buoyancy methods are perfectly capable of generating serious power, we need a better design than either of the two shown here as the Hidro appears to be very expensive to build.

The Thirty Kilowatt Motor

The recent website http://www.rarenergia.com.br/ shows a gravity-powered motor which is capable of driving a 30-kilowatt electrical generator.

This is certainly not a home-build project and the cost of construction and day-to-day maintenance cost makes this appear to be a very uneconomic project. However, one enormous advantage of the building of these two generators is that they show very clearly that free-energy is available and perfectly viable. The people building these two constructions point out very clearly that these are gravity-powered motors rather than just electrical generators. While these motors can drive electrical generators, it is emphasised that they can also perform any task which needs a motor, such as pumping, drilling, etc. The size of these motors is substantial as can be seen from the following pictures:
Bhaskara’s Gravity Wheel

I have recently been made aware of the Baskara gravity wheel invented in 1150 in India. This is a most interesting idea which appears to have considerable potential. There is what appears to be a marginal replication at http://www.dailymotion.com/video/xygxsv_bhaskara-wheel-overbalanced-chain_tech. Any gravity-powered device needs to be large and heavy if it is to produce serious usable power. The tiny device shown in the video is shown stationary which shows that the bearing friction is far too great for the weight of liquid involved. Properly built, it would be impossible to have the wheel stationary unless it were locked in place as the weight imbalance would start it rotating from any stationary position. The overall design of the wheel is generally shown like this:
The idea is that the liquid on the right has its Centre of Gravity further from the axle of the wheel, than that on the left. The “Centre of Gravity” of any object is the point at which all the weight of the object is considered to act. It is usually at the centre of an object which has a regular shape. In this case, the turning effect is created by very small differences in lever arm lengths:

Here, the Centre of Gravity of each body of liquid is marked with a blue dot. The lever arms “d1” and “d2” show the distances for two tubes on opposite side of the axle. Although it is not obvious in this illustration, the length “d1” is actually longer than the length “d2”. The tubes are fixed in position and do not move relative to the wheel and so, the only moving part is the liquid and the rotating wheel. As shown here, the mechanism is not efficient as much of the potential power is not being accessed. The turning force of the liquid is created by the liquid flowing outwards, away from the axle. That flow is being severely limited by the short tube lengths. It would be much more realistic to use a much longer tube like this:
Just by lengthening the tube, there is a major increase in the movement of the liquid away from the axle. The increased tube length has no noticeable effect on the rising side of the wheel.

Most people think of the wheel as being small with a few small tubes attached to it. If actual power extraction is the objective, then the wheel becomes a cylinder and the “tubes” extend all the way across the cylinder. I would suggest that the cylinder diameter is made about one meter and the cylinder length about half a metre if you are going to carry it through a doorway, and much longer if not. In this arrangement, the “tubes” become shallow, flat containers, making the arrangement something like this:

![Diagram of a cylinder with shallow flat containers](image)

If the liquid containers are made of, say, 3 mm MDF, then I would suggest that the sides are made using MDF of 6 mm thickness to make the container rigid as the weight of liquid will be quite high. The inside of the container is sealed if the construction material is not waterproof, then a coating of varnish, paint or one of the waterproofing sprays will prevent water absorption. The liquid is added before the top of the container is glued in place. Exactly the same amount of liquid should be poured into each container before sealing and a measuring jug should be used to make sure that each half-filled container matches the weight of each of the other containers.

A twelve volt DC motor can be used as a generator, driven by a belt and two pulleys, in order to get some useful electrical output from the device. Materials other than a liquid have been suggested as the heavier the material is, the more powerful the generator becomes. Mercury would be very good as it is very heavy, but as it is so poisonous, (not to mention expensive), it is not a realistic choice. Lead shot or steel ball bearings have been suggested but they would probably not flow across the containers well enough to be a good choice, and so a liquid is perhaps the best thing to use, water being an obvious choice.

The Torque Generator of William F. Skinner

In 1939, William Skinner of Miami in Florida, demonstrated his fifth generation generator powered by spinning weights. His demonstration can still be seen at [http://www.britishpathe.com/video/gravity-power](http://www.britishpathe.com/video/gravity-power) where he shows his design powering a twelve-foot lathe, a drill press and a power hacksaw, all simultaneously. The newsreel commentator states that the output power was “1200% of the input power” which is COP=12 but it is highly likely that he should have said “1200 times” rather than “1200%” because he continues to state that using the design would allow a one-horsepower (746 watts) input power to power 3,500 homes. If it were COP=12 then each of those 3,500 homes would receive less than 2.6 watts, which is clearly wrong. At the much more likely
COP=1200, each household would receive on average, 255 watts, which might be just possible in 1939 when few appliances were electric. Anyway, Skinner’s impressive equipment could be driven by a single cotton thread drive band while powering his whole workshop. It looked like this:

This design has four nearly vertical shafts, each braced to give additional rigidity. These rotating shafts pass their rotating power to the mechanical output drive belt seen on the left. Each of these rotating shafts has a heavy weight in the form of a thick, short cylinder mounted high up near the top of the shaft and what is probably an even heavier weight in the form of a long narrower cylinder attached near the bottom of the shaft as seen just to the right of the output drive belt. These four identical sets of shafts with their pairs of weights spin two or three times per second and produce the whole of the output power.

As far as I am aware, Skinner never patented his design or disclosed how it worked. However, the operating principle is very simple indeed although it may take you a while to grasp how it works. You can check this out quite easily for yourself if you have access to an old-fashioned chair with four rigid legs like this:

Tilt the chair over so that it is balanced on one leg. You will notice that almost no effort is involved in keeping it in that position as all of the weight is supported by the floor through just one of the legs. Now, move the top of the chair by a very small amount and keep the top of the chair in that position. You will notice two things: first, very
little effort was needed to move the top of the chair and second, the chair now swings around and becomes stationary on the same side that the top of the chair was moved.

Notice two other things: the chair swung around because of your moving the top slightly and you did not swing it around, and if the chair is heavy, the amount of energy in the swinging chair is very much greater that the amount of energy which you applied to the top of the chair.

If you were to keep moving the top of the chair in a tiny circle, then the chair will spin around continuously for however long that you choose to wobble the top of the chair. The amount of energy in the spinning chair is very much greater than the energy which you are expending to make the chair spin. So from where is that extra energy coming?

What is happening is that the chair swings round under gravity to reach the lowest possible point for it with the new position of the top of the chair. But, before it can get there, you move the top of the chair further around and so the chair has to swing further in order the reach the lowest point. But before it can get there, you move the top again ..... The chair keeps swinging round and round, pulled by gravity, for as long as you choose to keep moving the top. But, no matter how heavy the chair, very little effort is needed from you to cause the spinning.

Skinner had a mechanism at the top of each vertical drive shaft, and that mechanism kept moving the top of the shaft in a small circle while allowing the shaft to rotate freely at all times. That caused the very heavy weights attached to the shaft to keep spinning around, and he used that power of the heavy spinning weights to power his whole workshop. Moving the top of the shafts required so little power that he used a 93-watt electric motor and to show that he was not even using all the power of that small motor, he used a single cotton thread as a drive band to move the tops of the four power output shafts.

His mechanism looks complicated. This is partly due to the fact that there are four identical power shafts with their weights, mounted in the one compact frame and that makes the device look more complicated than it really is. It is also due to the fact that the system shown in the newsreel is William’s fifth version of the device. It is likely that his earlier, much more simple versions worked well and encouraged him to build even fancier versions.

There are two forums where members of those forums are trying to work out exactly how his final version machine worked and then replicate the design for current day use as it is a neat system for accessing additional usable power. Those forums are at: http://www.overunity.com/14655/1939-gravity-power-multiply-power-by-1200/#.U5y0gXaqmJA  and  http://www.energeticforum.com/renewable-energy/17195-william-f-skinner-1939-gravity-power.html

It needs to be remembered however, that it is not actually necessary to replicate William’s fifth version, but instead it would be quite enough to use the principle of the spinning chair to produce a simple mechanism where the input power is far less than the output power.

If we consider what is happening, then perhaps we can understand Skinner’s complicated-looking arrangement. We can consider just one of the four axle shafts. The large weight is spinning around in a circle and that motion is then used to power the output shaft. In order to reduce the effort needed to spin the weight, the axle shaft has been made thinner and four bracing rods have been used to brace the shaft in exactly the same way that sailing yacht masts are usually braced with “spreaders” to hold the bracing out from the mast and so give greater overall stiffness. So we can ignore those bracing bars as they have nothing to do with the actual operation of his design, but are merely his choice out of many different construction options.

Remember the spinning chair and consider what has to be done to spin Skinner’s heavy weight. The top of the shaft has to be moved in a small circle. Looking down from the top the situation is like this:  

Stationary  |  First move  |  Assisting weight
When the system is switched off, the weight attached to the bottom of the shaft comes to rest directly underneath the top of the shaft. When the system is started again, the first move is to shift the top of the axle shaft ninety degrees around. This is the start of the rotary movement and initially, the movement is slow as it takes the heavy weight some time to get moving. To reduce the effort of moving the top of the shaft ninety degrees ahead of the big lower weight, Skinner has added a weight at the top to assist the movement in that direction.

Skinner also took advantage of his very large workshop to use a belt-driven mechanism above the top of the shaft, in order to reduce the effort of moving the top of the axle shaft even further (to the level where it could be driven by a cotton thread). He used four separate identical shafts in his construction for two reasons: first, the overall output power is increased and second, any sideways forces stressing the mounting frame are matched on every side, which is helpful when you have heavy weights on a rotating arm as Skinner did.

As the output shafts appear to be rotating at about 150 rpm, Skinner opted to use a straight mechanical drive. Back in 1939, electrically-driven equipment was not as widespread as it is today, but nowadays we would probably prefer to have an electrical output rather than a mechanical drive although that mechanical drive could be used for driving pumps and other low-speed devices. So, we are faced with introducing some form of gearing which can raise that 150 rpm to the much higher level preferred by most alternators.

While it would be possible to use an ordinary 12-volt motor as a generator and produce a 12-volt electrical output, it is likely to be more convenient to use an off-the-shelf electrical generator, perhaps a very low-friction one like this which has been designed for wind-power operation and which has a 12V or 24V 3-phase output:
The fact that the output is 3-phase can sound a little daunting, but the conversion to DC is quite straightforward:

The output can be converted to DC with six ordinary diodes or a integrated diode arrangement can be used where there is a connecting tag for each of the three outputs and a separate tag for the DC Plus and for the DC Minus. The currents involved are quite high as 400 watts at 12-volts represents more than 33 amps and the peak output of 500 watts is a current of about 42 amps. For that reason, the 3-phase rectifier blocks are rated at 50 amps which sounds very high until you do the calculations and discover what the current is likely to be. It should also be borne in mind that the DC output wire has to carry that level of current on a continuous basis and so fairly robust wire is needed. If the voltage were 220V then the wire would be carrying more than 9 kilowatts at that current flow, and so the normal 13-amp mains wire is just not sufficient and instead, we need to use thick wire or more than one strand of wire for both the Plus and the Minus connections.

This particular generator is not expensive and can output 400 watts of electricity (33 amps) continuously. As the Skinner type appears to be spinning at 150 Hz, a gearing up of the output speed would allow greater output, so perhaps for a home-builder, the physical arrangement might be like this:
There are, of course, many different forms of construction which might be used, but with each of them, the question is, “how do you make the angled shaft rotate powerfully?”. If you can work out the complexities of Skinner’s fifth version shown in the newsreel, then that would certainly do the job. However, we would prefer a much more simple design and so we do not necessarily have to copy what Skinner did but instead we can just apply the principle which he demonstrated. One possible arrangement might be to imitate the chair experiment using a strong shaft with a weight attached to one side of it, perhaps like this:

Version “A” uses the weight to stiffen the shaft but doing that raises the centre of gravity of the combined shaft and weight which may not be convenient. Version “B” increases the torque for any given weight by moving the centre of gravity of the weight away from the centreline of the shaft by means of extension arms. As the shaft rotates at a constant rate, the load on the shaft will be essentially constant and there should not be any significant flexing of the shaft although it might bend and remain with that same bend during all of the time when it is spinning if the weight is very high relative to the stiffness of the shaft.
We do have to input some power to rotate the top of the drive shaft, but if we arrange things in any one of the hundreds of viable configurations, then the output power will be massively greater than our input power. An alternative arrangement which allows speed control (and so, output power control) is to take some of the generated output of electricity and use that to power an electrical drive which positions the top of the drive shaft.

There will be many different ways of achieving that movement. One method for doing this might be:

![Diagram of motor with gearing and speed control](image)

**SEEN FROM UNDERNEATH**

Here, the small electric motor shown in green is geared down and used to move the top of the drive shaft at whatever rate of revolution that we consider to be satisfactory, using a standard DC motor speed controller.

It should be noted that no matter what angle is chosen for the axle shaft, that is always a constant relative to the motor arm moving it round in the circle at the top of the shaft. This means that no roller bearing is needed as there is no relative movement and the shaft will automatically take up that fixed angle. The drive motor arm moving the top of the shaft will probably not be long, as Skinner appeared to be moving the top of his shafts by about 40 mm away from the centreline of the bottom pivot, making only one degree or so for the angle of the shaft on every side of the vertical.

It is, of course, not essential to convert the output power to electricity and instead it could be used in the same way that Skinner did, driving mechanical equipment such as water pumps for irrigation or extracting water from wells, milling operations for processing grain or for operating any form of workshop equipment. It is also not necessary to build the device anywhere near as large as Skinner did, and small versions could be used to power lighting systems, operate fans or cooling systems or for any other minor household requirements.

The power output from the machine can be increased by increasing the weight attached to the output shaft, or by increasing the length of the arm holding the weight, or by tilting the output shaft through a greater angle (which increases the input power needed, but probably not by much), or perhaps by scaling the whole thing up so that it is physically bigger. Skinner’s design uses stiffening bracing on the output shaft, which suggests that the lighter the shaft is, the better the performance. Because of this, a prototype build might use a timber shaft of perhaps, 33 mm square as that is both light and very strong and rigid and it is a good shape for ensuring that there is no slipping of the arm which supports the weights. The top of the shaft is reduced slightly so that it has a circular cross-section. A 300 rpm motor rotates at a maximum of 5 turns per second and so is suitable for rotating the axle shaft. A suitable, low-cost motor of that type, looks like this:
The motor needs to be linked to the shaft in a simple way which ensures that there will be no shaft slippage:

Perhaps cutting a suitable sized hole through a strip of material and using a strip of metal pressed into the flat face of the motor drive shaft (in addition to the hole being a tight push fit) would be adequate for this. A screwed collar or layer of epoxy resin holds the plate firmly to the motor as the plate is positioned below the motor and so gravity tends to pull the plate off the motor shaft at all times.

It would initially be assumed that a ball bearing or roller bearing would be needed in this motor arm, but that is not the case as the axle shaft does not rotate relative to the motor arm and while the axle shaft can be a loose fit in the hole, there is certainly no need for a bearing.

A commercial DC Motor Speed Controller can be used to bring the shaft rotation speed gradually up from a stationary start to the chosen rate of revolution:
Using a commercial module like this means that no electronics knowledge is needed to build a working generator of this type.

There are many options for providing the necessary weight which drives the generator. One possibility is to use a barbell shaft with as many weights as are required, that being a very simple alteration:

One of the hand grips can be cut and used directly as part of the mounting, perhaps like this:

This simple arrangement allows the weight discs to be added and secured in any combination desired. As dumbbells are supplied in pairs, there are four discs of each side which allows a wide range of weight options going up in jumps of just 1 Kg which is very convenient. If the axle shaft has a square cross section, there is no tendency for the lever arm to slide around the shaft.

The following sketches are not to scale, but one form of construction might be:
For this style of construction, four pieces of, perhaps, 70 x 18 mm Planed Square Edge timber are cut to perhaps 1050 mm and two 33 x 33 x 65 mm pieces epoxied and screwed to two of the pieces, 18 mm in from the ends:
Then the four pieces are screwed together while resting on a flat surface:

![Diagram of four pieces screwed together](image1)

Then corner bracing triangles of MDF are screwed in place:

![Diagram of bracing triangles](image2)

Then a 130 x 25 mm thick plank is attached across the width at the centre point and screwed in place:

![Diagram of plank attached](image3)

Next, two lengths of the 18 mm thick timbers about 180 mm long are epoxied and screwed to the centre of the 25 mm thick plank, leaving 70 mm clearance to the end of the plank:
Two timber strips 1350 mm long, are cut and erected vertically, being attached by screws coming upwards through the 25 mm thick plank, and by MDF bracing triangles on one side and across the lower end of the verticals. If a spirit level is used to ensure that the vertical timber is actually vertical, then first, the four corners of the floor frame need to be weighted down to overcome any twisting and the floor frame confirmed to be actually horizontal before attaching the vertical timbers:

Each vertical needs to be braced on both sides with diagonal strip, either metal or timber:
An 18 mm thick timber strip is screwed to the tops of the verticals. This deliberately positions the timber 18 mm off centre as the motor which rotates the top of the axle shaft has to be attached to the middle of this newest timber and that places the motor shaft very close to the central point of the base:

One slight disadvantage is that a packing piece is needed for the triangular MDF bracing pieces which increase the frame rigidity at the top:

At this stage, the construction will look like this:

At this point, the 300 rpm motor with its actuator arm and the speed-control box can be fitted. The motor is located centrally, and the control box can be positioned anywhere convenient. The control box is merely a 12-volt battery pack of 1.2V NiMh AA-size batteries connected through a push-to-make press button switch and the commercial DC Motor Speed Controller, to the 300 rpm motor. With this arrangement, the motor can be powered up by pressing the button and adjusting the speed slowly up from stationary, getting the rotor weight moving gradually faster and faster until its best operating speed is reached. When everything is in place, then the rectified output of the alternator is fed into the control box, so that the Start button can be released and the device becomes self-powered from part of the output power. The initial step looks like this:
It should be explained that, with the exception of the 25 mm thick plank, all of this construction is only loaded very lightly as rotating the top of the axle shaft does not take much power or effort at all. Almost all of the rotating weight is located at the bottom of the axle shaft and that weight rests on some form of bearing which rests in the middle of the 25 mm plank.

For a small version of the generator, such as this one, the rotating weight does not need to be all that great and so, the forces generated by the weight and its rotation about the bearing need not be a major thing. However, in spite of the fact that we are only dealing with limited forces which can be handled by simple components, people may be inclined to use a thrust bearing instead of allowing the weight to rest on the shaft of the alternator. A bearing of that kind may look like this:

Here, the base and inner ring do not move while the top outer ring revolves freely and can support a major load while it rotates. If we choose to use one of these, then an arrangement like this could be used:

This combination has a cap (shown in yellow) with a central vertical shaft (yellow) attached to it, tightly encasing the upper ring of the bearing whose lower ring is securely attached to the 25 mm thick plank (grey) perhaps using
epoxy resin (purple). This allows free rotation of the upper ring and vertical shaft while carrying significant loading. The power take-off in the arrangement shown is from the shaft projecting beneath the plank. Generally speaking, the electrical power output increases with increased speed of rotation, so gearing the alternator up so that it rotates much faster than the axle shaft is desirable and this arrangement may be convenient for that. If it is important to have the power take-off above the plank, then a strong bracket can be used to raise the bearing high enough above the plank to accomplish that.

There are two separate forces acting on the bearing. One is always downwards as the bearing supports the rotating weight:

Then there is the sideways forces caused by the rotation of the (unbalanced) weight:

This sideways force is normally considered to be a major problem, however, in this instance, the weight is not being whirled around and trying to escape from the shaft in a horizontal direction, but instead, the weight is turning under gravity powered by its own weight, and the forces generated are quite different and in a different direction. Also, the rate of rotation is very small compared to the speeds which we automatically think about when considering an orbiting weight, typically, this rotation only being between 150 and 300 rpm.

As far as the loading on the axle drive motor is concerned, the situation is like this:
This is the position when at rest. The pull on the motor shaft at the top of the axle shaft is \( W \times d / h \) where \( W \) is the weight at the end of arm \( d \). The situation changes immediately the top of the axle shaft is rotated and the weight \( W \) starts to swing under the influence of gravity.

I am told that the axle shaft needs to be light. With small weights, a rigid wooden shaft is adequate and it does not flex under the loading. I am assured that the bottom of the axle shaft needs a universal joint and a major version of this generator where the weights are very high, that is certainly true as the shaft will flex if designed to its minimum specification, but under these much less stressed conditions, there will be no flexing of the shaft when it is pulled sideways and as the shaft angle is a constant, I do not believe that any such joint is necessary. However, many people will wish to include one. These bearings come in different forms, and one of them looks like this:

It must be remembered that if a joint like this is fitted, then it will not be in constant motion, that is, the joints will take up one particular position and will maintain that position during the whole of the time that the generator is in operation.

A compromise would be to provide a hinged movement in one plane by pivoting the axle shaft joint just above the thrust bearing:
The electrical connections are quite straightforward:

The 12-volt battery pack of 1.2V AA-size batteries is connected to the motor speed controller when the button of the press-button switch is held down. This powers the motor, and as the axle shaft speeds up progressively, the generator starts producing power which is always fed to the speed controller box. As soon as the generator gets up to speed the press button switch can be released and the system runs on power produced by the generator. Excess power will be drawn from the generator output, but those links are not shown in the diagram.

Chapter 5: Energy-Tapping Pulsed Systems

Note: If you are not at all familiar with basic electronics, you might find it easier to understand this chapter if you read chapter 12 first.

One very interesting feature of free-energy devices is that although various devices which appear to be completely different and have different apparent applications, the background operation is often the same. It is clear that a sharp positive going DC electric pulse interacts with the surrounding energy field, making large quantities of free-energy available for anyone who has the knowledge of how to gather and use that extra energy.

Let me stress again that "over-unity" is an impossibility. Over-unity suggests that more energy can be taken out of a system than the total energy which goes into the system. This is not possible as you can’t have more than 100% of anything. However, there is another perfectly valid way of looking at the operation of any system, and that is to rate the output of the system relative to the amount of energy that the user has to put in to make it work. This is called the “Coefficient Of Performance” or “COP” for short. A COP = 1 is when all of the energy put in by the user is returned as useful output. A COP>1 is where more useful energy comes out of the device than the user has to put in. For example, a sailing boat in a good breeze transports people along without the need for the energy of movement to be supplied by the crew. The energy comes from the local environment and while the efficiency is low, the COP is greater than 1. What we are looking for here is not something to tap wind energy, wave energy, sunlight energy, river energy, thermal energy or whatever but instead we want something which can tap the invisible energy field which surrounds us all, namely the “zero-point energy” field or the “ambient background”.

For this, let us look at pulsing circuits used by a wide range of people in a number of apparently quite different devices. An electrical “pulse” is a sudden voltage rise and fall with very sharply rising and falling voltages. However, pulses are seldom generated as isolated events when working with practical devices, so it is probably better to think of a train of pulses, or a “waveform” with very sharp rising and falling edges. These can be called oscillators or signal generators and are so commonplace that we tend not to give them a second thought, but the really important factors for using an oscillator for zero-point energy pick-up is the quality of the signal. Ideally, what is needed can be a perfect square wave with no overshoot, and the voltage level never going below zero volts, or a complex waveform, also with very sharp attack and decay times. These waveforms are a good deal more difficult to generate than you might imagine.

Even in these days of sophisticated solid-state electronic devices, the best method of creating a really sharp voltage pulse is still considered to be a spark gap, especially one which has the spark chopped off suddenly by the use of a strong magnetic field at right angles to the spark gap. For an example of this style of operation, consider the following device.

Frank Prentice’s COP=6 Pulsed Aerial System.

Electrical Engineer Frank Wyatt Prentice of the USA invented what he described as an ‘Electrical Power Accumulator’ with an output power six times greater than the input power (COP = 6). He was granted a patent in 1923 which says:

My invention relates to improvements in ELECTRICAL POWER ACCUMULATORS and the like, wherein the earth, acting as rotor and the surrounding air as a stator, collects the energy thus generated by the earth rotating on its axis, utilises it for power and other purposes.

In the development of my WIRELESS TRAIN CONTROL SYSTEM for railways, covered by my United States Letters Patent Number 843,550, I discovered that with an antenna consisting of one wire of suitable diameter supported on insulators, three to six inches above the ground and extending one half mile, more or less in length, the antenna being grounded at one end through a spark gap, and energised at the other end by a high frequency generator of 500 watts input and having a secondary frequency of 500,000 Hz, would produce in the antenna, an oscillatory frequency the same as that of the earth currents and thus electrical power from the surrounding media was accumulated along the length of the transmission antenna and with a closed oscillatory loop antenna 18 feet in length run parallel with the transmission antenna at a distance of approximately 20 feet, it was possible to obtain by tuning the loop antenna, sufficient power to light to full candle power a series bank of 50 sixty-watt carbon lamps. Lowering or raising the frequency of 500,000 Hz resulted in a diminishing of the amount of power received through the 18 foot antenna. Likewise, raising the transmission antenna resulted in a proportionate decrease of power picked up on the receiving antennae and at 6 feet above the earth no power whatsoever was obtainable without a
change of voltage and frequency.

It is the objective of my generic invention to utilise the power generated by the earth, by the means described here and illustrated in the drawings. The two drawings show simple and preferred forms of this invention, but I wish it to be understood that no limitation is necessarily made as to the exact and precise circuits, shapes, positions and structural details shown here, and that changes, alterations and modifications may be made when desired within the scope of my invention and as specifically pointed out in the claims.

Referring particularly to Fig. 1, 1 and 2 are alternating current feed wires supplying 110 volts 60 cycles per second to a high-frequency generator. 3 is a switch with poles 4 and 5, while 6 and 7 are the connections to the high-frequency transformer 8, which is used to step-up the frequency to 500 kHz and the voltage to, say, 100 kV. 9 is an inductor, 10 is a spark gap, 11 is a variable capacitor, 12 is the primary winding and 13 the secondary winding of transformer 8. The secondary winding is connected to ground through variable capacitor 16, and wire 17. Wire 14 connects transformer 8 to the main transmission antenna 19 which is supported along its length on insulators 20. Spark gap 21 is positioned between the main transmission antenna 19 and the ground 24, passing through connecting wire 22 and variable capacitor 23. The main transmission antenna 19, can be any desired length.

In Fig. 2, 25 is a closed oscillating loop antenna of any desired length. For greatest efficiency, it is run parallel with the main transmission antenna 19 of Fig. 1. Wire 26 is connected to the secondary winding 27 of a step-down transformer which winding then goes to ground 31 through variable capacitor 29. The primary winding 32 of the step-down transformer has variable capacitor 33 connected across it and it feeds directly into winding(s) 34 of frequency transformer(s) which supply current through winding(s) 35 to a motor “M” or other electrical load(s).

Having described the drawings, I will now describe the operation of my invention. Operate switch 3 to connect the input power. Adjust spark gap 10 and variable capacitor 11 so that 100,000 volts at a frequency of 500,000 cycles per second is delivered to step-up transformer 8 of Fig. 1. Next, adjust spark gap 21 of the transmission antenna 19 so that all (voltage) peaks and nodes are eliminated in the transmission of the 100,000 volts along the antenna by the current surges across spark gap 21. The high-frequency alternating current flowing through spark gap 21 passes through variable capacitor 23 to ground 24 and from there, back through the ground to earthing point 18, through variable capacitor 16 and back to winding 13 of transformer 8. As the 500,000 Hz
current is the same as the earth-generated currents and in tune with it, it naturally follows that accumulation of earth currents will amalgamate with those for transformer 8, providing a reservoir of high-frequency currents to be drawn upon by a tuned circuit of that same 500 kHz frequency, such as that shown in Fig.2, where the antenna 25 is turned to receive a frequency of 500 kHz, which current then passes through transformer 27, any frequency-adjusting transformer(s), and on to power the load(s) 38.

The return of current through the earth from transmission antenna 19, is preferable to return through a wire as the ground return current picks up more earth currents than a wire does. I also prefer under certain conditions, to use a single antenna wire in place of the closed loop antenna shown in Fig.2. Under certain operational requirements, I have had improved performance by having the transmission antenna elevated and carried on poles many feet above the earth, and with that arrangement it is necessary to use a different voltage and frequency in order to accumulate earth currents.

This system of Frank's effectively applies very sharply pulsed DC pulses to a long length of wire supported in a horizontal position not far above the ground. The pulses are sharp due to both the spark gap on the primary side of the transformer, along with the spark-gap on the secondary (high voltage) side of the transformer. An input power of 500 watts gives a 3 kW power output from what appears to be an incredibly simple piece of equipment.

Dave Lawton's Solid-State Circuit.
A solid-state semiconductor circuit which has proved successful in producing pulses like this is shown as part of Dave Lawton's replication of Stan Meyer's Water Fuel Cell. Here, an ordinary NE555 timer chip generates a square wave which feeds a carefully chosen Field-Effect Transistor the BUZ350 which drives a water-splitter cell via a combined pair of choke coils at point “A” in the diagram below.

Stan Meyer used a toroidal ferrite ring when he was winding these choke coils while Dave Lawton uses two straight ferrite bars, bridged top and bottom with thick iron strips. Chokes wound on straight ferrite rods have been found to work very well also. The effects are the same in all cases, with the waveform applied to the pipe electrodes being converted into very sharp, very short, high-voltage spikes. These spikes unbalance the local quantum environment causing vast flows of energy, a tiny percentage of which happens to flow into the circuit as additional power. The cell runs cold, and at low input current, quite unlike an ordinary electrolysis cell where the temperature rises noticeably and the input current needed is much higher.
John Bedini's Battery-Charging Circuit.

John Bedini uses this same pulsing of a bi-filar wound coil to produce the same very short, very sharp voltage spikes which unbalance the local energy field, causing major flows of additional energy. The figure shown here is from his US patent 6,545,444.

John has produced and generously shared, many designs, all of which are basically similar and all using a 1:1 ratio bi-filar wound transformer. This one uses a free-running rotor with permanent magnets embedded in it’s rim, to trigger sharp induced currents in the windings of the coil unit marked “13b” which switches the transistor on, powering winding “13a” which powers the rotor on its way. The pick-up coil “13c” collects additional energy from
the local environment, and in this particular circuit, feeds it into the capacitor. After a few turns of the rotor (dictated by the gear-down ratio to the second rotor), the charge in the capacitor is fed into a second “on-charge” battery.

The rotor is desirable but not essential as the coils marked 1 and 2 can self-oscillate, and there can be any number of windings shown as 3 in the diagram. Winding 3 produces very short, sharp, high-voltage spikes, which is the essential part of the design. If those sharp pulses are fed to a lead-acid battery (instead of to a capacitor as shown above), then an unusual effect is created which triggers a link between the battery and the immediate environment, causing the environment to charge the battery. This is an amazing discovery and because the voltage pulses are high-voltage courtesy of the 1:1 choke coils, the battery bank being charged can have any number of batteries and can be stacked as a 24-volt bank even though the driving battery is only 12 volts. Even more interesting is the fact that charging can continue for more than half an hour after the pulsing circuit is switched off.

It can be tricky to get one of these circuits tuned properly to work at peak performance, but when they are, they can have performances of COP>10. The major snag is that the charging mechanism does not allow a load to be driven from the battery bank while it is being charged. This means that for any continuous use, there has to be two battery banks, one on charge and one being used. A further major problem is that battery banks are just not suitable for serious household use. A washing machine draws up to 2.2 kilowatts and a wash cycle might be an hour long (two hours long if a “whites” wash and a “coloureds” wash are done one after the other which is not uncommon). During the winter, heating needs to be run at the same time as the washing machine, which could well double the load.

It is recommended that batteries are not loaded much beyond their “C20” rate, that is, one twentieth of their Amp-Hour nominal rating. Say that 85 Amp-Hour deep-cycle leisure batteries are being used, then the recommended draw rate from them is 85 Amps divided by 20, which is 4.25 amps. Let’s push it and say we will risk drawing double that, and make it 8.5 amps. So, how many batteries would we need to supply our washing machine assuming that our inverter was 100% efficient? Well, 2,200 watts on a 12-volts system is 2,200 / 12 = 183 amps, so with each battery contributing 8.5 amps, we would need 183 / 8.5 = 22 large, heavy batteries. We would need twice that number if we were to treat them right, plus twice that again for household heating, say 110 batteries for an anyway realistic system. That sheer size of battery banks is not realistic for your average householder or person living in an apartment. Consequently, it appears that the Bedini pulse-charging systems are not practical for anything other than minor items of equipment.

However, the really important point here is the way that when these short pulses are applied to a lead-acid battery, a link is formed with the environment which causes large amounts of energy to flow into the circuit from outside. This is extra “free-energy”. Interestingly, it is highly likely that if the pulses generated by Dave Lawton’s water-splitter circuit shown above, were fed to a lead-acid battery, then the same battery-charging mechanism is likely to occur. Also, if a Bedini pulse-charging circuit were connected to a water-splitting cell like the Lawton cell, then it is highly probable that it would also drive that cell satisfactorily. Two apparently different applications, two apparently different circuits, but both producing sharp high-voltage pulses which draw extra free-energy from the immediate environment.

The Tesla Switch.
It doesn’t stop there. Nikola Tesla introduced the world to Alternating Current (“AC”) but later on he moved from AC to very short, sharp pulses of Direct Current (“DC”). He found that by adjusting the frequency and duration of these high-voltage pulses, that he could produce a whole range of effects drawn from the environment - heating, cooling, lighting, etc. The important point to note is that the pulses were drawing energy directly from the local environment. Leaving aside the advanced equipment which Tesla was using during those experiments and moving to the simple-looking 4-battery switch, we discover the same background operation of sharp voltage pulses drawing free-energy from the environment.
Consider the Electrodyne Corp. circuit (shown in "The Manual of Free-Energy Devices and Systems", 1986) tested by them for a period of three years:

Please note that when I shared this circuit diagram several years ago, someone persuaded me that the diodes were shown the wrong way round, and because of that, I have previously shown these diodes incorrectly. The diagram above is the one shown by the Electrodyne Corp. staff, and is correct.

As the switching used by this device was a mechanical device which has six switches where three are ON and three are OFF at any moment, the Electrodyne Corp. staff present the circuit diagram like this:

With switching like this:
It is recommended that this simple-looking circuit has an inductive load, preferably a motor, but consider the results of that very extended period of testing. If the switching rate and switching quality were of a sufficiently high standard, then the load could be powered indefinitely. The batteries used were ordinary lead-acid batteries, and after the three years of tests, the batteries appeared to be in perfect condition. Their tests revealed a number of very interesting things. If the circuit was switched off and the batteries discharged to a low level, then when the circuit was switched on again, the batteries returned to full charge in under one minute. No heating occurred in the batteries in spite of the massive charging rate. If the circuit was switched off and heavy current drawn from the batteries, then heat would be produced which is quite normal for battery discharging. The system operated lights, heaters, television sets, small motors and a 30-horsepower electric motor. If left undisturbed, with the circuit running, then each battery would charge up to nearly 36 volts with no apparent ill effects. Control circuitry was developed to prevent this over-charging. This, of course, is easy to do as all that is required is to place a relay across one battery and have it disconnect the circuit when the battery voltage reaches whatever voltage is considered to be a satisfactory maximum voltage.

These test results show spectacular battery charging and battery performance, quite outside the normal range associated with these ordinary lead-acid batteries. Are they being fed very short, very sharp pulses, like the previous two systems? It would look as if they were not, but one other very interesting piece of information coming from Electrodyne is that the circuit did not operate correctly if the switching rate was less than 100 Hz (that is 100 switchings in one second). The Electrodyne switching was done mechanically via three discs mounted on the shaft of a small motor.

One other detail reported by the Electrodyne testers, is that if the switching speed exceeded 800 times per second, that it was “dangerous” but unfortunately, they didn’t say why or how it was dangerous. It clearly was not a major problem with the batteries as they were reported to be in good shape after three years of testing, so definitely no exploding batteries there. It could well be as simple a thing that the voltage on each battery rose so high that it exceeded the voltage specifications of the circuit components, or the loads being powered, which is a distinct possibility. It is possible that at more than 800 pulses per second, the charging produced excessive cooling which was not good for the batteries.

It is generally accepted that for a circuit of this nature to work properly, the switching has to be very sudden and very effective. Most people have an immediate urge to use solid-state switching rather than the mechanical switching used by Electrodyne. A ‘thyristor’ or ‘SCR’ might be suitable for this, but the sharp switching of a PCP116 opto-isolator driving an IRF540 FET is impressive and a TC4420 FET-driver could substitute for the opto-isolator if preferred. It is possible that having a slight delay after the switches have turned On and Off, can prove very effective.

The Electrodyne Corp. staff used three identical discs mounted on the shaft of a motor as shown above. This allows the contact "brushes" to be located on opposite sides of the discs. There are, of course, many possible alternative constructions and I have been asked to show how I would choose to build this type of mechanical switching. The common idea of using mechanical relays is not very practical. Firstly, relays have trouble switching at the speeds suggested for this circuit. Secondly, with a contact life of say, two million and a switching speed of just 100 times per second, the relays would reach their projected lifespan after two weeks of operation, which is not a very practical situation.

The objective is to have a simple construction which produces several switchings for each revolution of the motor, easy adjustment of the timing of two separate sets of three switches (one set being OFF when the other set is ON), a construction which can be taken apart and then assembled again without altering the timing, and an electrical connection method which is straightforward. Obviously, the construction needs to use components which are readily available locally, and ideally, only require simple hand tools for the construction.

This suggested construction allows adjustment of the timing for both the start of the first set of switches and the start of the second set of switches. It should also be possible to introduce a short gap between the operation of these two sets of switches. This particular design is assuming a gap between each switching operation as that may be beneficial.

The switch contacts are rigid arms, pulled against the rotating drum by springs. The contacts touching the drum can be of various types and the ones shown are brass or copper cheese-head screws or bolts which are particularly convenient as they allow standard solder tags to be used to make the connections to the switch wires which then run across to ordinary electrical screw connectors, all of which can be accessed from above. I would suggest that four screw connectors should be used as a block as that allows them to be fastened in position with two screws which then stops them rotating when the wires are being tightened. There should not be any need for the conducting inserts in the switching cylinder to be particularly wide in the direction of rotation.
A practical construction method might be:

The contact arms are shown as attached to each other in pairs. A lower level of construction accuracy can be allowed if they are all kept separate and a spring used for each arm rather than one spring for two arms as shown.
in the drawing. I strongly recommend that the switching drum be solid and the brass or copper insets be a fair
thickness and keyed securely into the drum. The surface of the inserts should be very gently eased into exact
alignment with the surface of the drum, possibly by the very careful use of a small file or lathe if you are lucky
enough to have access to one.

The pivots for all of the switching arms can be a length of threaded rod with lock nuts at each end. There should
be almost no movement of the switching arms when the drum is spinning, so no enormous precision is needed for
the holes in the switching arms, through which the threaded rod runs. Having said that, it must be understood that
each switch in the set of three, must turn On and Off at the same time, so the contacts on the spring-loaded
arms must slide on to and off the conducting strips in the switching cylinder, at exactly the same time.

The drawing shows three conducting inserts at each of eight evenly-spaced positions around the circumference of
the drum. The number around the drum is not critical although this suggestion gives eight switchings per
revolution. If you choose to use a different number, you need to remember that the positioning of the arms
underneath the drum will be different. You need to arrange it so that just after one set runs off its conducting
strips that the other set slides on to it's conducting strips. Both sets of switches must not be ON at the same time
as that short-circuits the batteries, which is probably not a good idea.

The timing adjustment is achieved by moving the supporting block slightly, by easing the four clamping screws,
sliding the block and tightening the screws again. This, of course, is done when the drum is not rotating.

Each set of six switching arms needs to have all of the arms exactly the same length between the sliding contact
(shown as a bolt head) and the pivot hole. Each of the conducting strips inset into the drum, need to be aligned
exactly and be exactly the same width, otherwise the switching action will be ragged and not properly
synchronised.

The supports for the switching arms can be either a single block with slots cut in it or the easier construction
shown, where it is fabricated from several standard rectangular pieces and glued and/or screwed together.

The unequal amount of conducting strip compared to the non-conducting part means that there will be a timing
gap between each pair of On/Off switchings. In spite of that, the battery switching will be a 50% Duty cycle as
required. The switching sequence will then be: On / Off / Pause, On / Off / Pause, On / Off / Pause ….. and that
may well be a desirable arrangement as having an inter-pulse delay can be very good for battery charging.

However, please don't imagine that the Tesla Switch described here is a 'plug-and-play' device which you can
switch on and it will give you the sort of outputs mentioned above, as that is very much not the case. You need to
see the Tesla Switch as being a long-term development project with high potential.

If you use the Tesla Switch circuit with manual switches and run each phase for many minutes before altering the
switching, it can give up to four times better performance than running the load off the four batteries in parallel.
That is not what the Tesla Switch is all about.

The Tesla Switch is one of the more difficult devices to get operational, in spite of the fact that it appeals to a large
number of people. There are three possible modes of operation. If the diodes are turned the wrong way round so
that they can feed current from each battery, then the operation will definitely be COP<1 but it will be a good deal
better than operating without the switch circuit in place.

Another way was developed and tested over three years by staff of the Electrodyne Corporation in America. In
this version, the diodes are reversed and they only feed sharp voltage spikes back to the batteries, through the
diodes which supposedly don't allow current to flow in that direction. This is a very different form of operation
where the operating power flows into the circuit from the local environment. The batteries need to be 'conditioned'
through long periods of being operated this way as the 'hot electricity' which the batteries have been using up to now.
This long conditioning period is generally enough to make the average builder give up and believe that the circuit just doesn’t work. Dave Lawton was faced with exactly the same type of problem when he attempted to replicate Stan Meyer's "Water Fuel Cell". It appeared 'dead' and produced nothing during a whole month of testing, and then it suddenly burst into life, producing large
amounts of HHO gas mix for almost no electrical input. Without his exceptional patience, Dave would never have
succeeded. I believe that the same applies to the Tesla Switch when wired correctly with the diodes blocking
current flow from the batteries – it is likely to take long-term and patient testing before the system swings into life.

One experimenter who did not believe the diodes could possibly work that way round, tested the arrangement and
discovered that in spite of the theory, in practice, those particular reverse-biased diodes actually break down and
pass very sharp voltage spikes to the batteries, so the effect may well be like a slick version of the various battery
circling circuits shown in chapter 6.
It is interesting to note that in the 1989 patent US 4,829,225 granted to Yury Podrazhansky and Phillip Popp, their evidence is that batteries charge much better and have a longer life if they are pulsed in a specific way. Their formula is that the battery should be given a powerful charging pulse lasting for a period of time between a quarter of a second and two seconds, the pulse being the Amp-Hour rating of the battery. That is, for an 85 AHr battery, the charging pulse would be 85 amps. That pulse is then followed by a discharging pulse of the same, or even greater current but only maintained for only 0.2% to 5% of the duration of the charging pulse. Those two pulses are then followed by a resting period before the pulsing is repeated. They quote the following examples of their experiences when using this method:

<table>

Interestingly, this appears to confirm the charging potential of the Tesla Switch style of operation, especially if there is a short rest period between the two sets of switch operations. Here is a solid-state version of the circuit:

Here, six 2N3055 transistors (or the more convenient version the TIP3055) are switched On and Off by six audio transformers (possibly the Radio Shack #273-1380 transformers). The 8-ohm transformer primary windings are connected in series and driven by a square-wave generator through a large capacitor. This circuit is shown in red in the circuit diagram above. When the square wave is positive, transformers 1, 2 and 3 have their primary windings loaded by a forward-biased diode which limits the voltage across them to a maximum of about 0.7 volts.
and that keeps their operation short when they switch On. The other three transformers 4, 5 and 6 have the 
diodes across their primary windings positioned to block a positive voltage and so their transistors remain Off.

When the output voltage of the square-wave generator goes negative, the situation is reversed and transformers 
4, 5 and 6 switch on briefly while transformers 1, 2 and 3 remain Off. The diodes across the primary windings are 
1N4148 diodes which have a very fast switching time which can be very important for circuits of this type. The 
other diodes are 1N1183 which are rated at 50 volts and 40 amps.

A Three Battery Switching System
Continuing the Tesla Switch style of operation, it is possible to get the same effect as the Tesla Switch circuit, 
using only three batteries (or three capacitors). Discussed almost a century ago by Carlos Benitez in his patents, 
and more recently described by John Bedini, just three batteries can be used if more complicated circuit switching 
is used. Carlos points out that there has to be an energy loss due to wires heating up and batteries not being 
100% efficient. He overcomes these problems with some very clever circuitry which is covered in the following 
section. However, it is not at all certain that this is actually the case as experimentation indicates that it is 
possible for this kind of battery switching to maintain the battery charge levels far beyond the expected.

Here is an untested suggestion for how it might be possible to produce a portable, self-powered powerful light. 
There are many possible variations on this, and the following description is just intended as an indication of how a 
three battery switching system might be constructed. If you are not familiar with simple electronics, then I suggest 
that you study the basic electronics tutorial of chapter 12.

Battery charging can be accomplished in various different ways. Obviously, the more the electrical loading can be 
reduced, the lesser the need for recharging. Two methods for doing this involve passing the same electrical 
current repeatedly through the load, as shown here:

The switching for this arrangement can be implemented in various different ways, but essentially, in Stage 1, 
batteries ‘B1’ and ‘B2’ provide twice the voltage of batteries ‘B3 ’ and ‘B4’, causing current to flow through the load 
‘L’ and into batteries ‘B3’ and ‘B4’, driven by the voltage difference which is normally, the same as the voltage of 
any one of the batteries on its own. Each of the batteries ‘B3’ and ‘B4’ receive only half of the current supplied by 
batteries ‘B1’ and ‘B2’, and so, there is, not surprisingly, an energy loss. However, for half of the time, batteries 
‘B3’ and ‘B4’ are receiving charging current instead of supplying current to the load.

In Stage 2, the batteries are swapped around and the process repeated with batteries ‘B3’ and ‘B4’ supplying 
current to the load and batteries ‘B1’ and ‘B2’. Tests have shown that with this arrangement, the load ‘L’ can be 
powered for longer than if all four batteries were connected in parallel and used to supply the load directly. With 
this system, each battery receives half of the load current for half of the time.

An alternative method which uses the same principle, but three batteries instead of four, and where each battery 
receives all of the load current for one third of the time, is like this:
Here, the batteries are switched around sequentially, with two of them in series causing current flow through the load ‘L’ and into the third battery. There is, of course, an overall energy loss, and so, additional energy from an external source needs to be introduced to keep the load powered continuously. However, as with the four-battery system, the load ‘L’ can be kept powered longer by the batteries arranged like this than would occur if all three batteries were connected in parallel and used to power the load directly.

As before, the switching for a system of this kind can be implemented in various different ways. For long-term reliability, solid-state switching is preferred, and as NPN transistors are low-cost and readily available, they are shown here in one of the preferred configurations:

As each inter-battery connection is different for each of the three stages of operation of this circuit, it is necessary to have four switches for each stage. In order to establish the necessary details for connection of the transistors, as this circuit does not have the normal positive and negative rails, the (nominal) current flow directions need to be examined. These are shown here:

Obviously, the current flows from the higher series-connected voltage to the lower single battery voltage. The twelve virtual switches are numbered from ‘S1’ to ‘S12’ respectively, and if each represents an NPN transistor, then we also need to ensure that the current flow direction is correct for the transistor and to identify a higher voltage point which can be used to feed current into the base of each transistor. These details are listed here:

The suggested switching arrangement therefore, looks like this:
While the above diagram shows each stage with permanently connected base resistors, that is, of course, only to display the conceptual arrangement. Each resistor is passed through an opto-isolator and each set of four opto-isolators are driven by one of three separate outputs of equal duration. One possible arrangement for this could be as indicated below.

The CD4022 Divide-by-Eight chip can be arranged to divide by three rather than eight, by connecting its pin 7 to pin 15. The physical chip connections are:

The chip needs a clock signal in order to function. There are many different ways of generating a clock signal, and the one shown here is very cheap, simple and has adjustable frequency and adjustable Mark/Space ratio, although, as the signal is to be used to trigger the action of a Divide-By-Three chip, there is no need for this clock signal to have a 50% Mark/Space ratio. The chip supply current is so tiny, that it really does not matter what the Mark/Space ratio is:
Using this circuit as the clock signal, the opto-isolator circuit could be:

There are various opto-isolators available and while the rather expensive high-speed varieties are tempting, since we have to provide three sets of four, the ISQ-74 quad chip seems very suitable for this application although it is slower:
The overall circuit for the opto switching is then:

The output transistors are expected to switch 1 amp and so the TIP132 NPN and matching TIP137 transistors have been selected. These are cheap, Darlington transistors with current gains in excess of 1000 which means that the base current requirements are about 1 milliamp, which suggests that the base transistors could be 8.2K for a 12V system. These transistors can switch 12A at up to 100V and have a power dissipation of 70 watts, indicating that they will be running so far below their capability that they should run cool.

With this kind of circuit, it is desirable to have a fairly large current flow (relative to the battery capacity) in order to give a marked difference between the discharging and charging cycles for each battery. One possible load for this circuit could be the potentially low-cost G4 LED lighting unit shown here:

This quite remarkable device has a massive 160 lumens output with a lighting angle of 160 degrees and an input power of just 1.2 watts (100 milliamps at 12 volts). That light output is startling when seen in a completely dark place and some heat is generated, which is unusual for LEDs. A 100-watt filament light bulb has a light output of about 1600 lumens and a lighting angle of 360 degrees (some of which is normally not used usefully), and so, for the equivalent level of lighting, we would need ten of these G4 LED units, with a total power input of about 1 amp at 12 volts. Checking this in dark conditions, suggests that a much lesser lighting level would be more than acceptable. These LED lighting units are available in pure white and in “warm white” versions, and it is probable that the “warm white” version would suit most people better than the pure white versions.
Tests on one of the pure white units, shows a quite remarkable variation in the light output as the current is reduced, as the effect is highly non-linear:

At 12 volts the current is 1 amp. At 9.8 volts the current has dropped to a tiny 23 milliamps and while the light is nothing like as bright, there is still a considerable amount of light. At 9.42 volts, the light level is still significant and the current has dropped to a mere 10 milliamps. This suggests two main options: 10 LED units at 12 watts, providing a massive lighting level, or perhaps the same LED units run at 9.42 volts for just 1.2 watts of input power.

Using a 104 mm x 50 mm board size which will slot directly into a standard plastic slotted-side box, a stripboard layout (where the red circles indicate a break in the copper strip on the underside of the board) for the transistor switching section might be:
Each base resistor has an output link (O1b through O12b) which is connected through its opto-isolator to the destination shown in the “Base” column in the table. Each set of three NPN transistors and one PNP transistor are switched together via a single ISQ-74 quad opto isolator chip. Each of the three ISQ-74 chips is powered in turn by one of the outputs from the CD4022 Divide-by-Three connected chip, which driven by the CD40106B hex Schmitt inverter chip wired as a clock as shown above. It is expected that a suitable clocking frequency would be about 700 Hz. A possible layout for the clock, Divide-by-Three and twelve opto-isolators on a 104 mm x 50 mm strip board, is shown here:
The timing and switching circuits form part of the load which is being switched. However, if we assume that there will be a power loss when running this system, then we should consider the very clever designs of Carlos Benitez in 1915.

The Self-powered Free-Energy Generators of Carlos Benitez

The Mexican Civil Engineer Carlos Benitez devised what is essentially the 3-battery switch discussed above. He was working at a time when solid-state electronics was not available and so his design is all the more impressive for that. Here is some of his patent information:

Carlos Benitez Patent GB 17,811 13th May 1915

System for the Generation of Electric Currents

I, Carlos F. Benitez, Civil Engineer, 141 Ocampo Street, Guadalajara, Mexico, do hereby declare the nature of this invention:

The invention relates to a new process for obtaining electric currents under unusually simple, economic and practical conditions. I use synthetically in combination: apparatus for the production of electric currents for charging one or several capacitors whose collectors or inner coatings are connected to one of the terminals of the primary winding of one or several induction coils and the other coatings of those capacitors are alternately grounded through the primary winding of a transformer, or connected through the transformer primary to the above collectors, appropriate means for collecting the currents produced in the secondary windings of these transformers and for applying charging to the above collectors, and an appropriate means for discharging those collectors, and for the application of all or part of its energy to the successive replication of the process already described, in this way, increasing the generation of electrical energy, or maintaining a constant, pre-determined electrical output.

Furthermore, the invention consists of a new combination of parts from which are derived advantages which will be fully understood by the consideration of the two different cases illustrated in the accompanying drawing, in which:

1 is a bank of capacitors.
2 is a rotating commutator to make and break the circuit connections at the appropriate instants.
3 is the primary winding of a transformer or induction coil.
4 is the secondary winding of that transformer or induction coil.
5 is a second bank of capacitors.
6 is an oscillator spark gap.
7 is the primary winding of a second transformer.
8 is the secondary winding of that transformer.
9 is a third bank of capacitors.
70 is the primary winding of a third transformer
71 is the secondary winding of that transformer.
10 is a fourth transformer.
11 is a series of incandescent lamps.
12 is an electric motor.
(a), (b), (c), (d), (e) and (f) are mercury-vapour converters or cathodic valves, allowing electric current flow only in the direction shown by the arrows.
Or using current day symbols:
The capacitor bank 1, is connected through wire 13 to a source of electric current, providing the initial charge to capacitor bank 1. This initial charge is used to start the system running and can be disconnected at any time by means of switch 14.

Wire 15 connects the inner leaves of capacitor bank 1 with poles 16 and 17 of the commutator 2, and it’s pole 18 is connected via wire 19 to one of the terminals of transformer primary winding 3, whose other end is connected through wire 20 to the outer leaves of capacitor bank 1. The secondary winding 4, of this transformer, is connected by wire 21 to the inner plates of capacitor bank 5, and by wire 22, to the outer plates of capacitor bank 5. In the same manner, wires 23 and 24 pass those connections on to the two sides of the primary winding 7 of the second transformer. Wire 23 also contains an oscillator spark gap 6, and wires 21, 22, 25, 26 and 72 contain the one-way cathode valves a, b, c, d, e and f. The secondary winding 8, of this second transformer, connects to the inner plates of capacitor bank 9, whose outer plates are connected to ground through the primary winding 70 of the third transformer. The secondary winding 71, of this third transformer is also connected through wire 72, to the inner plates of capacitor bank 9. Wires 27 and 28 also connect these inner plates to commutator poles 29 and 30, which form a change-over switch through commutator contact 31, which is connected to the inner plates of capacitor bank 1 through wire 32. Switches 33 and 34, allow the connection or disconnection of the primary winding of transformer 10, whose secondary winding supplies current to the incandescent lamps 11 and motor 12. Finally, one of the ends of primary winding 3 is connected through wire 35 to both pole 36 and pole 37 of the commutator 2, and their corresponding commutator contact 38 is connected to ground by wire 39.

As the construction and use of all of these components (with the exception of the commutator) is perfectly understood, it would be pointless to describe them. The commutator 2, is enclosed in a tank 40, whose end walls 41 and 42 support the ends of the contact-mounting bar 43, and the bearings of the rotating shaft 44. The contact bar is made of a non-conducting material to which are immovably attached, the copper contact strip brushes 16, 17 and 18, 36, 37 and 38, and 29, 30 and 31. Secure contact between these brushes and the rotating cylinders mounted on shaft 44 is ensured by the rotating lever arm 47 and its associated weight 48.

The three rotating cylinders mounted on shaft 44, are made of a non-conducting material and have a conducting strip around their centre. This strip has two conducting spurs running outwards, one to the right and one to the left, positioned 180 degrees apart around the circumference of the cylinder. When shaft 44 is rotated, this causes the central contact (for example, 18) to connect first to one of its associated contacts (say, 17) and then disconnect and connect to the other contact (say, 16) forming a change-over switching mechanism.

The switching strips on the central cylinder are positioned 90 degrees around the circumference when compared to the position of the switching strips on the two outer cylinders which are aligned with each other.

This can be seen in the diagram, where in the shaft position shown, 38 and 36 are connected and 31 and 30 are connected, while 18 is not connected to either 16 or 17.

When shaft 44 is rotated through 90 degrees, 18 will be connected to 17, while 31 and 38 will both be isolated.

When shaft 44 is rotated through an additional 90 degrees, brush 18 will be isolated while brush 38 will be connected to 37 and brush 31 will be connected to 29.

When shaft 44 is rotated through an additional 90 degrees, brush 18 will be connected to brush 16, while brushes 31 and 38 will be isolated.

[Note: if the diagram is correctly proportioned, there will be four positions in each rotation where the three central brushes are not connected to any of the outer brushes, producing the switching sequence Make, Break, Make, Break, Make, Break, Make, Break for each revolution. These breaks in the switching sequence have been shown to have a significant effect when batteries are being charged. This mechanism would be built as solid state switching nowadays.]

Shaft 44 is elongated and projects through the end wall 42, so that a belt drive 45, or other suitable method, may be used to rotate the shaft, driven by motor 12 or possibly by crank handle 46. The tank 40, is filled with oil or any other insulating liquid, in order to prevent sparking between the brushes, which would lower the efficiency of the system.

This system is operated as follows:

With the commutator in the position shown in the drawing, that is, with brush 36 connected to 38 and brush 30 connected to 31, and supposing capacitor bank 1 is connected through wire 13 to a source of electric power (say, a Wimshurst Machine), switch 14 being closed, electric current passes through wire 13 to charge capacitor bank 1, causing a current to flow through wire 20, primary winding 3, wire 35, brush 36, brush 38 and wire 39 to earth.
This current flow through primary winding 3 induces an inverse current in secondary winding 4, which flows through wire 21, charging capacitor bank 5 and then a direct induced current flowing through conductor 22, charging capacitor bank 5.

The current flow to both sets of plates in capacitor bank 5, charges it and creates a spark across the spark gap 6, causing a very sharp current pulse through primary winding 7. This in turn, causes a considerable number of high-frequency oscillating current flows in the secondary winding 8 and these pass along wires 25 and 26, and via diodes c and d, thus charging capacitor bank 9 and causing a corresponding set of high-frequency pulses to flow to ground through the primary winding 70. This induces current flow in the secondary winding 71, which flows through diodes e and f, and onwards via wire 72, further boosting the charge on capacitor bank 9.

Therefore, capacitor bank 1 being charged by an external source, capacitor bank 9 will be charged indirectly and successively re-charged several times, resulting in a quantity of electricity considerably greater than that of capacitor bank 1. By this means, the system can be self-powered with no need for the power source used to start it, which means that switch 14 can be opened.

When shaft 44 rotates through 90 degrees, brush 17 connects with brush 18, while brushes 31 and 38 are both disconnected. This causes capacitor bank 1 to be completely discharged through transformer primary 3, causing the already described process by which capacitor bank 9 receives a substantially larger electrical charge. This results in capacitor bank 1 being totally discharged and capacitor bank 9 being highly charged with a great deal of electricity. Consequently, if we now close switch 33 and rotate shaft 44 through another 90 degrees, the following situation results:

1. Brushes 17 and 18 will be disconnected.
2. Brushes 37 and 38 become connected which in turn connects the outer plates of capacitor bank 1 to ground. Brushes 29 and 31 are connected, which then connects the inner plates of capacitor bank 9 to the inner plates of capacitor bank 1.
3. Part of the high charge on capacitor bank 9 will flow as an electric current, through wire 32 and into capacitor bank 1.
4. This current flow from the inner plates of capacitor bank 9 causes an immediate matching negative charge to flow from ground through primary winding 70, to offset the charge imbalance.
5. This induces a current flow in the secondary winding 71, which passes additional electrical power to the outer plates of both capacitor bank 9 and capacitor bank 1, and that further intensifies the current flow through primary winding 70 quite considerably.
6. Further, as capacitor bank 1 has just been newly charged, it drives additional current through primary winding 3, causing new induced currents which will, as before, produce much increased charge on the inner plates of both capacitor bank 5 and capacitor bank 9, as described earlier.

If shaft 44 is rotated through a further 90 degrees, then a connection between brushes 16 and 18 will be made and all other circuits will be opened, causing capacitor bank 1 to be discharged again, thus repeating the entire process described above provided that shaft 44 is rotated continuously.

This system produces a constantly increasing supply of electric current flowing through wire 32, and so, switch 34 can be closed, allowing transformer 10 to provide the electrical power to run motor 12 which maintains shaft 44 in continuous rotation, making the system self-powered with no requirement for any form of outside power supply. Additional transformers inserted in wire 32 can be used to power additional equipment.

Without employing the high-frequency currents described above, similar results may be attained by means of the arrangement shown at the lower right hand side of the following drawing:
Here, primary winding 50 is connected as shown by the dashed lines, with wires 19 and 20 of the former arrangement, and wire 53 connects to both wire 27 and wire 28. This arrangement has primary winding 50 connected through its end 51 to wire 20 and so is permanently connected to the outer plates of capacitor bank 1, and its other end 52 being connected to wire 35 will be intermittently connected to ground. Wire 53 being connected to wires 27 and 28 will intermittently connect together, the inner plates of capacitor bank 54 and the inner plates of capacitor bank 1.

With this arrangement, both ends of the secondary winding 55 are connected through diodes 56 and 57, to wire 53. The outer plates of capacitor bank 54 are permanently connected through primary winding 50 to ground. Both ends of the secondary 59 are connected through diodes 60 and 61, back to wire 53. As a result, if capacitor bank 1 is charged, it drives a current through wire 20 and so, through primary winding 50, and on to ground through wires 35 and 39. This induces current in secondary winding 55 which gets stored in the inner plates of both capacitor bank 54 and capacitor bank 1, as in this moment, the circuit is closed between brushes 29 and 31, and so, wire 53 is connected to wire 32. On receiving these new charges, both capacitor bank 1 and capacitor bank 54 will create new induced electric currents flowing through primary windings 50 and 58. These multiple charging pulses will decrease with time until they are insignificant, at which time, due to the rotation of shaft 44, the connection between brushes 29 and 31 and between brushes 36 and 38 will no longer be maintained, and instead, brushes 18 and 17 will become connected, discharging capacitor bank 1 through primary coil end 50 which is a very strong discharge, charging capacitor bank 54 as wire 53 is now disconnected from wire 32. This, in turn, causes powerful current flow through primary winding 58, further charging capacitor bank 54 which then feeds capacitor bank 1 when shaft 44 rotates further, making the system both self-powered and capable of supplying useful electrical power to other equipment.

It should be clearly understood that the use of mercury-vapour converters or cathodic valve diodes as described, are not in any manner indispensable in the system as those devices can be replaced by a suitable arrangement of capacitors which would receive separately, the direct and inverse currents of the secondaries.
When a bell is struck just once, it vibrates many times, passing those vibrations to the air and so, making the sound which we hear. The bigger the bell, the slower the vibrations and the lower the pitch of the note which we hear. The same thing happens when a sharp voltage pulse is applied to a coil of wire as just one pulse causes many vibrations in the coil. Like the bell, the frequency of the vibrations depends on the structure of the coil and not on how it is pulsed, although, like a bell, a sharp pulse for a coil or a sharp blow for a bell, produces a greater effect.

You will notice here that Carlos uses the resonant ‘ringing’ of an air-core coil to get an energy gain which is then used as positive feedback to further charge a capacitor bank. A single sharp pulse generated by one spark, causes a large number of coil oscillations, each of which contributes output power, producing an energy gain. The ringing frequency is liable to be around 3 MHz. It is also worth noting that with this design, electricity generation can be achieved without any battery and just the manual turning of a Wimshurst electrostatic generator and the initial operation of the commutator shaft.

Carlos also produced another design, this time working with batteries (although he tended to think in terms of 60-volt battery banks rather than 12-volt batteries) and his patent includes what we tend to call “the Tesla Switch” nowadays. However, instead of switching it rapidly, Carlos uses a switching time interval of one hour. The lower voltage overcomes the need for the switching contacts to be submerged in oil. The problem with lead-acid batteries is that they are only 50% efficient. In practical terms, you only get out of a charged battery half of the current fed into it when it is being charged. So, if you just switch four batteries and power a load that way, the batteries will definitely discharge. In the case of the Electrodyne Inc. staff, they used fast switching and interconnecting diodes which break down when reverse-biased, passing a sharp voltage spike to the batteries at a rate of perhaps, 400 times per second. Benitez, working before electronic components were readily available, chose to use the standard technology of his day - an induction coil which produces at least 10 pulses per second, and through a step-up transformer winding on the induction coil, feeds power to both the load and the drive battery, using an arrangement like this:

```
Carlos Benitez Patent GB 14,311  17th August 1916

System for the Generation of Electric Currents

I, Carlos F. Benitez, Civil Engineer, 141 Ocampo Street, Guadalajara, Mexico, do hereby declare the nature of this invention:

The invention which forms the object of this Patent of Addition, relates to new improvements in the system for the generation of electric currents, described in the main patent No. 17,811 and in the patent of addition No. 5591, filed 14th April 1915.
```
The system may be still further simplified and improved by the addition of batteries, which, suitably adjusted in conjunction with system previously described, can be charged and discharged alternately, producing an excess of electrical energy which can be used in any desired manner.

In other words, in this arrangement, I use in combination: two batteries connected in series and two batteries connected in parallel, these pairs being used so that the discharge of one pair is used to charge the other pair, and vice versa.

Another object of this new arrangement is to allow the use of low voltages, small capacity capacitors and additional facilities for starting the system.

The advantages of such an improvement will be better understood by considering the following drawing which illustrates one method of carrying out the invention:

In the diagram, 1, 2, 3 and 4 are batteries which, when charged from some external source, will maintain their charges indefinitely, in the following manner:

With the connections established as shown in the diagram, that is, with batteries 1 & 2 connected in series through switch 5 (switch 6 being open), batteries 3 & 4 are connected in parallel through switch 7 (switch 8 being open). Under these conditions, assuming that the four batteries are similar, having similar voltages, batteries 1 and 2 being in series will have a combined voltage greater than batteries 3 and 4 which are connected in parallel, and so, a load connected between them will have a current flowing from batteries 1 & 2 and into batteries 3 & 4.

In other words, if wire 13 is connected to the positive terminal of the battery 1 & 2 combination, and to the positive poles 10 & 32 of the battery 3 & 4 combination, then an electric current will be established between the two sets of batteries, until their voltages match. Of course, the current provided by batteries 1 & 2 would produce a smaller charge in the batteries 3 & 4, but that current can be increased by any of the methods described in my earlier patents (No. 17,811/14), and by these means it is always possible to alternately charge and discharge the battery.
pairs from each other, keeping a constant, pre-determined charge, and furthermore, producing an excess of electrical energy which can be used for any chosen purpose.

With these objectives in view, and using as an illustration, the arrangement shown in Figure 1 of the Patent of Addition No. 5591/15, wire 13 connects to capacitor 14. The primary winding 15 of an ordinary induction coil provided with an interrupter, is connected by its ends 16 and 17, to wire 13. The ends 18 and 19 of the secondary winding of that induction coil 15 are connected to connections 20 and 21 of capacitor (or bank of capacitors) 22. Connections 20 and 21 are also connected through spark gap 23, to ends 24 and 25 of the primary winding 26 of a high-frequency transformer. The ends 28 and 29 of the secondary winding 27 of that transformer are connected to ends 16 and 17 of the induction coil 15. Finally, wires 30 are connected across capacitor 14 and they are used to power external loads such as the incandescent lamps shown in the diagram.

This arrangement being made, the electrical energy stored by batteries 1 & 2, passing through terminal 9, wire 13, primary winding 15, terminal 10 of battery 4, pole 31 of switch 7 and terminal 32 of battery 3, will go back through terminal 12 of battery 3 to the battery 1 and 2 combination.

As a consequence of the current passing through primary winding 15, high-voltage current is produced in its secondary winding and collected in capacitor 22, discharging through spark gap 23, generates high-frequency currents in the high-frequency transformer primary and secondary coils 26 and 27. As coil ends 28 and 29 are connected to coil ends 16 and 17, this greatly augments the current flow provided by batteries 1 & 2 and so the storage batteries 3 and 4 now receive adequate charging current to keep them fully charged as well as driving additional loads via wires 30.

Under these conditions, as the voltage in one of the batteries is decreasing while the other is increasing, after some hours, both voltages match and it is then impossible to produce any current flow unless switches 5, 6, 7 and 8 are operated, reversing the functions of the batteries and allowing the process to continue entirely as before with batteries 1 & 2 being connected in parallel and batteries 3 & 4 being connected in series.

When the resistance of the primary winding of transformer 15 is not high, it is possible to simplify the above circuit by obtaining the high-frequency currents directly from induction coil 15, in which case, ends 18 and 19 of the secondary winding are connected directly to ends 16 and 17 of the same coil and the second bank of capacitors 22 and the high-frequency transformer 26/27 can be omitted. Under these conditions, the breaker or interrupter which is part of the induction coil construction, acts as a spark gap, and capacitor 14 discharges in the form of oscillations through the primary winding 15 of the same coil, thus directly increasing the amount of electrical energy furnished by the accumulators.
An essential part of this design which is not indicated clearly in the patent, is that what was common practice a hundred years ago, namely, that the input power connection to point 17 of the primary of the (step-up) transformer 16, is fed through an “interrupter” contact. This connection opens when the coil 16-to-17 is energised, causing the insulated iron wire bundle core of the coil to become magnetised, and attract the pivoted arm of the interrupter, which breaks the current to the coil very sharply, causing high frequency resonant oscillations in both windings of the transformer 15, which generates the excess power which runs the system and its additional loads. In Benitez’s day, door bells used this style of interrupter to produce a hammering action on a metal bell. These were very cheap, very simple and very reliable.

As I understand it then, the voltage difference between the two pairs of batteries, charge capacitor 14 and apply power to the primary winding 16-17 of step-up transformer 15. This causes a current to flow in this winding, making the core attract the pivot arm of the interrupter in the same way that a relay operates. This breaks the current flow very sharply, causing a powerful back-EMF pulse in the primary winding. The primary winding has a resonant frequency, very considerably lowered by the presence of the iron core which itself is a low-frequency material, and the coil oscillates at its resonant frequency, not for just one cycle but for many cycles. Each of those cycles generates a high voltage in the secondary winding 18-19 and every one of those cycles contributes high-voltage power to the system. That power is fed to three outlets. Firstly, it flows back to provide charging power to one of the battery pairs. Secondly, it adds additional power to the capacitor driving its own primary winding. Thirdly, it provides power for the load which is shown as a series of lamps connected in parallel.

That is just for the first interrupter pulse. The broken current through the primary winding 16-17 causes its core to cease to be an electromagnet and so it ceases to attract the pivot arm of the interrupter and while that seems very quick in human terms, it is very slow compared to the multiple oscillations ringing in the winding. When the pivot arm returns to its starting position, it establishes the current flow through the primary winding once again. However, the charge on the capacitor powering the primary winding has been boosted by those resonant oscillations in the secondary winding and so is more highly charged than when the interrupter contact opened previously. This process continues repeatedly, providing battery charge and power to the load.

According to Carlos, there is a slight overall drain on the battery system and so, after about an hour, the switches are operated, changing the series-connected batteries to become parallel-connected and the parallel-connected batteries to become series-connected. This timing seems odd as switching the batteries over much more frequently only requires batteries with a much lower capacity.

As we are not familiar with induction coils and interrupters now that solid-state electronics is available, we can get constructional and operational information from that period in the book “Wireless Telegraph Construction for Amateurs” by Alfred Powell Morgan, published in 1913, which is available as a free download from here: [http://www.free-energy-info.tuks.nl/Morgan.pdf](http://www.free-energy-info.tuks.nl/Morgan.pdf).

For example, the interrupter details include:

“Some means of charging the capacitor is necessary. An induction coil is the most practical for the amateur. The induction coil consists of a primary coil of wire wound around a central iron core and surrounded by a secondary coil consisting of many thousands of turns of carefully insulated wire. The primary coil is connected to a source of direct current which also includes an interrupter to “make” and “break” the current in rapid succession. Every “make” of the circuit and consequent magnetisation of the core, induces a momentary inverse current in the secondary winding, and every “break” and corresponding demagnetisation induces a momentary direct current. Normally, the induced currents would be equal, but by means of a capacitor connected across the interrupter, the circuit when “made” requires considerable time for the current and magnetisation of the core to reach a maximum value, while when broken, the demagnetisation and current drop are nearly instantaneous. The value of the induced electromotive force in a circuit, varies with the speed at which the magnetic lines of force cut the circuit, and so, the induced e.m.f. at “break” becomes high enough to leap across a spark gap.

The formulas connected with induction coils depend on conditions which are never met in actual practice and cannot be relied on. To construct a coil of a given size, it is necessary to use dimensions obtained empirically. Therefore, the amateur should stick closely to the lines or hints given here, or which appear in some up to date book on induction coil building.

For a long time, the induction coil was an expensive, inefficient instrument, until wireless telegraphy demanded of it more rigid and efficient design and construction. It was the aim of manufacturers to produce the longest possible spark length with a minimum amount of secondary wire. As a result of this demand, wireless coils are now made with a core of larger diameter and give heavier and thicker sparks. The secondary in this case, is short and uses wire of large cross-sectional area in order to reduce the resistance and minimise the heating.
No one part of an induction coil may be developed to its maximum efficiency without seriously influencing and lowering the efficiency of the other parts. The following suggestions regarding the construction are given so that they may prove to be a useful guide for the amateur coil builder. The parts will be considered in their natural order of construction.

**Core:** Some experimenters who are not quite familiar with the principles of magnetism, think that if an induction coil were provided with a closed core like that of a transformer, then the efficiency of the coil would be materially increased. But that is not the case because then the magnetisation and demagnetisation of the iron cannot take place rapidly enough in a closed core when an interrupted direct current is used instead of an alternating current.

The core of an induction coil is therefore always straight. For the same reason, it is never solid but instead is always made up of a bundle of soft iron wires in order that rapid changes in magnetism may take place. The wires are always of as high a permeability (magnetic conductance) as possible so as to create a strong magnetic field. Swedish or Russian iron of good quality is the best as its hysteresis losses are small. The smaller the diameter of the wire, the less will be the eddy current losses and consequent heating, but the permeability is also reduced and the core will not be so effective, as the amount of iron is thereby decreased and the oxidised surface increased. No. 22 gauge wire is the best size for the average core.

Wires of a good quality may be purchased already cut to various lengths. To buy them in this form will save a great deal of the labour required when building a core. If the wires are not quite straight, they may be straightened by rolling them, one at a time, between two boards. It is best to re-anneal the wires. To do this, place the wires in an iron pipe and plug the ends of the pipe with clay. Then lay it in a coal fire until the whole mass reaches a red heat. The fire is then allowed to die out gradually, with the pipe and wires remaining in the ashes until cool. When cool, remove them from the pipe and rub each one with emery paper until bright. After this cleaning, the wires are dipped in hot water and then dried. They are then dipped in a good quality varnish and allowed to dry again.

The varnish provides a resistance to the flow of eddy currents in the core and reduces those losses very considerably. A strong paper tube having an internal diameter equal to the diameter of the finished core is made by rolling the paper on a form and cementing it with shellac. When it is perfectly dry, the tube is removed and the wires packed tightly inside it. The following table gives the core dimensions for practical coils of different sizes:

**Primary Winding:** The ratio of the number of primary turns of an induction coil to the number of secondary turns, bears no relation to the ratio of the primary and secondary currents. It has been found in practice, that two layers of wire wound tightly on the core, form the best primary. The primary should always be thoroughly covered with shellac or other insulating varnish. Since there is almost no ventilation in the primary, the wire must be large enough to avoid all heating. A table containing the various sizes of primary wires is given here:

In large coils, the inductance of the primary causes a “kick-back” and sparks are liable to pass between the adjacent turns. For this reason, it is always a good idea to use double cotton covered wire and to further thoroughly insulate it by soaking the primary and core in a pan of melted paraffin wax and allowing the wax to harden with them inside it. Afterwards, the pan is slightly warmed to loosen the cake of paraffin and the excess wax removed by scraping with a blunt instrument so as to avoid damaging the wires. Paraffin wax contracts when it hardens and the proper method for impregnating a porous substance is to allow it to soak and become set in it upon cooling.

A good method of reducing the “kick back” as well as the size of the capacitor connected across the interrupter, is to make the primary with a number of turns of smaller diameter wire wound in parallel, the effect being to produce a conductivity equal to a wire of large diameter and at the same time, make a more compact winding of the primary on the core. This method of winding is very desirable in large coils, as it reduces the cross-section of the primary and allows the secondary to be placed nearer to the core where the magnetic field is the strongest.

The primary winding should cover nearly the whole length of the core, since there is no advantage in carrying the core very far beyond the end of the primary as most of the magnetic lines of force bend at the end of the primary winding and return without passing through the extreme ends of the core.

**Insulating Tube:** The successful operation of an induction coil without breaking down when heavily stressed, depends largely on the insulating tube which separates the primary and the secondary windings. Hard rubber tubes are perhaps the best. A tube may easily be built up of several layers of half inch sheet hard rubber by steaming it so as to soften it, and then wrapping it around a former. The tube should fit tightly on the primary and be about one inch (25 mm) shorter than the core. After the tube is in place, it is poured full of beeswax and rosin in order to fill all interstices and prevent sparks due to the capacitor effect of the windings from jumping from the inside of the tube to the primary.

**Secondary:** A coil used as a radio telegraph transmitter must have wire of a large cross-sectional area in its secondary, so as to produce a heavy disruptive discharge. Number 34 and number 32 gauges are generally used for small coils and number 30 and number 28 gauge for large coils. Silk covered wire is the usual practice, but enamelled wire is coming into use. Cotton covered wire takes up too much space and has poor insulating qualities.

Enamelled wire is insulated with a coating of cellulose acetate, which has a dielectric strength of about twice that of cotton and it takes up much less room than silk covered wire, giving a great saving in space and a greater number of turns may be wound in the secondary without increasing its mean distance from the core.

When winding enamelled wire, it must be taken into consideration that the insulation of enamelled wire is rigid and has no give. Consequently, to allow for expansion, enamelled wire must be wound more loosely than fibre or silk covered wire. The occasional insertion of a layer of paper in the winding gives room for expansion and does not add greatly to the diameter. The length of the secondary is generally not more than half the length of the core.

Coils producing sparks up to 2 inches (50 mm) in length, may be wound in two sections or in layer windings, but the layer winding is not recommended for coils giving sparks over one inch in length. It is best in a coil of this type, to insert an occasional layer of paper. The paper should be well shellacked or paraffined and be a good grade of linen. It should project about one quarter of an inch (6 mm) from the ends of the secondary as shown in this cross-section:
This insertion of paper increases the insulation and reduces the possibility of sparks jumping from layer to layer when the layers are very long. The secondaries of large coils are made up of “pies” or “pancakes” from one eighth (3 mm) to three eighths of an inch (9 mm) in thickness. The “pies” are separated from each other by a triple thickness of blotting paper which has been thoroughly dried and then soaked in melted paraffin. When each “pie” is completed, it is tested for continuity and rejected if not perfect. They are connected in series:

Methods of Connecting the Secondary Sections

If connected as shown in example “A”, where the inside of one section is connected to the outside of the next section, the maximum voltage which can exist between the adjacent sections in this case is equal to the e.m.f. generated by one “pie” and is equal throughout. Connecting as shown in case “B” where the outside of one coil is connected to the inside of the next one, the voltage ranges from zero at the points where they are connected, to twice the e.m.f. developed by any one section. This is the better method and every second coil is turned around horizontally to allow for the reversed direction of current flow.

After the secondary is assembled, the coil should be submerged in an airtight tank containing melted paraffin wax. The tank is then connected to a vacuum pump and the air pumped out. This causes any air bubbles in the windings to be pumped out. After standing for a while, the vacuum is released and the air pressure then causes the bubble gaps to be filled with paraffin wax.

It should be noted that the very experienced Alfred Morgan flatly contradicts the standard theory of symmetrical transformer operation when he states that “the ratio of the number of primary turns of an induction coil to the number of secondary turns, bears no relation to the ratio of the primary and secondary currents”. That is a highly significant statement.

Carlos Benitez also produced another very clever design, still using four batteries and a very slow switching rate, although no longer using the series and parallel switching which we think of as the Tesla Switch. In this design, he shows a remarkable high-frequency power-gain system where 400 watts of input power produces 2400 watts of output power (COP=6):
Carlos Benitez Patent GB 121,561 24th December 1918

New Process for the Generation of Electrical Energy

I, Carlos Benitez, Civil Engineer, of 141, Ocampo Street, in Guadalajara, Mexico, do hereby declare the nature of this invention and in what manner the same is to be performed, to be particularly described and ascertained in, and by, the following statement:

This invention relates to a new utilisation of the high frequency currents or electrical oscillations, by means of which, a constant production of electrical energy can be secured, under unusually simple, economic and practical conditions.

Such results are attained by means of the procedure disclosed in present applicant's English Patent specification No. 14,311, filed on October 9th, 1915, but in order to obtain a better utilisation the high-frequency currents and the automatic operation of the mechanisms employed in such a procedure, I have invented a novel arrangement of parts from which is derived several other advantages that will be here described and set forth.

Two batteries are used, one of which has already been charged. This charged battery discharges through a circuit which utilises the greater part of this power and the remainder drives an oscillating circuit connected to the second battery. This oscillating circuit contains a rectifier which directs the electrical oscillations in such a manner that they are forced to pass constantly through the second battery from the positive to the negative terminal. As the number of oscillations per second in that circuit can be varied at will, the current intensity developed by those oscillations can be regulated so that the second battery is fully charged in the same period of time during which the first battery is discharged. Therefore, it is only a matter of reversing the connections to the two batteries in order to obtain the continuous production of electrical energy.

The invention is illustrated here:
This circuit shows the circuit connections of the arrangement and a perspective view of a commutator. Figure 2 is a lateral view of a part of the same apparatus, and figures 3 and 4 are parts of the same machine, whose location and use will be explained later.

The figure shows two battery banks 1 & 2 and 3 & 4, both of which are connected in series. Their positive poles 23 and 25 are connected to terminals 17 and 20 of the commutator, through the ammeters 22 and 24. The commutator is a cylinder 5, mounted on a rotating shaft 6, which passes through two supports 7 and 8. The cylinder is provided with conductive paths 9, 10, 11 and 12 insulated from the cylinder 5. It also has conductive paths 14 and 15 which can be seen better in Figure 2 and which make contact with brushes 17 & 18 and 19 & 20, properly insulated and fixed to ring 16 which encircles cylinder 5 and is fastened to the base of the apparatus. These brushes connect to the batteries and terminal 17 is connected to the positive pole 23 of battery 1 & 2. Terminal 20 is connected to the positive pole 25 of battery 3 & 4 through ammeter 24. Terminal 18 connects through wire 26 to terminal 27 of a DC motor whose terminal 28 connects through the variable resistor 29 and wire 30 with terminal 31 of the commutator. Finally, terminal 19 is connected through wire 32 to terminals 33 and
This apparatus is also provided with terminal 39 which is alternately connected to the negative poles of the batteries through the brushes which can be seen in the figure, in contact with cylinder 5. Under these conditions, the apparatus 40 and 41, which are employed to provide a practical output independent of the running of the "plant", and which are connected to both terminals 31 and 39, will be alternatively in circuit with the discharging battery, and thus, part of the power produced by the battery discharging, is used by this apparatus without impairing the normal running of the whole mechanism, as explained below.

On the other hand, an alternator 42, is coupled to the motor 27-28, which in this manner can be rotated at the speed needed to attain the desired frequency. Both terminals of the alternator are connected through the inductive resistance 43, with the poles 44, 45 of the primary winding of a step-up transformer, whose secondary winding 46, 47, connected to capacitor 48, will finally produce the high-voltage alternating currents needed to charge the capacitor. However, the use of this motor and alternator is not essential in this process as the same results could be attained if the primary 44, 45 of the transformer, were connected through an ordinary interrupter to the discharging battery.

The terminals 49, 50 of capacitor 48 are connected through an arc lamp of the Poulsen type 51, 52, or through an adequate spark-gap with the rectifiers 33, 34, 35 and 36, and with the battery under charge (3 & 4 in this case). Extending into the arc chamber are the poles of a strong electromagnet, the coils of which are in series with the arc, so that their excitation current is the arc current.

Connected in this manner, the strong magnetic field which exists between the poles of the magnets, acts on the arc, and owing to this action, combined with the influence of the voltage developed by the secondary of the transformer 46, 47, it happens that this action and influence being about equal in value, are each of them alternately greater than the other, so that the voltage across the arc automatically rises and falls. Therefore, when the action of the magnetic field is greater than the voltage produced by the secondary winding of the transformer has not enough power to pass across the arc and so the capacitor 48 is charged to a higher voltage. But, an instant later the action decreases in value and the capacitor discharges again across the arc.

On the other hand, owing to the oscillatory nature of the circuit (which is arranged with proper values of capacity, inductance and resistance), the charging and discharging of the capacitor can occur several million times per second if desired, and in this manner, a current of a great number of amperes can be obtained through the oscillating circuit, even with a small amount of electricity stored in the capacitor.

In the same manner, one gallon of water could produce a flow of one thousand gallons per second through a pipe if such a pipe were connected with two different vessels and the gallon of water could be forced through the pipe by a piston which could transfer that gallon of water from one vessel to the other one thousand times per second. Obviously, what can be easily performed with electricity is not so feasible with water.

In other words, the small amount of electrical power taken by the DC motor 27, 28, appears (with a small loss) at the alternator 42, and that power is delivered to the transformer primary 44, 45. Again, the inductive action of this transformer produces at the secondary 46, 47, a similar amount of power (diminished slightly due to the efficiency of the transformer), and finally, the capacitor is charged with a small amount of electricity which is then converted into oscillatory energy. Obviously, if such electric power, instead of being stored by the capacitor, had simply been rectified and used to charge one of the batteries, such power would produce only a very small effect on the battery and the entire discharge of one battery would never cause the complete charge of the second battery.

Contrary to that, if that same power is stored in capacitor 48, and that capacitor is properly connected to an oscillatory circuit in which one of the batteries can be joined, and furthermore, if by means of a rectifier, the high-frequency currents produced in such an oscillatory circuit are forced to pass from the positive to the negative pole through the battery, it is obvious to state that it is always possible to secure by these means, the number of amperes required to charge the battery in the available time. That is to say, with a small number of coulombs stored in capacitor 48, it is possible to produce in the oscillatory circuit, a great number of amperes, if that same small number of coulombs are forced to pass and repass through the circuit, thousands or millions of times per second, just as was explained in the water analogy.

On the other hand, the values of the above named quantities: capacity, resistance, inductance and voltage can be varied within very wide limits, and therefore it is always possible to attain the required conditions in each case, in order to produce a given number of oscillations per second: The capacity of the capacitor can be adjusted to a certain value by increasing or reducing the inter-meshed surface area of its plates. The resistance of the circuit can be adjusted to the required value by varying the length of the arc in the Poulsen lamp, or varying the number of lamps connected in series or parallel in the circuit. The inductance of the circuit can be varied by winding part of the circuit on an insulating frame, in such a manner as to obtain the number of turns required to produce the
desired inductance, and finally, the charging voltage can be regulated by increasing or decreasing the number of turns in the secondary winding of the transformer or by varying the diameter of the wire used in the coil. In order to obtain a better efficiency from alternator 42, it is convenient to use the resonance coil or adjustable inductive resistor 43. By so doing, it is possible to adjust the resistance in order to obtain a state of resonance in the circuit, and in that state, the current produced by the alternator will be in phase with the impressed E.M.F., therefore the effective watts will be a maximum in the primary and secondary circuits.

The variable resistor 29, which is placed in the circuit which connects each battery with motor 27-28, is used to adjust the current of the discharging battery to a fixed value, since it is important to obtain a constant number of revolutions per second of the alternator 42.

The commutator is also provided with voltmeters 56 and 57, and by means of the switches 58 and 59, the circuits connecting both poles of each battery, can be closed and the voltage of the discharging current may be determined when desired. Finally, by means of switch 60 connected across the terminals of the apparatus 40 and 41, the apparatus may be switched off when not required.

It is easy to understand the whole operation of this mechanism. Suppose initially that battery 1-2 has been charged and that cylinder 5 has been rotated to the position shown in the drawing. Battery 1-2 will immediately discharge via battery terminal 23, ammeter 22, wire 21, contacts 17-18, wire 26, motor 27-28, variable resistor 29, wire 30, rotary transformers 40 and 41, (or through any other apparatus which may be used instead of those transformers in order to use part of the current flowing from the battery), pole 39, and commutator path 9-12, through which the whole discharging circuit is closed.

As a result of this discharge from the battery, the electrical power produced will be dissipated in three ways: A first part is wasted in overcoming the internal resistance of the various components in the circuit. A second part is used to power the DC motor 27-28, and the third part powers the apparatus connected to poles 31-39 of the commutator, that is, the useful equipment powered in addition to the running of the system.
It is well known how the mechanical power developed by the rotary motion of motor 27-28 can be converted to electrical energy by alternator 42, and in the same manner, it is well known how such electrical energy of low voltage can be transformed into one of high voltage using a transformer, and it is well known too, how such high voltage electrical energy can be converted into oscillatory energy, and how the alternating currents produced by such oscillations can be rectified in order to produce a direct current. However, all such combinations of apparatus arranged to charge a battery while another similar battery is discharging, was perfectly unknown before this invention, and a short consideration of the calculations involved in determining the different values of capacitance, resistance, inductance and voltage required by the various combined circuits of a small working plant of this kind, may be useful in giving an idea of the procedure which can be followed in general practice.

Suppose that both of the batteries are accumulators with a voltage of 60 volts each and a capacity of 40 Ahr. Under such conditions, if battery 1-2 discharges at the rate of 40 amperes, it will be fully discharged in one hour. [Please note that this is not so and is only being stated here for discussion purposes. A lead-acid battery will be damaged if discharged at a rate greater than the “C20” rate which is the rated Ahr value over a period of 20 hours, and so, a lead-acid battery of 40 Ahr should not be discharged at more than 40 / 20 = 2 amps. Also, batteries are highly non-linear and discharging a 40 Ahr battery at 40 amps will result in a fully discharged battery in a lot less than one hour.] The power developed over that time period will be 60 volts x 40 amps = 2,400 watts.

On the other hand, in order to charge battery 3-4 fully in one hour it is necessary to provide a current of at least 40 amps. Suppose that in order to develop such a current, it is desired to take from the power produced by the discharging battery only a portion, say 40 amps x 10 volts = 400 watts. With this objective in view, the DC motor should be arranged so as to create a current of 40 amps causing a drop of 10 volts on the line.

Suppose that the electrical efficiency of the DC motor is 95%, then the desired 400 watt output will not be attained but instead will be reduced to 400 x 0.95 = 380 watts.

Then, suppose that the electrical efficiency of alternator 42 is 95% then that will reduce the output to just 361 watts. Then, if this 361 watts is passed to the transformer and that transformer has an efficiency of say, 89%, then the resulting energy output will be further reduced to just 321 watts, and that is the amount of power passed to the oscillating circuit in order to obtain the required 40 amps of current.

Now, suppose that the frequency of alternator 42 is 500 Hz. As is well known, with an alternating generator, a high voltage is obtainable twice in each cycle and so there will be 1000 voltage peaks per second. As capacitor 48 discharges at the instant of maximum voltage, it will discharge 1000 times per second. Therefore, the quantity of electrical energy which must be stored in it can be calculated as follows: Suppose that the oscillating circuit has an impedance of 15 ohms. As the required current is 40 amps, the required voltage to develop such current will be 40 amps x 15 ohms = 600 volts. But in order to produce 600 volts from the discharge of the capacitor, it is
necessary to get it charged up to 1200 because the average voltage during discharge is \( V / 2 \).

If the energy produced by the transformer secondary is assumed equal to 321 watts and the voltage required for the charge of the capacitor is 1200 volts, then the current delivered by the secondary will be 321 watts / 1200 volts which is 0.267 amps.

On the other hand, as the frequency of the alternator is 1000 peaks per second, then in one thousandth of a second the secondary has to deliver to the capacitor 0.000267 coulombs which is 267 microcoulombs.

Hence, the capacity of capacitor 48 must be adjusted to store that amount of electricity, and its value can be determined by \( Q = K \times V \) where \( K \) is the capacity of the capacitor in microfarads when \( Q \) is given in microcoulombs and \( V \) is the maximum voltage, and so, \( K = 267 / 1200 \) which is \( 0.222 \) microfarads.

It is also well known that if you want to produce an oscillatory discharge through a circuit, the capacitance, resistance and inductance of the circuit must be arranged so that the square root of \( 1000 \times L \) millihenrys / \( K \) microfarads is greater than the resistance of the circuit in ohms (\( K \) being the capacitance of the capacitor).

It has been supposed that the resistance of the oscillatory circuit is 15 ohms. Using 20 ohms in the above equation will allow a suitable value of inductance to be calculated, one which will satisfy the required conditions for the production of the oscillatory discharge in the circuit, and so the inductance in millihenrys is \( 400 \times K / 4000 \) or 400 x 0.222 / 4000 which is \( 0.0222 \) millihenries, or equal to 22,200 centimetres of wire.

It is possible to determine the number of oscillations per second which can be achieved in any such circuit, and that is given by \( Hz = 5033000 / \text{the square root of } L \times K \) where \( L \) is in centimetres and \( K \) is in microfarads. And so, knowing the inductance and the capacitance we get \( Hz = 5033000 / \text{sqrt}(22200 \times 0.222) \) which is \( 71900 \) Hz. That represents 72 oscillations in each of the 1000 sparks per second.

The current strength developed by these oscillations can be determined from the formula below which uses the Voltage \( V \) in volts, the resistance of the circuit \( R \) in ohms, the inductance \( L \) in henrys, and the capacitance \( K \) in farads:

\[
\text{Current} = \frac{V}{\sqrt{R \times R + (6.28 \times Hz \times L - 1/(6.28 \times Hz \times K))^2}}
\]

or in our case:

\[
\text{Current} = 600 / \sqrt{15 \times 15 + (6.28 \times 71900 \times 0.0000222 - 1/(6.28 \times 71900 \times 0.00000222))^2}
\]

Which works out as 40 amps, meaning that the impedance of the oscillating circuit is equal to the resistance in ohms of that circuit, since the inductive reactance and the capacitative reactance are so combined that the resultant value of the total reactance is equal to zero, and the only voltage required to produce the current of 40 amps is that needed to overcome the ohmic resistance of the circuit which is 15 ohms. This also means that the E.M.F. is in phase with the current, and therefore, the watts are a maximum.

Hence, there can be no doubt that battery 3-4 will be fully charged during the period when battery 1-2 is discharging, especially since the charging current can be further increased at will, even without taking more power from the discharging battery. In fact, it is easy to increase the number of turns in the transformer secondary 46-47 in order to increase the voltage. Obviously, as the amount of power delivered to the primary 44-45 of this apparatus is always 321 watts, if the voltage is increased, the quantity of electricity which the capacitor 49 receives will be reduced accordingly. Consequently, the value of that capacitor must also be reduced and so the number of oscillations per second will also be increased. Finally, by increasing the voltage, the current intensity is increased proportionately.

Therefore, it is always possible to combine, in the manner described, the values of resistance, inductance, capacitance and voltage in the oscillating circuit, so as to obtain the required current strength to fully charge one of the batteries during the period when the other battery is discharging.

Once this battery charging has been attained, if the plant is to continue in operation, then the batteries need to be swapped over by altering their connections to the circuit. To accomplish this, cylinder 5 is rotated until the conductive paths 11 and 12 come into contact with the brushes which are connected to the negative poles of the batteries, and then, battery 3-4 which is fully charged will be connected with the motor 27-28, and its discharge will now be produced by this path: battery terminal 25, ammeter 24, commutator poles 20 and 18 (now connected together due to the rotation of the cylinder 5 through 90 degrees), wire 26, motor 27-28, variable resistor 29, wire 30, apparatus 40 and 41, and commutator path 11 which closes the circuit to the negative pole of battery 3-4.
In other words, the motor 27-28, apparatus 40 and 41, and alternator 42, will still be operating in exactly the same way as described above, and in the same manner, the high-frequency currents are still developed, producing the same current intensity which is now passing via terminal 50 of capacitor 48, arc-lamp 51-52, diode 34, wire 32, commutator contacts 19-17, wire 21, ammeter 22, and positive terminal 23 of battery 1-2 (which is now connected to contact 38 of the commutator through path 12), wire 37, diode 36, inductor 55, and capacitor terminal 49; also through duplicate path from capacitor terminal 49, diode 33, wire 32, commutator contacts 19-17, wire 21, ammeter 22, positive terminal 23 of battery 1-2, commutator path 12, commutator pole 38, wire 37, diode 35, arc lamp 52-51, and capacitor terminal 50.

It is obvious to state that this same procedure can be repeated indefinitely by the simple altering of the battery connections from time to time in accordance with the battery capacity and the rate of discharge. Only 400 watts is taken from the discharging battery for battery recharging, leaving 40 amps at 50 volts (2000 watts) available for doing continuous useful work.

The patent continues with a description of how a modified clock can be made to move the commutator once every hour. This is a brilliant 2 kilowatt, self-powered, free-energy design. However, operating the design as described would not be realistic. Batteries nowadays have limited operational lives offering, typically, between 400 and 1000 charge/discharge cycles within the C20 discharge current limits. Exceeding the C20 discharge rate will reduce the battery life by a major amount, that amount being determined by the degree of abuse which the battery suffers. If we ignore that factor and say that our batteries will manage 1000 cycles, at the proposed rate of say, one hour discharge and one hour charging time, then battery replacement is liable to be required in just 500 hours of operation. That is, within three weeks of continuous operation.

The essential, rapid switching of this circuit is performed by the spark-gap but in contrast to that, the commutator switching of the batteries does not require high speed operation. It is feasible then, to replace the commutator with simple solid-state switching and swap the batteries over every second or two. That way, the batteries are never discharged and long battery life can be expected.

Bozidar Lisac’s Power-Boosting System.

Recently, a patent application has been lodged on what is effectively the Ron Cole one-battery switch and the Tesla Switch. I am including the re-worded patent here. Some experimenters have reported overall battery energy gains with switching speeds of 0.5 Hz or less, which means that in circuits of that type, mechanical switching should give a reasonable switch contact life. This patent has needed a fair degree of attention as the person writing it does not have a full grasp of English and confused the word "load" with the word "charge". Let me say again, that the following patent application is included here primarily for interest sake, rather than being the definitive way of making a circuit of this type.

METHOD AND DEVICE FOR SUPPLYING A LOAD WITH ELECTRIC ENERGY RECOVERY

ABSTRACT

In the invention an electric current circulates from the battery UB, through the electric motor M, and the diode D1 charges the capacitors CA and CB, connected in parallel, which, once charged, are connected in series, giving rise to a difference in voltage in relation to the battery, causing half the charge of the capacitors to be returned to the battery through the diode D2, whilst with a new parallel connection, the capacitors recharge, this charge being equal to that which had been previously transferred from the capacitors to the battery, so that by means of the
cyclic connection of the capacitors in parallel and series the energy is transferred from the battery to the capacitors and from the capacitors to the battery, thus considerably extending the range of the battery and operation of the motor.

**OBJECT OF THE INVENTION**

This invention relates to a method and device enabling the electrical energy with which a charge is supplied to be recovered using a self-rechargeable electricity source in which, which by means of a circuit, the current circulating from an accumulator or battery through a load, e.g. a motor, is fully returned to the same energy level, thereby considerably extending its range.

More specifically, two capacitors that are connected cyclically from parallel to serial and vice versa are charged through a motor during the connections in parallel, whilst in series connection, when its voltage doubles, they return the electricity, recharging the battery. This source represents a closed system which does not require an energy supply from the outside, except to compensate for the losses produced, the range of the battery being limited by the number of charges and discharges that the same technically permits.

**BACKGROUND TO THE INVENTION**

A load, such as an electric motor, is connected to a battery or accumulator with a certain charge, which will be progressively discharged by it, this discharge being directly proportional to the connection time and to the current circulating through the motor. It is therefore necessary to supply fresh energy from an external source to recharge it. Systems that enable the energy consumed by the load to be reused are not known in the state of the art.

**DESCRIPTION OF THE INVENTION**

A first aspect of the invention relates to a method for supplying a load with recovery of electrical energy, which comprises supplying a load with electrical energy deriving from the first electrical energy accumulator, and returning at least a proportion of that electrical energy after it passes through the load to the first accumulator for the purpose of recovering the energy supplied.

The electrical energy, after passing through the load, is recovered by second electrical energy accumulator, from where it is transferred to the first accumulator, giving rise to cyclic transfer of electrical energy between the first and second energy accumulators.

The recovery of energy from the second accumulator and transfer to the first accumulator may be achieved without passing the energy through the load. In another alternative implementation, the energy is recovered from the second accumulator and passed to the first accumulator through the load, in which case the polarity of the load is reversed during the recovery of energy through the load.

The transfer of energy is brought about by cyclically connecting two or more electrical energy accumulators between parallel and serial connections.

A second aspect of the invention relates to a device for supplying a load with recovery of electrical energy, which comprises a first electrical energy accumulator and a second electrical energy accumulator, where the load is connected between the first and second accumulators. The device may be provided in one embodiment with a unidirectional connection device, for example, a diode which is connected in parallel to the load, causing circulation of the electrical energy recovered after passing through the load, and via which the electrical energy is returned to the first accumulator.

The first electrical energy accumulator may be a battery. The second electrical energy accumulator might be two or more capacitors with switching to cyclically connect them between parallel and serial connection configurations.

The invention constitutes a self-rechargeable source of electrical energy which enables the range of a battery to be considerably extended so that the current circulating from the same through a motor charges two capacitors connected in parallel, up to the voltage level of the battery, by means of contacts. These capacitors, once charged, are connected in series, producing double their voltage, and they then return the energy to the battery, thereby extending its range. Once the losses have been compensated for, the duration of the extended range depends on the charging and discharging properties of the capacitors.

The existence of the difference in voltage between the battery and the capacitors connected both in parallel and in series, and which give rise to the displacement of energy from the battery to the capacitors and vice versa, is used to supply the motor connected between the battery and the capacitors, comprising the self-rechargeable source of electrical energy.
When connected in parallel, the capacitors are charged through a motor and a diode, and when connected in series, they are charged through another diode, the voltage of the motor being half that of the battery. On the other hand, if the motor is connected between the battery and the serially-connected capacitors, the latter, which are charged in parallel through a diode and are discharged by means of the motor and the other diode, will supply the motor with a voltage equal to that of the battery, whilst a capacitor connected in series to the winding of the motor guarantees its operation without loss of power.

Instead of the two capacitors, two batteries connected in series and another two connected in parallel may be used, between which batteries a motor is connected, the current circulating in this case from the batteries connected in series through the motor to the batteries connected in parallel. The serially-connected batteries are then connected in parallel, by means of switching contacts, and the other two parallel-connected batteries are then connected in series, reversing the direction of the current, whilst the connections of the motor are inverted by means of the simultaneous switching of other contacts in order to maintain the polarity and direction of rotation of the motor.

In one possible embodiment of the invention, another two capacitors and a transformer with two primary windings, or a motor with two windings are added to the device previously described, each pair of capacitors cyclically switching from parallel to serial connection and vice versa so that during the parallel connection cycles, two of the capacitors are charged through one of the windings up to the voltage level of the battery at the same time that the other two capacitors are connected in series, double their voltage and are discharged by means of a second winding to the battery.

The reduced level of energy losses brought about mainly by the dissipation of heat and in the capacitors, as well as by the charge factor of the batteries, is compensated for from an external source, and because the sum of the current circulating through a winding of the motor or transformer charging two of the capacitors and the current simultaneously circulating from the other two capacitors through the second winding, recharging the battery, plus the current which is supplied from the external source, is equal to zero, because of the work carried out by the motor or the loads which are connected to the alternating voltage induced in the secondary of the transformer, no discharge of the battery takes place.

**DESCRIPTION OF THE DRAWINGS**

In order to supplement the description now being given, and with the aim of contributing to a better understanding of the characteristics of the invention, according to a preferred practical embodiment, a set of drawings is attached as an integral part of this description, in which, for informative and non-restrictive purposes, the following is shown:

![Fig. 1](image-url)

**Fig. 1** shows a practical circuit in which, by means of switching, two capacitors connected in parallel are charged from a battery through a motor and a diode, and after the contacts are switched, they are connected in series, thereby discharging the battery through another diode.
Fig. 2 shows a practical circuit in which, through switching, the two capacitors are connected in parallel and are charged from a battery through a diode, and after the switching of the contacts they are connected in series, thereby charging the battery through the motor and the other diode.

Fig. 3 shows the connection of the two batteries in series, connected through a motor to another two batteries connected in parallel, and which, by means of contacts, switch alternatively, this giving rise to effects similar to those described in relation to the use of the capacitors.
Fig. 4 shows the electrical diagram corresponding to the connection between the battery and the two pairs of capacitors of a transformer with two primary and one secondary winding, in which an alternating voltage is induced which is rectified, filtered and converted to a sinusoidal voltage.

Fig. 5 shows the electrical diagram of an alternating current motor with two windings connected between the battery and two pairs of capacitors.
Fig. 6 shows the electrical diagram of a direct current motor with two windings connected between the battery and two pairs of capacitors, in which two switch contacts ensure their correct polarisation and direction of rotation.

PREFERRED EMBODIMENT OF THE INVENTION

In a preferred embodiment shown in Fig. 1, the load consists of a direct current motor \( M \), the battery \( UB \), and the second accumulator which consists of a pair of capacitors \( CA \) and \( CB \). The capacitors \( CA \) and \( CB \) are connected to each other in parallel by means of two switches \( S1 \) and \( S2 \). These capacitors are charged through the motor \( M \) and diode \( D1 \) to a voltage level equal to that of the battery \( UB \), the charge being \( Q = (CA+CB)UB \), and while these capacitors are being charged, the motor \( M \) is rotating.

When both capacitors are fully charged, they are connected in series by the switch contacts \( S1 \) and \( S2 \). This produces a voltage which is twice the value of the voltage of the battery \( UB \), resulting in the charge which is given by 

\[
Q = 2 \times UB \times (CA+CB) / 2
\] 

which is 

\[
Q = (CA+CB)UB
\]

which shows that once charged, the charge \( Q \) of both capacitors is identical both in parallel and in series.

Diodes \( D1 \) and \( D2 \) ensure that current flow through the motor \( M \) is only ever in one direction. Immediately after capacitors \( CA \) and \( CB \) are connected in series, they return half of their charge through diode \( D2 \). Switches \( S1 \)
and S2 then connect the capacitors CA and CB in parallel. In this arrangement, they start off with half of the battery voltage. They charge immediately, regaining the battery voltage through the motor M and the diode D1.

By means of repeated cyclic switching of the capacitors CA and CB from parallel to serial connection mode, the current circulating from the battery UB through the motor M to the capacitors, and from these to the battery, recharging it and extending its range, constitutes a self-rechargeable source of electrical energy.

In a second practical embodiment shown in Fig.2, the motor M is connected between the battery UB and the capacitors CA and CB by means of the diode D2. The capacitors are charged directly through the diode D1 and are discharged through the motor M and the diode D2, the values of the charges on the capacitors CA and CB previously described in the example shown in Fig.1 remain unchanged, the difference in this circuit is that the voltage applied to the motor M is the full battery voltage in this case.

The charging rate of the capacitors CA and CB is determined by the intensity of the current flowing through the motor M, to which is connected in parallel, the capacitor CM which guarantees that the operation of the motor is maintained at maximum power. It is possible to substitute a battery, preferably a rapid charge battery, for capacitor CM.

In another embodiment shown in Fig.3, the first and second accumulators consist of pairs of batteries B1, B2 and B3, B4. Therefore, in this embodiment, two pairs of batteries are used instead of the capacitors CA and CB. Batteries B1 and B2 are connected to the switches S1 and S2, and the pair of batteries B3 and B4 are connected to the switches S3 and S4. The switches S1 to S4, connect the pairs of batteries with which they are associated, into series or parallel configurations, depending on the position of the switches.

While the batteries B1 and B2 are connected in parallel, the other two batteries B3 and B4 are connected in series, and the motor M rotates as a result of the difference in voltage between the batteries, as it is connected...
between both pairs of batteries. At the same time, the current circulating through the motor from the serial connected batteries recharges the two parallel-connected batteries. The switches S1 to S4, which connect the batteries B1 and B2 in series and the batteries B3 and B4 in parallel then switch, thus reversing the direction of the current flow, and at the same time, the switches S5 and S6 change positions in order to maintain the correct polarity for the motor and its direction of rotation.

The two capacitors and the batteries may be switched by means of any mechanical, electromechanical, electrical, electronic or other element that meets the conditions described with the purpose of obtaining a self-rechargeable electrical energy source. These switching operations may be controlled by any known method, for example, a programmable electronic circuit.

In the preferred embodiments previously described, the load consists of a direct current motor, but as an expert in the field may understand, the load may also consist of any type of resistive (?) and/or inductive load.

Another preferred embodiment is shown in Fig.4, where a transformer T with two primary windings L1 and L2 is connected between the battery UB and the two pairs of capacitors C1 and C2, plus C3 and C4, causing the two capacitors C1 and C2 to switch their connections from parallel to serial and back again by means of the contacts S1 and S2, and causing the capacitors C3 and C4 to switch by means of contacts S3 and S4, so that during the cycles of connection of the capacitors C1 and C2 in parallel, the latter are charged via the winding L1 up to the voltage level of the battery, whilst at the same time the capacitors C3 and C4 are connected in series and provide double their voltage, the battery being discharged by means of the winding L2, in which case the charging and discharging currents to circulate in the same direction. On the other hand, during the cycles of connection in parallel of the capacitors C3 and C4, which are charged through the winding L2 up to the battery voltage level, the capacitors C1 and C2 are connected in series to provide double their voltage and are discharged into the battery through the winding L1. The direction of the charging and discharging current therefore changes, thus inducing in the secondary winding L3 an alternating voltage whose frequency depends on the speed of switching of the contacts mentioned, and after being rectified by means of the bridge of diodes P and filtered by the capacitor CP, the resultant DC voltage is converted to a sinusoidal voltage by means of a circuit K.

The connection in parallel of one pair of capacitors and the connection in series of the other pair take place at the same time. Therefore the sum of the current circulating from the battery through one of the windings, charging two of the capacitors, and the current circulating from the other two capacitors through the other winding to the battery, is approximately zero.

From an external energy source FE the minimum energy losses caused essentially by dissipation of heat and in the capacitors, as well as by the charging factor of the battery, are compensated for, with the result that the sum
of the current circulating from this source external to the battery and the charging and discharging currents of the capacitors is equal to zero. Therefore the battery is not discharged and its range does not depend on the work developed by the motors or the loads connected to the secondary winding \( L_3 \) of the transformer \( T \), since the greater the power of the loads, the higher the intensity of the charging and discharging currents of the capacitors.

Fig. 5 shows another embodiment in which an alternating current motor \( M \) is connected to two windings \( L_1 \) and \( L_2 \) so that during the connections in parallel of the capacitors \( C_1 \) and \( C_2 \), the latter are charged by means of the winding \( L_1 \) at the same time that the capacitors \( C_3 \) and \( C_4 \), connected in series, are discharged by means of the winding \( L_2 \) to the battery \( U_B \), the charging and discharging current circulating through the windings in the same direction. The capacitors \( C_1 \) and \( C_2 \) are then connected in series and the capacitors \( C_3 \) and \( C_4 \) are connected in parallel. The direction of the charging and discharging current of the capacitors is therefore reversed, thus producing at terminals of the motor an alternating voltage with a frequency that depends on the speed of switching of the contacts. The energy losses caused are compensated for from an external source \( FE \), the sum of the current circulating from this source to the battery and the currents circulating through the two windings during charging and discharging of the capacitors being equal to zero. The battery is therefore not discharged as a result of the work developed by the motor.
Fig. 6 shows the connection of a direct current motor \( M \) to two windings \( L_1 \) and \( L_2 \) between the battery \( U_B \) and the two pairs of capacitors \( C_1 \) and \( C_2 \) plus \( C_3 \) and \( C_4 \), so that during the connections in parallel two of the capacitors are charged by means of the winding \( L_1 \), and during the simultaneous connections in series, the other two capacitors are charged by means of the winding \( L_2 \) to the battery. Coinciding with the switching of the contacts \( S_1, S_2, S_3 \) and \( S_4 \), which connect to each pair of capacitors from parallel to serial and vice versa, the contacts \( S_5 \) and \( S_6 \) switch, polarising the windings of the motor so that the charging and discharging currents of the capacitors circulate in the same direction, producing a direct voltage. The sum of the current supplied from the external source \( F_E \) and the charging and discharging currents of the capacitors is equal to zero, and thus there is no battery discharge.

Don Smith’s High-Power Devices.
Don Smith was a very talented American who has understood all of Tesla’s work and has produced literally dozens of practical devices based on his understanding. You will find more specific details in chapter 3, but in broad outline, a twelve-volt battery can be used to generate the pulsing magnetic field needed to nudge the local environment into providing massive amounts of electrical energy. The device described in detail in chapter 3, has an output of around 160 kilowatts, which is far, far more than any individual would need. In other words, it is a device which could easily power your home, and considering that an electric car needs about 65 kilowatts, one could easily power a vehicle, making it into a fuel-less mode of transport. This is not magic, just standard electrical theory being applied correctly for a change.

The key component in many of Don’s devices is the humble, commercial power supply used to drive neon sign displays. This module produces some 9,000 volts at a frequency of 35,100 Hz (cycles per second). As Don points out, when you double the pulsing frequency and double the pulsing voltage, the available power goes up by a factor of sixteen times, because the effect of both of these things is squared. You will recall that Bob Boyce is pulsing his toroid very sharply at 42,000 Hz and that high frequency has a major effect on the power produced in his system.

Don then boosts his working voltage further with a step-up transformer called a Tesla Coil. This brings us into an area of massive power. People have the very mistaken idea that a Tesla Coil can only produce voltage and not current. The reality is that if the primary coil is positioned in the centre of the secondary coil, then the voltage and current produced will be roughly the same, and that is a very, very high level of power. One device of Don’s looks like this:

![Image of a Tesla Coil setup](image)

This prototype is actually more complicated than it needs to be. It uses three very high-voltage capacitors which are not necessary if you opt for a slightly different method of construction. However, in this version, the twelve-volt battery (which is not shown), powers a true sine-wave inverter in order to provide the mains voltage and frequency needed by the neon-tube driver circuit. The voltage limitations of the capacitors, in particular, the 8,000-volt output storage capacitors, make the 9,000 volt output of the neon-tube driver too much for safe usage. To deal with this, Don uses a Variac-style variable transformer to lower the voltage supplied to the neon-tube
driver circuit, and this lets him limit the output voltage to the 8,000 volts of the output storage capacitors.

A key detail is that the wire length in the turns of the short primary winding of the Tesla Coil is exactly one quarter of the wire length of the turns in the long secondary winding. This makes the coils resonate which is a vital factor in the operation. The final, exact tuning, can be done by sliding the primary coil to a slightly different position. In this prototype, Don chose to do the final fine tuning by attaching a small capacitor across each of the windings. This is not necessary.

In the prototype shown above, Don then uses four diodes to rectify the output to DC to feed the storage capacitors. This results in an 8,000 volt supply which can provide 20 amps of current. That is an output power of 160 kilowatts, and is limited by the output capacitor voltage rating.

Don points out that it is not necessary to do it that way and instead, a step-down transformer can be used to lower the output voltage and boost the available current. If this is done, then the voltage limitations disappear (provided that you are using very high-voltage cables) and so no Variac is needed and no high-voltage capacitors are needed either.

There are two options. Either you can aim for a mains-voltage, mains-frequency, AC output, or you can produce a DC output and use an off-the-shelf inverter to run any mains equipment powered by the device. With the first option, Don connects a single resistor across the primary of the step-down transformer and that drags the frequency down to the wanted level, provided that the resistor has the right value:

The alternative method which aims for a DC output does not need to alter the frequency:

In both of these cases, the twelve volt driving battery can be charged continuously by part of the output power, and there are various ways of doing that. However, care needs to be taken that the battery is not overcharged as the input power is very low.

You will notice the similarity between Bob Boyce's toroid system and Don Smith's Tesla Coil system. In each case, a very carefully wound circular winding is pulsed at high frequency, and in each case, substantial amounts of excess electrical power becomes available, flowing in from the surrounding environment, courtesy of the pulsating magnetic field.

Tariel Kapanadze's Self-Powered Generators.
Tariel Kapanadze produced a similar style of device which is self-powered and produces a mains electricity output. He has demonstrated this for a TV documentary. Further details available are in chapter 3.
Walter Ford's High-powered Crystal Set

In the 1961 edition of the Electronics Experimenter's Handbook, there is an interesting circuit from Walter B. Ford for a high-power crystal set capable of powering a 2.5-inch loudspeaker:

He says: Here's a pint-sized crystal radio with enough power to drive a 2.5" speaker. This little unit's selectivity is far better than you would expect to find in a crystal receiver and volume is equal to that obtained with sets using a transistor. No external power source is required.

The unusual selectivity of this radio is due to its special double-tuned circuit. A pair of diodes connected as a voltage-doubler provides the extra power to operate the small speaker. An output jack is provided for headphone listening and for connecting the set to an amplifier.

Construction: The model was built on a 2.5" x 4.5" wooden chassis with a 3.5" x 4.5" metal front panel. However, size is not critical, and other materials can be substituted if desired.

Two standard ferrite loopsticks, L2 and L3, are used. Both must be modified by the addition of a second winding. L1 and L4, respectively. Each of the added windings consists of 22 turns of No. 24 cotton-covered wire wound on a small cardboard tube as shown in the picture. (Actually, any wire size from No. 22 to No. 28 with cotton or enamel insulation will do the job).

The diameter of the cardboard tube should be slightly larger than L2 and L3 so that L1 and L4 will slip over L2 and L3 easily.

Resistor R1 is used only for feeding the set into an amplifier; it should be omitted for both earphone and loudspeaker operation. Trimmer capacitor C2 should be soldered across the stator terminals of two-gang variable capacitor C1a/C1b as shown. The speaker and output transformer can be mounted wherever convenient.

If a metal chassis is used, then be sure to insulate the aerial and earth connection sockets from the chassis.
When all of the parts have been mounted on the chassis, wire them together following the schematic and pictorial diagrams. Be sure that diodes D1 and D2 and capacitors C3 and C4 are connected correctly, paying attention to their polarity.

While this is interesting, what appears to be a key factor is contained in the drawings, where he states that the only important thing is that it is essential for the two sets of coils to be mounted perpendicular to each other:

**Alignment and Operation.** To align the receiver, connect it to an antenna and ground. The optimum length of the antenna varies with location, but 50 feet will usually be suitable in areas which receive several broadcast stations. Next, plug a high-impedance earphone into jack J1. Tune a station near the high frequency end of the
broadcast band – say, 1500 kHz – and adjust the trimmer capacitors on variable capacitor C1a/C1b to get the loudest signal.

Trimmer capacitor C2 should then be adjusted for the best selectivity and volume over the entire broadcast band. Finally, Coils L1 and L4 can be moved to their optimum positions by sliding them backwards and forwards over coils L2 and L3. If a nearby station interferes with the reception of a weaker station, tune the slug of L2 to get minimum interference. For loudspeaker operation, simply unplug the earphone. Strong local stations should be received at fair volume.

How It Works: The receiver employs a double-tuned circuit feeding a crystal diode voltage-doubler/detector which drives a small loudspeaker. Radio frequency signals picked up by the antenna system are induced into coil L2 from coil L1. The desired signal is selected by the tuned circuit C1a/L2 and coupled through capacitor C2 to a second tuned circuit C1b/L3, which improves the selectivity by narrowing the radio frequency bandpass. The twice-tuned signal is then induced into coil L4 from coil L3.

The positive half of the radio frequency signal appearing across L4, passes through the 1N34A germanium diode D2 to charge capacitor C4. The negative half of the signal passes through diode D1 to charge capacitor C3. The polarity of the charges on C3 and C4 are such that the effective voltage is doubled. This voltage appears across the primary of output transformer T1 which converts the high-impedance signal to a low-impedance output suited to the loudspeaker.

While this looks like a very good design for a crystal set, the fact that it is insisted that the coil pairs must be mounted at right angles to each other raises an interesting parallel with the work which states that if the high-frequency excitation field is at right angles to the output coil, then there will be a free-energy inflow into the circuit from the local environment. Perhaps this crystal set design gains extra power to drive its loudspeaker from an inflow of environmental energy.

Lawrence Tseung's Self-Powered “FLEET” Generator.
The "FLEET" ("Forever Lead-out Existing Energy Transformer") device is a self-powered electrical generator which has no moving parts and which can be constructed cheaply. It has been developed by a Hong Kong based team of people: Mr Lawrence Tseung, Dr. Raymond Ting, Miss Forever Yuen, Mr Miller Tong and Mr Chung Yi Ching. It is the result of some years of thought, research and testing and it has now reached an advanced stage of testing and demonstration and is nearly ready for commercial production.

Mr Tseung has applied his "Lead-out" theory to the category of low-power circuits known as the "Joule Thief" circuits. These circuits originated with an article by Mr Z. Kaparnik, in the "Ingenuity Unlimited" section of the November 1999 edition of the "Everyday Practical Electronics" magazine.

The initial circuit allowed the very last energy to be drawn from any ordinary dry-cell battery, and used to light a white Light-Emitting Diode ("LED") for use as a small torch. It allows a battery which is considered to be fully discharged, to drive the circuit until the battery voltage drops right down to 0.35 volts. The initial circuit uses a bi-filar coil wound on a ferrite ring or "toroid". Bi-filar means that the coil is wound with two separate strands of wire side by side, so that each adjacent turn is part of the other coil. A coil of that type has unusual magnetic properties. The Joule Thief circuit is like this:
It is important to notice how the coil is wound and how it is connected. It is called a "toroid" because it is wound on a ring. The ring is made of ferrite because that material can operate at high frequencies and the circuit switches On and Off about 50,000 times per second ("50 kHz"). Notice that while the wires are wound side by side, the start of the red wire is connected to the end of the green wire. It is that connection which makes it a "bifilar" coil instead of just a two-strand coil.

This "Joule Thief" circuit was then adapted by Bill Sherman and used to charge a second battery as well as lighting the Light-Emitting Diode. This was achieved by adding just one more component - a diode. The diode used was a 1N4005 type because that was to hand at the time, but Bill suggests that the circuit would work better with a very fast-acting Schottky-type diode, perhaps a 1N5819G type.

The circuit produced by Bill is:

When driven by a 1.5 single cell battery, this circuit produces about 50 volts with no load and can supply 9.3 milliamps of current when the output is short-circuited. This means that you could charge a 6-volt battery using a 1.5 volt battery.

"Gadgetmall" of the www.overunity.com Joule Thief forum has taken the circuit further and found a very interesting situation. He has modified the circuit and used a "batt-cap" which is a very high capacity, very low-loss capacitor. This is his circuit:

He has added an additional winding to his one-inch (25 mm) diameter ferrite toroid, and he uses that to power a 1 watt LED. Why he has done this is not immediately clear to me, except possibly, that it shows when the circuit is
operating. He runs the circuit driven by a small rechargeable battery, which feeds 13 milliamps into the circuit, for a period of fourteen hours. At the end of that time, the batt-cap has gathered enough energy to fully recharge the driving battery in a minute or two, and then power a heater winding of nichrome wire (as used in mains-powered radiant heaters) for four and a half minutes. Alternatively, that amount of extra power could boil a kettle of water. The really interesting thing about this is that the driving battery gets recharged every time and so the circuit is self-sustaining although it is not a powerful circuit.

However, Jeanna has developed the circuit significantly as she shows in her series of videos:

http://www.youtube.com/watch?v=Y4IMgDRGpHE
http://www.youtube.com/watch?v=1tVlCJiuWH4
http://www.youtube.com/watch?v=y6pbrzhrBR-8
http://www.youtube.com/watch?v=tNoZrV3w4f8
http://www.youtube.com/watch?v=XzhbsLBwc54
http://www.youtube.com/watch?v=4qi7IFCXw9Q

Her main point is that using the collector of the transistor as the power take-off point of the circuit, is inefficient as that draws a lot of input current without a corresponding increase in output current. She adds a 74-turn secondary winding on top of her two 11-turn Joule Thief bi-filar windings, and that appears to give a far better power output. She uses the very small AAA size 1.2V battery and further drops the output (because “the light is too blinding”) by putting a resistor in series with the battery and using many LEDs in series. She has recorded the following results:

With no resistor, the output voltage is 58V peaks at 62.5 kHz (open circuit output, with no load at all)
With a 10 ohm resistor, the output voltage is 49V peaks at 68 kHz.
With a 33 ohm resistor, the output voltage is 25V at 125 kHz.

‘LidMotor’ states that Jeanna also produced a Joule Thief circuit which could light a 15-watt straight fluorescent tube for about five hours when being driven by a single AA battery. He states that he was not satisfied with that level of lighting and at https://www.youtube.com/watch?v=KAakZTR_4LE he shows a version (which he thinks is Jeanna’s design and which Jeanna thinks is his design) driving a 10-watt Compact Fluorescent Light which has had the ballast circuitry removed. The build uses an expensive 3.25 inch (83 mm) outer diameter ferrite toroid, and the lighting from a single AA battery looks like this:

The ferrite ring is wound like this:
The main winding is 300 turns of AWG #30 enamelled copper wire with a diameter of 0.255 mm. Please notice the gap between the ends of that winding. That gap is important as high voltage is developed between the two ends of the winding and if the winding were continued all the way round the toroid, then the insulating enamel coating the wire would be liable to burn out due to the very high voltage difference between the first and last turns, causing a short-circuit. The two other windings are with AWG #24 enamelled copper wire which has a diameter of 0.511 mm and those two windings are positioned closely side by side in the middle of the gap between the ends of the 300-turn winding. The circuit is like this:

The optional 25 ohm wire-wound variable resistor wastes power but creates a voltage drop across it, reducing the voltage reaching the circuit and so, dimming the light progressively, all the way down to zero. The base resistor "R" has been set at 22 ohms by 'Lidmotor' who says that it really should be 100 ohms but he has lowered it to get brighter lighting. Please note which side of the 3-turn and 13-turn windings are connected in the circuit as the direction of winds is very important for those two windings.

It is not uncommon for people to comment on the faint whistling sound make by a Joule Thief circuit (especially a low-voltage version like this). It is my experience that the sound is caused by the transistor resonating with the frequency of oscillation of the circuit, the TIP3055 being particularly prone to this. I suggest therefore, that bolting on a heat sink (which is most definitely not needed to dissipate heat produced by this circuit) will alter the resonant frequency of the transistor/heat sink combination and so stop the whistling.

Personally, I have always had the greatest difficulty in getting any satisfactory light out of a Compact Fluorescent Lamp when driven by a Joule Thief circuit and so, for me, the best light source is one of the “G4” LED arrays with a “5050” driver chip. These look like this:
Quite good lighting can be had from a single Joule Thief circuit driving up to twelve of these simultaneously. The larger lighting area produces a more even and more gentle light which is quite effective in total darkness.

Most Joule Thief circuits specify a ferrite toroid, but a 75 mm diameter pancake coil also works well, and interestingly, pressing a second pancake coil tightly against the Joule Thief pancake coil, allows an additional LED array to be powered without increasing the current draw of the Joule Thief circuit:

It is also possible to cross-connect two or more Joule Thief circuits so that as well as producing 12V LED array lighting, each charges the battery being used by the other circuit:

And this works well with three circuits cascaded:
When working with these circuits, I bought a light-meter to take the guesswork out of assessing light levels as the human eye is very bad at doing that, although the visual impression of the lighting produced by any arrangement is actually more important than the measured lighting level. For example, there are 1-watt tiny LEDs, which have a theoretically high light output, but due to their tiny lit area are pretty useless for home lighting.

When I used the light meter (which measures in lux) I got a considerable shock. I used it with a light box to measure the light produced by two G4 LED arrays side by side, first with straight battery input and then with a Joule Thief input. The major shock was that the G4 LED arrays are actually more efficient at converting electric current to light than when a Joule Thief is used to drive those same LED arrays. That was completely unexpected. The figures for voltage / current draw / light produced using 1.2V (nominal) NiMh batteries were:

9 batteries 11.7V 206 mA 1133 lux: 2.41 watts 470 lux per watt (the manufacturer’s intended performance)
8 batteries 10.4V 124 mA 725 lux 1.29 watts 562 lux per watt
7 batteries 9.1V 66 mA 419 lux 0.60 watts 697 lux per watt (a very realistic performance level)
6 batteries 7.8V 6 mA 43 lux 0.0468 watts 918 lux per watt

A Joule Thief circuit driving two G4 LED arrays powered by 4 batteries giving 5.2V with the current draw controlled by selection of the transistor’s base resistor:
358 mA 259 lux 1.86 watts 139 lux per watt
200 mA 212 lux 1.04 watts, 204 lux per watt
180 mA 200 lux 0.936 watts 101 lux per watt
158 mA 182 lux 0.822 watts 221 lux per watt

This was quite startling, and the surprising conclusion is that using just four LED arrays driven by a 9V battery supply, produces a very respectable 800 lux for just 135 milliamps which is about 1.2 watts total – a very unexpected result. When the four LED arrays are fitted into a desk lamp and covered with frosted plastic to give a diffused light, the result is an excellent level of desk lighting which also lights the rest of the room quite well.

If you choose to do that, then it is possible to collect all of the current passing through the Joule Thief circuit, like this:

Here, the drive battery “B1” is made up with one battery more than the wanted voltage and all of the current passing through the four LED arrays is used as charging current for one additional battery which can be used to power a Joule Thief charging circuit.
As the LED array lights are essentially diodes anyway, they have no problem with being supplied with current from a battery which is being pulse-charged by a Joule Thief, so there is the option of leaving the Joule Thief circuit connected all the time as shown above. That, of course, is optional.

One further thing which can be done is to allow for doubling the Joule Thief voltage when the light is off. While the Joule Thief charging circuit is perfectly capable of charging the “B1” battery when driven by a 1.2V battery, it can charge faster if its voltage is doubled, which can be done quite easily using a standard 3-pole, 4-way rotary switch:

Here, the “B2” battery is made using two 1.2V batteries connected in parallel when the light is on, and when the light is switched off, the two batteries are connected in series, driving the Joule Thief charging circuit with double the voltage. Another option is to connect in a 6V or higher solar panel to charge the “B2” battery during the day. It appears that although the charging circuit can run at all times, it is actually more effective if the battery charge is stored and the pulse-charging only starts when the light is switched off.

It needs to be remembered that NiMh batteries are only 66% efficient, which means that when they are driving a load, you will only ever get back again, two thirds of the current fed into them. Where the above circuits show just one Joule Thief charging circuit, there will normally be two, three or more charging circuits to raise the rate of charging during daylight hours. Also, if the battery powering the Joule Thief has a higher voltage than the battery being charged by it, extra diodes will be needed so that their combined voltage drop will prevent the charging battery feeding a large current directly into the battery being charged.

Mr Lawrence Tseung has taken the Joule Thief circuit and modified it to become a circuit with a very serious output, moving it into a completely different category.

As a first step towards what the team calls their "Fleet" device, the toroid has been enlarged to a much greater diameter. The coil is now wound on a section of plastic pipe, 170 mm (6.5 inches) in diameter and 45 mm (1.75 inch) deep:
This section of pipe is "bi-filar" wound with two wires side by side as already described for the Joule Thief construction. As before, the start of one wire is connected to the end of the other wire. Then, the winding is given a layer of electrical tape to hold it in place and to provide an easy working surface for a second winding.

The wire used for the winding is the widely available red and black pair of wires, sometimes called "figure of eight" because the cut end of the wires looks like the numeral 8. The wire should be able to carry 2.5 amps. It must be side-by-side wire and not one of the twisted varieties. It looks like this:

The second winding is made in the same way but the connections are slightly different. As before, the end of the first wire is connected to the start of the second wire, but that connection is then insulated and not used in the following circuitry. This just connects the two windings one after the other, known technically as being connected "in series" and is the equivalent of making the winding with just a single strand of wire. The completed coil may look like this:

This particular design is still in its early stages and so many different coils sizes and constructions are being tested:
The arrangement is for the inner winding of the toroid to be oscillated by the Joule Thief circuit already described. This causes a pulsating magnetic field to envelope the outer winding of the toroid, producing an electrical output which is capable of doing useful work. The really important thing about this arrangement, is the fact that the amount of power coming out of the circuit is very much greater than the amount of power needed to make the circuit operate. The additional power is led out of the local environment and drawn into the circuit, becoming available to do useful work.

The overall circuit then looks like this:

While the outer winding is shown here with thicker wire of a different colour, this is only to make the arrangement easier to understand. In reality, the outer winding is with exactly the same wire as the inner winding, and it will normally go all the way around the toroid. The total amount of wire needed to make the windings is about 70 metres and so it is normal to buy a full 100 metre reel of the twin-core wire, which allows both windings to be made and leaves spare wire for other things.

For those of you who are very technically minded, the output waveform looks like this:
and the voltage pulses in this output are occurring about 290,000 times per second.

What has worked better for me is using a bridge of four diodes rather than a single diode:

I have used this circuit, driven by a 1.5 volt battery, to charge 12-volt batteries, but the best results are in the five to six volt range. I have used this circuit to confirm COP>1 by charging one small 12V lead-acid battery with an identical battery, swapping the batteries over and repeating the process several times. The result was that both batteries gained genuine, usable power. I suspect that the effect would have been much greater if I had charged two or more batteries in parallel. The toroid was an 8-inch diameter, 10 mm by 12 mm offcut from a plastic pipe which happened to be to hand and the wire used was plastic covered 6-amp equipment wire, again, because it was to hand at the time. Winding the toroid and setting up the circuit was done in a single evening.

Overall, this is a very simple, cheap and easily constructed COP>10 device which has the potential of providing large amounts of free, useable, electrical power. With further development, it may well be possible to produce a version which could deliver the power needed by a whole household. It is also likely that these devices will become available for purchase at quite a low cost. All in all, this is a very important device and full credit must go to the development team who have carried the research to this point and who are continuing to refine the design to produce more and more power.

Advanced versions of the Joule Thief Circuit.

A contributor who prefers to go by his ID of "Ace_Propulsion" shows here a series of clever, innovative variations on the well-known Joule Thief circuit.

What is a Joule thief? A Joule Thief circuit is a minimalist self-oscillating voltage boosting circuit which is small, low-cost and easy-to-build. It is normally used for driving light loads. It can use nearly all of the energy in a single-cell battery, even those which are already far below the voltage level where other circuits consider the battery to be 'fully discharged' (or "dead").

Notice the description "voltage booster". This means that the output voltage is increased at the expense of a higher input current draw. Conventional science says that a Joule Thief circuit can never ever achieve COP>1. A conventional Joule Thief circuit as shown below, will always have an energy loss between the Collector and Emitter of the transistor.
With proper modifications this circuit can acquire energy from the environment to power the output. This is quite simple to achieve. First, before we start discussing circuits, I'm going to tell you the weird stuff about LEDs:

Notice that you can illuminate an LED with just 1.5 Volts and get a brighter light by using 3 Volts. But if you connect two LEDs in series then that 3 Volts is too low to light them and so there is no light at all and zero current draw. Well, the weird stuff is that you can power ONE LED with 1.5V and can't power TWO LEDs in series with 3volts?!? And, while resistors control the brightness of the light they do not change the voltage required in any way. Now that's it! I (Ace_Propulsion) used this on a Joule Thief and when I did, I got COP>1 using this circuit:
This circuit has an input current of 12.5 milliamps at 2.35 volts (which is 30 milliwatts) and an output current of 8 milliamps at 6.60 volts (which is 52.8 milliwatts) and that is COP=1.8 or 80% greater output power than the input power. The ferrite toroid is wound using 0.4 mm diameter enamelled copper wire (#26 AWG) and while the trns are shown slanted in the diagram, the actual direction of the turns is radial, and anyway, the direction of the turns has no effect on circuit performance. It is expected that the diameter of the ferrite ring is not at all critical but only one diameter was available for testing. The fast-acting diode could be an FP607, UF5408 or similar, and it is also possible to use a transistor with the Base and Emitter connected together, instead of a high-speed diode. The LEDs used are 8 mm diameter types.

In this circuit it was found that the input voltage is important. The best input voltage is between 2.2 volts and 2.5 volts, so two Ni-Cad or two Ni-Mh batteries are about the optimum input as higher voltages just cause higher input currents without any improvement in the output power.

The key to free energy from this circuit is to use at least two LEDs connected in series. Place them in the current flow to the base of the transistor and the current fluctuations caused by their ‘weird stuff’ will boost the energy coming from the output.

one very important point is that there must be at least two LEDs and the circuit must not self-start, because if it does, then the input voltage is too high and the circuit will operate at COP<1. Because of this, you need to start the circuit operating by hand, and another very important point is that the output voltage should at least twice as much as the input voltage.

Features of this technique:
• COP>1 can be achieved and then with proper modification the circuit can become self-powered.
• You can extract energy from “dead” batteries and supplement it with additional energy drawn from the environment.
• Go to work and leave the circuit charging batteries at home while you are working.
• Interestingly, high-frequency sound is emitted by the circuit, and that sound tends to keep mosquitoes away!

Fine-tuning the circuit:
There are 5 parameters involved in the operation of this circuit:
1. Input voltage,
2. Output voltage, The coil winding,
3. The diameter of the toroid,
4. The number of LEDs, and
5. The resistor which feeds current to the base of the transistor.

The first step in assembling the circuit is to check the LEDs which you are going to use. These LEDs are going to be connected in series, so start with two and connect them across the battery. If the LEDs light up, then add an extra LED until the chain of LEDs do not light when connected across the battery. Doing this, will raise the COP of the circuit over 1 as the output power will then exceed the input power.

When setting up the toroid assembly, remember that winding more turns on the toroid will make a coil which has higher impedance which will increase the COP value, but too many turns may result in lower current which means a slower rate of charging from the output. The output voltage should always be more than twice the input voltage (for example: Input 2.35V Output 6.60V).
When the circuit has been built as shown above, if it starts running when the switch is closed, then the input voltage is too high, so keep adding an additional LED until the circuit will no longer self-start. Then, use your fingers to start it running by using your body resistance to bypass the LED chain very briefly to get the circuit oscillating. This is a low voltage section of the circuit and so there is no danger at all of getting a shock by doing this. An alternative would be to put a resistor in place instead of your fingers and use a press-to-make switch to trigger the circuit.

A further refinement is to add even more LEDs until the point is reached where the circuit will not start, even if you use your fingers to try to get it operating. When that point is reached, remove one of the LEDs and get the circuit running. Compare the input and output power levels, and then remove one more LED and repeat those power measurements. Keep doing that while you still have more than two LEDs until you determine what is the most effective number of LEDs in your circuit, that is, you find the best COP performance that your circuit can achieve.

In this circuit the LEDs are there to cause base current fluctuations as a mechanism to get COP>1 performance, and so, they are not there for lighting. You may increase the resistor value and so, lower the amount of input current used, but doing that results in lower output power. In my circuit, I used a 1100 ohm resistor.

Further Experiments:
This section is about some experiments which I have done to see if I can improve the performance of the Joule Thief. Obviously, I have not tried every possible arrangement and so I invite you (the reader) to do further experiments as the Joule Thief is clearly a very good circuit with which to experiment.

Charging at just 8 milliamps is too low a rate for a 1000 Milliamp-Hour 7.4 Volt Li-Po battery pack, and so, it is necessary to increase the rate of charge. This can be done by using two or more of these circuits connected in parallel as shown here:
Batteries which are almost fully discharged, have a higher internal resistance than a new battery, and so the higher the current drawn by the circuit the lower the efficiency of the circuit will be. As a result of this, the effective input voltage used by this circuit is actually lower than the 2.34 volts shown in the circuit diagram.

So perhaps it should be arranged like this:

Remember that the output voltage should always be more than twice the input voltage. So if you want to charge Ni-Cad batteries which have a lower voltage, then you should use a step-down transformer as shown here:
With the appropriate modifications it can become self-powered and self-charging as shown here:

The performance of this circuit can be boosted further by using an asymmetrical transformer such as Lawrence Tseung's Magnetic Frame or Thane Heins' transformer as shown here:
Perpetual Lighting circuit:
Higher voltage results in lower LED resistance and so will decrease the efficiency of the circuit through negative feedback and so the circuit can become stabilised as shown here:

Also, check out the high-power Joule Thief circuits with 1-watt output and various other useful products at http://www.madscientisthut.com/Shopping/agora.cgi?product=Energy%20Harvesting&user4=Joule%20Thief%20Kits.
We come now to circuits designed by Johnny Aum of Romania who is an independent free-energy researcher since 1982 in spite of everyone around him saying that free-energy is not possible, shows some of his work on his johnnyaum3 YouTube channel. Johnny has shared three of his many high-efficiency designs, including his successful permanent magnet motor design, on the JL Naudin website since 1999.

The following two circuits are still under development. They can be considered to be Joule Thief circuits as they do roughly the same thing, but strictly speaking, these are not Joule Thief circuits but instead are completely new innovative designs, initially developed between 2009 and 2010.

The following circuit is aimed at minimum current draw and while it looks quite like a Joule Thief, you will notice that the end of one of the toroid windings does not connect to the start of the other winding, and while the wires are bi-filar wound side by side as in a Joule Thief, the different connection of the windings makes it a quite different circuit. It runs from 44 to 49 kHz with increased COP at the higher frequency.

This circuit has a spectacular COP of around 650 at very low currents and you will notice that with a resistor value of 1Megohm, the current draw is only 7 microamps. Both of these circuits can recharge the battery to a certain degree and can recondition the driving battery. It is generally found that in any device, as the power level increases, the COP drops off. To get the full light output from the LED, the current increases to 1 milliamp, which, of course, is very impressive performance, and you can imagine how long a NiMh 3000 milliamp-hour AA battery could keep the LED lit at full power.

The second circuit from Johnny Aum is intended for more useful lighting levels for use where the mains is not available and can run for ten days on one battery due to the slight degree of battery recharging produced by the circuit. Here are some of Johnny’s prototypes in operation:
Johnny stress that this circuit generates healing properties and the light is whiter than that produced by a classic circuit. This circuit runs at around 15 kHz. It should be pointed out that an obvious way to increase the lighting level is to have additional LEDs lit, whether by using more than one connected in parallel, and/or using two or more circuits, this is quite feasible as the circuits are very small, lightweight and cheap to make. One-watt LEDs in many different varieties are readily available from different suppliers.

The circuit for driving these powerful LEDs is somewhat different, with a PNP transistor being connected directly to a 2N1613 NPN transistor, boosting its gain by a factor of about 20 times. This connection method has no appreciable voltage drop when switched on and is convenient for circuits which use very low voltages, such as this circuit. The ferrite toroid in this circuit is wound around its whole circumference with thin 0.2 mm diameter wire. On the prototypes, this resulted in 150 turns of the two wires side by side. This winding is a genuine bi-filar winding, but it is not connected like a Joule Thief. Instead, the end of one wire is connected to the start of the other wire, but not to anything else, leaving just two wires coming away from the toroid winding. It looks like this:

As you can see, this is a very simple-looking circuit with very few components, and yet it is very effective in driving a powerful LED.
A Suggestion

This is an arrangement of readily available, cheap parts for operating a useful light. Probably the most efficient circuit for this task is the ‘Joule Thief’ circuit and the light bulb usually chosen for this circuit is the compact fluorescent lightbulb (“CFL”) which is widely available around the world and although there are many variations, looks something like this:

The arrow is pointing to a join in the construction where the bulb section joins the lower section which houses circuitry and the mains connector which can be one of many different types. However, that type of bulb has mains circuitry built into it which means that in order to get the higher efficiency which we would like, each bulb needs to be physically modified which is far from ideal. The circuitry inside a bulb of this type, converts the alternating current of the mains into Direct Current and then uses that direct current to supply an oscillator circuit which generates high-frequency pulses which power the bulb. Unfortunately, that circuitry gets in the way of low-power operation and so needs to be removed. People who have done this, say that the bottom can be popped off just by inserting a screwdriver into the crack and twisting the screwdriver to force the two pieces apart. If you try that, then let me wish you luck as it has never worked for me, even when applying enough force to permanently damage the material on both sides of the crack. Instead, I do it by cutting the plastic base 8 mm below the arrow line resulting in this:

The 8 mm clearance is because the glass tubes project down below the join and we need the remaining section of the plastic housing to support the bulb when we mount it on our circuit box. The cut should be made when holding the base section as the glass tubes are very fragile and easily damaged. If available, a Dremel or similar tool which has a small cutting disc very well suited to making this cut. The cut should be just deep enough to go through the plastic wall but not further than that. There is a tiny circuit board contained in the lower part, generally, with some very nice components which can be used for other circuits. The cut-down light bulb can be mounted on the circuit box using a strong adhesive, or a hole can be drilled very carefully in the centre, between the tubes (holding the base and not the tubes when doing this) and the base can then be bolted to the component box.

The glass tubes are U-shaped and there are two inter-tube horizontal connecting tubes in order to make all of the U-tubes function as one long zig-zag discharge path and get all of the tubes lit up at the same time. The two tubes which do not have this horizontal interconnecting tube, have two wires coming out of the bottom of them, and used to connect the circuit to the tubes. These four wires need to be cut, leaving them as long as possible, then each pair has the insulating enamel scraped off them and then soldered to a length of wire which will be used to connect to the new circuit, or alternatively, direct to the board if very small ‘fiddly’ work is no problem.

This adaption makes this low-cost method unsuitable for applications where an off-the-shelf bulb is needed so that replacements can be made without the need for any technically skilled person to be available. What we need therefore, is a bulb which does not have the mains circuitry (called “ballast”) built into it, and the earlier ‘PLD’ bulbs are in that category. Unfortunately, they are more expensive and not so widely available. They look like this:
These have the enormous advantage of not requiring any work on the bulb in order to operate immediately with our circuit. We can build a suitable circuit from scratch, but it is very popular with home constructors making a one-off experiment to use the very cheap circuit found in Fuji’s “Quick Snap” disposable camera which is very widely available. It looks like this:

There are various ways of adapting the circuit board found inside the camera, and thanks is due to ‘Gadgetmall’ of the [http://www.overunity.com/10723/fuji-joule-thief-full-instructions-video-and-pics/new/#new](http://www.overunity.com/10723/fuji-joule-thief-full-instructions-video-and-pics/new/#new) forum for sharing his method of adaption and expertise with these circuits, which has allowed him to run a fluorescent light for 38 hours powered by just one AA size 1.5 volt battery.

**Disclaimer:** This document must not be considered to be a recommendation for you to actually attempt to undertake any of the following modifications, and should you decide to do so, then any loss, damage or injury are wholly your responsibility and not that of anyone else.

The camera needs to be taken apart in order to get at the circuitry inside it. A word of warning here, there is a high-voltage capacitor inside the camera and if it happens to be charged, then it is quite capable of giving you a really nasty shock, so as soon as the circuit board is exposed, I strongly recommend that you take great care to avoid a shock, even though it is not likely to be a fatal shock. As soon as the capacitor is exposed, then short across it’s wires using a metal tool which has a plastic handle, such as a screwdriver or pair of pliers with a well-insulated grip. If the capacitor happens to be charged, then that may produce a bright spark which makes a loud crack.

The camera is taken apart like this:

1. The green covering which is a piece of very sticky, strong plastic is peeled off. The join is underneath, where the black colouring ends.

2. In the middle of the bottom, there is a flap which you lever up, uncovering the battery. There are various varieties of Fuji “Quick Snap” camera with different circuitry, the one shown here was supplied by Asda (Wal-Mart in the UK) in 2012 and the circuit board is marked A07 or A60 while some earlier versions have a different layout for some components and even have the battery inserted the other way round. Before you remove the battery which in the UK is a 1.5V AAA alkaline battery, make a careful note of which way round the battery is inserted. In this case, the plus of the battery connects with the long copper arm. Remove the battery.

3. Pull off the black plastic covers on the underside of the camera, located at each end of the battery compartment, and then using a screwdriver, force the two halves of the black camera case apart, which leaves the front of the camera looking like this:
4. Make sure that the flash is not charged, first, by using a non-conducting item to press together the switch contacts marked “A” in the following picture, and then using some metal object with a plastic handle, bridge across the gap between the soldered points ringed around and marked “B” as they are the ends of the high-voltage capacitor. If the capacitor happens to be charged, then there will be a spark and a loud sound, but this is unlikely with a new camera unless you have been pressing the buttons since unwrapping it.

5. Press the black plastic latch marked “C” in the picture above, over towards the left and that releases the circuit board which can be lifted out and looks like this:
6. The board is quite small, being about 40 mm x 25 mm when the capacitor and flash unit are removed which is the next thing to do, probably by cutting the very tough capacitor leads and then cutting off the plastic pins holding the flash unit to the board, levering it upwards and cutting away it's metal contacts which link it to the board.
7. The two switches which form the camera's flash-charging switch and it's shutter release switch need to be wired permanently closed. These are marked “Switch 1” and “Switch 2” in step 5. above. I suggest that you cut the arms of Switch 1 to about half length, clamp them together with a pair of long-nosed pliers and bend them over to crimp them flat, and then solder them together. Switch 2 needs to be bridged across to make it permanently closed. A clip can be used to clamp the upper and lower contacts together so that they can be bridged with solder.

8. The rest of the modification is seen from the top of the board:

This is to achieve this 'Gadgetmall' circuit:

Gadgetmall comments that increasing the voltage supplied to this circuit, puts the 2SD1960 transistor at risk as it will overheat. That transistor is tiny, has no heat sink or space to fit one and was only intended to be on for a few seconds while the capacitor charges up in preparation for operating the flash bulb. This circuit modification runs the transistor continuously for very long periods and so we are already stepping outside the Fuji circuit designer's operating conditions. Also, we would like to run the circuit with somewhat higher voltage in order to get improved operation of the fluorescent tube or bulb. Consequently, we might consider using a more powerful transistor. The 2SD1960 transistor is rated at 30-volts, 5-amps, 170 MHz and 0.75
watts, so we might consider swapping it for, say, a BD245C transistor rated at 100-volts, 10-amps, 3 MHz and 80 watts as our circuit runs at under 0.1 MHz and the BD245C transistor can be mounted on a heat sink, although with it's much greater handling capacity, it should stay cool at these tiny powers. We can boost the gain of the BD245C by a factor of 200 or so, by using a BC109C or a 2N2222 transistor to form a Darlington pair, making the circuit:

**LaserSaber's Joule Thief Lighting Circuits.**

Another very successful variation on the basic Joule Thief was put into the Public Domain on 4th October 2012. Details are on his web site [www.laserhacker.com](http://www.laserhacker.com). His variation is extremely simple, both in concept and construction:

![Image of LaserSaber's Joule Thief](image)

and in his video: [http://solarpower.energygratis.com/2012/10/09/solar-electricity-super-joule-ringer-3-0-real-world-power-made-easy/](http://solarpower.energygratis.com/2012/10/09/solar-electricity-super-joule-ringer-3-0-real-world-power-made-easy/) he demonstrates it lighting a mains-voltage LED bulb (seen above), a mains filament bulb, a halogen bulb and a compact fluorescent bulb with the ballast still in place, that is, as is sold in shops without any modification. The circuit is:
This “Super Joule Ringer 3.0” circuit is unusual in that the feedback to the base of the 2N3055 transistor is through the load (the bulb). The circuit is a high-frequency DC inverter which could hardly be any more simple, but please be aware that the high-frequency output voltage spikes are not sine wave, nor are they voltage controlled, and so this is not a circuit for driving things like TV sets. The transistor oscillates at high frequency governed by the characteristics of the 72-turn primary winding of the transformer. The output voltage level is a combination of the battery voltage and the turns ratio of the transformer.

To raise the output voltage, the number of turns in the secondary can be increased. The number of turns is not specified, other than to say that the turns are laid close, side-by-side along the whole length of the 8-inch (200 mm) long ferrite rod, using enamelled copper wire of 0.32 mm diameter (28 AWG or 30 swg). Using arithmetic, that would suggest that there are some 600 turns wound directly on to the ferrite rod. The ferrite rod itself has a diameter of 0.625 inches (15.88 mm) which makes it an item which is likely to be difficult to find. However, I strongly suspect that the diameter of the ferrite rod is not at all critical.

Both of the coils are wound on the ferrite rod in the same direction, the secondary being wound first, placing it underneath the primary which is wound with 72 turns of insulated wire of 1.63 mm diameter (14 AWG or 16 swg). No current draw is indicated and it seems likely that it is quite high there being just two helical coils in the drive section. The (110-volt) bulbs demonstrated in his video are:

A second, very practical lighting system from ‘LaserSaber’ is a Joule Thief driven LED lighting box, running from just one AA rechargeable battery. It looks like this:
Mounted on the end of the box is a single small solar panel:

which is able to charge the battery during the day. The unit is built into a small box which opens up to allow easy wiring, and different angles for positioning the LED lights. Not seen in these pictures is one other large LED cluster light which is also lit. It is a slight pity that the case does not allow the LED lights to shine on the solar panel when the lights are on, as that would provide some battery charging when the light is being used. The LED lights can provide a good deal of light:
A video of this unit being demonstrated is at http://www.youtube.com/watch?v=sFpzkyP6DCU.

Ed Gray's Power System.
The power tube presented to the public by Edwin Gray snr. operates by generating a series of very short, very sharp pulses using a spark gap. This device is reputed to have a power output which is one hundred times that of the power input. Ed Gray and his electric pulse motor are very famous, but as far as I am aware, nobody has successfully replicated this claimed performance. Further, an in-depth examination of the background details by Mr Mark McKay have turned up a number of facts which present a very different picture, and while it is perfectly correct to say that spark-gap pulses generate a good waveform for shocking the local zero-point energy field into the sort of imbalance which can provide a massive power inflow into a device or circuit, we need to be careful to get the full facts in this case.

First, let us put the whole thing in its proper perspective. In May 1973, Cal-Tech in the US performed an independent assessment of an engine provided to them by Edwin Gray. They measured the input and the output and certified that the output power was 275 times greater than the input power. This demonstrates clearly that excess power can be drawn into an engine and provide a performance which can power both the engine as well as doing additional useful work.

Having said that, it needs to be made clear that Edwin Gray did not build that small motor, did not understand how it worked, nor did he ever disclose the design in any of the patents which he obtained afterwards. We need to follow the sequence of events and notice when each thing happened. The history is as follows:

In 1957, a Russian immigrant to the USA, one Alexei Popoff, showed Edwin Gray a circuit which he said that he had been shown by Nikola Tesla. Edwin Gray did not understand the circuit and had no idea how to create anything useful based on it. He then joined up with his next-door neighbour Marvin Cole, who held a Masters degree in Mechanical Engineering and who, unlike Gray, was able to understand the circuitry.

In 1958, Ed Gray left the Los Angles area in a hurry.

From 1958 to 1967 Marvin Cole, working alone, designed and built ever more powerful prototype engines, and it was a small one of these which was tested by Cal-Tech. In this period, Marvin also developed ever more powerful power supplies, which are the really important item in all of this.

In 1967, Ed Gray rejoins Marvin Cole and together from 1967 to 1972 they solicited venture capital and promoted the technology.

Early in 1972, Marvin Cole disappeared and never saw Gray again. It is not clear if he was intimidated, died, or just did not want to be involved in all the publicity and effort needed to turn the prototype engines into a commercial product. No matter what the reason, the result was that Edwin Gray was suddenly disconnected from the brains behind the project, and that left him in a very difficult position. He didn't want to let go of the dream of becoming rich through this spectacular development, and so he tried to continue the development on his own.

As already mentioned, in May of the following year (1973), Gray had a small Marvin Cole motor independently third-party tested at the famous Cal-Tech laboratory in Los Angles, where a measured input of just 27 watts produced a measured output of 10 horsepower (7460 watts). The objective was to provide solid evidence of a new technology which was capable of changing the world and so would attract investors. To further boost his image and convince potential investors, in that same year of 1973, Edwin staged demonstrations which jumped electromagnets up into the air, showing the strength of the power which drove the Marvin Cole engines.

It is very important to understand that all of Edwin Gray's patents were applied for after the departure of Marvin Cole. These do not disclose the technology tested by Cal-Tech and it must be understood that Edwin was very much afraid of revealing anything important in any of the patents in case some other person would understand the things which were a mystery to him and snatch away the prize of commercial success. Try watching Peter Lindemann's informative video at http://www.youtube.com/watch?v=dmf10hggUm4 for considerable additional information.

Marvin Cole's power system produced "cold electricity" which could power lights and other devices. It was frequently demonstrated that the output was not conventional electricity and powered light bulbs which were placed under water and at the same time, it was quite safe for a hand to be put into that same water along with the lit bulb. The glass of the conventional bulbs used in these demonstrations would have shattered when placed under water if they had been powered by conventional "hot electricity" as the sudden change in temperature
would have broken the glass. Powered as they were by “cold electricity”, they ran cool and so there was no stress on the glass when submerged in water.

Peter Lindemann points out that Ed Gray’s power conversion tube circuit is effectively a copy of Nikola Tesla’s circuit for doing the same thing:

![Diagram](image)

This was disclosed by Tesla in his ‘Philadelphia and St Louis’ lecture in 1893 and shows how loads can be powered when a high voltage source is pulsed by a magnetically-quenched sparks - this creates DC pulses of very short duration.

![Diagram](image)

The diagram above, illustrates the difference between the Magnetic field generated around a conductor fed with a pulse of Direct Current and the Radiant Energy waves created by that pulse. If a sharp current pulse is driven down a vertical wire, it causes two different types of field. The first field is magnetic, where the lines of magnetic force rotate around the wire. These lines are horizontal, and rotate clockwise when viewed from above. The magnetic field remains as long as the current flows down the wire.

The second field is the Radiant Energy wave. This wave will only occur if the current pulse is in one direction, i.e. it will not occur if the wire is fed with alternating current. The wave radiates out horizontally from the vertical wire in every direction in the form of a shock wave. It is a one-off event and does not repeat if the current in the wire is maintained. The Radiant Energy briefly unbalances the zero-point energy field and that causes an energy flow as the field moves back into equilibrium again.

The Radiant energy wave is not restricted to a single plane as shown in the diagram above, which is intended to indicate the difference between the electromagnetic field circling around the wire, and the Radiant Energy field which radiates away from the wire. Both of these fields occur at all points along the full length of the wire as shown here:
Radiant Energy, when converted to electrical power, produces a different kind of electrical power to that produced by batteries and by the mains supply. Power a motor with conventional electricity and it gets hot under load. Power the same motor by Radiant Energy electricity and under load the motor gets cold. Really overload it by stalling it and the motor housing is likely to be covered with frost. That is why this form of electricity is referred to as “cold” electricity.

In his book “Cold War Secrets - HAARP and Beyond”, Gerry Vassilatos quotes research work done in this area by Tesla and others:

**Tesla’s Experiments.**

In 1889 Tesla began experimenting with capacitors charged to high voltages and discharged in very short time intervals. These very short pulses produced very sharp shockwaves which he felt across the front of his whole body. He was aware that closing a switch on a high-voltage dynamo often produced a stinging shock. This was believed to be static electricity and it occurred only at switch-on and only for a few milliseconds. However, in those few milliseconds, bluish needles of energy stand out from the electrical cables and they leak to ground, often through the bodies of any people standing nearby, causing immediate death if the installation is large. While the generators of that time were rated at some thousands of volts, these discharges were millions of volts in intensity. The generator problem was eliminated by the used of highly insulated switches which were provided with a very large ground connection.

Tesla was intrigued by this phenomenon which appeared to match the effect of his capacitor discharges. He calculated that the voltages produced were hundreds of times greater than could be supplied by the capacitor or generator. It was clear that the power supplied was being amplified or augmented in some way, but the question was, from where was the extra energy coming?

Tesla continued to investigate through experiments, taking precautions against the high voltages being produced. He was soon able to produce these shockwaves whenever he wanted to. The shockwaves produced a stinging sensation no matter where he stood in his laboratory, and hands and face were particularly sensitive to the wave. These waves radiated out and penetrated metal, glass and every other kind of material. This was clearly not an electromagnetic wave, so he called the new wave ‘Radiant Electricity’.

Tesla searched the literature to find references to this radiant energy but he could not find much. In 1842, Dr. Joseph Henry had observed that steel needles were magnetised by a Leyden Jar spark discharge located on a different floor of the building. The magnetising wave had passed through brick walls, oak doors, heavy stone and iron flooring and tin ceilings to reach the needles located in a vault in the cellar.
In 1872, Elihu Thomson took a large Ruhmkorff Spark Coil, attached one pole of the coil to a cold-water pipe and the other pole to a metal table top. This resulted in a series of massive sparks which electrified the metal door knob of the room and produced the stinging shockwaves which Tesla was investigating. He found that any insulated metal object anywhere in the building would produce long continuous white sparks discharging to ground. This discovery was written up briefly in the Scientific American journal later that year.

Tesla concluded that all of the phenomena which he had observed, implied the presence of “a medium of gaseous structure, that is, one consisting of independent carriers capable of free motion - besides the air, another medium is present”. This invisible medium is capable of carrying waves of energy through all substances, which suggests that, if physical, its basic structure is much smaller than the atoms which make up commonplace materials, allowing the stream of matter to pass freely through all solids. It appears that all of space is filled with this matter.

Thomas Henry Moray demonstrated this energy flow passing through glass and lighting standard electric light bulbs. Harold Aspden performed an experiment known as the “Aspden Effect” which also indicates the presence of this medium. Harold made this discovery when running tests not related to this subject. He started an electric motor which had a rotor mass of 800 grams and recorded the fact that it took an energy input of 300 joules to bring it up to its running speed of 3,250 revolutions per minute when it was driving no load.

The rotor having a mass of 800 grams and spinning at that speed, its kinetic energy together with that of the drive motor is no more than 15 joules, contrasting with the excessive energy of 300 joules needed to get it rotating at that speed. If the motor is left running for five minutes or more, and then switched off, it comes to rest after a few seconds. But, the motor can then be started again (in the same or opposite direction) and brought up to speed with only 30 joules provided that the time lapse between stopping and restarting is no more than a minute or so. If there is a delay of several minutes, then an energy input of 300 joules is needed to get the rotor spinning again.

This is not a transient heating phenomenon. At all times the bearing housings feel cool and any heating in the drive motor would imply an increase of resistance and a build-up of power to a higher steady state condition. The experimental evidence is that there is something unseen, which is put into motion by the machine rotor. That “something” has an effective mass density 20 times that of the rotor, but it is something that can move independently and take several minutes to decay, while the motor comes to rest in a few seconds.

Two machines of different rotor size and composition reveal the phenomenon and tests indicate variations with time of day and compass orientation of the spin axis. One machine, the one incorporating weaker magnets, showed evidence of gaining strength magnetically during the tests which were repeated over a period of several days.

This clearly shows that there is an unseen medium which interacts with everyday objects and actions, and confirms Tesla's discovery. Tesla continued to experiment and determined that a very short uni-directional pulse is necessary to generate the radiant energy wave. In other words, an alternating voltage does not create the effect, it has to be a DC pulse. The shorter the pulse time and the higher the voltage, the greater the energy wave. He found that using a capacitor and an arc discharge mechanism with a very powerful permanent magnet placed at right angles to the spark, improved the performance of his equipment by a major factor.

Additional experiments showed that the effects were altered by adjusting the duration of the electrical pulse. In each instance, the power of the radiated energy appeared to be constant irrespective of the distance from his apparatus. The energy was in the form of individual longitudinal waves. Objects placed near the equipment became powerfully electrified, retaining their charge for many minutes after the equipment was switched off.

Tesla was using a charging dynamo as a power source and he found that if he moved his magnetic discharger to one side of the dynamo, the radiant wave was positive. If he moved the magnetic discharger towards the other side of the dynamo, the radiant wave became negative in sign. This was clearly a new electrical force which travelled as light-like rays, showing them to be different in nature to the electromagnetic waves of Maxwell.

Investigating the effects of adjusting the duration of the pulses, Tesla found that a pulse train which had individual pulses with durations exceeding 100 microseconds, produced pain and mechanical pressures. At this duration, objects in the field visibly vibrated and were even pushed along by the field. Thin wires subjected to sudden bursts of the radiant field, exploded into vapour. When the pulse duration was reduced to 100 microseconds or below, the painful effect was no longer felt and the waves are harmless.
With a pulse duration of 1 microsecond, strong physiological heat was felt. With even shorter pulse durations, spontaneous illuminations capable of filling rooms with white light, were produced. Even shorter pulses produced cool room penetrating breezes with an accompanying uplift in mood and awareness. These effects have been verified by Eric Dollard who has written about them in some detail.

In 1890, Tesla discovered that if he placed a two-foot long single-turn deep copper helix coil near his magnetic disrupter, the thin-walled coil developed a sheath of white sparks with long silvery white streamers rising from the top of the coil. These discharges appeared to have much higher voltages than the generating circuit. This effect was greatly increased if the coil was placed inside the disrupter wire circle. The discharge seemed to hug the surface of the coil with a strange affinity, and rode up its surface to the open end. The shockwave flowed over the coil at right angles to the windings and produced very long discharges from the top of the coil. With the disrupter charge jumping one inch in its magnetic housing, the coil streamers were more than two feet in length. This effect was generated at the moment when the magnetic field quenched the spark and it was wholly unknown at that time.

This train of very short uni-directional pulses causes a very strange field to expand outwards. This field resembles a stuttering electrostatic field but has a far more powerful effect than would be expected from an electrostatic charge. Tesla was unable to account for the enormous voltage multiplication of his apparatus using any of the electrical formula of his day. He therefore presumed that the effect was entirely due to radiant transformation rules which would have to be determined through experimental measurements. This he proceeded to do.

Tesla had discovered a new induction law where radiant shockwaves actually auto-intensified when encountering segmented objects. The segmentation was the key to releasing the action. Radiant shockwaves encountered a helix and “flashed over” the outer skin, from end to end. This shockwave did not pass through the windings of the coil but treated the surface of the coil as a transmission path. Measurements showed that the voltage increase along the surface of the coil was exactly proportional to the length travelled along the coil, with the voltage increase reaching values of 10,000 volts per inch of coil. The 10,000 volts which he was feeding to his 24 inch coil were being magnified to 240,000 volts at the end of his coil. This was unheard of for simple equipment like that. Tesla also discovered that the voltage increase was mathematically linked to the resistance of the coil winding, with higher resistance windings producing higher voltages.

Tesla then began to refer to his disrupter loop as his special “primary” and to the long helical coil as his special “secondary” but he never intended anyone to equate these terms to those referring to electromagnetic transformers which operate in a completely different way.

There was an attribute which baffled Tesla for a time. His measurements showed that there was no current flowing in the long copper ‘secondary’ coil. Voltage was rising with every inch of the coil, but there was no current flow in the coil itself. Tesla started to refer to his measured results as his “electrostatic induction laws”. He found that each coil had its own optimum pulse duration and that the circuit driving it needed to be ‘tuned’ to the coil by adjusting the length of the pulses to give the best performance.

Tesla then noticed that the results given by his experiments paralleled the equations for dynamic gas movements, so he began wondering if the white flame discharges might not be a gaseous manifestation of electrostatic force. He found that when a metal point was connected to the upper terminal of the ‘secondary’ coil, the streamers were directed very much like water flowing through a pipe. When the stream was directed at distant metal plates, it produced electronic charges which could be measured as current at the receiving site but in transit, no current existed. The current only appeared when the stream was intercepted. Eric Dollard has stated that this intercepted current can reach several hundred or even thousands of amps.

Tesla made another remarkable discovery. He connected a very heavy U-shaped copper bar directly across the primary of his disrupter, forming a dead short-circuit. He then connected several ordinary incandescent filament bulbs between the legs of the U-shaped bar. When the equipment was powered up, the lamps lit with a brilliant cold white light. This is quite impossible with conventional electricity, and it shows clearly that what Tesla was dealing with was something new. This new energy is sometimes called “cold electricity” and Edwin Gray snr. demonstrated how different it is by lighting incandescent-filament bulbs directly from his power tube, submerging them in water and putting his hand in the water. Cold electricity is generally considered to be harmless to humans. Ed Gray’s power tube operates by generating radiant electricity waves by using a spark gap, and collecting the energy using three encasing copper cylinders surrounding the spark gap. The cylinders are drilled with many holes as that enhances the pick-up and the load is driven directly from the current in the cylinders. When lighting bulbs, Ed used an air-cored transformer made of just a few turns of very heavy wire. I, personally, am aware of two people who have independently reproduced Ed’s power tube.

Tesla viewed the streamers coming off his coils as being wasted energy so he tried to suppress them. He tried a conical coil but found that this accentuated the problem. He then tried placing a copper sphere at the top of his
coil. This stopped the streamers but electrons were dislodged from the copper sphere, creating really dangerous conditions. This implied that metals generate electron flows when struck by the coil streamers (as had been seen when the streamers had been aimed at remote metal plates and current was generated as a result).

Tesla designed, built and used large globe lamps which required only a single external plate for receiving the radiant energy. No matter how far away these lamps were from the radiant source, they became brilliantly lit, almost to the level of an arc lamp and far, far brighter than any of the conventional Edison filament lamps. By adjusting the voltage and the pulse duration of his apparatus, Tesla could also heat or cool a room.

Tesla’s experiments suggest that a method of extracting free-energy is to use a Tesla coil which has a metal spike instead of the more common metal sphere at the end of the ‘secondary’ coil. If the Tesla coil is fed with sufficiently short uni-directional pulses and the ‘secondary’ coil pointed at a metal plate, then it should be possible to draw off serious levels of power from the metal plate, just as Tesla discovered. This has been confirmed by Don Smith who uses two metal plates separated by a layer of plastic dielectric, forming a capacitor. He states that a well designed Tesla coil is capable of producing currents as high as the voltages and he demonstrates a hand-held 28 watt Tesla Coil played on the first plate producing a substantial continuous spark discharge between the second plate and ground. I estimate that the spark produced would have to be thousands of volts at a significant current, which puts it in the kilowatt range, like most of Don’s other devices. Video: http://www.metacafe.com/watch/2820531/don_smith_free_energy/ Don’s patent is in Chapter 3 and his .pdf document here: http://www.free-energy-info.tuks.nl/Smith.pdf in which he explains many of his high-power designs.

Don also points out that the positioning of the primary coil relative to the secondary coil of a Tesla Coil determines the amount of current which can be provided. Contrary to most opinion, it is possible to have Tesla Coil current as high as the voltage. Don always stresses that you have the option of picking the electrical component (as conventional science has done) which leads to “heat death” while the alternative option of selecting the magnetic component makes “the world your oyster”. With a magnetic ripple imposed on the zero-point energy field, which Don prefers to call the ‘ambient background energy’, you can make as many electric conversions as you wish, without depleting the magnetic event in any way. In other words, you can draw off serious amounts of current from capacitor plates positioned at right angles to the magnetic flow, and every additional pair of plates gives you an additional source of major current without any need to increase the magnetic disturbance in any way. With his single metal plate, Tesla mentioned currents of a thousand amps being available. Please remember that a Tesla Coil produces seriously high voltages and is not a toy. Great care is needed around a Tesla Coil so, when it is running, keep well away from it.

Don also states that the collection and transfer of energy requires temporary storage which occurs as the capacitors and coils of a resonant circuit are cycled on and off. The frequency at which the capacitors and coils are pumped, determines the amount of electrical energy that moves onwards. The amount of Energy transferred relates directly to the density of lines of magnetic flux present. The Kinetic Energy formula is helpful in establishing the amount of energy present. This formula points to mass multiplied by the square of the velocity. In the case of electrical energy, intensity of voltage and amperes multiplied by cycles per second, replace velocity. Note that the “acceleration” of the Voltage and the Amperage, increases in a non-linear fashion as the Law of Squares applies, with each unit of increase causing a squaring of the flux lines present. In resonant air-core coil energy transfer, the increase in flux lines present disturbs more electrons than previously and this results in greater output energy than input energy being present and available.
Energy stored, multiplied by the cycles per second, is the energy being pumped by the system. Capacitors and inductors (coils) temporarily store electrons.

**Capacitor formula:** \( W = 0.5 \times C \times V^2 \times Hz \) where:

- \( W \) is the energy in Joules (\( \text{Joules} = \text{Volts} \times \text{Amps} \times \text{seconds} \))
- \( C \) is the capacitance in Farads
- \( V \) is the voltage
- \( Hz \) is the cycles per second

**Inductor formula:** \( W = 0.5 \times L \times A^2 \times Hz \) where:

- \( W \) is the energy in Joules
- \( L \) is the inductance in Henrys
- \( A \) is the current in amps
- \( Hz \) is the frequency in cycles per second

Both one Henry and one Farad equal one volt. The higher the frequency, including the squaring of the flux lines, causes a large increase in the amount of energy being produced. This, combined with the use of a resonant energy induction system (all electrons moving in the same direction at the same time), make the move into COP>1 practical.

The damping process of conventional electrical power generation, has all of the available electrons bouncing randomly, mostly cancelling out each other, and so the useful energy available is only a very small percentage of the energy which is present. In a resonant induction system, a very high percentage of the energy present is useful. When resonating, \((\text{ohms-impedance-}Z)\) becomes zero and all of the energy present becomes available, without being degraded in any way. Ohms is load or wasted energy and amperes is the rate of that wasting.

Now, apply this information to an air-core coil resonant transformer energy system. L-1 and L-2 coils are now present. L-1 has fewer turns and is several times the diameter of L-2. Input from a 12-volt ‘gelcel’ high-voltage laser module, produces 8,000 volts with low (wasted energy) amperage into 4 turns of coil L-1. Each turn of L-1 then acquires 2,000 volts of resonant potential. Each turn of L-2 is then exposed to an electric flux of 2,000 volts. Each turn at the bottom end of L-2 acquires 2,000 volts. The flux lines are squared and are additive as the voltage and amperage progress towards the top end of L-2’s many turns.

A huge number of flux lines which were not previously present, occur at the top end of L-2. These flux lines excite the electrons nearby in it’s earth and air and groundings. This high level of excitement above the ambient, causes a large number of electrons to become available, electrons which previously, were not part of the energy present. At this point, large amounts of excess energy is present. This COP>1 device produces energy at radio frequencies in the megahertz range and this allows it to be small in size and yet produce large amounts of energy. A megawatt sized unit will sit comfortably on a breakfast table. The energy is changed to direct current, and then, to the desired working frequency.

The energy powering these devices is drawn from the surrounding energy field and is not conventional electricity and it does not flow through the wire of the ‘secondary’ coil, but instead, it runs along the outside of the coil and through space to strike the surface of the metal plate, where it generates conventional electric current. Thomas Henry Moray demonstrated that this energy flowing along the outside of the wire can pass through glass without being affected in any way.

In his 1995 paper Don Smith presents the following diagram:
While Tesla’s experiment used a metal plate, he patented (US 512,340) a coil type which he said is very effective in picking up this radiant energy. This "pancake" coil type goes by the rather impressive name of "bi-filar serial-connected coil", which, despite its impressive name is not difficult to wind using two separate strands of wire as shown here:

If a strong magnetic field is positioned across the spark gap as shown above, it sharpens the cut-off of the spark and enhances the uni-directional character of the pulse of current. It should be remembered that if a very short sharp pulse of uni-directional current such as is produced by a spark jumping across a spark gap as in the arrangement shown above, occurs in a conductor, then a strong wave of radiant energy radiates out in a plane at right angles to the pulse of current.

This radiant energy wave is quite different from the electromagnetic field generated around the wire carrying the pulse of current. In the Tesla coil arrangement shown above, it should be possible to gather additional free energy through one or more co-axial (like layers of an onion) cylindrical coils around the spark gap leads. These coils will work better if they are wound as bi-filar, serially-connected coils. The reason for this is that the self-induction of the coils can be zero at any particular frequency because a Tesla pancake (or cylindrical) coil can act as a resonant coil at one particular frequency. This effect is because the capacitance between adjacent turns of the coil is dramatically altered by the raised voltage difference produced by the winding method, and as a result, the combined capacitance of all the turns along with the coils self inductance, gives a result where the coil appears to have just magnetic and resistance characteristics and no self-inductance at all, as pointed out in Tesla’s US 512,340 patent.

Tesla was granted US Patent 685,957 "Apparatus for the Utilisation of Radiant Energy" in which he shows various ways of handling the energy collected by the metal plate. It is likely that the pick-up techniques shown in the patent of Hermann Plauston, which is in the Appendix, would also work very effectively with this collected energy. Old patents sometimes mention a “condenser” which is the original term for what is nowadays called a “capacitor”.

5 - 84
After careful consideration and many experiments, Tesla concluded that the radiant rays which he was utilising, radiated out so rapidly that electrons were unable to keep up with them. The rays were being carried via a medium consisting of extremely mobile, almost mass-less particles, very much smaller than electrons and which, because of their size and speed, could pass easily through most materials. In spite of their small size, their extreme speed caused them to have considerable momentum. A fact which is very difficult to come to terms with is that these rays seem to propagate outwards instantly, with no time delay at all, as if transmitted through matter which is wholly incompressible. It is sometimes called “Radiant Energy” or “RE” for short and appears to have no net charge in conventional terms. This is a unique feature of the universe, with unique characteristics, which if utilised, provides a whole host of new applications and capabilities.

Tesla considered that this newly discovered field acted like a fluid. A hundred and fifteen years later, the cover story of the December 2005 edition of the ‘Scientific American’ journal states that experimental models hint that space-time could be a kind of fluid. It has taken a long time for modern science to start catching up with Tesla. In actual fact, it was Michael Faraday (1781 - 1867) who came up with the idea in the first place.

**The Alberto Molina-Martinez Generator.**

US patent application US 20020125774 of 6th March 2002, shows a self-powered electrical generator. Like that used by Bob Boyce, this is a toroidal (ring-shaped) frame with several windings on it, as shown in the diagram below. Once it has been powered up with AC mains frequency voltage, it produces so much power that it can supply its own input power requirement as well as powering other loads such as light bulbs. This patent application is shown in full in the Appendix.

It is said that the Toroid device built by Stephen Mark and shown in web videos, is a replication of this generator design. The forum at present at [http://www.overunity.com/index.php/topic,2535.0.html](http://www.overunity.com/index.php/topic,2535.0.html) is dedicated to replicating Stephen Mark’s device and considerable progress has been made. This group is operating on the basis that instead of a metallic toroid core as shown here, that a Mobius-loop toroidal wire core is used. At this point in time, their efforts have not yet produced a circuit which exhibits a COP>1 performance.

You will notice that very many different devices, aimed at doing different things, all operate by generating very sharp DC pulses.

So, a wide range of different devices have the same background technique for making them work. Meyer used the pulsing for water-splitting in a hydroxy gas cell. Bedini uses the pulsing to charge batteries with cold electricity. Tesla used the pulsing to charge batteries, provide heating, cooling and lighting. Boyce uses pulsing to obtain electrolysis at 1,200% of Faraday’s stated maximum rate of electrolysis. Gray used the pulsing to...
capture cold electricity to drive a powerful electric motor. Many different applications all based on using very short, very sharp, high-voltage pulses.

Alfred Hubbard’s Self-Powered Generator.
In 1919 at Portage Bay on Lake Union, Seattle, Washington in America, Alfred Hubbard, an acquaintance of Nikola Tesla, demonstrated a self-powered electricity generator design. The generator was about 14 inches (350 mm) tall and 11 inches (280 mm) in diameter. It powered a 35 H.P. electric motor, which pushed an 18-foot boat which contained no batteries, continuously around the bay for several hours. This demonstration was witnessed by thousands and ended because the wiring was beginning to overheat. It was said that the cable used contained seven strands of 0.09-inch (2.286 mm) diameter. Each of those strands would be able to carry 12 amps and so if this is correct, the cable had a current-carrying capacity of about 84 amps. The diameter of the wire including the insulation was said to be 0.34 inches (8.5 mm). The inner core was said to be made of a pipe containing 16 iron rods with 43 turns of wire around it, which if correct, would suggest 43 turns in 14 inches or 3 turns per inch, implying a cylindrical coil with the turns side by side, touching each other.

However, a great deal of misleading information, not to mention a good deal of speculation has been spread around concerning the Hubbard design, which Alfred took three years to develop. Several years after the demonstration, when Hubbard was employed by the Radium Company, he said that radium was used in the device, which is something which I personally, find very hard to believe, and strongly suspect that Hubbard was persuaded to say that by his employers who were selling radium at that time.

Hubbard made a sketch of one of his smaller generators which was used for ordinary household electrical appliances and that showed a very simple design which had eight cylindrical primary coils each of which was wound on a solid iron bar and connected in series. These primary coils surrounded a slightly larger secondary coil of some 35 turns wound around a hollow tube filled with metal bars or wires (presumably of soft iron). This smaller device was about six inches (150 mm) tall (maximum wire diameter 4 mm including the insulation) and about five inches (125 mm) in diameter. Each core had only one layer of thick insulated wire and not many turns were used.

I understand that when a patent was applied for, the patent application was seized and a spurious “Of National Security Importance” order slapped on it, acting as an unlawful gag order on Hubbard, prohibiting him from ever developing, using, showing or selling it or anything akin to it. The US Patent Office is a privately owned commercial company, and while they will probably be using the design themselves, they certainly have no intention of ever allowing the public to have access to it as energy freedom is a major step towards complete freedom. Consequently, we know next to nothing about Hubbard’s successful design.

The general arrangement might have been something vaguely like this:
In Joseph Cater’s book “The Awesome Life Force” he attempts to explain the theory of its operation, but it must be clearly understood that what Cater says is just speculation on his part as Hubbard’s actual design was never disclosed publicly.

What Cater says is certainly plausible, and even if it is not Hubbard’s design, it is worth investigating and experimenting with. The mechanism put forward by Cater is based on the well-known and widely accepted graph of the magnetisation of soft iron versus applied levels of magnetic force. This graph is highly non-linear and the central section of the graph rises steeply, indicating that there is a considerable increase in the magnetisation of the iron for relatively little increase in energy input.

Cater stresses that the input waveform should be pulsating DC. The method of applying pulsing DC is then, almost the same as for the Clemente Figuera design shown in chapter 3, with an offset base level of DC current flow which needs to be maintained at all times. Here is the magnetisation graph for soft iron:

Fig. 29 shows a graph of the magnetisation of an iron core plotted against ampere turns per unit length. The term “ampere turns” is the number of turns of the coil per unit length of the coil multiplied by the number of amps of current flowing through the coil.

The steep section of the curve appears to start at around 3.5 Tesla, and so, a constant DC current in the magnetising (Hubbard primary) coil needs to provide that level of magnetisation at all times, and the applied pulsing DC half-sinewave waveform applied on top of that and since the induced EMF in a coil is directly proportional to the rate of change of magnetic flux, it follows that the higher the frequency of this sine wave supply, the better. Using a ramp waveform might well be more effective.
Normal working transformers have ampere-turns which are well below this critical point. The additional EMF induced in the coils by the magnetisation of the iron offsets the natural inductive impedance of the coils. This is why transformers have such a high degree of efficiency. If any material other than iron or special steel were used for the core, the efficiency would drop significantly. Hubbard used part of the output power to provide the input power, and so he only needed to provide input power for less than a second to get the device running. The power supply might well be of this nature:

![Diagram](image)

Here, instead of letting the high frequency rectified sine wave (or ramp generator signal) reach zero volts, and additional DC current supply is maintained, and while the signal generator pulses add to the overall voltage applied to the device, the voltage is never allowed to reach zero.

There is possibly another factor which could contribute to the success of the Hubbard device. At that time, the only insulated wire available had thick and heavy insulation. This means that adjacent turns of wire in the coil were separated by a distance equal to twice the thickness of the insulation. Consequently, the gap resulted in a cancellation of magnetic effects produced by electrons flowing in the wire. Since inertia is dependent on the ability to generate a magnetic field, the inertial properties of the electrons would be almost nullified.

There is an optimum distance between the wires which would produce the maximum effect. It seems likely that the thick insulation on Hubbard’s wire produced this optimum distance. Most of the resultant magnetic field was that which encircled both wires and that would be the weaker part of the field. This means that a relatively low EMF could accelerate a larger number of electrons to a high velocity during a very short period of time. As the electrons leave the coil, inertia returns. This would result in a backup of a high concentration of electrons in the coil. Since electrostatic repulsion is not affected, electrons would be ejected from the coil at a high velocity despite their increased inertia. This would produce an output of both high voltage and high amperage.

**Joseph Cater's Version of the Hubbard Generator.**

Although containing conflicting information, there is what appears to be an implementation of the Hubbard coil system, or perhaps a very closely related device from Joseph H. Cater. As usual, information on it is limited and not particularly clear, so the following is just my attempt to piece together some information from different sources. Much of this information comes from a document which has Geoff Egel’s name on it and although it seems likely that Geoff is quoting some other source, my thanks goes to him for sharing what we have here. The diagrams give the names of various minor websites none of which exist any longer and so these have been removed as they have no useful purpose any longer. Here is an original diagram from this information:
As it seems to me that there are many conflicting details in this information, I am presenting it here in pretty much the same form in which it reached me. You will notice that the composite central coil is now presented as the secondary rather than the primary. It should be stressed that Hubbard never disclosed his design publicly and so this, and similar information elsewhere, has to be considered to be guesswork.

The Generator of André Coutier

Some twelve years after Hubbard’s public demonstration, on 12th January 1933, André Coutier was awarded patent FR739458 which is entitled Self-generating Electrical Generator. This design is so similar to the Hubbard device that it seems very likely that it is the Hubbard device under a different name.

Description

The apparatus is composed of a closed magnetic circuit (Fig.1) consisting of one soft iron central core coil, surrounded by a number of smaller diameter soft-iron cored coils. While the diagram shows six coils, that is not a fixed number. The smaller diameter coils have the same number of wire turns wound around them and so each of those small coils produces the same current as that which flows in the coil wound around the large inner coil. The cross-sectional core areas of the satellite coils is set to be the same as the cross-sectional area of the central coil core.

The overall design is very simple as shown here:
According to the patent, each of the surrounding coils has an output current equal to that of the central coil. So, if a current of say, 1 amp, is fed to the central coil, then each of the six surrounding coils will have an output current of 1 amp. As the six output coils are wired in parallel, the output current should be 6 amps, giving a COP value of 6 or if you prefer, an electrical efficiency of 600%.

No system is 100% efficient as there are some losses from the wire resistance, the heating of the wire, eddy currents flowing sideways in the iron cores, etc. in each coil. So, the overall efficiency will be less than 600% but the overall energy gain will still be substantial. The voltage remains essentially unchanged but please remember that as the current increases, so must the wire diameter in order to carry that increased current.

Coutier uses three of these coil sets as part of his arrangement and he then takes off a controlled amount from the output to provide the needed input for the system:

The output is alternating current. Coutier chooses to use an isolating transformer in his feedback control which feeds the necessary input current to his oscillator circuit. He also uses a mechanical vibrator as his oscillator as way back in 1933 there were no readily available semiconductors. His overall circuit diagram uses infinity symbols to indicate Alternating Current and it looks like this:
An attempted translation of the patent text is:

The device consists of a closed magnetic circuit (fig. 1) consisting of one central core of soft iron, in the shape of a cylinder. There are N similar satellite cores, set parallel to the central core and placed in a circle around the central core. The central core is an inductive coil with the number of turns required to achieve saturation of the magnetic circuit with the chosen inductive current. Each of the satellites coils has the same number of turns as there are in the central core coil.

Given the particular provision of the magnetic circuit, each of the satellite coils is an isolated transformer and so the current induced in each of the satellite windings has the same power as the central coil current. Thus, the unit produces a multiplication of electrical energy. As the output energy exceeds the initial input energy, we see immediately the opportunity to use some of the output energy to provide the necessary input energy on a continuous basis.

The device used for the industrial model of the perpetual self-powered electricity generator, established for use in industry, maritime and river navigation, and traction on railways, is shown schematically in Fig. 2.

Three multiplier devices (there can be any number of these devices) are combined in series, so that the core e of one circuit is powered by electricity from the combined satellite circuits f, of the previous device. The satellite coils of set 1 feed the central coil of set 2. Similarly, the set 2 satellite circuits feed the central coil of set 3.

Each unit with 6 satellites (there can be any number of satellites) determine the factor of power amplification of each set, and in this case it is 6. With the three coil sets shown, the power amplification is $6 \times 6 \times 6 = 216$ times the input power.
It is easy, using an output power tap and the rheostat $h$, to provide the energy required as the input current. The coil $i$ is magnetically linked to coil $j$, as they are mounted on the same core and they form a 1-to-1 ratio transformer. The output of coil $j$ is used to operate a buzzer $k$ whose AC coil output is used to feed the central coil $e$ of the first power multiplier circuit.

The device also includes two batteries $l$ and $m$ - intended to deal with any eventuality. One battery can be charged while the other is available for use if there is an accidental stop of the generator.

Claims

Multiplication of electrical energy carried out by induction of satellite windings, grouped in a circle around an inductive central winding. The sum of the cross-sectional areas of the satellite cores is equal to the cross-sectional area of the central core. Self-generating perpetual electrical energy is achieved by taking energy from the last multiplier and using it to provide the input current.

Floyd Sweet’s “VTA” Self-Powered Generator.

Another device in this category of pulsed devices which tap external energy was produced by Floyd (“Sparky”) Sweet. The device was called “Vacuum Triode Amplifier” or “VTA” by Tom Bearden. There is very little practical information available on this device, though there is a video of it in operation on the web, with an input power of just 0.31 milliwatt and a continuous power output of more than 500 watts (112 volts AC at 60 Hz) which is a COP of more than 1,612,000 which is spectacularly impressive.

The device was capable of producing more than 1 kW of output power at 120 Volts, 60 Hz and can be connected so as to be self-powered. The output is energy which resembles electricity in that it powers motors, lamps, etc. but as the power increases through any load there is a temperature drop instead of the expected temperature rise, which is why it is called “cold” electricity.

When it became known that he had produced the device he became the target of serious threats, some of which were delivered face-to-face in broad daylight. It is quite possible that the concern was due to the device tapping zero-point energy, which when done at high currents opens a whole new can of worms. One of the observed characteristics of the device was that when the current was increased, the measured weight of the apparatus reduced by about a pound. While this is hardly new, it suggests that space/time was being warped. The German scientists at the end of WWII had been experimenting with this (and killing off the unfortunate people who were used to test the system) - if you have considerable perseverance, you can read up on this in Nick Cook's inexpensive book “The Hunt for Zero-Point” ISBN 0099414988.

Floyd found that the weight of his device reduced in proportion to the amount of energy being produced. But he found that if the load was increased enough, a point was suddenly reached where a loud sound like a whirlwind was produced, although there was no movement of the air. The sound was heard by his wife Rose who was in another room of their apartment and by others outside the apartment. Floyd did not increase the load further (which is just as well as he would probably have received a fatal dose of radiation if he had) and did not repeat the test. In my opinion, this is a potentially dangerous device. It should be noted that a highly lethal 20,000 Volts is used to ‘condition’ the magnets and the principles of operation are not understood at this time. Also, there is insufficient information to hand to provide realistic advice on practical construction details.

On one occasion, Floyd accidentally short-circuited the output wires. There was a bright flash and the wires became covered with frost. It was noted that when the output load was over 1 kW, the magnets and coils powering the device became colder, reaching a temperature of 20 degrees Fahrenheit below room temperature.

On one occasion, Floyd received a shock from the apparatus with the current flowing between the thumb and the small finger of one hand. The result was an injury akin to frostbite, causing him considerable pain for at least two weeks.

Observed characteristics of the device include:
1. The output voltage does not change when the output power is increased from 100W to 1 kW.
2. The device needs a continuous load of at least 25W.
3. The output falls in the early hours of the morning but recovers later on without any intervention.
4. A local earthquake can stop the device operating.
5. The device can be started in self-powered mode by briefly applying 9 Volts to the drive coils.
6. The device can be stopped by momentary interruption of the power to the power coils.
7. Conventional instruments operate normally up to an output of 1 kW but stop working above that output level, with their readings showing zero or some other spurious reading.

It appears that Floyd's device was comprised of one or two large ferrite permanent magnets (grade 8, size 150 mm x 100 mm x 25 mm) with coils wound in three planes mutually at right angles to each other (i.e. in the x, y and z axes). The magnetisation of the ferrite magnets is modified by suddenly applying 20,000 Volts from a bank of capacitors (510 Joules) or more to plates on each side of it while simultaneously driving a 1 Amp 60 Hz (or 50 Hz) alternating current through the energising coil. The alternating current should be at the frequency required for the output. The voltage pulse to the plates should be applied at the instant when the ‘A’ coil voltage reaches a peak. This needs to be initiated electronically.

It is said that the powering of the plates causes the magnetic material to resonate for a period of about fifteen minutes, and that the applied voltage in the energising coil modifies the positioning of the newly formed poles of the magnet so that it will in future, resonate at that frequency and voltage. It is important that the voltage applied to the energising coil in this ‘conditioning’ process be a perfect sinewave. Shock, or outside influence can destroy the ‘conditioning’ but it can be reinstated by repeating the conditioning process. It should be noted that the conditioning process may not be successful at the first attempt but repeating the process on the same magnet is usually successful. Once conditioning is completed, the capacitors are no longer needed. The device then only needs a few milliwatts of 60 Hz applied to the input coil to give up to 1.5 kW at 60 Hz at the output coil. The output coil can then supply the input coil indefinitely.

The conditioning process modifies the magnetisation of the ferrite slab. Before the process the North pole is on one face of the magnet and the South pole on the opposite face. After conditioning, the South pole does not stop at the mid point but extends to the outer edges of the North pole face, extending inwards from the edge by about 6 mm. Also, there is a magnetic ‘bubble’ created in the middle of the North pole face and the position of this ‘bubble’ moves when another magnet is brought near it.

The conditioned slab has three coil windings:

1. The ‘A’ coil is wound first around the outer perimeter, each turn being 150 + 100 + 150 + 100 = 500 mm long (plus a small amount caused by the thickness of the coil former material). It has about 600 turns of 28 AWG (0.3 mm) wire.

2. The ‘B’ coil is wound across the 100 mm faces, so one turn is about 100 + 25 + 100 + 25 = 250 mm (plus a small amount for the former thickness and clearing coil ‘A’). It has between 200 and 500 turns of 20 AWG (1 mm) wire.

3. The ‘C’ coil is wound along the 150 mm face, so one turn is 150 + 25 + 150 + 25 = 350 mm (plus the former thickness, plus clearance for coil ‘A’ and coil ‘B’). It has between 200 and 500 turns of 20 AWG (1 mm) wire and should match the resistance of coil ‘B’ as closely as possible.

Coil ‘A’ is the input coil. Coil ‘B’ is the output coil. Coil ‘C’ is used for the conditioning and for the production of gravitational effects.

At time of writing, information and photographs of the original device can be found on the website: http://www.intalek.com/Index/Projects/Research/Construction%20of%20Floyd%20Sweet%20by%20Michael%20Watson.htm where a paper by Michael Watson gives much practical information. For example, he states that an experimental set up which he made, had:

The ‘A’ coil with a resistance of 70 ohms and an inductance of 63 mH,
The ‘B’ coil, wound with 23 AWG wire with a resistance of 4.95 ohms and an inductance of 1.735 mH, and
The ‘C’ coil, also wound with 23 AWG wire, with a resistance of 5.05 ohms and an inductance of 1.78 mH.
Chapter 3 has additional information on the VTA.

Rosemary Ainslie’s COP=17 Heater.
As Kevin Ashton states in his book How To Fly A Horse, 16th April 1958 saw the death of the
scientist Rosalind Franklin at the age of thirty-seven. Rosalind was a talented X-ray
crystallographer working on the problem of how viruses reproduce (essentially, how life works, as her work was
understanding the mechanics of a life). The following day the World’s Fair opened in Brussels with the main
attraction being a scale model of a virus. That model was built by Rosalind as she was dying.

She held a research position at the University of London, and later, an appointment, at Birkbeck College, where
she studied the tobacco mosaic virus. For a long time, the only people who knew what she had really
accomplished were the three men who had secretly stolen her work: James Watson, Francis Crick, and Maurice
Wilkins. Watson and Crick were researchers at Cambridge University. Wilkins had been at King’s College. All
three men wanted to be first to answer the question of the age: what is the structure of DNA, the acid that carries
the information of life, and how does it work?

Rosalind Franklin was educated at Cambridge University’s Newnham College. Had she been born a few
generations earlier, she would not have been admitted to Cambridge. Even when women were admitted, the
university believed that women were not equal to men and despite being placed first in the university’s entrance
exam for chemistry, Franklin could not be a member of the university or an undergraduate. Women could not
earn a degree. The number of women allowed to attend Cambridge was capped at five hundred, to ensure that
ninety percent of students were men. Science, while pretending to be dispassionate and rational, has long been
an active oppressor of women. Britain’s ‘Royal Society’ of scientists barred women for almost three hundred
years, on grounds including the argument that women were not “legal persons”.

This disgraceful attitude was, and still is, widespread. Lise Meitner discovered nuclear fission only to see her
collaborator Otto Hahn receive the 1944 Nobel Prize for her work. Things have changed little since then. This is
not because women have less aptitude for science than men have. For example, Rosalind Franklin took better
pictures of DNA than anyone had taken before, then used a complex mathematical equation called the “Patterson
function” to analyse them. The equation, developed by Arthur Lindo Patterson in 1935, is a classic technique in
X-ray crystallography. The two main properties of electromagnetic waves are their intensity, or “amplitude,” and
their length, or “phase”. The image created by an X-ray shows amplitude but not phase, which can also be a rich
source of information. The Patterson function overcomes this limitation by calculating the phase based on the
amplitude. In the 1950s, before computers or even calculators, this work took months. Franklin had to use a slide
rule, pieces of paper, and hand calculations to work out the phases for every image, each one of which
represented a slice of the three-dimensional crystal molecule which she was analysing. While Rosalind Franklin
was concluding this work, without her consent or knowledge, Maurice Wilkins showed her data and pictures to
James Watson and Francis Crick. Watson and Crick leapt to the conclusion which Franklin was diligently proving,
that the structure of DNA was a double helix. They published it, and shared the Nobel Prize with their secret
source, Wilkins. When Rosalind Franklin died, they still did not credit her.

This attitude to women scientists does not appear to have changed much and the reluctance of humans as a
whole to accept anything new in science is widespread. Not only science is opposed to women. The very
successful book Fifty Shades of Grey was published under the name “E L James” as the author Erika Mitchell
stated that she wanted her pen name to avoid implying that the author was a woman. Is it a major stretch of
imagination that the highly successful Harry Potter series of books by Joanne Rowling was published under the
name “J K Rowling” which also avoids any indication of gender?

I, personally, was never in any doubt that Rosemary Ainslie would encounter fanatical opposition to her scientific
paper, not just because “scientists” (for want of a better word) are unwilling to accept her simple system with
vastly more power output than the user’s power input, but also because of the (highly offensive) opposition to
women scientists.

Rosemary Ainslie has produced a pulsed heater system which has been measured at a performance of COP =
17. This is a recent design and as far as I am aware, has not yet been replicated by other people. Panacea-
bocaf.org are working with Rosemary's original developers to produce an independent implementation of the heater. At this point in time, the heater has been built to a prototype testing scale for laboratory examination and measurement and not been produced in the kilowatt range, which, hopefully, will come at a later date.

Panacea have produced a 250-page document describing the research, the testing, the theory, etc. and that can be downloaded free using this link:

As that document contains the details which scientists need to see for serious testing and development, it may be a little technical for some people, so Panacea have produced a simplified description aimed at the average home-build investigator and that can be downloaded free using this link:

In very broad outline, the circuit produces the same very short, very sharp voltage pulses that are the basis for so many "free-energy" devices. The circuit used looks very simple but in spite of that, the way that it operates is not at all simple. The circuit is shown below and to a quick glance, it looks like a standard 555 timer chip circuit, used in many existing applications. However, if the circuit is operated as a 555 pulsing circuit, then the output is not COP>1.

Looking more closely, we notice that the link between the output of the 555 chip on pin 3 and the input gate pin of the Field-Effect Transistor, is unusual as it is not the usual voltage divider between pin 3 and the 0-volts ground line. Instead, the gate is directly coupled to the 555 chip output by a single, low-resistance preset resistor.

Normally, an NE555 chip struggles to reach 50,000 cycles per second and a large number of 555 chips on the market can't even operate at even that frequency. To get Rosemary's circuit into it's COP>1 operation, the resistor marked "GATE" is adjusted very slowly to find the point at which the circuit becomes unstable, over-rides the normal operation of the 555 chip and starts oscillating at the resonant frequency of the overall circuit, forcing the 555 chip to become a feedback component. The circuit then produces the sharp, short voltages spikes at more than ten times the operating speed of the 555 chip and pulsing the 10-ohm heating element marked "LOAD" at about 500,000 pulses per second.

That rate of operation is clearly well outside the possible performance of an NE555 chip, besides which, the timing elements of the chip should be producing a much lower frequency, as indeed it does before the "GATE" resistor adjustment causes the circuit to break out of its normal design-mode operation and start the high-speed spike generating, resonant performance. The circuit used is shown here:

As Panacea-bocaf are working to test and develop this circuit further, it would be a good idea to download their free documentation on the design and keep an eye on their progress in this field. The two documents give very considerable detail on the work which has already been done, and of course, you can yourself experiment with this circuit and see what results and adjustments you can discover yourself.
Joseph comments: The experiments of Schauburger and others have confirmed the enormous and almost unlimited quantities of electricity housed in water. The following is an absurdly simple and practical method of extracting this energy. It employs the "Coanda" or "cloud-buster" effect.

A plastic tube 14" to 16" (350 mm to 400 mm) long and about 2.5" (65 mm) in diameter is filled with distilled water. At each end, exposed to the water, is a copper terminal which is used for both the electrical input and output. Rechargeable dry cells of suitable voltage are connected in series with the input terminals. When the two output terminals are short-circuited or connected to a load, electricity starts flowing. This is current entrained by the input current. When high voltage is applied, the output voltage is almost as great as the input voltage. However, the amperage is inadequate. The answer to the problem is ultrasonics. It is an experimental fact that ultrasound of 600,000 Hz focussed on a container of water causes the water to boil. This means that sound of this frequency disintegrates large quantities of "soft" electrons in the water. The sudden release of "hard" electrons produces tremendous thermal agitation of the water molecules.

A DC ultrasonic transducer attached to the tube would produce sufficient free electrons to be entrained for the unit to have almost unlimited output potential. The tube functions like a sounding board. Mr Cater has been given powerful evidence that two different individuals who received this information got sensational results from the generator. They had access to such a transducer. They tried to set up in business but the vested interests saw to it that they were put out of business and persuaded to remain silent ever since.

An associate of Mr Cater built a fist-sized siren which generated a frequency of 600 kHz. When focussed on a small container of water, the water boiled. This demonstrated that it could be used instead of a solid-state DC ultrasonic transducer on the water generator. A small DC motor could operate the siren. It would be far more effective as it produces a much more intense sound. The construction is shown here:
Dr Oleg Gritskevitch's 1.5 Megawatt Self-Powered Generator.

Dr Oleg V. Gritskevitch of Vladivostok in Russia, the holder of some seventy patents, designed and fully tested an electrical generator along the same lines as Joseph Cater's device mentioned above. It uses no fuel and has given a DC output of 220 volts at 6,800 amps (1.5 megawatts) for more than two years. As built by Dr Gritskevitch, this is not a home-builder's ideal project as massive electrical input is needed to get the device started, and his prototype weighs 900 kilograms (nearly 2,000 lbs). Details are given on the very good RexResearch web site: http://www.rexresearch.com/gritskevich/gritskevich.htm but in broad outline, the device is a toroidal pipe some two metres (6'-6") in diameter, coated on the inside with barium titinate and filled with ultra-pure distilled water mixed with 'heavy water'. Inside the toroid are electromagnetic coils and surrounding it, copper pipes carrying cooling water to keep the temperature down to 50 degrees Centigrade. Also inserted into the toroid at intervals around the circumference are electrical contacts.

The device is started by giving the water a massive high-voltage discharge of some 100,000 volts at 50 mA for three to five minutes. This power input gets the water ionised and circulating. The circulation is maintained by the electromagnetic coils and the power output is around COP=100.

Oleg died without ever getting funding for his design (a typical method of blocking free-energy devices from reaching the market). A more detailed description of the device and it's operation comes direct from Oleg:

This is a description of the construction and operation of Oleg V. Gritskevitch's hydro-magnetic dynamo, which is an example of a very powerful new energy system. The prototype in Armenia has averaged some 1,500 kilowatts of power over a period of several years.

Oleg was born on 14 August 1936 and grew up in Vladivostok, Russia. He married and has a son Boris. Gritskevitch was a physicist by education. He worked in the Far-East branch of the USSR Academy of Sciences. Since 1985 he worked independently as an inventor. He has more than 70 patents on inventions ranging from household engineering up to high technologies, which he has been trying to apply in our country although he encountered major difficulties in this. After numerous attempts to obtain the patents, he became convinced that the information had become widely known. Therefore he received the state certificates of know-how (a French way of patenting), for all his inventions.

Introduction

During the 1999 Symposium of the Institute for New Energy, he lectured on his hydro-magnetic dynamo. This paper is his attempt to explain the construction and operation of his dynamo. To protect his secrets from investigators, he, on occasion, provided misleading information. For example, the drawing accompanying the Russian patent mentioned below, shows a cylinder across the toroid to mislead readers. The real dynamo has the toroid alone, without the cylinder. Even its name “hydro-magnetic dynamo” is somewhat deliberately misleading.

Oleg stated that he had some familiarity with the new energy field. Nearly all purported new energy devices are fairly small electrical generators. The dynamo may be the only new electrical generator which most nearly meets all the requirements of an ideal large-scale electrical generator. Oleg claimed that his dynamo really is the single most valuable invention the world has ever known.

Alexander V. Frolov of St. Petersburg recommended Oleg to contact Dr. Patrick Bailey of the Institute for New Energy since Patrick has lots of contacts who could possibly help with patenting his invention of a new source of energy in USA.

Oleg worked on the theory and creation of the electrostatic generator-converter the “Hydro-Magnetic Dynamo” for about 20 years. The first primitive equipment was created when Oleg worked in the Academy of Sciences. During that time, various changes were introduced in the generator and in the theory of how it works. As a result, it is now ready for manufacture, installation, and applications in industry.

Oleg made the first public report on his work in 1991 at a symposium in Volgodonsk city. His report received positive reactions and reviews from the experts in the nuclear industry in USSR. That same year, he was accepted into the International Nuclear Society. During those years he offered development of this technology to different state bodies and private enterprises. But the answer from everybody was “It is a very interesting and important project, but we cannot fund it.

Eventually, Oleg tried to transfer this technology to the USA through the embassy in Moscow. The former ambassador to the USSR, Dr. J. Matlock knows about it. He wanted to meet Oleg, but at that time there were forces opposed to the carrying out of his plans. So he started to look for other possible investors. He was ready to consider any offers of co-operation, joint patenting, sale of technological information, creation of a joint venture,
etc. etc. Oleg was awarded some 70 Russian patents covering a wide range of important technical topics.

History
This project was the result of one article in the August 1972 issue of a popular Russian magazine *Tehnika Molodyozhi*. The article written by A. Kaldamasov was entitled *Ball Lightning in a Liquid*. The article came to the attention of Michail Razovsky and Oleg in 1974. Oleg’s group of volunteers and enthusiasts was looking for a new source of energy and so this article served as a starting point for the understanding of chemical-physical processes occurring in water. During the period 1976 to 1978 one year was spent in the radiological lab of the Vladivostok city hospital, including Vladilen Bulgakov, radiology physician, and Michail Razovsky, theoretician in the plasma physics field and others, assembling a device, which was supposed to separate water into oxygen and hydrogen more efficiently. During the experiments, instead of the expected results, it produced electricity very efficiently! The input power during the experiment was one 800-watt water pump. The output was 1,400 watts (COP=1.75). This device was assembled using plastic pipes connected with hoses, where the water was circulating in a loop. This then led to the idea of creating the second device as a generator-toroid.

The second generator was assembled in the workshop of the Ocean Research Institute in Vladivostok (Director Academician Viktor Ilichov), and in the summer of 1990 it was transported to the testing station of the Ministry of Electronics Industry in Vladivostok. This lab was well equipped with all necessary sets of instruments. At the same time, patent papers were filed in the USSR State Committee of Inventions. In the spring of 1991 the State Commission, led by Yuri Lebedev, chairman of the Innovation Council and Chairman of the Russian Federation Council of Ministers, arrived in Vladivostok. This commission arrived to the town for two reasons: to recommend a financial request for manufacturing the dynamo; and to classify this energy source as a “Discovery”. (document #14-451).

After the next change in Russian government the financing for the project was terminated. The first article on the dynamo was published in the Russian magazine (*Tehnika Molodyozhi* 1990, #3, March issue, Page 17, entitled “Innovator’s Ideas”)

Several Armenian physicists, after reading that article, sent Oleg a letter asking to meet with him in Vladivostok for negotiations about the dynamo. They arrived in March 1991 and ran tests on the second generator, which was operational at that time. Oleg flew to Armenia, and work on the third generator started at the end of 1991. It was completed at the end of 1992. It was operating and producing energy until January 1997, when it was destroyed during the war. Some people were also killed and other people moved to the USA. This version of dynamo created an output which averaged 6,800 amperes at 220 volts DC (1.496 megawatts). It’s input power was only approximately 1% of the output power.

Oleg was an invited speaker of the Meeting of the Alternative Energy Institute (Dr. Hal Fox) in Salt Lake City in August 1999. The official announcement about his speech had several mistakes (for example, the name of Armenia was changed to Romania).

Dynamo Theory
The Hydro-Magnetic Dynamo is a large-scale, emission-free electrical generator, which does not require external fuelling. The dynamo is capable of powering large transportation vehicles such as buses, trucks, ships, locomotives, and aeroplanes. Doubt remains about making dynamos compact enough to power cars.

While three experimental prototypes have been built with Russian and Armenian expertise and equipment, a fourth demonstration prototype needs to be built with more modern Western engineering expertise and equipment to verify the dynamo’s performance claims and to further explore the dynamo’s potential capabilities.

The claimed performance is as follows:
- Dynamos are scaleable from 100 kilowatts to 1,000 megawatts. One 1000-megawatt dynamo is about the size of a two-car garage. For comparison, Hoover Dam’s 17 generators have a total capacity of 2,000 megawatts. A dynamo can reliably run continuously for 25 years or more with little or no maintenance, no external fuel source, and no pollution. If a dynamo’s output is 1,000,000 watts, its total input power is approximately 10,000 watts and so the dynamo’s energy efficiency is about 10,000%.

The source of the dynamo’s huge electrical output is a nuclear reaction, which is not generally known to mainstream science. However, it is known that the dynamo produces alpha particles, which are helium nuclei, made from fused deuterium, an isotope of hydrogen with one proton and one neutron. The electrons missing from the helium nuclei are what seem to provide a copious ‘sink’ of electricity, and that is the secret of the dynamo’s ability to generate an exceptionally large amount of electricity. It is also known that the dynamo uses high-density charge clusters. High-density charge clusters are thought by some theorists, to be the basis of plasma-injected transmutation of elements and the neutralisation of radioactive materials. Unlike hot fusion and fission reactors,
the dynamo does not accumulate any radioactive components.

The result of the dynamo’s processes is conversion of electrostatic fields to direct current. It should be noted that a clear understanding of terms like “Coulomb’s conversion” and “liquid Van de Graff generator” is very important.

Schematically, the dynamo is an electrostatic transformer, or in other words an electrostatic voltage multiplier. One version of the dynamo uses lasers to start up. There were three dynamo prototypes built. The first two small experimental prototypes were built in Vladivostok, Russia. The third and last prototype generated electricity continuously, (except when turned off to incorporate improvements), from 1992 to January 1997 in Armenia.

As mentioned above, the Armenian prototype generated a direct current of 6,800 amperes at 220 volts which is about 1.5 megawatts. Minimum power output has been 500,000 watts, and maximum power output has been 2,500,000 watts during winter experiments due to better cooling. The Armenian prototype dynamo’s toroid weighed 900 kilograms and had a diameter of approximately 2 meters. Cooling water is circulated through copper pipes wrapped around the toroid. The heat is expelled from the cooling water with a heat exchanger. The working temperature was typically 36 degrees Centigrade.

After a dynamo is assembled, the water is literally ‘jump-started’ (by discharging a large bank of capacitors) to get it circulating inside the toroid. The starting impulse pressure is as high as 400 atmospheres. The dynamo’s controls are temporarily set to generating a modest amount of electricity sufficient to sustain itself, possibly even while being transported from the factory to the place of its future operation. The control circuits are simple as only sensors and a control computer are used. We do not need any technical-maintenance personnel.

For the Armenian prototype dynamo, two 10-Farad capacitor-batteries were used to provide the initial water motion (acceleration and excitation of water). The capacitors were 20 kilograms each, with diameters of 50 centimetres, and were borrowed from Russian military radar stations. Using a total of 20,000 Joules, 100,000 Volts at 0.05 Amperes of current were applied to the Armenian dynamo for 3 to 5 minutes to ionise and polarise the water, which then started the generation of electricity.

The reason for the very high voltage provided by the large Russian radar capacitors, when starting the generator, appears to be to polarise the crystals of barium titanate. One comparison is with the electronic ignition on a gas stove. Once the barium titanate crystals are polarised, the generator is running.

After these capacitors had been used to ‘jump-start’ the Armenian prototype dynamo, a bank of buffer batteries sustained continuous operation when water motion and ionising began. This battery bank contained 8 powerful 12-volt, 150-ampere lead batteries. The Armenian dynamo’s sustaining input power was 14,400 watts. The nominal maximum output power was about 1,500,000 watts. On one occasion, the output current was accidentally increased to 40,000 amperes for almost a minute. Fortunately, the power was reduced to a safe level before the water started to boil. Internal coils (windings) provide the control of water velocity and therefore control dynamo power. The faster the water is moving, the more electricity the dynamo generates. Once the water stops circulating around the toroid, the dynamo must be ‘jump-started’ again to a minimum power level before it can sustain its electricity generation using it’s own output power.

The following is a condensed summary, with some editing and additional commentary, of the “Description” of the dynamo’s Russian patent IPC H 02 K 44/00 “Method of Deriving Electrical Energy and Realisation of Gritskevich’s MHD-Generator”:

The dynamo is a sealed polystyrene toroid filled with ultra-pure distilled water with heavy water (deuterium oxide) added. The movement of water inside the closed loop and the use of the unique properties of water as a polar liquid, cause a release of electrical energy as an outcome of a rupture of the hydrogen bonds. Additional electrical energy is drawn from nuclear reactions and micro-cavity processes. The liquid is ionised, polarised, and moving around the toroid at start-up time by a running magnetic field with the help of stimulating electromagnetic windings.

Electrostatic generator-transformer “Hydro-magnetic dynamo”. (“GT HMD”) works due to the process of amplification and maintenance of a stationary (oscillating in particular) electromagnetic field by hydrodynamic movements of the conductive medium. The stator (i.e. the toroid) is made of materials with a high dielectric permittivity. Liquid rotor is a recombined water (‘pure’ water with high-molecular compounds), which moves due to the high-voltage discharges and running electromagnetic field.

The main processes in GT HMD are:

A principle of Van-der-Graff’s electrostatic generator, where the solid insulating tape was changed to the liquid one.
A perpetual washout of the surface electrons from the spacer layer takes place;  
The Coulomb's transformations take place;  
A single-turn low-frequency generator works as a coaxial turn with 4 resonance points and energy carrying 
substance inside it that has very high resonance properties;  
The electrostatic breakdowns of cavitation-vacuum structures in water take place.  
The polar liquid (pure water) consists of dipoles only, i.e. strictly oriented charged molecules. During the 
interaction of ionized pure water with the layer BaTiO₃ the electrostatic field of above 10 million volts/cm is 
formed. During this process the breakdown of physical vacuum takes place.

The electrostatic field, coupled with the action of the BaTiO₃ layer (if we apply electrical filed to BaTiO₃, then this 
layer creates the sound vibrations of about 25,000 Hz, this vibration helps to break down the water molecules) 
and facilitates the further breakdown of the molecular-atomic structures of water. Also, due to the perpetual 
electrostatic discharges, the breakdown of the cavitation-vacuum structures occurs and the cold fusion nuclear 
reaction continues. With this fusion the energy of 500 kJ/mole is liberated in a vacuum and an energy of 6 kJ/mole 
is liberated in water. Thus, new hydrogen bonds form in vacuum with the energy liberation of about 20 kJ/mole.

Work on construction of the experimental generator started in September 1991 in Armenia and came to an end in 
March 1992. The active working weight of the prototype of dynamo (torus + water) was about 900 Kg. The 
diameter of the torus was about 2 meters. The torus was made from impact-resistant optic polysterol. This torus 
consisted of two halves, which were turned on the merry-go-round machine.

The monocrystalline barium titanate BaTiO₃ was sprayed on the internal surface of torus, its dielectric permittivity 
was 6000. The thickness of the layer was about 1 micron. The water was purified to the specific resistance of 
18,000,000 Ohm/cm.

As we mentioned above, to start the dynamo two condenser jars of 10 Farad each were used. The energy of a 
starting battery constituted 20,000 Joules, the voltage was 100,000 Volts and the current was 0.05 Ampere to 
provide the initial movement of water (acceleration and disturbance).

The electrodes were made of metal tubes with diameter of about 5 mm. The dynamo is started using these 
electrodes. A total of 32 of these electrodes were installed evenly spaced around the circumference of the toroid. 
The toroid's cooling system formed a closed circuit of copper piping with purified water circulated through it. The 
copper tubes used in this system were covered with glass insulation. They also were the turns of load winding. 
The temperature of toroid was maintained not higher than 50 Celsius degrees.

An average output power was 220 volts x 6,800 ampere = 1,490 kilowatts. The current was DC. Periodically the 
power could be increased to 2,500 Kw when sufficient cooling of the generator could be provided. The additional 
power was drawn from four resonant windings. This alternating current, after rectification, was used to charge the 
back-up battery. Thus, the total output power constituted more than 1,500,000 watts. The low-frequency voltage 
was obtained from the load windings and the direct current was obtained from the stabilisation chamber.

It should be noted that the high-voltage discharges of the 32 electrodes, ionise the partially pre-ionised water 
further. By means of the stimulation windings, a circulating magnetic field is created which moves the water in 
one direction inside the toroid. An electromotive force is created by the electromagnetic induction in a separate 
set of windings. As we already mentioned, during the movement of the water stream, free electrons are created, 
and an additional energy gets emitted because of the water's friction against the coating layer on the inside 
surface of the toroid, because of electrostatic breakdowns of cavity-vacuum structures, and because of the 
ongoing nuclear reaction.

If the dynamo’s output is 1,000,000 watts, it’s total input power is approximately 10,000 watts. So therefore the 
dynamo’s energy efficiency is about 10,000%.

In addition to the barium titanate deposited on the teflon-coated inner surface of the polystyrene toroid, the water 
itself also contains tiny barium titanate crystals which are suspended in the water. Ultrasound at 25,000 cycles 
per second is propagated through the water to form micro-bubbles on the surfaces of the suspended barium 
titanate crystals. Again due to the barium titanate's piezoelectric action, very high electrostatic fields are also 
developed within the micro-bubbles at the surface of the crystals. The electrons from the nuclear reaction are 
added to the electrons generated at the toroid's interior surface. The total amount of mono-crystalline barium
titanate in the Armenian dynamo was nearly 1000 grams. Satellites, locomotives, heavy trucks, airplanes, and ships are obvious transportation applications.

**Dynamo Economics**

The dynamo’s production cost is estimated at $500 per kilowatt which is very competitive when compared to nuclear power’s capital costs of $5,000 per kilowatt, windmill capital costs of $4,000 per kilowatt, etc. A well-run nuclear power plant can generate power for 1.5 cents per kilowatt-hour, coal 1.8 cents, natural gas 3.4 cents, and oil 4.1 cents, on average. The dynamo’s operating cost would be approximately 0.1 cent per kilowatt-hour with no external fuel needed and without any pollution being created.

These dynamos could replace all nuclear power plants, solar installations, wood-burning furnaces, hydro-electric generation, etc. A recent IEEE *Spectrum* article stated that the world’s demand for electricity increases by approximately 500 megawatts every day. To put this in perspective, that is the equivalent of building another Hoover Dam every four days to keep up with the world’s increasing electricity demand. Or, a dynamo manufacturing company would have to build another 500-megawatt dynamo every single day to keep up with world electricity increased demand (in addition to replace all existing generators fuelled by hydro, nuclear, and fossil fuels.)

The text of the patent application mentioned above is not in English although the abstract of the patent number WO 01/15305 A1 has been translated into English:

![Diagram of dynamo](image)

**WO 01/15305 A1**

(57) Abstract: The invention is directed at increasing output, reliability and environmental safety of MHD generators as well as at simplifying the design of said generators. The inventive method for the production of energy comprises the following steps: a polar liquid (8) is circulated in a predetermined direction along a hermetically sealed toroidal channel (1) by means of a travelling magnetic field, and electric power is collected by means of electromagnetic winding. The liquid is ionized at least at the stage of launching, by means of electrodes (4), for example. The internal walls (2) of the channel have a dielectric constant which is higher than the dielectric constant of said liquid.

Chapter 6: Pulse-Charging Battery Systems

Note: If you are not at all familiar with basic electronics, you might find it easier to understand this chapter if you read chapter 12 first.

It is possible to draw substantial amounts of energy from the local environment and use that energy to charge batteries. Not only that, but when this method of charging is used, the batteries gradually get conditioned to this form of non-conventional energy and their capacity for doing work increases. In addition, about 50% of vehicle batteries abandoned as being incapable of holding their charge any longer, will respond to this type of charging and revive fully. This means that a battery bank can be created at very low cost.

However, while this economic angle is very attractive, using batteries for any significant home application is just not practical. If you set up a new bank account and deposit £1000 in it, and when you come back to check on it some days later, you discover that there is only £500 in it. You ask the bank to check this error and they inform you that there is no error, all banks only return half of what is deposited in any account. What would you think of that? But, that is exactly what a lead-acid battery does for you – it only returns half of the current which you feed into it when charging it. In other words, you waste half of the power which you feed into a car battery. NiCad and the more popular NiMh batteries return two thirds of what is fed into them. Capacitors and banks of super-capacitors are 100% efficient and lose nothing as unlike batteries, they are not a chemical process.

It is recommended that batteries are not discharged more rapidly than a twenty hour period. This means that a battery rated at a capacity of 80 Amp-hours (80 AHr) should not be required to supply a current of more than 4 amps. If you exceed that discharge rate, then the number of times that the battery can be charged and discharged is cut back severely – something which you do not realise at the time, but discover later when the battery needs to be replaced as it no longer holds a charge. This is a devastating restriction which pushes battery operation into the non-practical category, except for very minor loads like lights, TVs, DVD recorders and similar equipment with minimal power requirements.

The main costs of running a home are those of heating/cooling the premises and operating equipment like a washing machine. These items have a minimum load capacity of just over 2 kW. It makes no difference to the power requirement if you use a 12-volt, 24-volt or 48-volt battery bank. No matter which arrangement is chosen, the number of batteries needed to provide any given power requirement is the same. The higher voltage banks can have smaller diameter wiring as the current is lower, but the power requirement remains the same.

So, to provide a 2 kW load with power, requires a total current from 12-volt batteries of 2000 / 12 = 167 amps. Using 80 AHr batteries this is 42 batteries. Unfortunately, the charging circuits described below, will not normally charge a battery which is powering a load. This means that for a requirement like heating, which is a day and night requirement, there needs to be two of these battery banks, which takes us to 84 batteries. This is only for a minimal 2 kW loading, which means that if this is being used for heating, it is not possible to operate the washing machine unless the heating is turned off. So, allowing for some extra loading like this, the battery count reaches, perhaps, 126. Ignoring the cost, and assuming that you can find some way to get over the acid problem, the sheer physical volume of this number of batteries is just not realistic for domestic installation and use. In passing, you would also need two inverters with a 2500 watt capability.

The recent charging system shown by 'UFOpolitics' in chapter 3, provides a very good and simple charging method which uses cold electricity. This can overcome the previous constraints imposed by using batteries, probably both with regards to current draw and with regards to recharging time. The Electrodyne Corp. staff who experimented extensively with the Tesla Switch circuitry, found that when a battery was fully conditioned to use cold electricity, that a battery could be disconnected, discharged independently to it's full capacity, and then recharged completely in under one minute. That style of operation completely overcomes the objections to using battery banks to power household equipment of any power, but it takes a long time to achieve as conditioning is a slow process.

Battery banks are used to power standard inverters which can look like this:
The battery connects at the back, using very thick wires, and one or more mains sockets on the front provide a power supply similar to the mains, matching it in both voltage and frequency. There is one variety of inverter called a “True Sine-Wave” inverter and costing much more than the ordinary non-sinewave inverters. Most equipment works well on the ordinary variety. It is usually the power available from the battery bank which is the limiting factor, combined with the long time taken to recharge the battery bank after use.

John Bedini’s Battery-Charging System.
John Bedini has designed a whole series of pulse-generator circuits, all based on the 1:1 multi-strand choke coil component disclosed in his patent US 6,545,444.

Roger Andrews’ Switching System.
The very neat switching arrangement used by John is shown in detail in the earlier patent US 3,783,550 issued in 1974 where the same magnet-triggered boosting electromagnet pulse is used to power a whole series of movements. One of these is two magnetic spinning tops made to spin in a shallow dish:

When the tops spin fast, they rise up the sloping base of the dish and spin near the outer edge. When they slow down they move back towards the centre of the dish and that triggers the battery/transistor/electromagnet built into the base of the dish. The pulse from the electromagnet boosts the spin of the top, sending it back up the
slope. This is a very neat arrangement as the transistor is off most of the time and yet the two tops keep spinning.

Another of Roger’s systems is shown here:

![Diagram of Roger’s system](image1)

It operates in almost the same way, with a magnetic wheel rolling backwards and forwards along a curved track. At the lowest point, the electromagnet is triggered by the induced voltage in some of the turns of the coil, powering the transistor and boosting the magnetic roller on its way.

Another Andrews device is the pendulum where the passing magnet of the pendulum triggers a boosting pulse from the solenoid, keeping the pendulum swinging. John Bedini has also used this mechanism for a pulsed battery charging system and Veljko Milkovic has demonstrated that substantial mechanical power can be extracted from a lever which is powered by a pendulum.

![Diagram of Andrews’ pendulum](image2)

Andrews also shows a switching arrangement for a motor. This design is essentially the same as used by John Bedini in many of his pulsing systems:

![Diagram of Andrews’ switching arrangement](image3)

Here, as the rotor magnet passes the curved electromagnet in the base, it switches on the two transistors which
produce a pulse which keeps the rotor spinning and the tiny generator turning. Andrews produced this for amusement as the rotor appears to spin on its own without any drive power.

As with the Andrews system, the Bedini rotor is started spinning by hand. As a magnet passes the triple-wound “tri-filar” coil, it induces a voltage in all three coil windings. The magnet on the rotor is effectively contributing energy to the circuit as it passes the coil. One winding feeds a current to the base of the transistor via the resistor ‘R’. This switches the transistor hard on, driving a strong current pulse from the battery through the second coil winding, creating a ‘North’ pole at the top of the coil, boosting the rotor on its way. As only a changing magnetic field generates a voltage in a coil winding, the steady transistor current through coil two is unable to sustain the transistor base current through coil one and the transistor switches off again.

The cutting of the current through the coil causes the voltage across the coils to overshoot by a major amount, moving outside the battery rail by a serious voltage. The diode protects the transistor by preventing the base voltage being taken below -0.7 volts. The third coil, shown on the left, picks up all of these pulses and rectifies them via a bridge of 1000V rated diodes. The resulting pulsing DC current is passed to the capacitor, which is one from a disposable camera, as these are built for high voltages and very rapid discharges. The voltage on the capacitor builds up rapidly and after several pulses, the stored energy in it is discharged into the “Charging” battery via the mechanical switch contacts. The drive band to the wheel with the cam on it, provides a mechanical gearing down so that there are several charging pulses between successive closings of the contacts. The three coil windings are placed on the spool at the same time and comprise 450 turns of the three wires (mark the starting ends before winding the coil).

The operation of this device is a little unusual. The rotor is started off by hand and it progressively gains speed until its maximum rate is reached. The amount of energy passed to the coil windings by each magnet on the rotor stays the same, but the faster the rotor moves, the shorter the interval of time in which the energy is transferred. The energy input per second, received from the permanent magnets, increases with the increased speed.

If the rotation is fast enough, the operation changes. Up to now, the current taken from the ‘Driving’ battery has been increasing with the increasing speed, but now the driving current starts to drop although the speed continues to increase. The reason for this is that the increased speed has caused the permanent magnet to move past the coil before the coil is pulsed. This means that the coil pulse no longer has just to push against the ‘North’ pole of the magnet, but in addition it attracts the ‘South’ pole of the next magnet on the rotor, which keeps the rotor going and increases the magnetic effect of the coil pulse. John states that the mechanical efficiency of these devices is always below 100% efficient, but having said that, it is possible to get results of COP = 11. Many people who build these devices never manage to get COP>1.

It is important that a standard mains powered battery charger is never used to charge these batteries. It is clear that the ‘cold electricity’ produced by a properly tuned Bedini device is substantially different to normal electricity although they can both perform the same tasks when powering electrical equipment. When starting to charge a lead-acid battery with radiant energy for the first time, it is recommended that the battery is first discharged to at least 1.7 volts per cell, which is about 10 volts for a 12 volts battery.

It is important to use the transistors specified in any of John’s diagrams, rather than transistors which are listed as equivalents. Many of the designs utilise the badly named “negative resistance” characteristics of transistors. These semiconductors do not exhibit any form of negative resistance, but instead, show reduced positive resistance with increasing current, over part of their operating range.

It has been said that the use of “Litz” wire can increase the output of this device by anything up to 300%. Litz wire is the technique of taking three or more strands of wire and twisting them together. This is done with the wires stretched out side by side, by taking a length of say, three feet, and rotating the mid point of the bundle of wires for several turns in one direction. This produces clockwise twists for half the length and counter-clockwise twists for the remainder of the length. Done over a long length of wire, the wires are twisted repeatedly clockwise - counter clockwise - clockwise - counter clockwise - ... along their whole length. The ends of the wires are then cleared of their insulation and soldered together to make a three-strand cable, and the cable is then used to wind the coils. This style of winding modifies the magnetic and electrical properties of the windings. It has been said that taking three long strands of wire and just twisting them together in one direction to make a long twisted three-strand cable is nearly as effective as using Litz wire. The websites www.mwswire.com/litzmain.htm and www.litz-wire.com are suppliers of ready made Litz wire.

A website which shows pictures of John’s devices is: www.rexresearch.com/bedini/images.htm

**CAUTION:** Care must be taken when working with batteries, especially lead-acid batteries. A charged battery contains a large amount of energy and short-circuiting the terminals will cause a very large current flow which may start a fire. When being charged, some batteries give off hydrogen gas which when mixed with air is highly dangerous and which could explode if ignited by a spark. Batteries can explode and/or catch fire if grossly...
overcharged or charged with an excessively large current, so there could be danger from flying pieces of the casing and possibly acid being thrown around. Even an apparently clean lead-acid battery can have caustic traces on the case, so you should be sure to wash your hands thoroughly after handling a battery. Batteries with lead terminals tend to shed small fragments of lead when clips are put on them. Lead is toxic, so please be sure to wash your hands after handling any part of a lead-acid battery. Remember too that some batteries can develop slight leaks so please protect against any leakage. If you decide to perform any experiments using batteries, that you do so entirely at your own risk and on your own responsibility. This set of documents is presented for information purposes only and you are not encouraged to do anything other than read the information.

Also, if you get one of John’s pulse motors tuned correctly, it will accelerate to perhaps 10,000 rpm. This is great for picking up energy but if ceramic magnets are used, the speed can cause them to disintegrate and fly in all directions. People have had magnet fragments embedded in their ceiling. It would be wise to build a housing enclosing the rotor and magnets so that if the magnets disintegrate, all of the fragments are contained safely.

Ronald Knight’s Professional Advice on Battery Safety.

Ronald Knight has many years of professional experience in handling batteries and in pulse-charging them. He comments on battery safety as follows:

I have not heard of anyone having a catastrophic failure of a battery case in all the energy groups to which I belong and most of them use batteries in the various systems which I study. However, that does not mean that it cannot happen. The most common reason for catastrophic failure in the case of a lead-acid battery, is arcing causing failure in the grids which are assembled together inside the battery to make up the cells of the battery. Any internal arcing will cause a rapid build up of pressure from expanding Hydrogen gas, resulting in a catastrophic failure of the battery case.

I am a former maintenance engineer for U.S. Batteries, so I can say with confidence, that when you receive a new battery from at least that manufacturer, you receive a battery which has undergone the best test available to insure the manufacturer that he is not selling junk which will be sent back to him. It is a relatively easy test, and as it takes place during the initial charge, there is no wasted time nor is there one battery that escapes the pass-or-fail test. The battery is charged with the absolute maximum current which it can take. If the battery does not blow up due to internal arcing during the initial charge it is highly likely that it will not blow up under the regular use for which it was designed. However, all bets are off with used batteries that have gone beyond their expected life.

I have witnessed several catastrophic failures of battery cases daily at work. I have been standing right next to batteries (within 12 inches) when they explode (it is like a .45 ACP pistol round going off) and have only been startled and had to change my under shorts and Tyvek jump-suit, and wash off my rubber boots. I have been in the charge room with several hundred batteries at a time positioned very closely together and have seen batteries explode almost every working day and I have never seen two side by side blow, nor have I ever seen one fire or any flash damage to the case or surrounding area as a result. I have never even seen a flash but what I have seen tells me it is wise to always wear eye protection when charging.

I have my new gel cells in a heavy plastic zip-lock bags partly unzipped when in the house and in a marine battery box outside in the garage, that is just in the remote chance of catastrophic failure or the more likely event of acid on the outside of the battery case.

Vented batteries are always a risk of spillage which is their most common hazard, they should always be in a plastic lined cardboard or plastic box with sides taller than the battery and no holes in it. You would be surprised at how far away I have found acid around a vented lead acid battery under charge.

Have an emergency plan, keep a box of baking soda and a water source around to neutralise and flush the acid in case of spillage. It is best to have plastic under and around wherever your lead-acid batteries are located.

Ronald Knight gets about fifteen times more power from his Bedini-charged batteries than is drawn from the driving side of the circuit. He stresses that this does not happen immediately, as the batteries being charged have to be “conditioned” by repeated cycles of charging and discharging. When this is done, the capacity of the batteries being charged increases. Interestingly, the rate of current draw on the driving side of the circuit is not increased if the battery bank being charged is increased in capacity. This is because the power which charges the batteries flows from the environment and not from the driving battery. The driving battery just produces the high-voltage spikes which trigger the energy flow from the environment, and as a consequence of that the battery bank being charged can be a higher voltage than the 12-volt driving battery, and there can be any number of batteries in the charging bank.
Ron Pugh’s Battery Charger.
John Bedini’s designs have been experimented with and developed by a number of enthusiasts. This in no way detracts from fact that the whole system and concepts come from John and I should like to express my sincere thanks to John for his most generous sharing of his systems. Thanks is also due to Ron Pugh who has kindly agreed for the details of one of his Bedini generators to be presented here. Let me stress again, that if you decide to build and use one of these devices, you do so entirely at your own risk and no responsibility for your actions rests with John Bedini, Ron Pugh or anyone else. Let me stress again that this document is provided for information purposes only and is not a recommendation or encouragement for you to build a similar device.

Ron’s device is much more powerful than the average system, having fifteen coil windings and it performs most impressively. Here is a picture of it rotating at high speed:

This is not a toy. It draws significant current and produces substantial charging rates. This is how Ron chose to build his device. The rotor is constructed from aluminium discs which were to hand but he would have chosen aluminium for the rotor if starting from scratch as his experience indicates that it is a very suitable material for the rotor. The rotor has six magnets inserted in it. These are evenly spaced 60 degrees apart with the North poles all facing outwards.

The magnets are normal ceramic types about 22 mm wide, 47 mm long and 10 mm high. Ron uses two of these in each of his six rotor slots. He bought several spare ones and then graded all of them in order of their magnetic strength, which varies a bit from magnet to magnet. Ron did this grading using a gauss meter. An alternative method would have been to use a paper clip about 30 mm in size and measure the distance at which one end of the clip just starts to rise up off the table as the magnet is moved towards it.
Having graded the magnets in order of strength, Ron then took the best twelve and paired them off, placing the weakest and strongest together, the second weakest and the second strongest, and so on. This produced six pairs which have fairly closely matching magnetic strengths. The pairs of magnets were then glued in place in the rotor using super glue:

It is not desirable to recess the magnets though it is possible to place a restraining layer around the circumference of the rotor as the clearance between the magnet faces and the coils is about a quarter of an inch (6 mm) when adjusted for optimum performance. The North poles of the magnets face outwards as shown in the diagram above. If desired, the attachment of the magnets can be strengthened by the addition of blank side plates to the rotor which allows the magnet gluing to be implemented on five of the six faces of the magnet pairs:
The magnets embedded in the outer edge of the rotor are acted on by wound "coils" which act as 1:1 transformers, electromagnets, and pickup coils. There are three of these "coils", each being about 3 inches long and wound with five strands of #19 AWG (20 SWG) wire. The coil formers were made from plastic pipe of 7/8 inch (22 mm) outer diameter which Ron drilled out to an inner diameter of 3/4 inch (19 mm) which gives a wall thickness of 1/16 inch (1.5 mm). The end pieces for the coil formers were made from 1/8 inch (3 mm) PVC which was fixed to the plastic tube using plumbers PVC glue. The coil winding was with the five wires twisted around each other. This was done by clamping the ends of the five wires together at each end to form one 120 foot long bundle.

The bundle of wires was then stretched out and kept clear of the ground by passing it through openings in a set of patio chairs. A battery-powered drill was attached to one end and operated until the wires were loosely twisted together. This tends to twist the ends of the wires together to a greater extent near the end of the bundle rather than the middle. So the procedure was repeated, twisting the other end of the bundle. It is worth remarking in passing, that the drill turns in the same direction at each end in order to keep the twists all in the same direction. The twisted bundle of wires is collected on a large-diameter reel and then used to wind one of the "coils".

The coils are wound with the end plates attached and drilled ready to screw to their 1/4 inch (6 mm) PVC bases, which are the bolted to the 3/4 inch (18 mm) MDF supporting structure. To help the winding to remain completely even, a piece of paper is placed over each layer of the winding:
The three coils produced in this way were then attached to the main surface of the device. There could just as easily have been six coils. The positioning is made so as to create an adjustable gap of about 1/4 inch (6 mm) between the coils and the rotor magnets in order to find the optimum position for magnetic interaction. The magnetic effects are magnified by the core material of the coils. This is made from lengths of oxyacetylene welding wire which is copper coated. The wire is cut to size and coated with clear shellac to prevent energy loss through eddy currents circulating inside the core.

The coils are positioned at equal intervals around the rotor and so are 120 degrees apart. The end pieces of the coil formers are bolted to a 1/4 inch (6 mm) PVC base plate which has slotted mounting holes which allow the magnetic gap to be adjusted as shown here:
The three coils have a total of fifteen identical windings. One winding is used to sense when a rotor magnet reaches the coils during its rotation. This will, of course happen six times for each revolution of the rotor as there are six magnets in the rotor. When the trigger winding is activated by the magnet, the electronics powers up all of the remaining fourteen coils with a very sharp, pulse which has a very short rise time and a very short fall time. The sharpness and brevity of this pulse is a critical factor in drawing excess energy in from the environment and will be explained in greater detail later on. The electronic circuitry is mounted on three aluminium heat sinks, each about 100 mm square. Two of these have five BD243C NPN transistors bolted to them and the third one has four BD243C transistors mounted on it.

The metal mounting plate of the BD243 transistors acts as its heat sink, which is why they are all bolted to the large aluminium plate. BD243C transistors look like this:

The circuit has been built on the aluminium panels so that the transistors can be bolted directly on to it, and provided with insulating strips mounted on top of it to avoid short circuits to the other components. Standard strip connector blocks have been used to inter-connect the boards which look like this:
The circuit used with this device is simple but as there are so many components involved, the diagram is split into parts to fit on the page. These diagrams are usually drawn with a common charging wire going to the top of the battery which is being charged. However, it needs to be understood that drawing it that way is just for convenience and better performance is achieved if each charging circuit has its own separate wire going to the charging battery as shown in Section 1 here:
While this looks like a fairly large and complicated circuit, it actually is not. You will notice that there are fourteen identical circuit sections. Each of these is quite simple:

This is a very simple transistor circuit. When the trigger line goes positive (driven by the magnet passing the coil) the transistor is switched on hard, powering the coil which is then effectively connected across the driving battery. The trigger pulse is quite short, so the transistor switches off almost immediately. This is the point at which the circuit operation gets subtle. The coil characteristics are such that this sharp powering pulse and sudden cut-off cause the voltage across the coil to rise very rapidly, dragging the voltage on the collector of the transistor up to several hundred volts. Fortunately, this effect is energy drawn from the environment which is quite unlike conventional electricity, and thankfully, a good deal less damaging to the transistor. This rise in voltage, effectively “turns over” the set of three 1N4007 diodes which then conducts strongly, feeding this excess free-energy into the charging battery. Ron uses three diodes in parallel as they have a better current-carrying capacity and thermal characteristics than a single diode. This is a common practice and any number of diodes can be placed in parallel, with sometimes as many as ten being used.

The only other part of the circuit is the section which generates the trigger signal:
When a magnet passes the coil containing the trigger winding, it generates a voltage in the winding. The intensity of the trigger signal is controlled by passing it through an ordinary vehicle 6 watt, 12 volt bulb and then further limiting the current by making it pass through a resistor. To allow some manual control of the level of the trigger signal, the resistor is divided into a fixed resistor and a variable resistor (which many people like to call a “pot”). This variable resistor and the adjustment of the gap between the coils and the rotor are the only adjustments of the device. The bulb has more than one function. When the tuning is correct, the bulb will glow dimly which is a very useful indication of the operation. The trigger circuit then feeds each of the transistor bases via their 470 ohm resistors.

John Bedini aims for an even more powerful implementation, wiring his circuit with AWG #18 (19 SWG) heavy-duty copper wire and using MJL21194 transistors and 1N5408 diodes. He increases the trigger drive by dropping the variable resistor and reducing fixed resistor to just 22 ohms. The MJL21194 transistor has the same pin connections as the BD243C transistor. This is the starting section of John’s circuit:

There are various ways of constructing this circuit. Ron shows two different methods. The first is shown above and uses paxolin strips (printed-circuit board material) above the aluminium heat sink to mount the components. Another method which is easy to see, uses thick copper wires held clear of the aluminium, to provide a clean and secure mounting for the components as shown here:
It is important to realise that the collector of a BD243C transistor is internally connected to the heat-sink plate used for the physical mounting of the transistor. As the circuit does not have the collectors of these transistors connected together electrically, they cannot just be bolted to a single heat-sink plate. The above picture might give the wrong impression as it does not show clearly that the metal bolts fastening the transistors in place do not go directly into the aluminium plate, but instead, they fasten into plastic tee-nuts.

An alternative, frequently used by the builders of high-powered electronic circuits, is to use mica washers between the transistor and the common heat sink plate, and use plastic fastening bolts or metal bolts with a plastic insulating collar between the fastening and the plate. Mica has the very useful property of conducting heat very well but not conducting electricity. Mica “washers” shaped to the transistor package are available from the suppliers of the transistors. In this instance, it seems clear that heat dissipation is not a problem in this circuit, which in a way is to be expected as the energy being drawn from the environment is frequently called “cold” electricity as it cools components down with increasing current as opposed to heating them up as conventional electricity does.

This particular circuit board is mounted at the rear of the unit:
Although the circuit diagram shows a twelve volt drive supply, which is a very common supply voltage, Ron sometimes powers his device with a mains operated Power Supply Unit which shows a power input of a pretty trivial 43 watts. It should be noted that this device operates by pulling in extra power from the environment. That drawing in of power gets disrupted if any attempt is made to loop that environmental power back on itself or driving the unit directly from another battery charged by the unit itself. It may be just possible to power the unit successfully from a previously charged battery if an inverted is used to convert the power to AC and then a step-down transformer and regulated power rectification circuit is used. As the power input is so very low, off-grid operation should be easily possible with a battery and a solar panel.

It is not possible to operate a load off the battery under charge during the charging process as this disrupts the energy flow. Some of these circuits recommend that a separate 4 foot long earthing rod be used to earth the negative side of the driving battery, but to date, Ron has not experimented with this. In passing, it is good practice to enclose any lead-acid battery in a battery box. Marine chandlers can supply these as they are used extensively in boating activities.

When cutting the wire lengths for coating and pushing into the coil formers, Ron uses a jig to ensure that all of the lengths are identical. This arrangement is shown here:
The distance between the shears and the metal angle clamped to the workbench makes each cut length of wire exactly the required size while the plastic container collects the cut pieces ready for coating with clear shellac or clear polyurethane varnish before use in the coil cores.

Experience is particularly important when operating a device of this kind. The 100 ohm variable resistor should be a wire-wound type as it has to carry significant current. Initially the variable resistor is set to its minimum value and the power applied. This causes the rotor to start moving. As the rate of spin increases, the variable resistor is gradually increased and a maximum speed will be found with the variable resistor around the middle of its range, i.e. about 50 ohm resistance. Increasing the resistance further causes the speed to reduce.

The next step is to turn the variable resistor to its minimum resistance position again. This causes the rotor to leave its previous maximum speed (about 1,700 rpm) and increase the speed again. As the speed starts increasing again, the variable resistor is once again gradually turned, increasing its resistance. This raises the rotor speed to about 3,800 rpm when the variable resistor reaches mid point again. This is probably fast enough for all practical purposes, and at this speed, even the slightest imbalance of the rotor shows up quite markedly. To go any faster than this requires an exceptionally high standard of constructional accuracy. Please remember that the rotor has a large amount of energy stored in it at this speed and so is potentially very dangerous. If the rotor breaks or a magnet comes off it, that stored energy will produce a highly dangerous projectile. That is why it is advisable, although not shown in the above photographs, to construct an enclosure for the rotor. That could be a U-shaped channel between the coils. The channel would then catch and restrain any fragments should anything break loose.

If you were to measure the current during this adjustment process, it would be seen to reduce as the rotor speeds up. This looks as if the efficiency of the device is rising. That may be so, but it is not necessarily a good thing in this case where the objective is to produce radiant energy charging of the battery bank. John Bedini has shown that serious charging takes place when the current draw of the device is 3 to 5+ amps at maximum rotor speed and not a miserly 50 mA draw, which can be achieved but which will not produce good charging. The power can
be increased by raising the input voltage to 24 volts or even higher - John Bedini operates at 48 volts rather than 12 volts.

The device can be further tuned by stopping it and adjusting the gap between the coils and the rotor and then repeating the start-up procedure. The optimum adjustment is where the final rotor speed is the highest.

The above text is intended to give a practical introduction to one of John Bedini’s inventions. It seems appropriate that some attempt at an explanation of what is happening, should be advanced at this point. In the most informative book “Energy From The Vacuum - Concepts and Principles” by Tom Bearden an explanation of this type of system is put forward. While the description appears to be aimed mainly at John’s motor system which ran continuously for three years, powering a load and recharging its own battery, the description would appear to apply to this system as well. I will attempt to summarise it here:

Conventional electrical theory does not go far enough when dealing with lead/acid batteries in electronic circuits. Lead/acid batteries are extremely non-linear devices and there is a wide range of manufacturing methods which make it difficult to present a comprehensive statement covering every type in detail. However, contrary to popular belief, there are actually at least three separate currents flowing in a battery-operated circuit:

1. Ion current flowing in the electrolyte between the plates inside the battery. This current does not leave the battery and enter the external electronic circuit.
2. Electron current flowing from the plates out into the external circuit.
3. Current flow from the environment which passes along the external circuitry and into the battery.

The exact chemical processes inside the battery are quite complex and involve additional currents which are not relevant here. The current flow from the environment follows the electron flow around the external circuit and on into the battery. This is “cold” electricity which is quite different to conventional electricity and it can be very much larger than the standard electrical current described in conventional textbooks. A battery has unlimited capacity for this kind of energy and when it has a substantial “cold” electricity charge, it can soak up the conventional energy from a standard battery charger for a week or more, without raising the battery voltage at all.

An important point to understand is that the ions in the lead plates of the battery have much greater inertia than electrons do (several hundred thousand times in fact). Consequently, if an electron and an ion are both suddenly given an identical push, the electron will achieve rapid movement much more quickly than the ion will. It is assumed that the external electron current is in phase with the ion current in the plates of the battery, but this need not be so. John Bedini deliberately exploits the difference of momentum by applying a very sharply rising potential to the plates of the battery.

In the first instant, this causes electrons to pile up on the plates while they are waiting for the much heavier ions to get moving. This pile up of electrons pushes the voltage on the terminal of the battery to rise to as much as 100 volts. This in turn, causes the energy to flow back out into the circuit as well as into the battery, giving simultaneously, both circuit power and serious levels of battery charging. This over potential also causes much increased power flow from the environment into the circuit, giving augmented power both for driving the external circuit and for increasing the rate of battery charge. The battery half of the circuit is now 180 degrees out of phase with the circuit-powering half of the circuit.

It is important to understand that the circuit-driving energy and the battery-charging energy do not come from the sharp pulses applied to the battery. Instead, the additional energy flows in from the environment, triggered by the pulses generated by the Bedini circuit. In other words, the Bedini pulses act as a tap on the external energy source and are not themselves the source of the extra power.

If the Bedini circuit is adjusted correctly, the pulse is cut off very sharply just before the tapped energy inflow is about to end. This has a further enhancing effect due to the Lenz law reaction which causes an induced voltage surge which can take the over-voltage potential to as much as 400 volts. This has a further effect on the local environment, drawing in an even higher level of additional power and extending the period of time during which that extra power flows into both the circuit and the battery. This is why the exact adjustment of a Bedini pulsing system is so important.

**Ossie Callanan’s Free-Energy System**

In 2007, Ossie Callanan published a document showing how and why he was getting COP>1 battery charging. Ron Pugh’s system kindly shared in detail above, with careful tuning and running on 24 volt input and 24 volt
output operates at COP>10 which is likely to be due to Ron’s skill in building and adjusting, both of which are very
good indeed, coupled with the use of many transistors working in parallel and tripled charging diodes to improve
their performance. The John Bedini SSG pulse-charging system is very easy to construct and works very well,
even with many sulphated batteries which have been discarded as useless. However, most people will not get
COP>1 performance from their own SSG build. Ossie explains why this is in the following section which is his
Copyright. He says:

I believe I may have this radiant energy system worked out to the point where anyone can build it and when you
build all of it, it can provide you with free and continuous energy. There are two sides to the circuit and just
having either side is no good, you must have both. One side is the pulse-charger side, and the other is the
battery and accumulator-converter side. At present, I am charging batteries at a performance level between
COP=2 and COP=10 and battery swapping is not a problem.

First we need to focus on the charger side of the system. Basically, you must build a charger which produces
large amounts of radiant energy in the form of radiant pulses. Radiant energy pulses are Back-EMF pulses
provided that they have very fast rising edges and falling edges and occur at high frequencies. They are not
transistor transients or switching transients! A spark-gap produces classical radiant energy pulses. They are
chaotic events but they are radiant energy events nevertheless. Switching a coil on very rapidly using a transistor
will produce one radiant energy pulse from the coil’s Back-EMF, but one pulse on its own is no good. You need
thousands or better still, millions of those pulses for them to be of any practical use.

John Bedini’s Simplified School Girl motor (the “SSG”) only produces a very small amount of radiant energy when
you have the base of the transistor tuned so that you get the longest self oscillating pulse train per magnet pass.
It is not very efficient as the base-clamping diode wastes this energy, passing it back through the base resistor-
bulb circuit but that circuit it is necessary so that you can synchronise the operation and provide a driving force to
the passing magnet. Without the base-clamping diode, you get an oscillator and the motor won’t turn - catch 22.
But still, even when tuned with the base-clamping diode in place, the self-oscillating pulse train is usually at most
3 to 6 pulses which is not very much and so, not much radiant energy is produced. For all those people trying to
tune the motor for only one pulse per magnet pass, they are wasting their time and only building a pulse motor
and not an efficient radiant energy generator.

The SSG is not a very powerful or good radiant energy generator and apart from being educational, it is really a
waste of time unless someone can explain to you how to tune it to get the greatest possible amount of radiant
energy from it with a long pulse train, and then tell you what to do with that radiant energy. John Bedini’s method
of using a bulb in the base-feed circuit is to keep the motor tuned to a particular number of pulses in the pulse
train per magnet pass or for the longest pulse train as the motor increases speed, also, the battery’s impedance
changes the speed as well. The two-strand coil where one coil is used just as the transistor trigger, along with the
wasted energy in the base circuit, add to the overall inefficiency and make construction more difficult.

In saying that about the SSG I would like to show you now a very simple and basic pulse oscillator or motor driver
circuit that you can build with off the shelf parts, one which will produce very large amounts of radiant energy
when adjusted correctly. Here is that circuit:

Do not be fooled by appearances - this is as close to a controlled spark gap circuit as you are going to get and it is
extremely efficient in the production of radiant energy! But most importantly, you must place and adjust the reed
switch appropriately and properly!!! Take a look at this picture:
As you can see, the trick is to place the reed switch so that it runs along the length of the solenoid coil and so is located in the coil's magnetic field. This couples the coil's magnetic field to the reed switch as well as the magnetic field of the passing rotor magnet. This provides a magnetic feedback and turns the reed switch into an oscillator. So when the magnet passes the reed oscillates with the coil's field and causes very many pulses, typically 20 to 50 pulses per magnet pass. Amazingly, unlike the clamping diodes in the SSG, this is not wasteful. This reed switch oscillation actually reduces the input current. Instead of the reed remaining closed for the whole of the pulse duration, it switches on and off and so, less input power is drawn from the driving battery. I run the motor so that when the coil is energised, the magnet is attracted to the coil. Here is a trace across the charging battery:

The trace above is from a motor that is only drawing 50 milliamps but is charging the battery many times faster than if it were drawing 300 milliamps with a single pulse per magnet pass! But there is more. Take a look at the following picture:
Using a very small and weak magnet, you can now control and adjust the reed switch. This allows you to adjust the switching so that the circuit oscillates continuously but still powers the passing rotor magnet. Below, is the trace across the charging battery and the battery is charging very rapidly although you are still paying for this as the input current will increase but nevertheless, you are really producing a vast amount of radiant energy for what is effectively, very little input current! Also, when you do this, the coils HISS very loudly! Yes, the coils HISS, not with a tone or frequency but with a hissing NOISE.

My prototype motor uses four of these circuit's, positioned 90 degrees apart around the rotor, and all connected in parallel. You can use just one reed switch to switch all four transistors and coils but it is more load and the reed switch does not hold up for very long. In fact, either way, if you use small reed switches, they will get worn and start to stick. I have bought larger reed switches but I am also working on an electronic switching version of this, although that is easier said than done. I have worked on this for a few months now so I have tried very many things and have not managed to match it with electronic switching yet. Limiting the current passing through the reed switch does not necessary increase the length of its operational life, besides which, doing that produces less radiant energy.

Now having shown you all this, we are only half way to a complete radiant energy system which will provide continuous free energy. The above circuit and motor, even though they do provide large amounts of radiant energy, will still only give you a COP equal to, or close to 1 when regularly swapping over between the source
battery and the charging battery. For battery swapping to work, you MUST have the second and equally important side to the system. The second side of the system is the radiant energy accumulator-converter.

Before I describe the radiant-energy accumulator-converter, I want to highlight how important it is to build and experiment with the circuit described above. Only after adjusting and watching the input current and how the charging battery charges can you truly see how these radiant energy pulses are affecting the charging battery. In terms of why it works or how it provides so much radiant energy you have to understand that if the reed switch stays closed, which will happen when they get worn and start to stick, with the 9 millihenry crossover choke solenoid coil (bought off the shelf) which I use, the transistor is turned fully on and at virtually it's lowest resistance and so the current draw is about 6 to 8 AMPS for a single coil circuit!!! It seems this is a key requirement for generating these radiant energy pulses with a transistor. You have to switch the transistor fully on at maximum current for the coil and input voltage. This is another thing the SSG does not do well. But yet, in this circuit, when the reed switch is adjusted correctly, you can get the input down to just a few milliamps if you want!

OK, now to the radiant accumulator-converter. The requirement for this appears to be because the charging battery is not very efficient at absorbing all of the radiant energy pulses. John Bedini had related this as being due to impedance matching but I am not sure of this at this stage, but impedance may be a factor. Because the charging battery does not absorb much of the radiant energy by itself, you MUST have an accumulator-converter to absorb and convert the radiant energy for the charging battery to use. Ok, that said, what is a radiant energy accumulator-converter?

A Radiant Energy Accumulator-Converter (“REAC”) is nothing more than a dipole! But the larger the dipole the better! The dipole can be a battery but that is silly when we are already charging a battery. Well in that case, it is a special battery. It is a battery that is mostly composed of potential but little current. The higher the potential the better the accumulation/conversion but some current is still required to be able to pass the energy back and charge the charging battery.

There are a number of traditional dipole's that fit what is needed. There is a simple long and raised wire antenna and ground, but this will not provide enough back current to charge our battery. There is an earth-battery setup, but unless you want to put in the effort and amount of materials to raise the voltage and still have some required current this needs a lot of work and materials. Finally, I found the best compromise to be "old, dead, sulphated lead acid batteries". At this stage of my research the condition of the battery does not really matter as long as it is “dead” and sulphated. As long as they are old and dead so that they can barely light up a 12V 100ma bulb, then they will do just fine. Gee I am glad I never threw away my old dead batteries that kept piling up.

If you go down to a battery recycler or junk yard, you can buy pallet loads of old and dead Uninterruptible Power Supply (“UPS”) batteries for very little cost. When I say pallet load, I mean pallet load. The bigger the bank of these you get the batter. Connect them both in series and parallel so that if they where good, you would get anywhere from 48-120 volts. When connecting in parallel make sure that each 12 volt segment has an approximately even capacity in Amp-Hours. You can put this bank under your house or table or even bury them in the ground. It is no problem as you will never have to do anything to them again (as long as they are sealed). They will NOT keep running down. They are already run down. All you need them for is to use their potential as a dipole and their hidden capacity. The very small amount of current they will provide for the size of the bank due to the crystalline resistance of the sulphation is all that is needed to provide the free energy that the will convert the radiant energy pulses and feed it back into your good battery which is being charged. I believe that these sulphate crystals may indeed be the main component that is doing the radiant energy conversion for us. Now for how to connect up your 'REAC'. See the following diagram:
You must connect the REAC directly to the charging battery as I have shown above. Amazingly, there is a great voltage difference when you measure the voltage directly across the charging battery compared to the voltage measured across the REAC while the reed motor is running. This voltage difference is seen even with thick cables connecting them, but distance does affect it as well. You must have two separate sets of cables. One set going directly from the radiant energy charger to the charging battery and the other set from the charging battery to the REAC. I have run the above setup for over one month now. Below is a picture of the “dead” batteries which I use as an REAC.

Using my good 33 Amp-Hour UPS batteries, I can charge them up from 10 volts to 14 volts in about 6 hours with the radiant energy reed motor running 4 coils drawing only 600 mA. I can then swap the source battery with the
charging battery and keep doing this until I have both batteries charged in about 24 hours. I have done this very many times and the charging rate appears to be improving over time.

But one thing I want to make clear. If you think that I am somehow just using the stored energy in the REAC bank, if I do not use my reed motor, then the charging battery will not charge. If I try replacing the reed motor with a regular battery charger, the battery will take as long to charge as a normal battery charger would to charge it. When using the reed motor, the REAC is converting most of the radiant energy and providing the energy back to the charging battery. There you have it, a fully working radiant free energy system. Enjoy! -- Ossie Callanan

The Self-Charging Battery Charger.
One major disadvantage of some of these battery pulse-chargers is the fact that it is thought that it is not possible to self-power the device nor to boost the running battery during the battery charging process. There is one variation of the pulse-charger which does actually boost the driving motor as it runs, and one particular implementation of this is shown here:
The rotor weighs about five pounds (2 Kg) and is very heavy for its size, because it is constructed from flooring laminate, and has a thickness of 1.875 inches (48 mm) to match the width of the magnets. There are ten magnets size 1.875” x 0.875” x 0.25” (48 mm x 22 mm x 6 mm) which are assembled in pairs, to produce the most evenly matched magnetic sets possible. That is, the strongest is put together with the weakest, the second most strong with the second weakest, and so on to produce the five sets, each half an inch (12 mm) thick. These pairs are embedded in the rotor at equal 72° centres around the edge of the rotor.

The battery pulsing produced by this circuit is the same as shown in John Bedini’s patent already mentioned. As the rotor turns, the trigger winding energises the 2N3055 transistor which then drives a strong pulse through the winding shown in red in the diagram above. The voltage spike which occurs when the drive current is suddenly cut off, is fed to the battery being charged. This happens five times during a single revolution of the rotor.

The clever variation introduced here, is to position a pick-up coil opposite the driving/charging coil. As there are five magnets, the drive/charging coil is not in use when a magnet is passing the pick-up coil. The driving circuit is not actually active at this instant, so the micro switch is used to disconnect the circuit completely from the driving battery and connect the pick-up coil to the driving battery. This feeds a charging pulse to the driving battery via the bridge of 1N4007 high-voltage diodes. This is only done once per revolution, and the physical position of the micro switch is adjusted to get the timing exactly right.

This arrangement produces a circuit which in addition to pulsing the battery bank under charge, but also returns current to the driving battery.

Another variation on this theme is shown on YouTube where an experimenter who calls himself “Daftman” has this video explaining the circuit he uses in his Bedini-style battery-charging motor: http://uk.youtube.com/watch?v=JJiiiOTsmrM&feature=channel and his video of his motor running can be seen at: http://www.youtube.com/watch?v=S96MjW-isXM and his motor has been running for months in a self-powered mode.

The Relay Coil Battery Charger.
One experimenter on the Energetic Forum has posted a video of his adaptation of the Bedini circuit at http://uk.youtube.com/watch?v=4P1zr58MVfI. He has found that adding a 6-volt relay coil into the feed to the base of the transistor has halved the power used and yet keeps the rotor at about the same rate of rotation. The circuit is shown here:
The build used has three electromagnet coils placed around a horizontal rotor:

The Modified Fan Battery Charger.
Other more simple methods of getting this radiant energy charging of batteries are also available. One simple method is to skip most of the mechanical construction and use a slightly adapted synchronous fan. This method is shown by “Imhotep” in his instructional video which is located at http://uk.youtube.com/watch?v=eDS9qk-Nw4M&feature=related. The original idea comes from John Bedini and the fan idea from Dr Peter Lindemann.

The most common choice for the fan is a computer cooling fan - the larger the better. These fans usually have four windings connected like this:

To use these windings as both drive and pick-up coils, the fan is opened up by lifting the label covering the hub of the fan, removing the plastic clip holding the fan blades on the spindle and opening the casing to expose the coils. The wire post with two wires going to it then has one wire removed and a fourth post improvised by drilling a small hole and inserting a short length of wire from a resistor. The fourth wire end is then soldered to it to give this arrangement:
This produces two separate coil chains: 1 to 2 and 4 to 3. One can then be used as the drive coil and the other as the power pick-up coil which passes the very short high voltage pulses to the battery which is being charged.

When opened up, the fan looks like this:

![Fan Opened Up Image]

And the circuit arrangement is:

![Circuit Diagram]

The fan is started by hand and then continues to spin, working as a fan as well as charging a battery. The current draw from the driving battery is very low and yet the radiant energy charging of the other battery (or battery bank) is not low. Please remember that batteries which are to be used with this radiant energy, need to be charged and discharged many times before they become adapted to working with this new energy. When that has been accomplished, the battery capacity is much greater than specified on the label of the battery and the recharging time also becomes much shorter. The circuit is adjusted with the variable resistor, which changes the transistor drive current, which in turn, alters the speed of the fan. It should be stressed that this device and the relay charger shown below, are simple demonstration devices with small coils and to get serious charging, you need to use a large-coil battery pulsing systems with a bank of lead-acid batteries being charged.

This circuit is a clever implementation of John Bedini’s Simple Schoolgirl (“SSG”) design. As it can be a little confusing to know which of the four wires coming out of the modified fan to use, let me explain how they operate. You now have two pairs of series-connected coils inside the fan. An ohm-meter (or battery and bulb) will let you see which of the four wires are the two ends of each of those coils. The coils are symmetrical and so it does not matter which coil feeds the base of the transistor and which coil is driven by the collector of the transistor. It does
not matter either, which way round the coil feeding the base of the transistor is connected but it does matter very much, which way round the drive coil is connected. Connecting it the wrong way round will not cause any harm but the fan will not operate because instead of the coil repelling the rotor magnets and pushing them on their way, it will attract them and oppose the rotation. So, if the fan does not spin when you give it a push, swap the drive leads over and it should work perfectly.

The neon bulb protects the transistor but it also give a good indication of how well the battery being charged is being fed. Adjust the variable resistor to get the minimum current draw from the drive battery while still having the neon lit well and that should give a good performance.

A very neat build of an 80 mm computer fan conversion to a pulse charger built by Brian Heath is shown here:

This unit runs with a PP3 9V battery as the drive battery, and charges a PP3 9V rechargeable battery when it is running. Both batteries are enclosed in the box in this very neat construction.

The Automotive Relay Battery Charger.
An even more simple charging method is also shown by “Imhotep” in another of his instructional videos at [http://d1190995.domaincentral.com.au/page6.html](http://d1190995.domaincentral.com.au/page6.html). Here he adapts an ordinary 40 amp car relay, converting it from having a “normally open” contact, to operating with a “normally closed” contact. It is not necessary for you to do this as automotive relays with “normally closed” contacts are readily available and are not expensive.

The relay is then wired up so that it powers itself through its own contacts. This causes a current to flow through the relay coil winding, operating the contact and opening it. This cuts off the current through the relay’s own coil, causing the contacts to close again and the process starts all over again.

The repeated opening and closing of the relay contacts happens at the resonant frequency of the relay and this produces a buzzing noise. Actually, buzzers were originally made this way and they were used in much the same way as a doorbell would be used today.

The circuit used is shown here:

As you can see, this very simple circuit uses only two components: one relay and one diode. The key feature is the fact that when the relay contacts open and current stops flowing through the relay coil, a very high voltage spike is generated across the relay coil. In transistor circuits which drive a relay, you will see a diode wired across the relay coil in order to short-circuit this high voltage at switch-off and stop the transistor getting destroyed by the
excessively high voltage. In this circuit, no protection is needed for the relay. Any number of batteries can be charged at the same time.

An ordinary 40 amp automotive relay like this:

![Image of a relay]

can have a “changeover” contact, which means that it has a “normally closed” contact and so can be used directly without any need to open or modify the relay itself.

In this circuit, however, that reverse voltage is being used in a very productive way. These voltage spikes are very sharp, very short and have a very fast voltage rise. This is exactly what is needed to trigger an inflow of radiant energy from the local environment, into the battery. This battery charging current is not coming from the driving battery but is coming from the environment. The small current from the driving battery is just operating the relay as a buzzer.

One user of this circuit commented that he was using a non-automotive relay with a greater number of turns in the coil, and he found that both of the batteries were getting charged at the same time, but of course, the drive battery was gaining charge at a slower rate. This will have been because the current draw with the more efficient relay was less than the rate of charging and so, even the drive battery gained power.

Please remember that at this time, we have no instrument which can directly measure the flow of radiant energy into the charging battery. The only reliable way of assessing the inflow is to see how long it takes to discharge the charged battery through a known load.

My experience with using relays for battery charging indicates that you get a better result if 24 volts is used to drive the circuit and as vehicle relays don’t have that much of a coil winding, there is a considerable improvement if a large coil is connected across the relay coil or coils as shown here:

![Relay Diagram]

When using one of these relay charging systems you will find that quite a lot of noise is generated. This can be reduced quite easily with a little padding and it does have the advantage of indicating that the charging system is running correctly.
The Self-Charging Motor.
A video at [http://www.youtube.com/watch?v=AWpB3peU3Uk&hl=en-GB&feature=related](http://www.youtube.com/watch?v=AWpB3peU3Uk&hl=en-GB&feature=related) shows an interesting home-built device which uses the motor out of an old video recorder, the bearing out of an old computer CD drive and pick-up coils made by removing the case and contacts from standard relays:

![Image of the motor](image)

The construction is very straightforward with a simple, uncluttered, open layout:

![Diagram of the motor](image)

With this arrangement, one pair of AA-size NiCad batteries drives the motor, spinning the motor, moving its magnets rapidly past the ring of converted relays, producing charging DC current via the bridge rectifiers and that current is sufficient to keep the device running continuously.

A comment made on the video is that if the ferrite magnets were replaced with neodymiums, then the charging voltage rises to around 70 volts. Unfortunately, the present rotor is too flexible and the neodymium magnets actually flex the rotor down towards the relay cores as they pass, so a more robust rotor is needed.
The ‘Alexkor’ Solid-State Battery Charger Circuits.
The “Alexkor” battery-charging system is very effective, cheap and easy to build. It is a version of the system described in Fig. 22B on page 7 of the http://www.totallyamped.net/adams/ web page:

While this description has been around for years, it is part of a discussion on the principles of the operation of EMF magnetic fields and pulsing in coils. ‘Alexkor’ has developed a practical circuit which he says works very well. It can be constructed as a single unit as shown here:

Here, the coil is wound with 200 turns of 0.7 mm enamelled copper wire and the actual construction is compact:

And to get an idea of the performance, Alex uses a capacitor to see the size of the voltage spikes produced by the circuit:
If building a circuit with a soldering iron and one of the commercial versions of prototyping board with copper strips is too difficult, then the circuit can be set up using a plug-in board like this:

The battery marked “1” provides power to run the circuit and the battery marked “2” gets charged. The resistors are all quarter watt. The enamelled copper 22 swg wire has a diameter of 0.711 mm and the coil can easily be wound on a cardboard tube. With a 30 mm (1.25 inch) diameter tube about 20 metres of wire would be needed and that weighs about 70 grams. I would like the output diode to be a UF5408 diode as the “UF” stands for “Ultra Fast”, but the wire leads are too thick to plug into a board like this and so the 1N5408 can be used, it is rated at 1000 volts and 3 amps.

This is the first step in the process as the same circuit can be used to drive many coils of this type. The resistor feeding the base of the transistor is about 500 ohms for the prototype, but using a 390 ohm resistor in series with a variable resistor of say, 1K, would allow a good standard resistor value to be selected for each transistor/coil pair:
As can be seen from the photographs, Alex uses preset resistors to adjust the settings to their optimum values. The simplicity of this circuit makes it very attractive as a construction project and using more than one coil should make for impressive performance figures. Alex says that the best results are achieved with just the one (1000V 10A) diode and not a diode bridge, which is borne out by the teaching comments on the above web site. Multiple transistor chargers like the one above, work best when there is a separate wire from each coil to the battery being charged.

Further development by Alex shows better performance when using the IRF510 FET instead of the BD243C transistor. He also has found it very effective charging four separate batteries and he has revived an old NiCad drill battery using this circuit:

It is possible to use various different transistors with these circuits. As some people have difficulty in working out a suitable physical construction for a circuit, here is a suggestion for a possible layout using an MJ11016 high-power high-gain transistor on stripboard.
Alexkor’s Self-Charging Circuit.
This is a particularly simple circuit which allows a 12V, 8 amp-hour battery charge a 48V, 12 amp-hour battery with radiant energy, in 20 hours using twelve times less current than a conventional charger would. The circuit can charge lithium, NiCad or lead-acid batteries. The circuit used is:
The coil is wound on a hollow former, using two separate strands of wire of 0.5 mm diameter, giving a resistance of just 2 ohms. The strands of wire are placed side by side in a single layer like this:

A possible physical layout using a small standard electrical connector strip might be:
If the coil is wound on say, a 1.25-inch or 32 mm diameter plastic pipe, then the outside pipe diameter is 36 mm due to the wall thickness of the plastic pipe, and each turn takes about 118 mm, so around 24 metres of wire will be needed for the 200 turns. If 13 metres (14 yards) of wire is measured off the spool and the wire folded back on itself in a sharp U-turn, then the coil can be wound tightly and neatly with close side-by-side turns. A small hole drilled at the end of the pipe allows the folded wire to be secured with two turns through the hole, and the 200 turns will take up a length of about 100 mm (4-inches) and the two loose ends secured using another small hole drilled in the pipe. The starting ends are cut apart and the ends of each coil determined using a continuity test.

An even more advanced circuit from Alex has even higher performance by using a high-speed transistor and a very fast-action diode, and a neon is not needed to protect the transistor:

The fast UF5408 diode used in this circuit is available, at the present time, on www.ebay.co.uk in packs of 20 for £3.84 inclusive of postage.
The transistor drive to the battery bank can be replicated for additional drive and an additional ten transistors could be used like this:

The 2700 pF capacitor is recommended for each additional transistor, but it is not an essential item and the circuit will operate ok with just the one on the bi-filar coil drive section.

A recent circuit design from Alexkor uses the tiniest of inputs; just 1.5 volts at a current which can be adjusted down from 4 milliamps to just 1 milliamp. This tiny circuit can charge a 12-volt battery, although admittedly, the charging rate is not very high as it takes ten hours per Amp-Hour to charge the battery. However, it is spectacular to get an input of just 1.5 milliwatts to charge a 12V battery. The circuit has very few components:

Coils: 0.5 to 1.0mm diameter solid copper  
wire length: 1 to 2 metres bi-filar wound  
Variable resistor adjusted for minimum current 1 to 4 mA  
Output is 40V spikes
The coil is tiny, bi-filar wound on ferrite or with an air-core. In the circuit diagram, the dots on the coil windings indicate the start of the two side-by-side windings. This makes it clear that the start of one winding is connected to the end of the other winding as well as to the positive side of the 1.5V battery. The variable resistor could be omitted and various fixed resistors tried until the 1 milliamp current level is reached. It should be emphasised that there is just one earthing point and it is a real connect-to-the-ground type of connection. Simple arithmetic will show you that if there is a charging current flowing into the battery to charge it, then even with an imagined 100% efficiency of the battery, the battery charge is many times greater than the draw from the battery driving the circuit. The circuit runs at a frequency between 200 MHz and 300 MHz.

Alex uses a commercial “choke” from http://it.farnell.com/murata/pla10an1522r0r2b/choke-common-mode-2x1-5mh-2-0a/dp/9528423?whydiditmatch=rel_3&matchedProduct=3532290 as shown here:

Jes Ascanius of Denmark has replicated this circuit and he makes these comments: The 10K variable resistor and the additional 1K resistor need to be 250 mW types as larger wattages cause a greater current draw. Also, the quality of the earth connection is important as his very efficient earth produces 60-volt pulses from the circuit (70-volts at night) and just by touching the earth connection can boost those pulses right up to 92-volts and so further experimentation may produce some other interesting effects.

Alexkor’s most advanced circuit to date is the one shown here:
This circuit uses the PLA inductor shown above. The initial reaction of somebody familiar with electronic circuits might well be "this is impossible as the battery being charged is 'floating' as it is not connected to either side of the driving battery". While that is true, the circuit works very well indeed and a battery bank of ten 1.2V Ni-Mh batteries rated at 1100 mAHr capacity which had been charged and discharged ten times before, is now charged by this circuit in just half an hour.

The input voltage can be anything from 12V to 36V without the need to change any of the circuit components. The choice of transistor is important and the STW12NK90Z is a very high-performance, high-voltage transistor (available at the present time from www.mouser.com), and while it is not cheap, I would strongly recommend its use if you decide to replicate this circuit. The SF28 diodes are also special components, rated at 600 volts and 2 amps, these are high-speed diodes, not to be replaced with any diode which happens to be available.

The coil is most unusual in that it is just four turns of very thick copper wire, 3 mm to 4 mm in diameter, although aluminium wire can also be used. This power cable is wound on to a spool of 100 mm to 130 mm (4-inch to 5-inch) diameter. The tiny 5 nF capacitor needs to be rated at a very high 6000 volts. The real Earth connection at point "A" gives a 20% to 30% improvement in performance but if the circuit has to be portable, then it will work with the lower level of performance if the earth connection is omitted and point "A" is connected to the 0V line of the input battery.

While the coils shown above are air-core to allow high frequency operation, coils, most other coils are generally much more efficient with some form of magnetic core, such as iron-dust or ferrite. While it is not likely to be able to operate at frequencies as high as 35 KHz, a very good material for coil cores is the metal of masonry anchors or "sleeve anchors" which look like this:

This metal is immune to rusting, easy to work and loses all magnetism as soon as the magnetic field is removed. You can confirm this for yourself by placing a permanent magnet on one end of the bolt or the tube and using the other end to pick up a steel screw. As soon as the permanent magnet is removed, the screw falls off as the metal does not retain any of the magnetism from the permanent magnet. These anchors are cheap and readily available from builder's supplies outlets, including those on the internet. It is unlikely that this material could operate at more than 1,000 Hz and the circuit above gains a lot of its performance from the high speed, fast switching and very short "On" time duty cycle.
If you use the bolt section of one of these anchors, the conical bump at the end of the shaft will have a delaying effect on the build-up and release of the magnetic field and so it might be advisable to either file it down gently by hand, or to cut off the conical section. There will always be eddy current losses in any solid metal core, but that does not stop them being very effective in operation. As with everything else, testing an actual device is the key to good performance and sound knowledge.

**Sucahyo's Charging Circuit**

In 2014, Sucahyo stated that some people found that pulse-charging batteries for a few times, caused those batteries to have “surface” charge where the voltage rose to normal without there being any corresponding genuine charge behind that voltage rise. This is not an effect which I have encountered, but perhaps I didn’t charge a battery enough times to reach the problem. Anyhow, Sucahyo has published a circuit which he has used on batteries repeatedly for four years without encountering a surface-charge effect. Pulse charging uses “cold” electricity and “cold” electricity can be converted to “hot” electricity by feeding it into a capacitor. Here is Sucahyo’s circuit:

![Sucahyo's Charging Circuit Diagram]

Notice that the 1N4007 diodes protecting the TIP41C transistors are connected to the transistor base and not it’s emitter as is more common. The coils being used are just simple single-filar CCW-wound coils with a DC resistance of about 1 ohm. Each coil is wound around a ferrite toroid:
You will notice in the circuit, that the TIP42C transistors which are PNP type, are connected in a way which would be considered to be "wrong". This method of connection is perfectly deliberate and it works well, drawing only a quarter of the current which would be drawn if they were connected the "right" way round and yet maintaining the same level of output charging current. As with any charger, it is not a good idea to overcharge the battery. The circuit (which Sucayho calls "Stingo") can charge a 1000 milliamp-hour AA battery in 15 minutes, a 12V 7 Amp-Hour battery in 5 hours and a 12V 70 Amp-Hour battery in 15 hours. There is additional information and discussion at [http://www.thetruthdenied.com/news/2014/03/12/radiant-a-suppressed-fast-battery-charger/](http://www.thetruthdenied.com/news/2014/03/12/radiant-a-suppressed-fast-battery-charger/).

**Howard Halay’s Battery Charging Techniques**

Howard Halay of the UK stresses the major difference between “conditioned” batteries and all batteries which have not been conditioned. He says: to condition a battery or capacitor, it needs to be repeatedly charged with ‘cold’ electricity and discharged again. Cold electricity is either high frequency AC electricity or alternatively DC at high voltage. With cold electricity, the electricity flows outside the wires (Steinmetz) and so, Current does not equal Voltage divided by Resistance as Ohm’s Law suggests. Instead, Current equals Voltage x Resistance x a Constant "C" which has to be determined by experimentation. It is also possible to get cold electricity from pulsed DC, provided that the DC voltage is over 80 volts. If using that technique, then the sharper and faster the pulses, the better.

When you first pulse an AC or DC capacitor, it behaves normally. After approximately 12 hours of continuous pulsing a change occurs in the behaviour of the capacitor. In the case of the water capacitor, it develops a nano coating on one side only. When measured with a resistance meter it shows no resistance at all. One can say that one side becomes quasi superconducting. In the case of an ordinary capacitor, there is no reason to believe that it behaves differently. The capacitor also charges much faster than before and when the power source is switched off it continues charging! Yes you read that correctly. In my case it fires pulses for up to 3 minutes after the power is switched off, which is why they are dangerous. The firing decays exponentially although I haven’t yet tabulated it scientifically – I’ll leave that to other people to do.

The result of this is that you can have two identical capacitors side by side. One behaves as if it is plugged into a charger, while the other capacitor behaves normally. All capacitors self-charge to a certain extent but “conditioned” capacitors are in a league of their own! I have tested a neon on a conditioned capacitor through two earth rods 10 feet apart. I gave up looking at the lit neon after half an hour!

I use a very low-powered high-voltage source with a power output of only 1.2 watts as I like to play safe with these things. With a low power source, I have charged batteries using pulses of up to 800 volts without the batteries showing any ill effects. Also, using one-wire electricity is safer as that transmits mostly voltage and so minimum current is fed. So, to condition a battery or a capacitor using cold electricity, you can use a circuit like this:
Here, the size of the voltage pulses fed to the battery or capacitor to be conditioned, is controlled by the strike voltage of the neon. The ordinary NE2 type neon lamps strike around 90V and so the 2N6509G SCR will feed pulses of about that voltage to the battery or capacitor. If two neons are connected in series and used instead of the single neon shown above, then the voltage pulses will be around 180V. This type of circuit appears to work better if several capacitors are used in series as shown here, as they seem to charge up faster and discharge faster as well. You have to leave the device running for a day to get the full benefit. I regularly charge a 1.6 Kw car battery bank, and after switching off, the battery bank voltage goes up!!

I have also tried 5 seconds of ON time and two minutes of OFF time, and the capacitors continue firing pulses. However the rate of firing is much less when the power is off than when the power is on. If you fail to use the capacitors for a while - in my case it was three weeks or so - you have to start the conditioning process all over again. In my case conditioning them again was harder and seemed to take days rather than hours. The capacitors are COLD. The wires leading up to them and out of them are COLD, but if you get a shock from them, then that shock is HOT!!

Because this charging process uses cold electricity, non-rechargeable batteries can be charged this way. In my case two out of three batteries recover their charge OK, and curiously they charge to a much higher voltage than their rated value. The battery can be replaced with a capacitor. Obviously, any battery or capacitor which is to be conditioned, needs to be able to be charged with a voltage of not more than 70 volts per neon, so for example, a 96V battery bank would need two neons in series across the SCR of the charging circuit. This circuit will keep on charging the battery for up to three minutes after the input power is switched off. An even more powerful version of the circuit boosts the cold electricity power by using a choke. The neons will light much more strongly. The neons should pulse or you've got a short-circuit. In other words, if the neon(s) is lit continuously, it is a bad sign.

You can use a variable resistor in series with the input power to vary the pulse rate. Negative radiant energy is delivered which produces cold electricity and conditions all capacitors in the output section of the circuit.
Be very careful with this circuit as it can kill you. This circuit is only for experienced experimenters. Capacitors will take about a day to get conditioned. This circuit is good for bringing dead car batteries back to life. When a battery is conditioned and the charging circuit input power is switched off, the battery will continue charging! Once they are conditioned, you can charge 4 car batteries in parallel using just a 6 watt 12 volt power supply, or a solar panel. However, this description must not under any circumstances be considered to be a recommendation that you should actually build this circuit as this presentation is for information purposes only.

The question has been asked, “why use five capacitors in series when any one of them can easily handle the voltage being used?” That is a good question as the answer is not at all obvious. The answer is because of the way that capacitors charge up. The voltage across a capacitor which is being charged, increases in a very non-linear way and it is generally illustrated like this:

The red lines show the average rate of charge and the steeper the line, the faster the rate of charge. The greater the charging voltage relative to the size of the capacitor, the steeper the start of the line is. Howerd uses this fact to his advantage by using just the first ten percent of the curve. This is done by connecting several high-voltage capacitors in series as shown in his circuit diagram. The combined set of capacitors charge up very fast indeed and before they reach 10% of their capacity the neon fires and the capacitor charge is driven into the battery (or capacitor) which is being conditioned. The intensity of that current is determined by the size of the capacitors in the chain, the larger the capacitors the more intense the pulse into the battery and as you can see, Howerd has chosen 2.2 microfarad capacitors of the plastic film type:

The Tesla Switch.
The Tesla Switch is covered in more detail in Chapter 5, but it is worth mentioning it again here as it does perform battery charging. The similarity ends there, because the Tesla switch does the battery charging while the circuit is providing serious current into a load. Also, the Tesla switch uses only four batteries, and still is capable of driving a thirty horsepower motor, which is the equivalent of 22 kilowatts of electrical power.
The simple circuit shown here was used by testers of the Electrodyne Corp. over a period of three years using ordinary vehicle lead-acid batteries. During that time, the batteries were not only kept charged by the circuit, but the battery voltage climbed to as much as 36 volts, without any damage to the batteries.

If the voltage on a battery under load actually increases, it is reasonable to assume that the battery is receiving more power than that delivered to the load (a load is a motor, a pump, a fan, lights, or any other electrical equipment). As this is so, and the circuit is not connected to any visible outside source of energy, it will be realised that there has to be an outside source of energy which is not visible. If the circuit is provided with powerful enough components, it is perfectly capable of powering an electric car at high speeds, as has been demonstrated by Ronald Brandt. This indicates that the invisible source of outside energy is capable of supplying serious amounts of additional power. It should also be remembered that a lead-acid battery does not normally return anything like 100% of the electrical energy fed into it during charging, so the outside source of energy is providing additional current to the batteries as well as to the load.

So, how does this circuit manage to do this? Well, it does it in exactly the same way as the battery pulse-charging circuits in that it generates a very sharply rising voltage waveform when it switches from its State 1 to its State 2 (as shown in detail earlier). This very rapid switching unbalances the local quantum energy field, causing major flows of energy, some of which enters this circuit and powers both the circuit and the load. Although it does use four batteries, and the batteries do get charged through the generation of sharp pulses, this is not a circuit which charges massive battery banks so that they can power a load at some later time.

The Self-charging Motor

It is possible to enhance the performance of a DC motor by attaching sets of neodymium magnets to the outside of the body of the motor. One example of this is shown in a video at http://www.youtube.com/watch?v=NoLbphKxMM&list=LLjpt7ksyRVQi3ITZwSeQxaw&feature=related shows such an arrangement and the video at http://www.youtube.com/watch?v=5Xv-rq4U8U&feature=related shows how the motor can be set up to produce this enhancement of its performance. The motor looks like this:

And a frame is used to hold four sets of bar magnets in position around it:
The frame is made from two pieces of 3 mm aluminium with plastic spacers holding the two aluminium discs apart. The plastic spacers are secured with brass screws. As the motor casing is about 3 mm thick steel, that tends to deflect the added magnetic field outwards, which is the reverse of what is wanted. So, a 6 mm thick strip of steel is placed outside the magnets in order to direct the field inwards. The magnets and steel strips are then inserted to complete the arrangement:
The motor is demonstrated when set up like that. Then four sets of very narrow magnets are added in intermediate positions and the number of broad magnets increased to three at each location, the steel strips discarded and four broad magnets used at each of the four locations around the motor:

With this arrangement, the motor runs at ten times its design speed (which would destroy it very quickly), so it is run with just one sixth of its design voltage. It is used to drive an electric generator shown in two videos at:
http://www.youtube.com/watch?v=0dkiHUasERA&feature=related and
http://www.youtube.com/watch?v=ZTLvgCiKadI&feature=related which explain the sophisticated design features of this generator which has been built with great care:
Given a couple of minutes of gentle turning of the crank, charges up the five batt-caps sufficiently to run the motor for anything up to two hours. The arrangement is clever with the stator magnets in a Howard Johnston sequence which is also angled inwards like the magnetic Wankel motor. One electromagnet is powered up briefly once per revolution and the back-EMF at switch-off is rectified and passed back to the capacitors, forming a very efficient generator. Other design features are explained in the videos which are definitely worth watching.

The generator, when running can discharge a rapid sequence of high-voltage sparks which the builder just uses for an interesting display. However, those spark discharges are quite capable of charging a bank of batteries (not to mention, running a Don Smith style power device). The builder then goes on to add an ordinary capacitor to the series-connected batt-cap bank, and couples the motor to it:

This allows the enhanced motor to become fully self-running as well as producing excess power which could easily charge a bank of large batteries. Incidentally, conventional science says that this is “impossible” and so they will only look at this machine with their eyes closed because they can’t afford to believe it — after all, that would require them to modify their present theories and the people who pay their salaries would not allow any such change.
This motor is shown running on capacitors, but if it is powered by an ordinary battery and run at it’s design speed of 3,300 rpm instead of the extremely low speed shown, then it should be able to charge up a serious bank of large batteries, one of which could then be used to power it for the next charging run.

The ‘UFOpolitics’ Motor

In chapter 2, there is a section on how an experimenter alters the wiring inside DC motors. This alteration has a major effect, boosting the output power by a major amount as well as providing an additional generated electrical output. One person who followed his instructions and rewound a tiny 3-volt 3-pole motor, then tried running that motor on a discharged 6-volt battery. The motor ran, slowly at first and then picked up speed. That seemed impossible as the motor draws 300 milliamps when running and the battery was just not capable of providing that current. However, impossible or not, the motor ran and not only did it run but it started recharging the battery driving it. This suggests that this is a self-sustaining system which provides output power and yet never needs to have the battery recharged.

The way that this happens is that what we think of as “electricity” is actually a more complex thing called “electromagnetism”. We think of electricity and magnetism as being two different things, while in fact, they are two different aspects of the single entity electromagnetism. The electric component always has an efficiency of less than 100% which the magnetic component always has an efficiency which is greater than 100% - something which we usually don’t notice as we tend to ignore the magnetic component.

In the case of this tiny 3-volt motor, it draws it's running ‘hot electricity’ current from the battery. That causes rotating magnetic fields inside the motor and these generate ‘cold electricity’ which flows back along the supply wires and charges the battery.

Some Battery Charging Suggestions

Using a vehicle to charge batteries.

It is very easy to overlook the obvious. It is possible for people who do a fair bit of driving, possibly to and from work, or maybe dealing with a delivery round, to charge some additional batteries from the car alternator. Once the engine is started, additional batteries can be connected in parallel with the car battery, that is, the plus terminal of the extra battery or batteries connects to the car battery plus.

This does draw some additional energy from the car engine and in theory should cause some additional fuel to be used, but the extra fuel should be fairly minor as most of the power of the engine is used to push air aside as air resistance goes up with the cube of the speed of the vehicle. The charged batteries can be removed from the vehicle in the evening and used to power lights, TVs, DVD players, etc. in the evening by using a small commercial inverter.

Experimenting with a battery charger.

There is an interesting possibility when using one of the pulse battery chargers shown earlier in this chapter, say, an Alexkor solid-state pulser. Commonsense tells you that if you want to light a lamp using a battery, then the longer the lamp is to be lit, the larger the battery needs to be.

Looking at this from a slightly different viewpoint, we could say that the shorter the period of time when the battery has to power the bulb, the smaller the battery can be. So, for example, if the bulb only needed to be lit for ten seconds, then the battery could be quite small.
But suppose we were to reduce that time period to just one second, then the battery could be very small indeed and if we were to reduce the time period to one tenth of a second, then the battery power would be tiny compared to the power needed to run the light for say, one hour. This may seem trivial and obvious, but it this is leading up to a strategy which could be useful.

Fairly recently, super capacitors have become available at reasonable price, with a 2.5V 5F capacitor costing as little as £3. Just to put this in perspective, in electronics, a 1000 microfarad capacitor is considered large and a 10,000 microfarad capacitor is considered to be very large. Well, a 5F capacitor is 500 times larger than a 10,000 microfarad capacitor. These capacitors charge up fully in just a few seconds, are 100% efficient and should remain operational for many years if not many decades.

Suppose then, that we were to connect a 6-volt bulb across a 6-volt lead-acid battery. If the battery were charged to say, 6.6 volts (measured one hour after being disconnected from a battery charger) and the lamp were connected across the battery and left lit until the battery voltage dropped to 5.0 volts (on load, as it will gain a good deal of voltage when the load is disconnected). Then that determines how long the battery can power the lamp when the battery is discharged that much.

It would be interesting to see if that length of time could be extended without using a larger battery. Suppose we were to connect a set of three of those super capacitors in series to form a 7.5V capacitors of 1.67F capacity, and then implemented the following circuit:

![Diagram of circuit](diagram.png)

using a simple NE555 circuit to drive the relay On and Off once per second. Then, the battery would only be connected to the lamp for half of the time and it would be ‘resting’ for half of the time. That sounds like a mad idea as when the battery is connected it will have to both light the lamp and top up the charge in the capacitor, and some current is needed to run the NE555 circuit and drive the relay. That results in a poorer performance than before.

However, as the battery is disconnected for half of the time, we can use that fact to our advantage by extending the circuit to this arrangement:

![Diagram of circuit](diagram2.png)

This makes the battery draw even worse as there are now two large capacitors which have to be topped up every second while the lamp is being powered and the NE555 circuit is also being powered. But, for half of the time, the relay is in its other position which connects capacitor “C2” to the battery pulse-charger, and at the same time, the ‘resting’ battery is connected to the output of the battery charger, feeding additional charge to it.

You might feel that a charging period of half a second is far too short to be of any use, but that is actually not the case. In chapter 5, there is mention of the 1989 patent US 4,829,225 granted to Yury Podrazhansky and Phillip
Popp, their evidence is that batteries charge much better and have a longer life if they are pulsed in a specific way. Their formula is that the battery should be given a powerful charging pulse lasting for a period of time between a quarter of a second and two seconds, the pulse being the Amp-Hour rating of the battery. That is, for an 85 AHr battery, the charging pulse would be 85 amps. That pulse is then followed by a discharging pulse of the same, or even greater current but only maintained for only 0.2% to 5% of the duration of the charging pulse. Those two pulses are then followed by a resting period before the pulsing is repeated. They quote the following examples of their experiences when using this method:

</table>

Of course, while this table of results does not apply directly to our proposed circuit, it does indicate that very satisfactory results can come from a very intermittent charging sequence and while I have, so far, spoken of a one-second cycle for our test circuit, that is purely due to the initial test use of a mechanical relay. If the test is satisfactory, showing a longer length of time for the battery to reach an on-load voltage of 5 volts, and the relay circuit is replaced with a solid-state (lower current draw) circuit, then a switching time of maybe one tenth of a second might be used.

If the battery charger runs at 300,000 Hz (which is only 10% of some of the Alexkor circuits), then with a timing of one tenth of a second On time and one tenth of a second Off time, then the battery would receive about 30,000 charging pulses five times per second, which is 150,000 charging pulses every second, which is very close to some very successful battery chargers which operate all the time.

This is an untested idea, but it looks as if it might produce a usefully extended battery life and if the switch “S” is included in the circuit, then when it is opened, the battery may well be able to self-charge. As this arrangement is so simple, it might well be worth testing. The NE555 integrated circuit can provide up to 200 milliamps and so it could probably drive most 6V relays directly if the relay is connected between pin 3 and the plus of the battery. Initially, the NE555 circuit can be powered by a separate battery or power supply while the effect of the circuit is being checked out. Later on, if the circuit happens to work well, it could be powered by being connected to the battery via a choke and a smoothing capacitor (with a varistor across the capacitor if you want to play really safe) to block the charging pulses from the timing circuit, or it could be powered via an additional super capacitor or from one of the two existing capacitors. There is, of course, no reason why the NE555 circuit should have an On time equal to the Off time and so the timer’s Mark/Space ratio could be made adjustable and tests run to see what the optimum setting would be. This could be an interesting experiment.

However, if you decide to test this idea, while you could use a relay to do the initial testing, it might be a good idea to test solid-state switching at the same time, as solid-state switching is likely to be much more reliable and have a much longer life. We might choose to use bi-polar transistors as they are the most reliable for lower voltage circuits, and so we might treat the circuit like this:
Maplins have 2.7V super capacitors at very reasonable prices. It would be necessary to connect four or five in series in order to meet the voltage requirements, although doing that reduces the overall capacitance substantially. It would be quite easy to add a dimmer control using a switched variable resistor and an emitter-follower transistor where the switch short-circuits the dimmer but when open, allows the voltage (and so, the current) applied to the LED bank, to be adjusted, as shown in the solar panel light suggestion at the end of chapter 14.

Initially, a slow-running 555 circuit could be used to drive one of the above circuits and invert the 555 output to drive the other circuit, using a transistor with a base resistor to protect it. A more practical charging circuit could be:

Here, the charger is connected to the battery at all times, through a diode (or perhaps more practically, through three or four diodes, such as UF5408, in parallel which feeds current better than one diode on its own), leading to a circuit something like this:
When pin 3 of the 555 goes low, resistors R1 and R2 control the current flow to transistors Tr1 and Tr2, switching them fully on in order to charge capacitors C1 and C2. Resistor R5 is a high value of say, 470K and is there just to provide a current flow path when the switch S is opened to turn the light off.

Resistor R3 is chosen to switch the 2N2222 transistor (or BC109, or other small-signal transistor) Tr3 fully on, when pin 3 goes high, and R4 is chosen to ensure that Tr3 switches fully off when pin 3 is low, switching the charger off by turning Tr4 off and starving it of current.

It is quite common for a charging circuit such as those from John Bedini or from Alexkor, to need the battery being charged to be connected in series to the battery which is driving the charging circuit (capacitor C2 in our case). This can be arranged like this:

Here, the size of capacitor "C" is increased as it is now supplying both the light and the charging circuit, which runs all of the time. As the voltage spikes are high voltage and the resulting charging current very high, solid-state implementations of this arrangement require prototype testing before being shown here.

Ideally, for a USB output, we want an arrangement which draws no significant current when not in use and yet, which does not need a mechanical switch. For that we might do something like this:

Here, the battery voltage of around 9V or 9.8V or whatever, is connected across a 100K variable resistor which will waste just under 0.1 milliamps. Two (low-cost) BC109C transistors are connected as a Darlington pair in emitter-follower mode with a 1M resistor as their load. These transistors have a gain which typically exceed 200, and so, two together like this draws only one 40,000 th of the proposed 10 mA current, and that is just 0.25 microamps which is about 0.25% of the current flowing through VR1 and so, even under load, the VR1 voltage will be steady. This wastes another 0.006 milliamps when VR1 is adjusted to give about 5.3V as an output when under load. A 100 ohm resistor is connected in series with this output and pin 1 of the ‘type A’ USB socket.
pins 1 and 4 are open-circuit, no current flows through this resistor until such time as a load is connected between pins 1 and 4.

If pins 1 and 4 were short-circuited – which is a most unlikely occurrence, then the current through the 120 ohm resistor would be 52.5 milliamps, which indicates that that resistor should be a half-watt type as that dissipation is 330 mW. The most effective way to make the initial adjustment would be to set the output voltage low, connect a mobile phone to the socket and adjust VR1 to give 5.3V or so on the socket. Preventing over-charging of the battery might be done with a circuit of this type:

![Circuit Diagram](image)

Point “A” is a reference voltage provided by resistor R1 and zener diode Z1 and held at a steady voltage by capacitor C1. The Op-amp IC1 acts as a voltage comparator between points “A” and “B” (which is set by the preset variable resistor VR1 and reflects the overall voltage of the battery). The output voltage of IC1 will change sharply if the voltage difference between “A” and “B” swaps over, but by no means to the rail voltages, so transistor Tr1 is there to give a full logic swing. The transistor base current is set by resistor R3 and resistor R2 is there to ensure that Tr1 switches off properly. Resistor R4 has quite a high value as it is just there to form a voltage divider pair with Tr1.

The op-amp might be an LM358 as it will operate with voltages as low as 4.5V, it is very cheap, and it draws almost no current. As the package has two op-amps in it, the second one can be connected as a buffer:

![Circuit Diagram](image)

As we want the circuit to switch as the battery voltage increases, point B must start at a lower voltage than point A. If connected as shown, then Tr1 will be on when the battery is charging and will switch off when the battery is fully charged at a voltage set by the position of the slider of VR1.

As the battery is receiving high-voltage spikes when being charged, the input to this section of the circuit is buffered by the 100 ohm resistor and the 100 nF capacitor is there to attempt to short-circuit spikes which get through the 100 ohm resistor. An inductor would probably be better than the 100 ohm resistor for suppressing voltage spikes and connecting a much larger capacitor in parallel with the 100 nF capacitor might be an additional help in keeping the voltage rails of this section of the circuit at a steady average voltage. The choice of resistor R1 and the voltage of the zener diode are not critical. The current through R1 can be very low as IC1 needs almost no current and as there is a reservoir capacitor across the zener diode and that will keep the voltage steady.

Resistors R2 and R3 are chosen to suit Tr1, R3 to ensure that it switches on properly when connected to the charger circuit and R2 to make sure that it switches off properly when then output pin 7 of IC1b drops to its lowest value of about 2 volts. It is likely that R4 will not be needed as Tr1 will probably be connected direct into the charging circuit in order to power it down or stop it oscillating.
The 3-Kilowatt Earth Battery

This battery does not need charging as such. Earth batteries are well known. They are pairs of electrodes buried in the ground. Electricity can be drawn from them, but they are generally of little interest as the power levels are not great. However, in his patent of 1893, Michael Emme, a Frenchman living in America determined how to get very serious levels of power from an earth battery of his design. In this particular unit which he describes in his US 495,582 patent, he gets 56 amps at just under 54 volts, which is three kilowatts or 4 HP. At that early date, there was generally, not much need for electricity, but Michael states that by selecting the number and connection method of the individual components, any desired voltage and/or current supply can be had. This, of course, is a simple system which involves no electronics.

Disclaimer: This document is for information purposes only and must not be considered to be a recommendation or an encouragement for you to actually construct an earth battery of this kind. If you choose to do so in spite of this warning, then all responsibility for the results is entirely yours. Please bear in mind that some forms of construction utilise strong acids and careless handling of strong acid can result in skin and other damage. Protective clothing should be used when handling acids and an alkali should be ready for immediate use if careless handling causes splashes.

Summarising his patent, Michael says:

My invention relates to chemical generators of electricity where a prepared body of earth is the support and excitation medium for the electrodes or elements. Any number of elements can be assembled in the same piece of ground and connected in a chain or series of chains in order to produce the desired voltage and/or amperage.

I find that several straight chains of elements can function separately provided that the gap between the chains is much greater than the gap between the elements which form the chain. Being quite separate, those chains can be connected in series to increase the voltage, or in parallel to increase the available current.

It is necessary to prepare the soil in the ground in the immediate area around the electrodes which form each element in the chain.

Fig.1 shows five elements connected in a chain. This view is from above with the rectangles indicating holes in the ground where each hole contains seven separate pairs of electrodes.

Fig.2 and Fig.3 show how individual electrodes are inserted into the prepared soil “C” which is surrounded by untreated ground “B”. Electrode “D” is made of iron and “E” is made of carbon.
Fig. 4 shows how wedge-shaped electrodes can be used as an alternative construction. The advantage is that it is easier to pull a tapering electrode out of the ground.

Fig. 5 shows the internal current flow circuits which operate when a chain of elements is used. The arrows indicate the direction of current flow.

Fig. 6 shows a convenient method for periodically moistening the prepared soil areas.

Soil of any type can be adapted for use with an electrical generator of this kind by saturating the soil immediately surrounding each pair of electrodes with a suitable solution which is rich in oxygen, chlorine, bromine, iodine or fluorine, or with a solution of a salt of an alkali.

For the electrodes, I prefer to use soft iron for the positive electrode and hard pressed coke carbon for the negative electrode. The positive electrode is preferably a U-shaped bar of iron which has a circular cross-section. The two limbs of the U straddle the rod of carbon. Cast iron can be used but it gives a lower voltage, presumably due to the carbon and other impurities in it.
Magnesium gives excellent results, producing 2.25 volts per electrode pair where carbon is the negative electrode.

In implementing my invention, I level a piece of ground of sufficient area to contain the generating chain or chains. For instance, for three hundred positive elements each twenty inches (500 mm) long and two inches (50 mm) in diameter, bent as shown in Fig.3, the length of the piece of ground should be about 107 feet (32 metres) and 3 feet (1 metre) wide. I dig 43 holes at a distance of 30 inches (735 mm) apart (centre to centre) in a line. Each hole is 10 inches (250 mm) wide and 30 inches (750 mm) long and deep enough to contain the seven pairs of electrodes.

The loose soil dug from the holes is mixed with the chosen salt or acid in order to make the generator active. For instance, if the ground is a vegetable mould, then commercial concentrated nitric acid should be added in sufficient quantity to saturate the soil, and manganese peroxide or pyrolusite should be mixed with the mass. If the soil has a sandy character, then hydrochloric acid or sodium carbonate ("washing soda") or potash can be used. If the soil is a clay, then hydrochloric or sulphuric acid and sodium chloride may be used, the salt being dissolved in water and poured into the hole before the acid is mingled with the soil. The bottom of the hole is moistened with water and the prepared soil mixed with water to the consistency of a thick paste is then placed in the hole, surrounding the electrodes. The 43 groups of electrodes when wired in series as shown in Fig.1, will yield 53.85 volts and 56 amps, developing a total of 3015 watts.

By increasing the number of cells, the capacity of the generator may be correspondingly increased to any desired power output. The prepared body of soil should be periodically moistened, preferably with the acid with which it was treated when first prepared for action. In a generator intended for continuous use, I prefer to provide a reservoir as shown as "A" in Fig.6, and run a pipe made of a material which is not attacked by the acid, along the chain of elements, with a nozzle over each element so that they all can be moistened very easily. Any accumulation of oxides or other products of the reaction between the prepared soil and the electrodes may be removed by raising the positive electrode and then forcing it back into place again. The carbon electrode can be cleansed by simply turning it without lifting it from its place.

I find that the period of use of the generator during which no addition of salt or acid is needed, increases with the period of use. For example, during the first day of use, the acid or salt should be added after 10 hours of use, after which it will yield 26 hours of service, and then after another moistening it will operate for 48 hours, and so on, progressively increasing in duration between being moistened. This generator operates very consistently and reliably.
Nowadays, we find mains voltage alternating current to be the most convenient to use. For a system like this, we would be inclined to use an ordinary inverter which runs on twelve volts or twenty-four volts. However, it needs to be remembered that the working input current is high and so, the wire used to carry that current needs to be thick. At 12V, each kilowatt is a current of at least 84 amps. At 24V that current is 42 amps (the inverter itself is more expensive as fewer are bought). Considerable household usage can be had from a 1500 watt inverter.

The soft iron / carbon construction described by Michael Emme produces 54V from 43 sets of electrodes, indicating around 1.25V per set at high current draw. It seems reasonably likely that ten or eleven sets of electrodes would give around 12V at high current and three of those chains connected in parallel should be able to power a 1500 watt 12V inverter continuously at extremely low running cost.

** A Battery Charger for Just One Battery **

Johan Booysen of South Africa used electrolyser circuitry developed by Bob Boyce of America, to charge a battery. The important thing is that there was only one battery involved as the battery being charged actually powered the charging circuit. The battery involved was a 12-volt 18 Amp-Hour lead-acid battery which therefore has an efficiency of only 50%, which means that the battery has to receive twice as much current compared to the current which it can return afterwards. Johan used the battery to power a toy car which his young daughter played with. He charged that battery overnight so that she could use it the next day to drive around.

While the maximum speed of the car is only two or three miles per hour, the important point is that real, genuine energy is being put into the battery every night, energy which powers the toy car each day. A device of that kind, which can charge a battery without sunlight, without the need for wind and without the need for fuel, has major applications for people living in remote areas where there is no mains power and never will be as it is not economic to run power lines there. The question is: can such a device be made which is reliable and safe to use?

** DISCLAIMER:** the following information is **NOT** for beginners but is solely intended for people who are experienced in electronics and who are aware of the dangers involved. Please understand clearly that I am **NOT** recommending that you should build anything based on the following information.

First, please understand that you live in a dangerous place. You are surrounded and immersed in a sea of major energy which flows through you at all times. A lightning bolt is millions of volts with a current of ten thousand amps or more. That is a massive amount of power and I’m told that around the world, there are between 100 and 200 of those lightning strikes every second. The energy field would not even notice power flows like that even though to us they appear to be massive amounts of power.

We do not notice the energy field because we have been inside it for all of our lives. It is said, and I’m inclined to believe it although I don’t know how to prove it, that it is not possible to create or destroy energy, and the most that we can do is convert it from one form into another (and when we do that, we generally manage to make the energy flow do useful work for us). One way to affect the energy field is to create a very short, very sharp, high voltage spike. That disturbs the surrounding energy field enough to make small ripples in it and we can sometimes gather those ripples and use some of them to do electrical work for us.

Another known way to access this enormous energy field is to create a rotating magnetic field, but you need to be very, very careful if you try doing that as you are messing around with an energy field of incredible power. You probably have heard of the famous equation $E = mc^2$ and while most people think that it came from Albert
Einstein, the reality is that it was produced years earlier by Oliver Heaviside and Einstein merely publicised it. What the equation says is that energy and matter are interchangeable and that a tiny speck of matter can be created from a very large amount of energy. Oliver Heaviside also calculated that the energy field which I have been trying to describe, fills every part of the universe, and that energy is so great that the amount inside one cubic centimetre is sufficient to create all of the visible matter which we can see in the whole of the universe. You don’t mess around with that energy field unless you know what you are doing, and even if you do know what you are doing, you still need to be very careful. Please understand that the electrical energy with which we are familiar, is a transverse wave while the universe is filled with longitudinal wave energy and those two forms are completely different, so the electrical effects which are familiar to you do not apply to the energy which charges Johan’s battery.

Bob Boyce is an unusually clever and perceptive man. He experimented with rotating magnetic fields and was hit by lightning as a result. I cannot stress too much, that rotating magnetic fields are very dangerous indeed. Ideally, you want to avoid a rotating magnetic field. Bob developed a very effective and safe toroidal power supply for his high-performance HHO electrolyser. That power supply is an open system which provides more power to the load than is drawn from the battery and it looks like this:

Which for a low-voltage system (not needing high voltage for 100 electrolyser cells in series) would presumably be:
Here, the steady-state DC voltage from the battery has added to it, the waveform generated by the electronics board pulsing the toroid. Regarding toroids, Bob says that he does not consider ferrite or laminated iron to be suitable toroids because it is just not safe to use them in circuitry of this kind unless at very low frequency which means low efficiency. In these systems, there has to be a trade off between control and power and an controlled runaway is highly dangerous. Remember here, that this system is tapping into the energy source which powers the whole universe continuously and what comes out of Bob’s toroid is mainly that same longitudinal wave energy. In passing, almost all, and quite possibly all free-energy devices including solar panels, water wheels, wave-power devices, biomass, etc. are powered by this literally universal energy field of longitudinal waves.

Looking at this in more detail, Bob’s toroid is a 6.5 inch (165 millimetre) diameter iron powder toroid sold by MicroMetals in America, and it is wound initially with the secondary winding which goes all of the way around the toroid:

![Diagram of toroid with wires](image)

The wire used must be single strand solid copper wire, coated with silver and covered with teflon plastic insulation. Different toroids operate in different ways and so would need experimentation using different wire types and number of turns in the windings. This secondary winding has to be wound with perfect accuracy giving exactly even spaces between turns around the outer edge of the toroid and it is then taped over with ordinary electrical tape (do NOT use fibreglass winding tape and do not use multi-strand wire as either of those will prevent the circuit from working properly).

Three primary windings are now wound on top of the tape which is covering the secondary winding (note that the primary winding wire starts over the top of the toroid and is wound from left to right):
Again, it is essential that the wire used is solid, single-core copper with silver coating and teflon covering. The completed toroid is bound with tape and screened by being placed inside an earthed metal box. The drive signals for the toroid are like this:

A similar system with a divide-by-two to produce each of the lower frequencies has been tried and it was found that it did not work as well as having three separate oscillators which are near the harmonic frequencies but not an exact harmonic, as that produces a complex series of repeated heterodyning of the signals and the resulting overall waveform is much richer than would be expected. So, if you attempt to replicate the waveform using an Arduino or other PIC microprocessor board, it might be advisable to set the lower frequencies at an odd number of clock ticks so that a complex waveform is produced. It is actually cheaper and more convenient to use discrete components: 555 timer chips with multi-turn preset resistors so that adjustment can be made without stopping a test run. The highest frequency is the key frequency and the two lower frequencies are helpful but of lesser importance. When tuning the circuit, the highest frequency is adjusted to give the best output. Then the gating for that frequency is adjusted to find the lowest input current which still gives that level of output. Then that same procedure is repeated for the second and then the lowest frequency modules.
You will notice here that each primary winding on the toroid is fed with its own separate signal and there is no suggestion whatsoever that the three windings are driven sequentially to form one of those very dangerous rotating magnetic fields. Although the above diagram may look slightly advanced, it is actually, very simple in broad outline. The circuits might be like this:

I am not very happy with the above circuit. We are working from a single voltage supply of a nominal 12-volts and the circuit has a signal generation section which operates at low-current, and a high current drive section for the toroid coil. The resistor and capacitor marked “B” are to provide power decoupling for the low current section with the PCP116 opto isolator separating the two sections of the circuit. However, that is not a very good solution as the current pulses along the power supply wire will definitely create high speed voltage fluctuations in that wire. There are a number of solutions. One might be to add in a small choke at point “A”, and/or provide a second supply wire connecting at point “A”:

All choke windings should be kept well away from the toroid windings to avoid inductive coupling, and they should be outside the screening box containing the toroid. No matter what arrangement is found to be suitable, three of these circuits are needed in order to drive the three separate windings on the toroid. The only difference in the second and third circuits is the frequency capacitor:
Please remember that it is Bob Boyce's technology which is tapping into this extra power of the ambient background energy which surrounds and flows through us. Also, understand that what comes out of the toroid is not just conventional ‘transverse wave’ energy, but instead, it is mainly longitudinal wave energy which we cannot measure directly. Bob points out that if your load is capable of absorbing longitudinal currents, such as water or to a somewhat lesser degree, a light bulb, then this longitudinal wave power will run it. If the input energy is correctly configured, then that causes modulated longitudinal wave energy to flow out of the toroidal transformer wires because that input energy modulates the local longitudinal wave energy field. When the toroid is wound and driven for peak efficiency, the unit behaves as a Tesla magnifying transmitter and a Tesla radiant energy receiver, all in a single package. There is an energy gain in the process, which is why Tesla called it a ‘magnifying’ transmitter. This energy gain is produced by the small energy source which we provide, modulating the very much larger energy source which is the longitudinal wave dominant energy source of the entire universe, and then we capture and use this modulated energy to do useful work.

The output of the toroid is a combination of conventional transverse wave energy and non-conventional longitudinal wave energy. It is the characteristics of the load which determines how much energy will be harvested from the longitudinal wave energy component of the output. Water only absorbs longitudinal wave energy if that energy is modulated at the correct frequency. Light bulbs and some motors can run directly on ("cold electricity") longitudinal wave current, but they do so at reduced efficiency. Many modern appliances and items of electronic equipment would need to have the longitudinal wave energy converted to transverse wave energy in order to be able to operate on this energy.

For the HHO gas production, the electronics and the toroid itself have been designed to produce dissociation of water in a relatively safe manner and that is why Bob insists that HHO experimenters stick with a pulsed field mode of operation. It is much lower in gain than a rotational field system would be and because of that lower gain it is much less inclined to go into a runaway condition where the output energy increases the longitudinal energy gain to the point where the system overloads and goes into avalanche runaway. By using water as the load, any increase in output energy is absorbed by the water and so it is a self-stabilising process. Even if an avalanche occurs in an HHO gas system, the low power density of the pulsed mode allows the water to absorb the power surge and that just causes more water to convert into gas. This means that in order to be safe, input energy must exercise full control over the tendency to self-feedback and a load MUST always be present when the device is running.

Water is preferred because it does not burn out, it just dissociates. We tune the primary frequency to be one which works well with water. It is a frequency which allows the water to absorb the longitudinal component best. That is why using just pulsing DC does not give the same effect. DC does not contain the longitudinal wave energy to which the water is responding in a resonance drive system. Unfortunately, the best frequency for longitudinal energy absorption by water is affected by many factors, so we must strive to keep the system in tune for the best absorption of that energy. The other two frequencies enhance this energy collection process without greatly increasing the associated risks.

Bob knows that this entire power technology sounds hocus pocus to those educated in traditional transverse wave energy behaviour, but longitudinal wave energy is very real and can be used to our advantage. Many
inventions and devices have been built that can tap into this unseen and unmeasured energy. The average water for fuel experimenter has no clue as to how dangerous this energy side of the technology can be, hence the amount of work which Bob expended in trying to make a relatively safe pulsed version which the average experimenter can use safely. Otherwise, experimenters are likely to kill themselves when trying to apply a very dangerous technology to a very simple application, all in the effort to generate more HHO gas on demand. Bob is not the only one to do this. Meyer, Puharich, and others, have managed to tap into this energy is a safe and controllable fashion.

When Johan tries to charge a lead-acid battery, there is no electrolyser filled with water to absorb an avalanche runaway. The only available water is in the acid contents of the battery and it is that which will dissociate into HHO gas inside the battery. That HHO gas mix is in the exact proportions for explosion back into water again. What has not been stressed is that the HHO gas produced is highly charged electrically and will detonate if the gas pressure exceeds about fifteen pounds per square inch. While any mention of an explosion is scary, the reality does not match up to what most people imagine. Earlier in this chapter, Ronald Knight who is an experienced battery tester (using only transverse wave energy), explains the situation clearly:

I have not heard of anyone having a catastrophic failure of a battery case in all the energy groups to which I belong and most of them use batteries in the various systems which I study. However, that does not mean that it cannot happen. The most common reason for catastrophic failure in the case of a lead-acid battery, is arcing causing failure in the grids which are assembled together inside the battery to make up the cells of the battery. Any internal arcing will cause a rapid build up of pressure from expanding Hydrogen gas, resulting in a catastrophic failure of the battery case. During the manufacturer’s testing, the battery is charged with the maximum current which it can take. If the battery does not blow up due to internal arcing during the initial charge it is highly likely that it will not blow up under the regular use for which it was designed. However, all bets are off with used batteries that have gone beyond their expected life. I have witnessed several catastrophic failures of battery cases daily at work. I have been standing right beside batteries when they exploded and I have only been startled by it.

I would suggest that when testing new, unorthodox circuitry such as this, that the battery is placed in a robust box which has vents covered with baffles so that gas can escape freely but any acid or fragments of case are kept inside the box. Personally, I have never had a battery explode, nor have I ever seen an exploded battery.

I understand that Johan connects the circuit output back to the battery in this way:

The choke shown in red in the diagram is about 18 turns on a small toroid which seems okay, but the two other coils appear to be just six or seven loops in the connecting leads, not wound side by side on a magnetic former, but just left as if shortening the cable length.
Consequently, it is distinctly possible that those two chokes have been omitted as the inductance of those loops must be very low indeed. The point of a choke is that it will pass DC while blocking sharp (transverse wave) voltage spikes. If those two chokes are as ineffective as they look, then the circuit would be:

![Circuit Diagram]

While the photograph above appears to show a fuse placed in the output wire before the choke, I am doubtful about doing that. The speed of longitudinal energy is so great that a fuse is most unlikely to operate fast enough to be any use. Also, longitudinal (“cold”) energy has the reverse effect to what is expected with transverse wave (“ordinary”) energy. Any fuse has a resistance and is supposed to blow when it burns out through raised heat caused by excessive current flowing through it. Transverse energy would cool the fuse rather than heat it. However, a fuse might well have an enhancing effect on the whole charging process because while a resistance impedes the flow of transverse wave energy it actually boosts the energy flow of longitudinal energy, drawing in additional power from our surrounding energy field. In a runaway power surge, the fuse would not be helpful but when running normally, it might well be. Let me stress here that this is only my untested opinion and, unlike Bob Boyce, I am certainly not an expert in this technology.

Let me stress again that this is **NOT** a recommendation for you to attempt to build or use something of this nature in spite of the fact that it has worked well for Johan. We need to remember that Johan was using a more advanced version of Bob’s electronic circuitry, one whose details have not been released. Because of that, it may be necessary to place a diode between the circuit output and the battery Plus terminal. This information is only a suggestion for experimentation which might just possibly be carried out by experienced electronics experts.
A Fast-Charge Joule Thief Variation

This somewhat unusual arrangement for a battery charger comes from Rene who has posted a video about it at: https://www.youtube.com/watch?v=lvKa4zneaRQ saying that it charges batteries very quickly.

The technique is to use a mains power supply unit of twenty volts to operate the circuit in conventional mains charging mode but instead of connecting the mains supply to the minus of the battery being charged, a simple Joule Thief circuit is inserted in that line. This means that the Joule Thief circuit operates on the voltage difference between the mains supply and the charging battery’s present voltage. As the battery charges up, the Joule Thief working voltage drops. Rene says that the diode across the mains unit is needed but he doesn’t know why. While this is an interesting circuit, let me just express a few opinions, on it, and let me stress that these are only opinions as I have not built and used this circuit.

Charging batteries from the back-EMF voltage swings produced by coils when their current is cut off, generally requires the negative of the battery being charged to be connected to the positive of the battery which is powering the circuit. This is not an essential feature of those circuits, but it is done because if you don’t, then current will flow directly from the powering battery into the charging battery. However, in this case, that is exactly what the designer wants to happen and so there is no obvious reason why there should not be a common negative line. That means that an ordinary 14V mains battery charging unit can be used and the Joule Thief can operate with a fixed voltage level. Unless Rene’s design gains charging power by having the Joule Thief circuit in series with the charged battery, I would suggest that the circuit might work better like this:

That arrangement gives the mains charging as before and constant voltage supply to the Joule Thief circuit which adds charging pulses to the mains DC supply to the battery being charged.

Charging circuits from Charles Seiler

In August 2009 Charles Seiler published some battery charging pulse circuits which are interesting. The first is based on Alexander Meissner’s 1913 circuit which looks like this:
This is a slightly unusual circuit which is compact and efficient. The 10K fixed resistor drops the voltage across the 10K variable resistor to about 6V to make the tuning easier. The variable resistor is adjusted so that the transistor is just about to switch on, and then the additional drive from the capacitor/coil pair makes the transistor switch on rapidly.

Charles has altered this circuit by replacing the frequency control capacitor “C” with the internal capacitance of the battery being charged, making the charging rate proportional to the state of the battery being charged:

When set correctly, this circuit runs cool without any need for a heat sink on the transistor. The size of the capacitor is not critical and can be adjusted for the best performance. The coils are wound with equal lengths of wire and wound with the wires side by side, either air-core or with an insulated welding wire core like this:
Charles states that the low coil resistance is helpful for charging lead-acid batteries as they have a very low internal resistance of about ten ohms. The coils are wound with 200 to 400 turns but in spite of that, the current drawn by the circuit is small.

The circuit can oscillate at 500 kHz but the rate of oscillation is affected by the state of the battery being charged and will typically be only 100 Hz to 2,000 Hz with a fully discharged battery. The pulse rate depends on the charge level of the battery as the battery is part of the timing mechanism of the circuit. One very important point is that the circuit has no protection against over-voltage and the 3055 transistor is only rated up to 60V, so if the circuit is switched on without the charging battery being connected, then the transistor will definitely be destroyed.

Another circuit suggested is the one shown below. This is a very unusual circuit:

In this circuit, the four (or more) coils are wound as one unit with all four wires laid down side by side. The additional diodes are there to protect the transistors and the base resistors are adjusted to give a realistic current flow into the circuit which keeps the transistors cool when the circuit is running.

Personally, I have always found pulse charging circuits to be temperamental and subject to a wide range of performance without any circuit change (that, of course, may be due to my poor constructional skills). However, if any charging circuit charges the battery faster than the current draw, then battery self-charging is possible. For that, a circuit like this can be used:
With an arrangement like that it is very encouraging to see the battery voltage rising and rising. The choke is only needed to block the charging voltage spikes from reaching the oscillator circuit. However, the oscillator circuit has to be COP>1 for this to work, but many of the circuits in this ebook have that characteristic. I have found the secondary winding of a 12V 300 mA mains transformer to be an effective choke.

Chapter 7: Aerial Systems and Electrostatic Generators

Note: If you are not at all familiar with basic electronics, you might find it easier to understand this chapter if you read chapter 12 first.

It is generally thought that aerials are not capable of gathering much power. The popular conception is that the only power available is low level radio waves from distant radio transmitters, and while it is certainly true that radio waves can be picked up with an aerial, the real sources of power are not radio transmitters.

For example, we will be looking at information from Hermann Plauson and he considered any aerial system of his which did not produce more than an excess power of 100 kilowatts, as a “small” system (admittedly, with many aerials). Thomas Henry Moray demonstrated his system to audiences repeatedly, pulling in power levels of up to 50 kilowatts from a single sort aerial. These power levels are not produced by radio station signals.

Nikola Tesla’s Aerial System.
Nikola Tesla produced an aerial device which is worth mentioning. It was patented on May 21st 1901 as an “Apparatus for the Utilisation of Radiant Energy”, US Patent number 685,957.

The device appears simple but Tesla states that the capacitor needs to be “of considerable electrostatic capacity” and he recommends using the best quality mica to construct it as described in his 1897 patent No. 577,671. The circuit draws power via an insulated, shiny metal plate. The insulation could be spray-on plastic. The larger the plate, the greater the energy pick-up. The higher the plate is elevated, the greater the pick-up.

This system of Tesla’s picks up energy day and night. The capacitor gets charged up and a vibrating switch repeatedly discharges the capacitor into the step-down transformer. The transformer lowers the voltage and raises the current available and the output is then used to power the electrical load.
It seems probable that this device operates primarily from static electricity, which some people believe is a manifestation of the zero-point energy field. Tesla’s equipment might well operate when fed by a motor-driven Wimshurst machine instead of a large aerial plate. Details of home-built Wimshurst equipment are available in the book ‘Homemade Lightning’ by R.A. Ford, ISBN 0-07-021528-6.

However, it should be understood that Tesla described two different forms of energy pick-up. The first is static electricity, picked up from very slight interaction of the pick-up plate with the zero-point energy field flowing through it, and the other being pick-up of dynamic radiant energy events, typically from lightning strikes. At a casual glance, the average person would not consider lightning as being a viable source of energy, but this is not the case as there are about two hundred lightning strikes per second - mainly in the tropics - and what is generally not understood is that they are radiant energy events and their effects are felt instantly everywhere on earth as transmissions through the zero-point energy field are instantaneous at any distance. To clarify the situation a little more, here are two of Tesla’s patents, one on pick-up of the static field which Tesla remarks appears to be unlimited in voltage, and one patent on pick-up of dynamic energy.

This is a slightly re-worded copy of this patent, as some words have changed their meaning since this patent was issued. If you wish to see the original, then http://www.freepatentsonline.com will allow you to download a copy without any charge.

Patent US 685,957  5th November 1901  Inventor: Nikola Tesla

APPARATUS FOR THE UTILISATION OF RADIANT ENERGY

To all whom it may concern:
Be it known that I, Nikola Tesla, a citizen of the Unites States, residing at the borough of Manhattan, in the city, county and State of New York, have invented certain new and useful improvements in Apparatus for the Utilisation of Radiant Energy, of which the following is a specification, reference being had to the drawings accompanying and forming a part of the same.

It is well known that certain radiations - such as those of ultra-violet light, cathodic, Roentgen rays, or the like - possess the property of charging and discharging conductors of electricity, the discharge being particularly noticeable when the conductor upon which the rays impinge is negatively electrified. These radiations are generally considered to be ether vibrations of extremely small wave lengths, and in explanation of the phenomena noted, it has been assumed by some authorities that they ionise, or render conducting, the atmosphere through which they are propagated. However, my own experiments and observations lead me to conclusions more in accord with the theory heretofore advanced by me that sources of such radiant energy throw off with great velocity, minute particles of matter which are strongly electrified, and therefore capable of charging an electrical conductor, or, even if not so, may at any rate discharge an electrified conductor, either by bodily carrying off its charge or otherwise.

My present application is based upon a discovery which I have made that when rays or radiations of the above kind are permitted to fall upon an insulated conducting-body connected to one of the terminals of a capacitor, while the other terminal of the capacitor is made to receive or carry away electricity, a current flows into the capacitor so long as the insulated body is exposed to the rays, and under the conditions specified below, an indefinite accumulation of electrical energy in the capacitor takes place. After a suitable time interval during which the rays are allowed to act, this energy may manifest itself in a powerful discharge, which may be used for the operation or control of mechanical or electrical devices, or rendered useful in many other ways.

In applying my discovery, I provide a capacitor, preferably of considerable electrostatic capacity, and connect one of its terminals to an insulated metal plate or other conducting-body exposed to the rays or streams of radiant matter. It is very important, particularly in view of the fact that electrical energy is generally supplied to the capacitor at a very slow rate, to construct the capacitor with the greatest care. I prefer to use the best quality of mica as the dielectric, taking every possible precaution in insulating the armatures, so that the instrument may withstand great electrical pressures without leaking and may leave no perceptible electrification when discharging instantaneously. In practice, I have found that the best results are obtained with capacitors treated in the manner described in Patent 577,671 granted to me on 23rd February 1897. Obviously, the above precautions should be the more rigorously observed the slower the rate of charging and the smaller the time interval during which the energy is allowed to accumulate in the capacitor. The insulated plate or conducting-body should present to the rays or streams of matter, as large a surface as is practical, I having ascertained that the amount of energy conveyed to it per unit of time is, under otherwise identical conditions, proportional to the area exposed, or nearly so. Furthermore, the surface should be clean and preferably highly polished or amalgamated. The second terminal or armature of the capacitor may be connected to one of the poles of a battery or other source of
electricity, or to any conducting body or object whatever of such properties or so conditioned that by its means, electricity of the required sign will be supplied to the terminal. A simple way of supplying positive or negative electricity to the terminal is to connect it to an insulated conductor supported at some height in the atmosphere, or to a grounded conductor, the former, as is well known, furnishing positive, and the latter negative electricity. As the rays or supposed streams of matter generally convey a positive charge to the first terminal of the capacitor mentioned above, I usually connect the second terminal of the capacitor to the ground, this being the most convenient way of obtaining negative electricity, dispensing with the necessity of providing an artificial source. In order to use the energy collected in the capacitor for any useful purpose, I also connect to the capacitor terminals, a circuit containing an instrument or apparatus which it is desired to operate, and another instrument or device for alternately closing and opening the circuit. This latter device can be any form of circuit-controller with fixed or moveable parts or electrodes, which may be actuated either by the stored energy or by independent means.

My discovery will be more fully understood from the following description and drawings, where Fig.1 is a diagram showing the general arrangement of the apparatus as usually employed.

Fig.1

Fig.2 is a similar diagram, illustrating in more detail, typical forms of the devices or elements used in practice.

Fig.2

Fig.3 and Fig.4 are diagrams of modified arrangements suitable for special purposes.

Fig.3
Fig. 1 shows the simplest form, in which \( C \) is the capacitor, \( P \) the insulated plate or conducting-body which is exposed to the rays, and \( P' \) another plate or conductor which is grounded, all being connected in series as shown. The terminals \( T \) and \( T' \) of the capacitor \( C \) are also connected to a circuit which contains a device \( R \) which is to be operated, and a circuit-controlling device \( d \) as described above.

The apparatus being arranged as shown, it will be found that when the radiation of the sun, or any other source capable of producing the effects described above, fall on plate \( P \), there will be an accumulation of energy in capacitor \( C \). I believe that this phenomenon is best explained as follows: The sun, as well as other sources of radiant energy, throws off minute particles of positively electrified matter, which striking plate \( P \), create an electrical charge on it. The opposite terminal of the capacitor being connected to the ground, which can be considered to be a vast reservoir of negative electricity, a feeble current flows continuously into the capacitor, and since these supposed particles are of an inconceivably small radius or curvature, and consequently, charged to a very high voltage, this charging of the capacitor may continue as I have actually observed, almost indefinitely, even to the point of rupturing the dielectric. If the device \( d \) be of such character that it will operate to close the circuit in which it is included when the capacitor voltage has reached a certain level, then the accumulated charge will pass through the circuit, operating the receiver \( R \).

In illustration of this effect, Fig. 2 shows the same general arrangement as in Fig. 1, and the device \( d \) is shown composed of two very thin conducting plates \( t \) and \( t' \) which are free to move and placed very close to each other. The freedom of movement can be either through the flexibility of the plates or through the character of their support. To improve their action they should be enclosed in a housing which can have the air removed from it.
The plates t and t’ are connected in series in a working circuit which includes a suitable receiver, which in this example is shown as an electromagnet M, a moveable armature a, a spring b, and a ratchet wheel w, provided with a spring-pawl r, which is pivoted to armature a as illustrated. When the radiation falls on plate P, a current flows into the capacitor until its voltage causes the plates t and t’ to be attracted together, closing the circuit and energising the magnet M, causing it to draw down the armature a and cause a partial rotation of the ratchet wheel w. When the current flow stops, the armature is retracted by the spring b, without, however, moving the wheel w. With the stoppage of the current, the plates t and t’ cease to be attracted and separate, thus restoring the circuit to its original condition.

Fig.3 shows a modified form of apparatus used in connection with an artificial source of radiant energy, which in this case may be an arc emitting copious ultra-violet rays. A suitable reflector may be provided for concentrating and directing the radiation. A magnet R and circuit-controller d are arranged as in the previous figures, but in this case, instead of performing the whole of the work, the magnet performs the task of alternately opening and closing a local circuit, containing a source of current B and a receiving or translating device D. The controller d may, if desired, consist of two fixed electrodes separated by a minute air gap or weak dielectric film which breaks down more or less suddenly when a definite voltage difference is reached at the terminals of the capacitor, and returns to its original state when the discharge occurs.

Still another modification is shown in Fig.4, in which S, the source of radiant energy is a special form of Roentgen tube devised by me, having only one terminal k, generally of aluminium, in the form of half a sphere, with a plain polished surface on the front side, from which the streams are thrown off. It may be excited by attaching it to one of the terminals of any generator with sufficiently high electromotive force; but whatever apparatus is used, it is important that the tube has the air inside it removed to a high degree, otherwise it might prove to be entirely ineffective. The working, or discharge circuit connected to the terminals T and T’ of the capacitor, includes, in this case, the primary winding p of a transformer, and a circuit-controller comprised of a fixed terminal or brush t and a moveable terminal t’ in the shape of a wheel, with conducting and insulating segments, which may be rotated at an arbitrary speed by any suitable means. In inductive relation to the primary winding p, is a secondary winding s, usually of a much greater number of turns, to the ends of which is connected a receiver R. The terminals of the capacitor being connected as shown, one to an insulated plate P and the other to a grounded plate P’. When the tube S is excited, rays or streams of matter are emitted from it and these convey a positive charge to the plate P and capacitor terminal T, while the capacitor terminal T’ is continuously receiving negative electricity from plate P’. As already explained, this results in an accumulation of electrical energy in the capacitor, and this continues as long as the circuit including the primary winding p is interrupted. Whenever the circuit is closed by the rotation of the terminal t’, the stored energy is discharged through the primary winding p, giving rise to induced currents in the secondary winding s, which operates the receiver R.
It is clear from what has been stated above, that if the terminal \( T' \) is connected to a plate supplying positive instead of negative electricity, then the rays should convey negative electricity to plate \( P \). The source \( S \) may be any form of Roentgen or Leonard tube, but it is obvious from the theory of action that in order to be very effective, the impulses exciting it should be wholly, or mainly of one sign. If ordinary symmetrical alternating currents are employed, then provision should be made for allowing the rays to fall on plate \( P \) only during those periods when they can produce the desired result. Obviously, if the source radiation is stopped or intercepted, or the intensity varied in any manner such as periodically interrupting or rhythmically varying the current exciting the source, there will be corresponding changes in the action upon the receiver \( R \) and thus signals may be transmitted and many other useful effects produced. Further, it will be understood that any form of circuit-closer which will respond, or be set in operation when a predetermined amount of energy is stored in the capacitor, may be used instead of the device already described in connection with Fig.2.

The second patent requires the equipment to be tuned to one quarter of the wavelength of the energy pulses being collected. This patent shows a transmission method as well as a receiving method, but our main concern here is the receiving section shown on the right of the diagram as that can receive naturally occurring energy pulses in the environment and so provides free usable energy.

As it may be a little difficult to visualise the coil arrangement in this patent as many people are familiar with the "Tesla Coil" arrangement where a few turns of thick wire or copper tubing are used as a winding placed around an ordinary cylindrical coil, much like, this illustration from Tesla's patent US 568,178:

![Illustration of Tesla's pancake coil](image)

In this case it should be understood that Tesla is speaking about his flat "pancake" coil design and not the well-known Tesla Coil configuration.

Patent US 649,621

15th May 1900

Inventor: Nikola Tesla

**APPARATUS FOR THE TRANSMISSION OF ELECTRICAL ENERGY**

To all whom it may concern:

Be it known that I, Nikola Tesla, a citizen of the Unites States, residing at the borough of Manhattan, in the city, county and State of New York, have invented certain new and useful improvements in Apparatus for the Transmission of Electrical Energy, of which the following is a specification, reference being had to the drawing accompanying and forming a part of the same.
This application is a division of an application filed by me on 2nd September 1897, US 650,343 entitled "Systems of Transmission of Electrical Energy" and is based on new and useful features and combinations of apparatus shown and described in that patent application.

This invention comprises a transmitting coil or conductor in which electrical currents or oscillations are produced and which is arranged to cause these currents or oscillations to be propagated by conduction through the natural medium from one location to a remote location, and a receiving coil or conductor adapted to be excited by the oscillations or currents propagated by the transmitter.

This apparatus is shown in the accompanying diagram where A is a coil, generally of many turns and of a very large diameter, wound in spiral form, either around a magnetic core or not as may be desired. C is a second coil formed by a conductor of much larger size and smaller length, wound around and in proximity to coil A.

The apparatus at one point is used as a transmitter, the coil A in this case forming a high-voltage secondary of a transformer, and the coil C the primary which operates at a much lower voltage. The source of current for the primary winding is marked G. One terminal of the secondary winding A is at the centre of the spiral coil, and from this terminal the current is led by a conductor B to a terminal D, preferably of large surface, formed or maintained by such means as a balloon at an elevation suitable for the purpose of transmission. The other terminal of the secondary winding A is connected to earth, and if desired, to the primary winding also in order that the primary winding may also be at substantially the same voltage as the adjacent portions of the secondary winding, thus ensuring safety.

At the receiving station, a transformer of similar construction is used, but in this case the coil A' constitutes the primary winding and the shorter coil C' is the secondary winding. In this receiving circuit, lamps L, motors M, or other devices for using this current, are connected. The elevated terminal D' connects with the centre of the coil A' and the other terminal is connected to earth and preferably, also, to the coil C' again for safety reasons as mentioned above.
The length of the thin wire coil in each transformer should be approximately one quarter of the wave length of the electric disturbance in the circuit, this estimate being based on the velocity of propagation of the disturbance through the coil itself and the circuit with which it is designed to be used. By way of illustration, if the rate at which the current flows through the circuit containing the coil is 185,000 miles per second, then a frequency of 925 Hz would maintain 925 stationary nodes in a circuit 185,000 miles long and each wave would be 200 miles in length.

For such a low frequency, which would only be resorted to when it is indispensable for the operation of ordinary motors, I would use a secondary winding wound from a wire 50 miles in length. By adjusting the length of wire in the secondary winding, the points of highest voltage are made to coincide with the elevated terminals D and D', and it should be understood that whatever wire length is chosen, this length requirement should be complied with in order to get the best possible results.

It will be readily understood that when these relationships exist, the best conditions for resonance between the transmitting and receiving circuits are attained and owing to the fact that the points of highest voltage in the coils A and A' are coincident with the elevated terminals, the maximum current flow will take place in the two coils and this implies that the capacitance and inductance in each of the circuits have the values which produce the most perfect synchronism with the oscillations.

When the source of current G is in operation and produces rapidly pulsating or oscillating currents in the circuit of coil C, corresponding induced currents of very much higher voltage are generated in the secondary coil A, and since the voltage in that coil gradually increases with the number of turns towards the centre, and the voltage difference between adjacent turns is comparatively small, a very high voltage is generated, which would not be possible with ordinary coils.

As the main objective is to produce a current with excessively high voltage, this objective is facilitated by using a current in the primary winding which has a very considerable frequency, but that frequency is in a large measure, arbitrary, because if the voltage is sufficiently high and the terminals of the coils be kept at the proper height where the atmosphere is rarefied, the stratum of air will serve as a conducting medium with even less resistance then through an ordinary conductor.

As to the elevation of terminals D and D', it is obvious that this is a matter which will be determined by a number of things, such as the amount and the quality of the work to be performed, the condition of the atmosphere and the character of the surrounding countryside. Thus, if there are high mountains in the vicinity, then the terminals should be at a greater height, and generally, they should be at an altitude much greater than that of the highest objects near them. Since, by the means described, practically any voltage which is desired may be produced, the currents through the air strata may be very small, thus reducing the loss in the air.

The apparatus at the receiving station responds to the currents propagated by the transmitter in a manner which will be well understood from the description above. The primary circuit of the receiver - that is, the thin wire coil A' - is excited by the currents propagated by conduction through the intervening natural medium between it and the transmitter, and these currents induce in the secondary coil C', other currents which are used to operate the devices connected to that circuit.

Obviously, the receiving coils, transformers, or other apparatus may be moveable - as for instance, when they are carried by a vessel floating in the air or by a ship at sea. In the former case, the connection of one terminal of the receiving apparatus to the ground might not be permanent, but might be intermittently or inductively established.

It should be noted that Tesla's suggestion of using the conductive envelope of a specially constructed balloon as a good method of increasing the active area of the elevated receiving plate, is one that was taken up by Hermann Plauson when he was building power stations operating on naturally occurring energy.

Jes Ascanius' Version of Nikola Tesla's Aerial System.

This sort of information may seem confusing and maybe a little too technical for you, so let me tell you about the practical and useful applications used by Jes Ascanius, a Danish developer, to whom thanks is due for sharing his design. Initially, he set up a system to charge his mobile phone battery overnight from an aerial. Then he went on to produce a full-size Tesla Aerial System as described at the start of this chapter. Let's start with the very simple system and progress from that to the more powerful arrangements.

The initial circuit uses one strand of solid wire which rises vertically to a 700 mm diameter drum where there are some twenty turns. The arrangement is like this:
The aerial wire is several metres long, and in the prototype, was supported by (and insulated from) the eaves of a house. The aerial should be vertical or near vertical and a proper earth connection provided by driving a metal rod into the ground or connecting a wire to a metal plate and burying the plate in the ground as a good electrical connection is needed here. The earth connection used here is a 12 mm copper pipe 3 metres long, driven into the ground and the ground around it saturated with water:

The wire used to connect with the earthing rod is very important and should not be less than 8 swg copper wire, that is, 4 mm diameter and 13 sq. mm. cross-sectional area. As with all free-energy devices, the exact constructional details are vital.

The diodes used are germanium 1N34 or 1N34a which are particularly suited to this application. Ceramic disc types are recommended for the 200 nF capacitors. The prototype build looked like this:
Now, consider this circuit as described, to be one modular building block which can lead to unlimited power from an aerial. I will represent the circuit shown above as a rectangle, showing the above circuit as:

While it is possible to use more than one module with the aerial to get more power, the Danish developer then switched to the full-blown Tesla arrangement by attaching a 600 x 800 x 2 mm aluminium plate inside the sloping roof of his house:

The plate being suspended using nylon cord to prevent it touching the roof or anything else:
The plate is positioned between 3 and 3.5 metres (10 to 12 feet) above the ground and the attachment to the plate is also heavy-duty 8 swg cable:

The cable is connected to the aluminium plate using a brass bolt and nuts which the builder thinks may be significant, quite apart from avoiding any galvanitic connection to the circuit. The cable is then run vertically downwards to the circuit. For this arrangement a second earthing point is also used. This is a galvanised iron pipe 3 metres long, driven vertically into the ground which is saturated with water. The second earth is 2 metres away from the first earth and there is no known significance in the use of an iron pipe as it was used because it was to hand at the time.

This arrangement provides serious power, enough to cause injury to, or kill a careless human. With two modules, it will light an LED very brightly, driving it to 2.6 volts. If the LED is removed, then the voltage climbs to about twenty volts and is easily sufficient to charge a 12V battery or battery bank although that takes time. With twenty modules a 12V battery can be charged over night. It is estimated that with two hundred modules, the power would be sufficient to power a household although that has not yet been done. It should be borne in mind that each module is easy and cheap to make, so arranging for a stack of them where additional modules can be added at a later date for more power, is an ideal arrangement. The circuit is like this:

This circuit looks completely mad as the aerial input to the circuit appears to be directly short-circuited by the second earth connection. In spite of this, the circuit works very well when connected this way. Additional modules can be added without any known limit. Increased power can be had by either raising the aluminium plate higher above the ground, to say, 10 metres (33 feet), or by adding one or more additional aerial plates. As you
have a good aerial connected through to a very good earth, there has to be the possibility of the equipment being hit by lightning, and so it is recommended that a protective spark-gap is installed between the aerial and the earth, close to the circuit, so that if high-voltage is suddenly applied to the aerial, the spark gap will fire and shunt the excess power through to the earth. Alternatively, possibly a better solution is to install a standard lightning rod system a few metres away from the aerial and a metre or two higher up, so that it forms a more attractive point for a lightning strike.

Further experimentation has shown that altering the connection point for the aerial has a significant effect on the results. If the connection is made at the mid point between the aerial plate and the earth connection, it produces a greater output:

With this arrangement a single module produces around 30 volts while the original method of connecting near the earth was giving about 26 volts with two modules. Jes Ascanius has carried out further experimentation and he states that diodes with response times under 30 milliseconds produce a greater output and he recommends the use of BYV27 diodes which have a 200-volt 25nS rating as he gets three times the output from them. He also recommends using them in Joule Thief circuits.

Dragan Kljajic has been experimenting with this circuit and has started by building many of these modules on a printed circuit board like this:
Using two of these boards, Dragan is pulling 96 watts continuously from his aerial plate. He intends to extend this arrangement much further, but is being hindered at present by a local civil war.

Here is a forum: [http://www.energeticforum.com/renewable-energy/10947-jes-ascanius-radiant-collector.html](http://www.energeticforum.com/renewable-energy/10947-jes-ascanius-radiant-collector.html) where some builders of this system share comments. One comment is that there is an increased risk of a lightning strike where you have an earthed aerial, and so it is advisable not to place the aerial plate inside a house, but perhaps suspended between two trees. Also, using a car spark plug connected across the module set can protect against lightning strikes damaging the circuitry.

As a result of queries, Jes stresses the following points:

1. The plate **must** be high off the ground.
2. The plate **must** be polished and insulated.
3. The wire **must** be single-strand solid wire.
4. There **must not** be any part of the wire above the circuit, which is not insulated.

He further comments: you can use aluminium foil and cling film to make many collector plates 0.4 m x 5 m and connect them close together to feed the aerial wire. Remember, no uninsulated wire anywhere. Any queries should be asked on the forum shown above.

**A modification** of this circuit of Jes Ascanius’ by a developer who prefers to remain anonymous, doubles the output of each module by adding a mirror image of the circuit like this:

As can be seen, the addition is of four diodes and two capacitors. Presumably, using BYV27 diodes rather that 1N34 diodes would create a further enhanced output.

**Thomas Henry Moray’s Aerial System.**

In this field, Thomas Henry Moray is outstanding. By 1936 he had developed a piece of apparatus which was capable of putting out high power with no human-generated input power at all.
Moray’s equipment is said to have contained a germanium diode which he built himself in the days before solid-state devices became readily available. The equipment was examined and tested many times. On dozens of occasions, he demonstrated the equipment driving a bank of twenty 150W bulbs, plus a 600W heater, plus a 575W iron (a total of 4.175 kW). The power picked up by this device needed only small diameter wires and had characteristics different from conventional electricity. One demonstration which was repeated many times, was to show that the output power circuit could be broken and a sheet of ordinary glass placed between the severed ends of the wire, without disrupting the supply. This type of power is called “Cold electricity” because thin wires carrying major power loads, do not overheat. This form of energy is said to flow in waves which surround the wires of a circuit and not actually through the wires at all. Unlike conventional electricity, it does not use electrons for transmission and that is why it can continue through a sheet of glass which would stop conventional electricity dead in its tracks.

On one occasion, Moray took his equipment away from all urban areas to a place chosen at random by a critic. He then set up the equipment and demonstrated the power output, well away from any man-generated electrical induction. He disconnected the aerial and showed that the power output stopped immediately. He connected the aerial again to generate the output as before. He then disconnected the earth connection which stopped the output again. When the earth wire was connected again, the output power returned. He found that the power output level fell somewhat at night. The aerial used in his demonstrations was reported to be like this:

From which it can be seen that even a relatively short aerial wire suspended not far from the ground, is capable of collecting substantial amounts of usable electrical power. The earth used in the remote demonstrations was a length of gas pipe which was hammered into the ground. It was noted that as each hammer blow drove the pipe deeper into the earth, the light bulbs (which formed the electrical load) shone more brightly, indicating that the quality of the earth connection is very important when serious power is being drawn from an aerial.
Thomas developed various versions of the device, the latest of which did not need the aerial or earth connections, weighed 60 pounds and had an output of 50 kilowatts. This device was tested in both an aeroplane and a submarine, thus showing the device to be fully self-contained and portable. It was also tested in locations which were fully shielded from electromagnetic radiation.

With his later devices, Moray leaves the area of aeria ls and moves into the same category as Barbosa and Leal, those two Brazilian men extracting 192 kilowatts of power directly from the ground. If you read Moray’s book “The Sea of Energy in which the Earth Floats” (http://www.free-energy-info.tuks.nl/P26.pdf) you will discover that Moray moved past the scientific thinking of his day, stating that the Earth is being bombarded with cosmic energy particles which cause atoms to change from matter into energy, enter the aether and there revert to matter again. This process is governed by frequency. Moray developed energy diodes which act like electrical diodes on the energy flow of the aether. He used a chain of these ‘tubes’. Each tube was tuned to one of the harmonics of the oscillating frequency of the aether. Each tube produced lower frequency waves and the following tube is tuned to those waves and is driven by a resonant harmonic of the aether oscillations, thus producing a device with no need of any power input from the user. Also, the aerial was replaced by a small, internal copper plate. So in true aerial mode – four kilowatts. In earth-only mode – 50 kilowatts. Moray’s ideas are supported by the work and books by Gustav Le Bon (http://www.free-energy-info.tuks.nl/The_Evolution_of_Matter.pdf and http://www.free-energy-info.tuks.nl/The_Evolution_of_Forces.pdf).

Moray was shot and wounded in an assassination attempt in his laboratory. This caused him to change the glass in his car to bullet-proof glass. He was threatened many times. His demonstration equipment was smashed with a hammer. When threats were made against his family, he stopped rebuilding his equipment and appeared to have turned his attentions to other things, producing a device for ‘therapeutic’ medical treatment.

In his book “The Energy Machine of T. Henry Moray”, Moray B. King provides more information on this system. He states that Moray was refused a patent on the grounds that the examiner couldn’t see how the device could output so much power when the valve cathodes were not heated. Moray was granted US Patent 2,460,707 on 1st February 1949 for an Electrotherapeutic Apparatus, in which he included the specification for the three valves used in his power device, apparently because he wanted them to be covered by a patent. As far as can be seen, the valve shown here is an oscillator tube. Moray claimed that this tube had the very high capacitance of 1 Farad when running at its resonant frequency. Moray liked to use powdered quartz as a dielectric in the capacitors which he made, and he had a habit of mixing in radium salts and uranium ores with the quartz. These materials may well be important in producing ionisation in these tubes and that ionisation may well be important in tapping the energy field.
The tube shown above has a six-layer capacitor formed from two U-shaped circular metal rings with the space between them filled with a dielectric material. The plates are shown in red and blue, while the dielectric is shown in green. Inside the capacitor, there is a separate ring of dielectric material (possibly made from a different material) and an inside ring of corrugated metal to form an ion brush-discharge electrode. The capacitor and electrode connections are taken to pins in the base of the tube.

Quartz is suggested for the material of the outer covering of the tube and the wire element numbered 79 in the diagram is said to be a heating element intended to be powered by a low-voltage current source. However, as Moray had an earlier patent application refused on the grounds that there was no heating element in his tubes, it is distinctly possible that the heating element shown here is spurious, and drawn solely to avoid rejection by the examiners. In his patent, Moray refers to the capacitor in this tube as a "sparking" capacitor, so he may have been driving it with excessively high voltages which caused repeated breakdown of the capacitor material.
The tube of Fig.16 above, uses a different technique where an X-ray tube is used to bombard a corrugated electrode through a screen containing an X-ray window. It is thought that a brief burst of X-rays was used to trigger very short, sharp bursts of ions between the anode and cathode of the tube and these pick up extra energy with every burst.

An alternative version of this tube is shown in Fig.18 below. Here the construction is rather similar but instead of an X-ray window, a lens and reflector are used to cause the ionisation of the switching channel between the anode and cathode. In both tubes, the corrugated electrode supports a corona build-up just prior to the short X-ray switching pulse, and it is thought that the ions contribute to the intensity of the resulting pulses which emerge from the tube. Very short uni-directional pulses are capable of causing conditions under which additional energy can be picked up. From where does this extra energy come? In 1873, James Clerk Maxwell published his “Treatise on Electricity and Magnetism” and in it he pointed out that the vacuum contains a considerable amount of energy (Vol. 2, p. 472 and 473). John Archibald Wheeler of Princeton University, a leading physicist who worked on the US atomic bomb project, has calculated the flux density of the vacuum. Applying Einstein's E=mc² formula indicates that there is enough energy in every 1 cc of “empty” space, to create all of the matter in the visible universe which can be seen with our most powerful telescopes. That amount of energy is so great as to be beyond imagining. This energy field is referred to as “Universal Energy”, “Cosmic Energy” or “Zero Point Energy”. At this time, we do not have any instrument which responds directly to this energy and so it is almost impossible to measure.

The existence of this energy field is now widely accepted by mainstream science and it is borne out by the situation found at quantum levels. It is generally thought that this energy is chaotic in form and for useful energy to be drawn from it, it needs to be restructured into a coherent form. It appears that uni-directional electromagnetic pulses of one millisecond or less, can be used to cause the necessary restructuring as they generate an outward coherent wave of radiant energy, from which energy can be extracted for use in most electrical devices, if a suitable receptor system is used. Tom Bearden states that at the quantum level, the seething energy of this field appears continuously as positive and negative charges. As these are evenly distributed, the net charge at any point is always zero. If a “dipole” (two opposite charges near each other) is created anywhere, then it polarises the energy field disrupting the previously even distribution of charges and causing massive streams of energy to radiate outwards from the dipole.

A voltage pulse acts as a dipole, provided the voltage rise is fast enough, and that is what causes a wave of radiant energy fanning out from the location of the voltage pulse. Batteries and magnets create continuous dipoles and so cause the local quantum energy field to send out continuous streams of massive power which can be utilised if (and only if) you know how to do it. The search for mechanisms to capture and use even a tiny fraction of these energy streams is what the “free-energy” field of research is all about. Some people say that there is no such thing as “free-energy” because you have to pay for the device which captures it. That is like taking a bus trip to a car dealership where they are giving away new cars, and saying that your new car was not a “free” car because you had to pay a bus fare to reach the car dealership.
Moray King suggests that the circuit used by Thomas Henry Moray was as follows:

There can be little doubt that Thomas Henry Moray built several versions of his apparatus, each of which produced output power well in excess of any input power needed. It seems highly likely that most of them used no input power whatsoever, and if there were any others, they will have been powered by a tiny fraction of the output power. If mild radioactive material was used as described, then the output power could in no way be attributed to that source alone, since the output power was thousands of time greater than any power available from the radioactive materials.

It is perhaps time to explain a little more about voltage, power and current. We have been raised with the notion that it is necessary to “burn” a fuel to get power, that batteries “run down” when used and that you have to keep turning the shaft of an electrical generator to be able to draw current from it. These things are not actually true. The relatively recent field of Quantum Mechanics shows that if a charge, such as an electron has, is positioned in what is supposed to be “empty” space, it is not alone. The “empty” space is actually seething with energy, to the extent that “virtual” particles are popping into existence for a fraction of a second and then disappearing again. They are called “virtual” because they exist for such a short time.

Because of the negative charge of the electron, the particles appearing and disappearing around it will all be positive in charge. The electron has “polarised” the space around itself because it has a charge. The instant that a positive “virtual” particle appears, there are two charges near each other - minus on the electron and plus on the particle. When you have two opposite charges near each other, they form a “dipole”. Dipoles form a gateway through which energy from the environment flows continuously. An instant later, the particle disappears, but its place is immediately taken by another virtual particle. The result is a continuous stream of energy flowing out from the dipole.
Batteries with their positive and negative terminals are electrical dipoles, so too are generators when the input shaft is spun. Permanent magnets with their North and South poles are magnetic dipoles. Both of these have continuous streams of energy flowing through them. So, why then do batteries run down and lose their charge? The reason is that we power circuits using a closed loop. The energy flowing out of one terminal flows into the opposite terminal and instantly destroys the dipole. A new dipole has to be created every split second if the circuit is to deliver power, and it is that self-destructive method of use which causes the battery to discharge or which needs the generator shaft to be rotated continuously.

If a different operating technique is used, where the dipole is not continuously destroyed, then devices which can provide a continuous stream of energy drawn from our natural environment can be constructed. This is not magic, just the next step in conventional science and engineering. Thomas Henry Moray managed it, initially with an aerial and earth like a crystal set to provide the dipole, his device was able to draw many kilowatts of power from the environment. No fuel was needed, the energy is already there surrounding us all, all of the time. As far as I am aware, nobody has managed to replicate Moray’s device (which was the reason for it being violently suppressed) but knowing that it existed and was repeatedly demonstrated to work perfectly well, is useful in that it shows that it is possible to tap the massive zero-point energy field with a practical, home-constructed device.

Here is a collection of additional items of information gathered from several different sources:

Moray started his experiments with 'the taking of electricity from the ground', as he described it, during the summer of 1909. By autumn 1910 he had sufficient power to operate a small electrical device, and demonstrated his idea to two friends. The early stages of this demonstration consisted of operating a miniature arc light. It soon became clear to him that the energy was not static and that the static of the universe would be of no assistance to him in obtaining the power for which he was searching.

During the Christmas Holidays of 1911, he began to realise fully, that the energy with which he was working, was of an oscillating nature. He also realised that the energy was not coming out of the earth, but instead, was coming to the earth from some outside source. These electrical oscillations in the form of waves were not simple oscillations, but were surging like the waves of the sea, coming continually to the earth but more in the daytime than at night, but always arriving as vibrations from the reservoir of colossal energy out there in space. By this time Moray was able to gather enough power to light a 16-candlepower carbon lamp to about a half of it's capacity, but he did not manage to gain any further improvement until the spring of 1925.

In 1912 Moray was called to go on a mission for the Church of Jesus Christ of Latter-Day Saints, and under a visitor's visa was allowed to enter Sweden during the Exhibition of 1912 in Stockholm. In his notebook, dated November 1, 1913, he included a note saying that he had obtained material from a railroad car at Abisco, Sweden the previous summer, also some more material from the side of a hill. He made electric tests of these materials, taking them home to try each as a detector for his energy machine. Tests indicated that this soft, white stone-like substance might make a good "valve-like detector". This "valve-like detector" is what led him to do research into semi-conductive materials, and from this soft white stone he developed his first valve and the valve which was used in some of his early Radiant Energy devices (silver wire touching a stone can act as a rectifier).

Moray demonstrated that energy was available by its actions on a resistive load, such as a flat-iron or a space heater, and by lighting bulbs. A resistive device acts as a load which is directly proportional to the amount of energy delivered to it. In heating a heater, or lighting a bulb, the number of watts produced can be calculated as equal to the number of watts provided to the device. This energy is fed into a load to give either heat, light, or power. A motor can be operated but it must be designed to run on a high frequency power supply. The Radiant Energy device used an antenna and a ground connected to his solid state Radiant Energy circuit:
The diagram shown above is reproduced from a rough sketch drawn from memory after seeing Moray's circuit diagram. The person who drew it does not understand how the circuit works, so please treat this diagram as being just an overall suggestion as to what Moray's circuit might have been like. It is actually much more likely that is was a cascade of pairs of tank circuits containing Moray's valve, each pair being one series tank circuit followed by one parallel tank circuit, the oscillating frequency dropping with each tank pair and the output power rising with each tank pair. Moray's circuit was started oscillating by stroking the U-shaped coil with a permanent magnet for a few seconds, and when the circuit started operating, then switch 'S' was closed, effectively removing the U-shaped coil from the circuit.

Moray was able to demonstrate that none of the output energy came from within his device. Internally the device was electrically dead when it had not been connected and tuned to the antenna. When his device was set up, he could connect it to an antenna and ground, and by priming it first and then tuning it as he primed it, the device would draw in electrical energy. This high frequency electrical energy produced up to 250,000 volts and it powered a brighter light than witnesses had ever seen before. Heavy loads could be connected to the device without dimming the lights already connected to it. This device worked many miles from any known source of electrical energy such as power transmission lines or radio signals. The device produced up to 50,000 watts of power and worked for long periods of time.

Moray initially assumed that this energy was electromagnetic in nature however, he never claimed that it was. He assumed at first that this energy came from the earth but later he believed it was flowing in from the universe. Finally he began to believe that it was present throughout all space, intermolecular space as well as terrestrial and celestial space. He did not necessarily understand how his detectors operated, only that if he built the device very carefully according to his calculations it would work. He was able to demonstrate the existence of an energy that today, though it has not been identified or proven, has been theorised by many researchers.

The largest instrument was about 6 inches high, circular in shape and about 8 inches in diameter. We went out on the roof of the chicken coop carrying the device on a small drafting board, erected an antenna upon the roof of the coop, the antenna being about 100 feet from the house. We pulled the main line switches in the house before going out upon the roof. Mr Judd had Moray move the drafting board from place to place and he also examined the inside of the coop for hidden equipment. The machine was then assembled in his presence and the device was started. Mr Judd timed me to see how long it would take to bring get the light operating. I was able to light the CGE lamp to its full brightness and to heat an old-style Hotpoint electric flat iron to sizzling point, which required 655 watts. Mr Judd asked for the antenna to be disconnected. When this was done, the light went out. The aerial was connected again and the light reappeared. We drove a new grounding rod at a spot selected by Mr Judd, made a connection to the new grounding point and the light burned dim, but came brighter and brighter as the new grounding rod was driven deeper and deeper into the ground.

If the ground or antenna is left disconnected for too long a time, the device becomes electrically dead and must be retuned in order to regain the energy flow. Dr Eyring found no fault with the demonstration and the worst that he could say about it was that it might be induction, but that if Moray would take the device out in the mountains away from all power lines, a distance of three or four miles, and it then operated, he would then acknowledge that it could not be induction and that his theory was wrong.
At last they decided to go up Emigration Canyon, as there are no power lines in that canyon. All three gentlemen were very well satisfied and pleased with what they saw. The antenna wire was put up without any aid or instructions whatever from Mr Moray, except that he suggested that the wire be stretched tighter to prevent so much sag at the centre. This was done and the wire then appeared to clear the ground by about 7 or 8 feet at its lowest point. The ground pipe was of half-inch water pipe consisting of two sections. The lower section was driven further down until it struck a hard object, so about 7 feet of pipe was in the ground.

The antenna wire was insulated from the poles with two glass insulators about 6 inches long and having holes in both ends. A piece of wire about 2 feet long connected each insulator with the pole. The lead-in wire was fastened to the antenna wire at a point about 10 or 15 feet from the east pole. I helped Mr Moray solder the connection. I paced the distance between the two antenna poles and estimated it to be 87 feet. Mr Moray's equipment, apart from the antenna and ground wires, consisted of a brown box about the size of a butter box, another slightly smaller unpainted box, a fibre board box about 6" x 4" x 4", which Mr Moray referred to as containing the tubes, and a metal baseboard about 14" x 4" x 1" containing what appeared to be a magnet at one end, a switch near the middle and a receptacle for an electric light bulb at the other end. There were also several posts for connecting wires on the baseboard.

When all of the wires were connected and everything was ready, Mr Moray began tuning in. Before tuning, he placed the key on the post: he said it would be in contact while the light burnt, but no light appeared. The tuning consisted of stroking the end of a magnet across two metal projections protruding from what I referred to above as being 'a magnet'. After tuning for slightly more than 10 minutes the key was put on the operating post and the light appeared immediately. Mr Moray put the key on the operating post two or three times before during the tuning operation but no light appeared. We allowed the light to burn for 15 minutes. In my opinion, the brilliance of the light coming from the 100-watt bulb, was about 75% as bright as a 100-watt bulb connected to an ordinary house socket. It was an steady light, without fluctuations of any kind.

While the light was burning Mr Moray disconnected the antenna lead-in wire from the apparatus and the light went out. He connected it again and the light appeared. He also disconnected the ground wire and the light went out. He then connected it and the light appeared again.

In another demonstration, Mr Moray opened the device and let everyone see everything except one small part that he placed his hand over and hid in his fist. This part he cut off and put in his vest pocket. Everything else, people were allowed to examine to their hearts' content. "If that part is able to make such power itself, then it's some device and worth selling. Such a battery would be worthwhile", were some of the remarks made.

On several occasions Dr Moray would disconnect the antenna wire momentarily, but not long enough to lose the light. In disconnecting and connecting the antenna wire a flash of electricity could always be seen at the

At a demonstration in 1928, the aerial used was about 200 feet long and positioned about 80 feet above the ground: the wire is a copper cable approximately a quarter of an inch in diameter, and well insulated. The earth connection used was the water pipe in the basement of Dr Moray's home. The device was assembled in a trunk through the sides of which were holes for the connections to ground and to the antenna and for observation; the holes were about one-half inch in diameter. There were two boxes about 10 by 20 by 4 inches, one on top of the other; both were closed and the covers fastened with screws. On the upper box was lying an insulating panel about an inch thick by 15 inches long and 3 inches wide; it was made of slate or hard rubber or some material of similar appearance. On this were two binding posts which could be connected together by a small switch; also mounted on this panel was an object about 2.5 inches square, wrapped in friction tape, from which protrude two poles about 1/4-inch in diameter, apparently of sift iron. Two light bulb sockets were connected in the circuit. In one of these there was a 20-watt bulb, and in the other a 100 watt bulb.

Dr Moray then took a magnet, which was a very broad, short limbed U, and began to stroke one pole of it on the poles in the taped body. Mr Jensen placed his fingers on the binding posts several times, and at last received a rather vigorous shock. Mr Moray then threw the switch and the bulbs lit up. As a further proof that the conversion of the energy was due to the mechanism in the box, Dr Moray hit the table on which the trunk was standing, a moderate blow with a hammer whereupon the light flickered and went off, due to the detector being shaken out of adjustment. The boxes, in which the mechanism had been housed during the test, were opened and the contents examined. There were capacitors, the detector, a transformer, and two tubes in them but nothing else. Nothing that in the least resembled a battery.

It is to be noted that after a total run of 158 hours the device supplied 635 watts; inasmuch as a horsepower is but 746 watts this equals 0.878 of a horsepower or slightly more than 7/8 horsepower. This alone is sufficient to dispose of any suggestion of a battery.
A report from 1929 says: It is now more than 2 years since I first became acquainted with Dr T. H. Moray and the work he is carrying on, and in that time he has demonstrated inventive ability of an exceptional order. Perhaps the most wonderful of his inventions is a device whereby he is able to draw electric power from an antenna. This energy is not derived by induction from power lines, as has been suggested by some, nor is it derived from radio stations, as has been demonstrated by taking the apparatus more than 26 miles from the nearest power line and over a hundred miles from the nearest radio station and showing that it operates just as well as anywhere else.

This device was subjected to an endurance test in which it was operated continuously for a week, and at the end of that time a 100-watt lamp was lighted simultaneously with the heating of a 575 watt standard Hotpoint flat iron, making a total of 675 watts; it is very evident that no batteries could sustain such a drain as this.

He has also invented a very sensitive sound detector whereby it is possible to hear conversations carried on in an ordinary tone of voice at a distance of several blocks. He has also worked out numerous radio hook-ups which eliminate many of the parts now considered necessary for good reception, yet there is no diminution in quality or volume; in fact, there is a notable elimination of interference from static when some of these are used. He has devised a means by which he is able to measure with some degree of accuracy the energy evolved during mental activity; that is, he gets definite, variable deflections of the needle of a sensitive galvanometer which appeared to be related to the vigour of mental activity. There are a great many other equally remarkable things which he has done, such as reducing old rubber from truck tires to the state of a viscous fluid which is readily vulcanisable without the addition of smoke sheet as is necessary with other processes; also a high frequency therapeutic device, and numerous other devices which show great ingenuity.

The 6 lamps are set up in parallel and a small diameter wire is used as the current enters the tube prior to and connecting with the step-down transformer, this takes the very high voltage to the transformer. This voltage will jump across a spark gap of at least six inches. The operating frequency is so high that I have no instrument in my laboratory that is able to measure the amperage or the voltage at this frequency. (Signed, Murray O. Hayes, PhD.).

Dr Milton Marshall was attempting to identify the material that Moray called his "Swedish Stone". Moray described the radio detector which he had developed. He compared it to what was commonly known as the crystal of a crystal set. However, his detector was superior since it could drive a loudspeaker without the use of a battery. He used the most easily demonstrated device, the germanium diode, that worked on the same principle to illustrate how he thought the Radiant Energy Detector worked (Moray originally built the radio simply for the purpose of showing how he was able to pick up radio signals with a solid-state device, producing sufficiently strong signals which could drive a loudspeaker, which was something unheard of in that day. His circuit did not have batteries, and it was very similar to the old crystal-set circuitry.

The device was housed in a wooden box something like 12" by 18", with an antenna and a ground going into it. Wires leading out of the box led to a bank of some forty 100-watt light bulbs and to an electric iron. Moray touched a switch at the top of the box with a hand electrostatic plate and the globes all lit up brilliantly. We all noted that the bulbs burned cold except each had a hot spot about the size of a dime on the top slightly off centre. I also recall that I could turn the lights on and off by approaching and retreating to and from the device, either with my whole body or my hand. If my memory is clear, the machine had to be tuned with a dial to be placed in this condition. (Chester M. Todd, 1971)

In 1938, after examining the transformer of the device, Mr E. G. Jensen stated that he considered that the amount of current which he had seen taken from the device was positive proof that the current developed by or in the machine was different to any in use at that time. This was because the transformer would have burned out if it had been carrying normal current, but the transformer showed no signs of even ever having been warm. He was informed by Dr Hayes that the transformer had been in use under the same loading conditions during many demonstrations in the past.

The "Number 1" capacitor consisted of two small sheets of aluminium of about 30 gauge, separated by and making contact with a piece of one-quarter inch thick plate glass. The plate glass was larger than the aluminium sheets and overlapped them.

The "Number 2" capacitor was a commercial unit manufactured by Igred Condenser & Mfg. Co. and had a capacity of 0.025 mfd.

They were used as shown here:
With the 60 watt lamp and the two capacitors attached to the antenna and the antenna and ground attached to the box containing the Radiant Energy equipment as shown in the sketch, the 100-watt lamp on the secondary or output side was lighted. Unscrewing the 60-watt lamp from its socket caused the 100-watt amp to go out, but it immediately lighted when the 60-watt lamp was screwed into its socket again. The 60-watt lamp did not light. Shorting the antenna and ground by placing a wire across them, caused the 100-watt lamp to go out. Similar shorting with the hands also caused the 100-watt lamp to go out. No electricity could be felt when shorting with the hands. If either the ground or the antenna wires were disconnected from the box, the 100-watt lamp would go out. Neither of the capacitors or the 60-watt lamp on the primary side of the box were necessary but were simply put there to show that the high frequency power will jump or pass through them.

Moray's patent application on this device was filed in 1931 and rejected on a number of grounds. Firstly, "Because no means was provided for causing the cathode to emit an appreciable number of electrons, the current produced in the cathode by the antenna will not heat the cathode to a temperature at which an appreciable number of electrons per second are emitted". In other words, according to Thomas E. Robinson, Commissioner of Patents, a solid state device, such as a transistor, cannot possibly work. Secondly, because "No natural source of electric wave energy is known to the Examiner and proof of the existence of such a source is required". In other words, it was not enough for Moray to demonstrate the effect of the energy source; he also had to identify it, which he could not do. None of the original patent applications that Henry made are any longer available at the US Patent Office. Although their file jackets are there, the contents and applications themselves are gone.

In 1942, Moray attempted to rebuild a Radiant Energy device, using the remaining bit of what was known as the "Swedish Stone". This material, which was the heart of his original RE detector, he had never managed to duplicate, and the shortage of this material limited the amount of power which he could draw. Consequently, in the large unit, he developed a second detector that forced him into extensive research involving nuclear materials and radioactive reactions. He became deeply involved in the study of synthetic radioactivity as described by Gustave LeBon in his book "The Evolution of Matter". The years slipped by and Moray spent most of his time working on what he called the "counter-balance" to eliminate the need for an aerial antenna.

Moray said:
Enough energy is coming to the earth to light over 1,693,600 100-watt lamps for every human being on the earth today. No fuel of any kind need be taken as this energy can be picked-up directly by ocean liners, railroads, airplanes, automobiles, or any form of transportation. Heat, light and power can be made available for use in all kinds of buildings and for all kinds of machinery. An example would be to pump water onto the desert lands, the power source being only a fraction of the weight of any steam plant or any kind of engine in use today and all this at a fraction of the current cost.

The total energy involved in "cosmic" radiations is very large. The mechanism of its generation involves a basic relationship with the total structure and action of the universe. Today it is believed that cosmic radiation consists primarily of protons and some heavier nuclei. At times this cosmic energy packs a wallop of around 100 quadrillion volts. Coming continuously with slight variations in time, the radiations have a uniformly directional isotropy. The earth is, therefore, surrounded in an atmosphere of radiation with cosmic rays coming continually to the earth from all directions, although there may be a slight deflection of the weaker rays by the earth's magnetic field. There is every indication that our sun is not the source of any appreciable amount of this radiation. The origin, therefore, is from the universe as a whole. The total energy of cosmic radiation is more than the entire luminous output of all the stars and nebulae of the universe combined. Unlimited power is being delivered to everyone's doorstep.

The Moray Radiant Energy discovery, using radiations from the cosmos as its power source, gives the greatest amount of energy per pound of equipment of any system known to man. Electrical power through an electric
motor or an electric jet far exceeds any form of energy in any engine in the delivery of power. There is no dead centre of lost motion in an electric motor nor loss of push in an electric jet. Also, the starting torque is much higher in the electrically powered engine than in the combustion engine.

Harnessing cosmic energy is the most practical method yet discovered by man. Furthermore, it is possible to utilise this vast source of energy from the universe without a prime mover at any point on the earth --- on the ground, in the air, on the water, under the water, or even underground. If one considers that an electrical generator is not in the true sense a generator - as electricity is not made by the generator - but is merely an electrical pump, the Moray Radiant Energy device may then be referred to as a cosmic ray pump: that is, a high speed electron oscillator serving as a detector of cosmic radiations which causes a pumping action or surging within its circuitry.

To account for the propagation of heat and light - two of the forms of Radiant Energy - man has postulated the existence of a medium filling all space. But, the transference of the energy of radiant heat and light is not the only evidence in favour of the existence of such a medium. Electric, magnetic, and electromagnetic phenomena and gravitation itself point in the same direction.

Attractions and repulsion take place between electrified bodies, magnets, and circuits conveying electric currents. Large masses may be set in motion in this manner, acquiring kinetic energy. If an electric current is started in any circuit, corresponding induced currents spring up in all very closely neighbouring conductors. To originate a current in any conductor requires the expenditure of energy. How, then, is the energy propagated from the circuit to the conductors? If we believe in the continuity of the propagation of energy - that is, is we believe that when it disappears at one place and reappears at another it must have passed through the intervening space and, therefore, have existed there somehow in the meantime - we are forced to postulate a vehicle for its conveyance form place to place.

When a particle is electrified, what one must first observe is that a certain amount of energy has been spent; work has been done. The result is an electrified state of the particle. The process of electrifying a conductor is, therefore, the storing of energy in some way in or around the conductor in some medium. The work is spent in altering the state of the medium, and when the particle is discharged, the medium returns to its original state, and the store of energy is disengaged. Similarily, a supply of energy is required to maintain an electric current, and the phenomenon arising from the current are manifestations of the presence of this energy in the medium around the circuit. It used to be that an electrified particle or body was supposed to have something called "electricity" residing upon it which caused electrical phenomena. An electric current was regarded as a flow of electricity travelling along a wire (for example), and the energy which appeared at any part of a circuit (if considered at all) was supposed to have been conveyed along the wire by the current. But, the existence of induction and electromagnetic interactions between bodies situated at a distance from each other leads one to look upon the medium around the conductors as playing a very important part in the development of these electrical phenomena. In fact, it is the storehouse of the energy.

It is upon this basis that Maxwell founded his theory of electricity and magnetism, and determined the distribution of the energy in the various parts of an electric field in terms of electric and magnetic forces. The medium around an electrified body is charged with energy and not of an imaginary electric fluid distributed over the electrified body or conductor. When we speak of the charge of an electrified conductor we are referring to the charge of energy in the medium around it, and when we talk of the electric flow or current in the circuit we are referring to the only flow we know of, namely, the flow of energy through the electric field within the wire.

The work in producing the electrification of a conductor is spent on the medium and stored there, probably as energy of motion. To denote this we shall say that the medium around the conductor is polarised, this word being employed to denote that its state or some of its properties have been altered in some manner and to a certain extent depending on the intensity of the charge. If the charge is negative the polarisation is in the opposite sense, the two being related, perhaps, like right-handed and left-handed twists or rotations.

Now consider the case of a body charged alternately, positively and negatively in rapid succession. The positive charge means a positive polarisation of the medium, which begins at the conductor and travels out through space. When the body is discharged the medium is once more set free and resumes its former condition. The negative charge now induces a modification of the medium or polarisation in the opposite sense. The result of alternate charges of opposite sign is that the medium at any point becomes polarised alternately in opposite directions, while waves of opposite polarisations are propagated through space, each carrying energy derived from the source or agent supplying the electrification. Here, then, we have a periodic disturbance of some kind occurring at each point, accompanied by waves of energy travelling outwards from the conductor.

The phenomenon of interference leads to the conclusion that light is the result of periodic disturbances or vibrations of the medium, but as to the nature of these vibrations, as to the exact nature of the periodic changes or what it is that changes them, we possess no knowledge. We know that alternating electric charges are
accompanied by corresponding changes of state or vibrations of the medium, and if the charge is varied periodically and with sufficient rapidity, we have a vibration at each point analogous to, perhaps identical with, that which occurs in the propagation of light - a combination of wave and particle properties. This then is the electromagnetic theory of the luminous vibration.

In the older elastic-solid theory, the light vibrations were supposed to be actual oscillations of the elements or molecules of the medium about their positions of rest, such as takes place when waves of transverse disturbance are propagated through an elastic solid. Such limitation is unwarranted to some extent, but one cannot afford to entirely disregard the particle theory of light either. A combination of the theories has merit. We know that the change, disturbance, vibration, polarisation, or whatever we wish to term it, is periodic and transverse to the direction of propagation. The electromagnetic theory teaches us nothing further as to its nature, but rather asserts that whatever the charge may be, it is the same in kind as that which occurs in the medium when the charge of an electrified body is altered or reversed. It reduces light and heat waves to the same category as waves of electrical polarisation. The only quality of the later required to constitute the former is sufficient rapidity of alteration. These speculations were given the strongest confirmation by experiments of Prof. Hertz many years ago.

When a resilient substance is subjected to strain and then set free, one of two things may happen. The substance may slowly recover from the strain and gradually attain its natural state, or the elastic recoil may carry it past its position of equilibrium and cause it to execute a series of oscillations. Something of the same sort may also occur when an electrified capacitor is discharged. In ordinary language, there may be a continuous flow of electricity in one direction until the discharge is completed, or an oscillating discharge may occur. That is, the first flow may be succeeded by a backrush, as if the first discharge had overrun itself and something like recoil had set in. The capacitor thus becomes more or less charged again in the opposite sense, and a second discharge occurs, accompanied by a second backrush, the oscillation going on until all the energy is either completely radiated or used up in heating the conductors or performing other work.

When capacitors are filled with energy captured by the Moray Radiant Energy device and then discharged through a circuit of proper impedance, reactance and inductance, thereby synchronising the oscillation of the device with those of the universe, electrical inertia is set up. In the reversal of the current, the capacitors are charged, discharged and recharged slowly until the energy stored in them is radiated in kinetic energy through the device, and this energy can be kept alive indefinitely by establishing resonance with the oscillations of the universe.

Considering oscillations from a mechanical, electrical and mathematical point of view, we find that electrical resistance is the same as mechanical friction and current is comparable to mechanical velocity. Inertia and inductance may then be considered analogous terms. In mechanics the greater the inertia of a body, the longer it will stay in motion. In the Radiant Energy device's resistance-inductance-capacity (REC or RLC) circuit, the greater the electrical inductance, the longer the current continues to flow once it is established by synchronisation with cosmic surges.

Expressed mathematically, the equations are the same for electrical or mechanical phenomena. Which means, that \( R < \sqrt{(4L / C)} \), where \( R \) is the resistance in ohms, \( L \) the inductance in henries, and \( C \) the capacitance in farads. When this is true, an oscillatory discharge will occur and a very powerful inductance inertia will assert itself. For low values of \( R \), the frequency of the oscillations can be shown by \( f = 1/2 \pi \sqrt{(CL)} \). The rapidity of the oscillations is governed by the capacitance and inductance.

In the vibrational forces of the universe, we find the key to the source of all energy. How can we utilise this energy for modern industry without being limited to mechanical prime movers is the question. And, the answer may be an energy generator, balanced so as to oscillate in synchronisation with the oscillations of the universe.

Dr Ross Gunn, a civilian scientist for the US Navy, stated years ago that the earth is a huge generator, generating over 200 million amperes of electric current continuously. For example, the aurora borealis is considered to be a very large definite electrical phenomenon produced by the passage of electric charges through the rarefied gases of the higher atmosphere. The earth has since been shown, by Dr Gunn and others, to have a negative charge amounting to 400,000 coulombs. Yet, six feet above the ground the air is charged with more than +200 volts with respect to the ground.

It is known that air conducts electricity away from charged objects. This being true, how does the earth maintain its charge since it is a charged object exposed to the surrounding atmosphere? If the air conducts electricity, the earth's charge must be constantly passing into the atmosphere. And it has been calculated that the earth has a continuous discharge into the atmosphere of 1,800 amperes. At this rate, the earth should lose 90% of its charge into the air in one hour, yet the earth's charge does not diminish. From where does the earth's energy come?

The conversion of matter to energy in the stars is accepted, and, reasoning from what occurs in radioactive disintegration during which energy waves are radiated, one may conclude that energy waves of very high
frequency are sent out from the stars (one of which is our sun). Now, of course, the conversion of energy into matter must equally be accepted.

It has been found that ionisation, which could be the medium for the flow of energy, increases with increasing altitude, instead of decreasing as would be expected. Since the source of energy is the universe, the generation of energy by rotary action and by all prime movers is an effect and not a cause. Oscillatory energy action, be it in a Leyden jar, another man-made capacitor, or in what we may call natural capacitors, always behaves the same. The oscillations will continue until they have reach their cycle of height and then there will be a backrush returning to where the oscillations originated. Every oscillation, whether large or small, is completed during the same interval of time. These oscillations all prove the same great fact, that they are governed by the same cycle of time, completed during the same interval of time. Waves of energy have a regular beat note, coming and going as the waves of the sea, but in a very definite mathematical order - coming to the earth from every direction with a definite rhythm.

Energy has a definite elastic or resilient rigidity and density, which is subject to displacement and strain. When strain is removed, the medium will spring back to its old position and beyond, surging back and forth, and will continue to oscillate until the original pressure is used up. If the internal impedance is too great, there will be no oscillations, but it will merely slide back in a dead beat to its unrestrained state.

By cutting down resistance to a minimum and synchronising the resilient ionic actions of the Moray device with the wave actions of the universe, periods of oscillation can be made to come quicker and quicker until inertia asserts itself, thus lengthening out the time of final recovery. This is done by carrying the recoil beyond the natural oscillations and prolonging the vibrations by capturing the in oscillatory action. When the recovery becomes distinctly oscillatory, a harmonic pattern is initiated and the oscillations continue, resonance thereby being established with the universe.

In the universe we see the same laws being obeyed as in our laboratories. As one traces down to the almost infinitesimal constituents of the atom, one finds that matter does not exist at all as the realistic substance which we have supposed it to be. There at the very foundation, it consists of nothing more than energy charges emitted at various wavelengths or frequencies. It is becoming more and more certain that the apparent complexity of nature is due to our lack of knowledge. And, as the picture unfolds, it promises a marvellous simplicity.

One of the most marvellous relationships that has ever been revealed in the entire science of physics is that between light and electricity and the existence of electronics in atoms of matter. Knowing what we do at the present time with regard to the structure of atoms, this relationship is not quite so surprising. However, considering the total absence of this knowledge about a half century ago, the discovery that light, and radiation in general, are vibratory phenomena was revolutionary.

Speaking of radiation, "Radiant" here means proceeding from a centre in straight lines in every direction. Energy is internal and inherent. "Energy" is defined as a condition of matter, by virtue of which, any definite portion may affect changes in any other definite portion. This was written in 1892, and discoveries since confirm it. Energy then is a state of matter, or rather, the result of a particular state or condition in which matter may be when any observed phase of energy appears.

In addition to possessing kinetic energy, the atom is capable of absorbing energy internally. This internal energy is associated with the configuration of the particles of which the atom is composed. Under ordinary conditions an atom is in what is known as a state of equilibrium, in which there is neither a giving off, nor an absorbing of energy. But, the internal energy of the atom can be altered. When the internal energy of the atom exceeds that of its normal state it is said to be excited. Excitations may be caused in several ways, e.g., the collision of an atom with rapidly moving positive or negative particles or the breaking of lines of force in an electromagnetic generator. Kinetic energy is released when excitation causes a particle to give up some or all of its kinetic energy to the atom during collisions. This is taking place in the universe all the time.

The electric motor and generator would never have been discovered if a dielectric (insulator) had not been discovered. If one discovers a dielectric valve for the energy of the universe, one has the answer to harnessing the energy of the universe! A limiting case of excitation is ionisation, wherein energy is absorbed by the atom sufficiently to allow a loosely bound electron to leave the atom, against the electrostatic forces which tend to hold it within the atom. An atom which has given up one or more electrons is said to be ionised. It is possible that ionisation, i.e., excitation, may take place in successive steps through absorption of quanta energy. The return of an ionised atom to a state of lower energy is associated with electromagnetic radiation. Also, from the process of ionisation, electrical energy may become associated with the vibrational forces of the universe coming into the earth as cosmic radiation. The higher the frequency, the greater the ionisation or excitation, a form of energy which is kinetic in nature. There are tremendous energies coming to the earth from outer space. These energies are only different manifestations of the energies we see in operation all around us. In most cases we are not even aware of their existence. They penetrate everything including our own bodies. Every one of us is alive by virtue
of these energies. Every part and particle of the universe is alive with them. The generators that now furnish our electric power do not create or originate any power or electricity; they merely direct, pump, the existing energy or electricity.

As in musical notes of high and low "C", the vibrational rates (frequencies) are different, but all "C" notes are essentially the same (harmonically related). This is the foundation upon which much of my investigation of vibratory phenomena is based.

It has been agreed that all forms of matter are vibrating at a particular rate or frequency. And, so it is with the various forms of energy - heat and light, magnetism and electricity. These are but forms of vibratory motion connected with and being generated from the same source, the universe. Matter vibrates at a particular rate, according to its character, and may be transmitted into other substance by lowering or raising its rate of frequency. If the frequency is raised high enough, the molecules will separate and the atoms become free. Raising the frequency still higher, the atoms resolve themselves into their original components. Matter then becomes a form of energy. Frequencies may be developed which will balance the force of gravity to a point of neutralisation. One can then go beyond the force of gravitation. Understanding the principles of vibration is truly understanding energy.

In gamma rays, we find potentials which are equivalent to as much as 1,000,000 volts, yet their wave lengths are not the shortest known. In octaves still higher there are rays which are known as "cosmic rays". Who can draw a definite line and say how much higher other octaves exist than those known as the cosmic rays? Our starting point from the discovery of these different waves was electrical conductivity of the air, and it has been found that this conductivity is just as strong by night as by day. Radiations emitted by the sun can scarcely be the sole cause of this energy. All space is saturated with vibration, energies, which are no doubt electrical in character. The relation of matte to energy and energy to matter then becomes the potential of the universe - one continuous series of oscillations.

Atoms maintain an equilibrium by oscillations, rotations, attractions and repulsions, but this does not interfere with a transformation of equilibrium, which, when the transformations of equilibrium are rapid enough, become energy, i.e., matter is turning into energy and energy into matter.

There can be no generation of electrical current and no kinetic energy if there is no disturbance of equilibrium, i.e., change of potential or change of energy levels. When one thinks of the oxygen and nitrogen molecules of the air all about us moving with the speed of bullets and striking us and everything else at this speed, one can form some idea of the agitation taking place here and in the universe.

The oscillations from outer space are emitting electromagnetic waves of many wavelengths and frequencies. The Moray device is so constructed that the frequency is very much lower on the secondary side than on the primary side, and almost complete resonance is established. I am convinced that the energies from the universe are active radiations produced by the evolution of matter into energy and energy into matter.

Dr Anderson's cloud chamber at the California Institute of Technology, in which the positron was discovered, has furnished much information about cosmic ray energies. He found that some positrons are born of cosmic rays smashing into matter. The cosmic ray energies deduced from the tracks left in the Anderson cloud chamber range from 100 volts to 3,000,000,000 volts. The Lemaire-Vallarts theory, together with Dr Johnson's asymmetry measurements, give definite values for the energy of half of the cosmic radiation, and shows it continuously distributed between 5 billion and 50 billion volts.

The figure of 100 billion volts is a result of Dr W. Kolhorster's measurement of penetrating radiation in the depths of the Strassfurt salt mines. He found that the minimum energy of these rays had a penetration which was greater than ever before demonstrated. Dr Axel Corlin of Sweden's Lund Observatory found radiation that still had energy after passing through somewhat greater depths and, therefore, the voltage figures can be made even higher. Energies of 100 billion volts or more are indicated by the great bursts set off by cosmic ray collisions, called the stosse, which have been observed particularly in Germany. The Moray RE devices have worked equally well in deep mines, under water or high in the mountains and in an airplane.

It is about 100 years since science began to consider light, heat, magnetism, galvanism, and electricity as natural forces. In the early part of the 19th century school books termed these things "imponderable substances". The corpuscle theory of light was taught, the sun was supposed to provide an endless supply of those corpuscles. After the corpuscle theory faded, scientists turned to the wave theory, but even that was based on a crude concept of movement of the ultimate principles or atoms, of matter. The electron theory has superseded the earlier ones now, and while the electron theory explains the observed and theoretical "facts" better than the previous concepts did, could it be that, as the greater light of knowledge leads us on, the electron theory in turn will fall short of providing "absolute" knowledge? The Einstein Theory may stand in need of revision or amendment; or, in time, it may join the theories of corpuscles and waves on the back shelf.
A specific case, in which the electric field performs the double function of molecular excitation and the creation of intermolecular and atomic ions, is being given by the system used by the inventor. It is a system utilising the principles of the wire corona with a concentric cylinder at different pressures. The system is modified in conformity to the concept that chemical reactions must take place when the oppositely charged molecular ions from an appropriate activated catalyst are accelerated against one another in the wire corona. It consists of a cylinder made of a suitable catalyst from which positive ions are emitted. The reactants (gases) streaming through the chamber parallel to the length of the wire attain the polarity of the negative molecular ions by the high electric field close to the wire. As these negative molecular ions are accelerated at the right angles to the wire in the direction of the electric field toward the positively charged catalyst cylinder, they are met by an avalanche of onrushing atomic ions from the catalyst. A certain amount of reaction takes place in that instant, $10^{-6}$ seconds. However, some of the negative molecular ions outside the mean free path of the positive atomic ions are free to rush headlong toward the positive cylindrical field where they are neutralised, and instantly given a positive charge by the avalanche of out-rushing positive ions. These positive molecular ions are accelerated back into the field and collide against the negative molecular ions coming from the direction of the negative electrode corona. This melee continues until the reaction has come to a point where the individual participants are either all gone or the mixture is outside of the electric field: backrush oscillations.

The Moray apparatus combined with other equipment, consists of a combination of specially constructed tubes which we will refer to as valves, "pressure transmitters", interceptors and oscillators. The valves are not rectifiers in the sense that they operate as radio valves in changing Alternating Current or High Frequency oscillations into Direct Current. They have an actual valve action in stopping the "flow" of energy which may be thought of as oscillatory action similar to the waves of the sea, without rectification, from returning to the outer circuit, much as a retaining wall could stop the waves of the sea from returning. The other modalities and "tubes" of the device are equally unique in their performance. Although no new laws of energy are being advanced or claimed as having been discovered, the application in the method of utilisation of the energy throughout space is unique in that "generation" is accomplished by oscillatory utilisation rather than by the conventional prime mover. These detector tubes have a synchronised pull with the specially developed oscillators of high faradic capacity and provide a means through which oscillating energy may pass to specially constructed valve oscillators whose relation to the first stage valve is such as to permit oscillations to come in from but not return to the outer circuit with an automatic variable relation to the oscillations from the universe, and capable of setting up within their circuits initial oscillations which coincide with the oscillations of the universe.

Special provision is provided to stop RE tubes from becoming blocked in their dissipation of the charges created by the oscillations that continually accumulate based on the oscillatory capacity backrush effect common to capacitors and are herein applied in vacuum tubes. This action of these devices has the effect of enlarging and prolonging the time of charge and discharge of the capacitors and the capacity energy in the circuit to an appreciable interval in perfect harmony with the natural energy wave through the interceptor's valves and oscillators in the circuit which set up in the circuit electrical pulsations corresponding to the energy waves captured by the interceptor and again kept from returning to the second outer circuit by "multi-walled" valves. The final tubes act as energy pressure transmitters with a means to prevent "shunting" condensation by a special form of "getter". This stops condensation accumulating at the base of the tubes which would block their ionic action.

One must "split" the energy discharge band into lines of variation (call this what you will), lines of energy or lines of light beyond the "light rays". The oscillations, therefore, do not become simple oscillations but through the action of the universe set up an energy flow which might be referred to as the assertion of inertia. When inertia sets in, the action will continue because of the oscillations of the cosmos, otherwise one would have a complete dissipation of energy and no oscillations. The oscillation will vibrate during the same period of time regardless of the potential, but the rate of vibration of the device depends on the "capacity" of its modalities, i.e., condensers, etc.

Put together in pure energy resonance, certain energy responding apparatus which synchronise with the resonance of certain vibrations in the universe, and what do you have? Useable energy from the universe. This energy may come to the planets as oscillations similar to the oscillations and tides of the sea. The Radiant Energy tubes receive this energy in surges which may last only a few microseconds by the pressure and current in those surges are so strong that sufficient energy is delivered to the equipment in resonance to be useable in multiples of flashes and in a magnitude which competes with the light of day. Remember resonance and pressure can do a lot to amplify energy. Also remember that the vibrations going out from the sources in the universe must also return to their sources. Nothing is lost. There is only a lowering of potential like water flowing over a water wheel.

The Radiant Energy tubes present no new laws of physics. They simply expand the application of known laws, thereby obtaining results not at first thought possible. This is the history of science. Radiant Energy tubes possess greater ability to obtain "saturation" and thus charge the accompanying capacitors at a more steady rate.
When a certain voltage is reached, ionisation occurs in the gases of the discharged tube and causes the capacitors of the valve circuit to discharge into other capacitors of the valve circuit, to discharge into other capacitors of the oscillators and the other modalities of the circuit.

When ionisation in the preceding tubes is no longer possible because of the reduced voltage, the process starts all over again. The first valve passes vibrations of energy into an oscillatory circuit; ionisation sets in, a discharge occurs, and energy passes through another valve into other oscillators. The process is repeated from the first stage on to the second stage, on to the third and so on, much like a bucket brigade. That is why I asked years ago, "Cannot a steady flow of water be obtained from the waves of the sea or energy from the vibrations of the cosmos?"

When a vibration of any kind strikes a boundary between two media of different vibratory impedances at an angle of less than 90 degrees, a transformation of the vibratory rate may be changed into another vibratory rate. The Radiant Energy device therefore will continue to capture energy by resonance, or call it what you will, as long as the "keep alive" vibration of the cosmos continues to oscillate the various stages of the valves and oscillators in the circuit. Simple, is it not? Just a case of the trapping of energy which is everywhere present in the primary circuit and causing it to oscillate through the secondary circuits through a blocked circuit of no return.

Our experiments have proved that there is an energy which exists in the universe which, by proper development of equipment, can be made available for commercial use.

Such an energy transformer or converter has been built. It has been operated, at full load continuously with no expenditure of fuels of any type, without a mechanical prime mover, kept alive by the oscillations of the energies from the cosmos; an energy converter, or transformer, which would be capable of converting the high frequency, high level energy of the cosmic radiation into current of usable frequency and voltage.

Basically the theory of operation is as follows:

Oscillations are started in the first stage or circuit of the device by exciting it with an external energy source.

The circuit is "tuned" until the oscillations are sustained by harmonic coupling to the cosmic wave frequencies.

The reinforcing action of the harmonic coupling increases the amplitude of the oscillations until the peak pulses "spill" over into the next stage through a special detector or valve which prevents the return or feedback of energy from succeeding circuits.

These "pulses" drive this stage, which oscillates at a lower frequency and is again reinforced by harmonic coupling with the ever present cosmic waves.

The second stage drives a third stage, and additional stages are coupled until a suitable power level at a useable frequency and voltage is obtained by means of special transformers.

The specific information on Moray's system is very limited, especially since his patent application has been removed. The diagram above and the diagram below have been reproduced from what is alleged to be the notes from which the patent application was composed. These notes are not very clear both in wording and in the quality of reproduction, however, the diagrams shown here are an attempt to show clearly anything which is reasonably certain in those diagrams.
This is supposed to be the construction information on the Moray Valve which was capable of being set to either rectify a signal or to amplify a signal. The casing is a metal cup which also forms one of the contacts for the valve. Inside the cup there are four pellets attached to the side. The outer two pellets are made of bismuth and are fused directly onto the metal case. The two inner pellets are attached to the case with tin instead of solder. Judging from the drawing, it looks as if the metal arm contacting the pellets can only connect with the inner two pellets. The arm presses sharply against the pellets in the same way that the "cat's whisker" diodes of the time were touched with a silver wire to make a point contact and produce rectification.

If it is correct that the rotatable arm only contacts one of the two inner pellets, then the reason for those outer bismuth pellets must be as an indirect part of the valve. So, this section of the case is an arrangement of the metal of the case, tin, bismuth and five junctions between different materials, not counting the contact arm. One of the two inner pellets is made of purified germanium with the addition of very small amounts of a doping material. Iron Sulphide (FeS), Molybdenum Sulphide (MoS), Bismuth, Uranium and Silver have been mentioned as possible doping agents. Another material mentioned is Lead which has had it's structure altered by the process described in Moray's patent US 2,460,707. The pellets are said to be produced under high pressure.

From this it can be seen that we do not have anything remotely like the full information on Moray's system. However, there are a number of important things which we can learn from this. Firstly, using just a good earthing connection and an aerial of just ninety feet (30 m) or so in length suspended only some eight feet off the ground, it is possible to draw significant current from the environment. The photograph shows 35 light bulbs being lit by Moray and that is a substantial amount of power. It is unlikely that we will be able to reproduce Moray's exact method of extracting power, but it is highly unlikely that his method is the only possible way of achieving efficient power extraction. So, if we experiment with the components and materials to hand today, it is distinctly possible that we could extract major amounts of power from a relatively small aerial wire positioned at quite a convenient height above the ground, and a good quality earth.

Hermann Plauson's Aerial Systems.
Hermann Plauson was granted US Patent 1,540,998 in June 1925. The patent is similar in style to Tesla's pick-up system and it illustrates the principle with a system which is very much like Paul Baumann's "Testatica" device hidden away in a Swiss religious commune. The patent is very detailed with 37 drawings showing different arrangements, and a more simply worded version is shown in full in the Appendix. In fact, the patent reads more like a tutorial rather than a patent.

A system of this type should most definitely be taken seriously: Hermann considers one of his systems with an output of 100 kilowatts as being a "small" system. However, it needs to be understood that each of Hermann's aerials, unlike those of Thomas Henry Moray, contributed less than one kilowatt each, and when Hermann speaks of a 100 kilowatt installation, he is referring to an array of more than one hundred separate aerials.

Hermann illustrates several different methods of energy capture and several methods of increasing the effectiveness of the captured energy. While an installation to capture a continuous supply of 100+ kilowatts is unrealistic for an individual, requiring many tall aerials, there is the distinct possibility of making a scaled-down version which is capable of providing serious levels of free power. Reading his patent through carefully is definitely to be recommended.
Herman starts by illustrating how working electricity can be taken from a Wimshurst machine. The Wimshurst output voltage is very high and the current capacity is very low and most people would dismiss it out of hand as being totally inadequate for any kind of practical work. However, Hermann boosts the power level by feeding the output into a step-down transformer which lowers the output voltage to a convenient level and raises the available current in proportion to the reduction in voltage. This is the same technique patented by Nikola Tesla. The apparatus which Herman illustrates is shown here:

His patent says: "By suitably selecting the ratio between the number of turns in the primary and secondary windings, with regard to a correct application of the coefficients of resonance (capacitance, inductance and resistance) the high voltage of the primary circuit may be suitably converted into a low voltage high current output". It should be remembered that a spark produces a very sharply rising voltage pulse and that unbalances the local quantum energy field, as described earlier, producing very large energy flows as the local environment returns to its balanced steady-state. The spark, which is produced by relatively low power, is used as a trigger for vastly larger energy flows, which feed the step-down transformer, producing serious current at reasonable voltage, capable of doing useful work, without the requirement for any input power from the user.

You will notice how simple this circuit is. Three capacitors "a1", "b1" and "c1" in a chain, form a single high-voltage capacitor. The blobs shown connected across these capacitors are emergency discharge spark gaps put there to deal with unusual events like the aerial being hit by a lightning strike. This circuit is very much like the Wimshurst machine circuit which Hermann uses as an illustration of the principle of operation of these kinds of circuits. In this circuit, he shows a special motor marked "M" which is driven by the circuit and he also shows output terminals which can have other equipment connected across them.

When the oscillatory discharges in the primary circuit become weaker or cease entirely, the capacitors are charged again by the static electricity until the accumulated charge again breaks down across the spark gap. All this is repeated as long as electricity is produced by the static machine through the application of mechanical energy to it. Herman states that without the spark gap arrangement across the three capacitors connected
between the aerial and the earth, "it is impossible to collect and render available large quantities of electrical energy."

In addition to the use of spark gaps in parallel, a second measure of security is also necessary for taking the current from this circuit. This is the introduction of protective electromagnets or choking coils in the aerial circuit as shown by S in the diagram below. A single "electromagnet" having a core of the thinnest possible separate laminations is connected with the aerial. In the case of high voltages in the aerial network or at places where there are frequent thunderstorms, several such toroidal-wound coils may be connected in series.

In the case of large units, several such magnets can be employed in parallel or in series parallel. The windings of these electromagnets may be simply connected in series with the aerials. In this case, the windings should be made up from several thin parallel wires, which together, make up the necessary cross-sectional area of wire. The winding may be made of primary and secondary windings in the form of a transformer. The primary winding will then be connected in series with the aerial network, and the secondary winding more or less short-circuited through a regulating resistor or an induction coil. In the latter case it is possible to regulate, to a certain extent, the effect of these choking coils.

Fig.5 shows an arrangement for producing large currents which can be used directly, without motors, to provide heating and lighting. The main difference here is that the spark gap consists of a star-shaped disc which can rotate on its own axis and is rotated by a motor opposite similarly fitted electrodes. When separate points of the stars face one another, discharges take place, thus forming an oscillation circuit with capacitors and inductor. A motor may also be connected directly to the ends of inductor.

The patent continues by showing many ways to increase the power of the aerial system and many ways of applying the output to practical electrical devices. It contains 37 diagrams, a wealth of practical information, and a copy of it is in the Appendix.

Roy Meyer's Aerial Device.
Roy Meyers was granted UK Patent 1913,01098 in January 1914. The patent, which is included in the Appendix, shows an extremely simple device which produces an electrical output without any form of visible input whatsoever. This intriguing device was discovered when testing a very simple form, where two horseshoe magnets were interconnected with soft iron wire and two bars of zinc placed between the legs of the magnets. Roy found that he got an output of 8 volts using just two 4-inch magnets with 1-inch square legs and zinc bars of similar size. The physical orientation of the device is very important. The patent says that current is collected if the open ends of the magnets are pointing in a North - South direction and not if they are positioned in the East -
West direction. However, replication attempts seem to indicate the reverse of this with energy pick-up occurring when the alignment is East-West. Indications are that this is not an easy device to get operating correctly.

The first arrangement is shown in the following diagram:

Roy developed his system further and found that while it works indoors, it does perform better if located outdoors and raised to a height of fifty or sixty feet. However, that is by no means essential, and the output power and voltage can be increased by increasing the number of collector units. Roy developed these to produce the style shown here:

The zinc acts more effectively if installed as sheets bent into a V shape. The magnets and zinc sheets can be stacked vertically and/or horizontally and the greater the number used, the greater the electrical output. A good earth connection is recommended and presumably, the average cold water pipe of any house provides a more than adequate earth connection which is convenient to use, provided the pipework is made of metal.

The Aerial System of Raymond Phillips Senior.

Presents an interesting patent US 4,685,047 of 4th August 1987, entitled “Apparatus for Converting Radio Frequency Energy to Direct Current”. While this patent speaks of radio-frequency energy, I can see no particular reason why that would be the only energy which could be picked up by this circuitry. The patent information is as follows:
Abstract:
This patent describes an apparatus and methods for converting radio frequency energy into direct current for generating electric power. It includes a dipolar antenna for receiving radio frequency energy and a circuit for converting the radio frequency energy to direct current. The circuit has a positive output line connected to one pole of the antenna and a negative output line connected to the other pole of the antenna. A positive transmitting diode is in the positive output line and a negative transmitting diode is in the negative output line. First and second bus lines and a pair of tuned circuits of opposite polarity couple the positive output line and negative line to the bus line with one of the bus lines being connected to ground. Each tuned circuit includes a first bridging line connecting the positive output line to the first and second ground lines and a second bridging line connecting the negative output line to the first and second ground lines. Each bridging line has in it, a diode connected with a polarity which is reversed with respect to the input diode. The bridging lines of each tuned circuit are connected to one another by an inductor and have capacitors placed between the diode and the bus lines. A Direct Current device is connected to the positive line of the circuit.

Background of the Invention:
This invention shows an apparatus for converting radio frequency energy to Direct Current of sufficient magnitude to power devices such as battery chargers and electric motors without the use of amplification.

There has long been interest in technology directed to transmitting electrical energy over a distance without using wires. Development of such a technology has enormous potential. This was first recognized by Nikola Tesla who in 1899 constructed a 200 foot Tesla coil rated at 300 kilowatts at 150 kilocycles. Tesla hoped to set up standing waves of electrical energy around the whole surface of the earth, so that receiving antennas set at optimum points could tap the power when needed. Tesla was able to light hundreds of lamps at a distance of about 40 kilometers with his device without using wires. The scheme has generally remained a scientific curiosity but has provided the initial groundwork for current developments wherein attempts are being made to transmit power using microwaves. However, power transmitted by microwaves is envisioned in the form of a beam of very high intensity which is focused from a microwave generator to a receiving antenna. This technology is envisioned as being used for many types of purposes, however, the focused microwave beam is not suitable for many applications because the beam must be directed toward a receiving antenna and cannot be transmitted through most objects, including living objects, without destroying those objects.

This invention relies on converting energy from standing waves which are emitted from radio frequency antennas in the RF range rather than the microwave range. Of particular interest are very low frequencies which are not used in communications and are available for transmitting power. Also of interest are the low frequency waves emitted by the earth due to pulsing of its magnetic field. These low frequency standing "earth" waves can be picked up by receivers tuned to them.

Summary of the Invention:
This invention shows an RF antenna for receiving radio waves. The RF antenna connected to a circuit configured to convert the RF signals to Direct Current. The radio frequency signals received by the antenna are transmitted to two leads, one being rectified to produce positive voltage and the other rectified to produce negative voltage. The positive voltage lead is connected directly to a positive output line and the negative voltage lead is connected directly to a negative output line. The positive output line is connected to a pair of bus lines through a first pair of capacitors, while the negative output line is connected to the pair of bus lines by a second pair of capacitors. Placed between the first bus line and the positive output line is a reverse diode of negative polarity, while placed between the negative output line and first bus line is a reverse diode of positive polarity. The positive and negative output lines are connected to one another through an inductor which is in parallel with the capacitors of the first and second pair connected between the second bus line and the positive and negative output lines.
In one implementation of the invention this circuit is duplicated for each positive and negative output line. In another the circuit is coupled to additional identical circuits in order to increase the direct current output of the arrangement. In another implementation, the antenna used is a dipolar antenna of aluminium wire arranged in a "butterfly" configuration.

This invention uses these elements to generate direct current of sufficient power to perform tasks such as charging batteries, lighting lamps and powering direct current electric motors without the use of amplifiers.

**Brief description of the drawing:**
The reference characters used show the same or similar parts in each views, and what is shown is a diagram of a circuit, a driven device and a dipolar antenna which receives radio frequency waves which are then converted to DC current for powering the driven device.

**Description of the preferred embodiment:**
Referring now to the drawing below, there is shown a dipolar antenna, designated generally by the numeral 10, which receives radio frequency waves from an RF transmitter.
These waves are passed to the conversion circuit through a coaxial cable 13 and the DC output current of the circuit is used to power an output device 15, which may be, for example, a battery charger, DC motor, or lighting device. The circuit has no other power inputs and so has no amplifiers for boosting the RF energy.

The source of frequencies which can be converted to Direct Current by the circuit shown may include sources of high frequency (HF), low frequency (LF), very low frequency (VLF) and extremely low frequency (ELF) radio waves as well as seismic vibration of the earth’s magnetic fields.

Preferably, the dipolar antenna 10 is formed of two triangular loops of aluminium wire 16 and 17, one of which is connected to the annular conductor 21 of the coaxial cable 13 and the other of which is connected to the centre conductor 22 of the coaxial cable. The size of the bipolar antenna 10 is dependent on the particular application to which it is put. In one embodiment of the invention, the antenna 10 is approximately 12 inches in width and 18 inches in length. Such an antenna is used to receive five watt energy, such as that generated by a walkie-talkie or citizen-band radio.

The outer conductor of the aerial is connected to positive lead 21 and the centre conductor of the coaxial cable is connected to the negative lead 22 of the circuit. A positive transmitting diode D1 is placed between the lead 21 and the positive output line 25. A negative transmitting diode D2 is placed between the lead 22 and the negative output line 26.

In order to provide a DC output of sufficient power, a number of inductance-capacitance RF tuned circuits 30, each forming a positive cell, or a negative cell, are used to connect the positive output line 25 and negative output line 26 to the first and second bus lines 31 and 32, respectively. Bus line 32 is connected to ground while bus line 31 can be connected to similar circuits. Inductor 35 serves as a radio frequency choke. As is seen of the drawing, the RF tuned circuit cell 30 is repeated a plurality of times. In the specific example shown, the circuit has separate cells 30, 37, 38 and 39. The cells 30 and 38 are of opposite polarity and balance one another, while the cells 37 and 39 are of opposite polarity and also balance one another. In order for the system to function, a pair of opposite polarised cells must be used. The particular number of cells 30 and the value of the components in it, are determined by the configuration of the dipole antenna 10 and the power and frequency of the RF transmitter.

This radio frequency to direct current conversion circuit may itself be connected to a duplicate circuit via pin 41 so as to provide additional direct current output on lines similar to positive output line 25 and negative output line 26 the output lines may be connected together in order to boost the total output of the system.

An operative embodiment of the invention uses the following elements:
Diodes: D1, D2, D3 and D4 - Germanium Diodes, type **1N34A**,  
Inductors: **35-47 millihenry** R. F. Choke  
Capacitors: C1 and C2 - **0.47 Pico Farads** at 200 volts  
Coaxial Cable: 13 - 50 ohms  
Dipolar Antenna: aluminium wire triangular loops approximately 12 inches by 18 inches.

From the foregoing description, one skilled in the art can easily ascertain the essential characteristics of this invention, and without departing from the spirit and scope of it, can make various changes and modifications of the invention to adapt it to various uses and conditions.

**The “Alexkor” Aerial System.**

‘Alexkor’ who provided some of the charging circuits shown in chapter 6, also uses an aerial system for charging batteries in the 1.5V to 6V range. It is a simple system which uses an aerial of the type used by Thomas Henry Moray, that is, the bulk of the aerial is horizontal:

![Diagram of the aerial system](Image)

The suggestion is that the aerial is suspended between the eaves of a house and a nearby tree, but I don’t know anybody who would be able to do that. The longer the aerial or the greater the number of aerials connected, the greater the charging power available. The aerial wire should be not less than 0.5 mm in diameter and it needs to be insulated from it’s supports – plastic cord can be used for that.

The circuit used is:

![Diagram of the charging circuit](Image)

A more powerful version of the circuit is:
Here, there are three sets of diodes placed between the aerial and the earth. Let me stress again that the earth connection is a thick copper wire connected to a long rod or pipe driven into the ground or a large metal plate buried in dampened ground.

As the circuit operates, the three sets of diodes with their isolation capacitors, build up an increasing voltage on capacitor “C1”. The voltage at point “B” will also increase and be about twelve volts less than the voltage on capacitor “C1”. Eventually, that voltage will rise high enough to cause a discharge through the tiny neon tube and that current pulse flows through the Gate connection “G” of the thyristor, switching it on. Once switched on, the thyristor stays on until capacitor “C1” has been discharged, after which, the thyristor switches off and the process starts all over again. The amount of power in these pulses is considerable and the thyristor gets quite warm when the circuit is running. The BT151-800R thyristor can handle as much as 800 volts and pass 7.5 amps of current continuously.

An important point to note is that the power available from this circuit increases with additional aerials. With two aerials connected, the power is doubled and with three aerials the power is tripled. That is, each additional aerial provides as much power as the first aerial did and there does not appear to be any limit to the number of aerials which can be connected.

The TREC
There is a powerful aerial system which has been developed by Lawrence Rayburn of Canada. Initially, Lawrence intended to market kits to make it easy for people to replicate his aerial design which was providing him with ten kilowatts of power. However, Lawrence shelved that idea as he decided that the risk to users was just too high. He was also concerned that the aerial/earth combination might attract lightning strikes, causing considerable local damage. So, it is VERY important that you understand that this is a dangerous and potentially LETHAL aerial system which is quite capable of killing you if you are careless. If you are not already experienced in working with high-voltage/high-current devices, then this is NOT something for you to experiment with, and anyone who does fool around with this design does so wholly at his own risk as this material is presented “for
information purposes only" and there is no recommendation whatsoever that you should actually construct one of these aerial systems.

The technique used is quite different from the other aerial systems mentioned earlier in this chapter. Here, the objective is to create a tuned, resonant cavity reaching up to the ionosphere where there is a massive amount of excess energy supplied by the sun.

The tuning mechanism consists of two spirals of 3/4-inch (20 mm) copper pipe wound so that they cover a four foot (1220 mm) diameter area. These spirals are covered above and below with a sheet of Lexan plastic. The diameter of the copper pipe is important and smaller diameter should not be used even though it would be much easier to bend into shape. Actually, bending the large-diameter copper pipe is unlikely to be an easy task. Presumably, a pipe-bending machine would be used and a conical spiral produced and then the cone flattened to form the flat spiral. The spiral has even spaces between the turns, at all points along it's length.

The two spirals are mounted, one vertically above the other with thirty feet (9145 mm) between them and the lower spiral being one foot (305 mm) above the ground. This means that this aerial system is only suited to people who can erect a structure of this height without inconveniencing neighbours or contravening local planning regulations.

The tuneable cavity is created by connecting the innermost ends of the two spirals together using 4 AWG wire which has a 5.19 mm diameter copper core. The outer end of the lower spiral is then connected to a large ground plate buried two feet (600 mm) below the surface of the ground, with four separate strands of the 4 AWG wire.
An adjustable spark gap is used. It can be positioned in the vertical wire between the two spirals, or in the middle of an extra 4 AWG wire run vertically between the outer ends of the two spirals. The power take-off is from the middle of the central vertical wire.

The cavity is tuned by sliding coils inside each other. This arrangement not only tunes the cavity but it also steps down the very high aerial voltage and raises the available current at the same time. This is where the danger comes in. The intermediate parts of this step-down tuning arrangement can have voltages of 600 volts at high current, and those voltages can easily kill you, which is why this is NOT a system for beginners and why Lawrence did not go ahead with selling kits for this aerial system.

The aerial output is fed into a final step-down transformer and a 50 Hz (cycles per second) or 60Hz signal from a signal generator is used to modulate the incoming power and allow it to be used with normal mains equipment which may need that frequency of AC. Resistive heaters and lights don’t need AC or care about the frequency of any AC which they are fed.

The tuning of the system is very sharp and whatever is being used as the load affects the tuning. The wire used for the tuning array is insulated, single solid-core copper wire. 4 AWG has a core diameter of 5.19 mm, 8 AWG has a core diameter of 3.26 mm, 10 AWG has a core diameter of 2.59 mm and 16 AWG has a core diameter of 1.29 mm. Page 1 of the Appendix shows other characteristics for these wires. These heavy wires are an essential part of this design.

You will notice that two separate earth connections are needed for this aerial system. The second earth connection should be a long copper rod driven deep into the ground and some distance away from the buried plate earth. For the separation of two earth connections, ten metres (eleven yards) is generally considered to be a reasonable distance between them. The main earth is a 4-foot x 4-foot plate buried exactly under the lower spiral and the connection runs to the centre of that plate.

It is suggested that the spark-gap be constructed using copper-clad carbon welding rods, mounted in a nylon housing which allows the gap to be adjusted with a nylon screw. Remember that this is not a connection which you can disconnect from the power supply when making connections or adjustments. Also, on one occasion when a 500-watt light bulb was connected across the spark gap, it burned out instantly with a bright flash of light. This system is not a toy so thick rubber gloves and rubber footwear should be used.

The 4 AWG copper wires can be connected to the copper rods forming the spark electrodes, using copper pipe clamps. A tapered nylon rod could be used to adjust the spark gap screw while keeping well away from the copper. The spark gap should start at a one-inch (25 mm) gap and adjusted to no less than a half-inch gap. The spark gap and it’s adjusting gear should be enclosed in a weather-proofing container and it has been suggested that it could be and advantage to fill that container with helium gas.

Please remember that coils, such as those in the tuning section of this system, have capacitance as well as inductance. The coil insulation is a dielectric and you standing on the ground form a good earth connection, so please don’t imagine that you can’t get a serious shock from handling an insulated coil carrying high-voltage high-frequency AC current, and in one implementation after modulation in the mixer at 60 hertz the pre-output transformer was measured at 3496 volts!

If you are not experienced in working with high-voltage circuitry, and still decide to try building and using this circuit, then please put your affairs in order and pre-pay your funeral expenses before you start building. (That statement is not intended to be humorous).

It is said that if the upper spiral is positioned at a height of just four feet (1200 mm) then the output is much lower and suited to charging a battery bank. As far as I am aware, this system has not been replicated and so there has been no practical feedback on building or using it.

The TREC appears to be not unlike the Patent Application US 2008/0191580 from Harold Deyo:

Harmonic Energy Exchange Device

ABSTRACT
This invention converts inertial impulses into electric currents. Specifically, it converts impulses created by the impacts of high-energy particles from the Sun and other cosmic sources into the Earth's Magnetosphere and the varying D, E, F1 and F2 layers of its Ionosphere to controlled electric currents. This invention presents a new method of utilising energy from the Sun and other sources of high energy articles as a virtually, inexhaustible, alternative-energy source for the world. 

BACKGROUND OF THE INVENTION

This invention relates to the conversion of impact energies created by the collision of high-speed cosmic particles and electromagnetic radiations with “Earth's Outer Layers” to produce inertial waves in the dielectric Troposphere which are subsequently converted into electricity by this invention.

The term “Earth's Outer Layers” refers to: Earth's Magnetosphere, Van Allen Belts, Ionosphere, Mesosphere, and Stratosphere as illustrated in Fig.2:

![Diagram of Earth's Outer Layers](image)

DESCRIPTION OF THE PRIOR ART

One day while reading an old scientific magazine I saw a small article on the research of Dr. John Trump of MIT (the basis for an electrostatic generator patented later by Onezime P. Breaux in U.S. Pat. No. 4,127,804). The article talked about a series of experiments which Dr. Trump had performed with a 2-plate, capacitor in a vacuum dielectric. Briefly, he discovered that by varying the distance between the two plates one could produce current flows in one direction or the other between either of the plates and ground.

The Solar Wind strikes “Earth's Outer Layers” constantly as do many other cosmic particles. At any given instant of time, the vector product of these impacts produces either a net pressure increase or decrease in the Troposphere. This creates random waves of pressure in the “Earth's Outer Layers” as one charged “plate” moves in relation to the oppositely-charged Earth's surface as the other “plate”. This variation of pressure in the “Earth's Outer Layers” is equivalent to moving an outer “plate” back and forth toward the Troposphere and the Earth's surface as the inner “plate” - thus giving rise to variations in voltage on both “plates”. In this case the Troposphere (see Fig.2) acts as the dielectric medium instead of the vacuum in the Trump experiments. Furthermore, the
Troposphere, itself, is also compressed and decompressed by these random waves of pressure on the “Earth's Outer Layers”. Thus, I reasoned that if one could create a charged envelope or field of sufficient voltage within the Troposphere, one could convert these random pressure waves in the dielectric Troposphere into current flow on the Earth's surface.

As “Earth's Outer Layers” surround the planet, any impact waves propagate throughout all of them when they are present - even to the night-time side of the planet. Thus, I also reasoned that one could extract power from these impacts anywhere on Earth's surface or in it’s atmosphere whether it be day or night. The pressure waves on the dark side of Earth would be less energetic than those occurring on the day-time side, because the night-time layers of the Ionosphere are compressed so much that the D-Layer of the Ionosphere disappears at night and the F1 and F2-Layers of the Ionosphere combine into one F-Layer. I calculated that the available energy from these impact waves would be significantly less by 30-45% depending upon one's location on the night side of the planet in respect to the terminator.

Many years ago, around 1900, Dr Nikola Tesla built and tested a device to extract energy from the Sun using an apparatus which forms part of my own invention (see U.S. Pat. Nos. 685,957 an 685,958 dated 5 Nov. 1901).

Subsequently, Dr. Thomas Henry Moray, another inventor and student of these Tesla patents made a device which apparently accessed the same source of energy but with a method different than my own. As Dr. Moray was never granted a patent for his device I cannot be certain that his work is considered prior art but I list it here as part of my due diligence. Apparently, he had trouble explaining to the patent reviewer, the source of energy which his device was converting, and thus, was not granted a patent for his impressive work. Dr. Moray's public disclosure of certain aspects of his invention are public knowledge through his published lectures and his book, “The Sea of Energy in Which the Earth Floats’ - published in 1931.

Since the beginning of the 20th century, mankind has been looking for new sources of electric power to feed the ever-increasing energy demands of the human population. In the last half of the 19th century, coal, whale oil, human and animal labour, moving water, wind and wood were the main sources of energy. However, in the first quarter of the 20th century, mankind began to use more electricity produced by hydroelectric generators and generators producing electricity by combustion of hydrocarbon fuels. With increasing use of petrol engines and the increasing use of electrical appliances the demand for electricity accelerated the addition of heat and greenhouse gasses into the Earth's ecosystem.

In the last half of the 20th century, many forward-thinking individuals began looking for alternative energy sources to reduce the emissions of greenhouse gasses. All of the alternative energy systems investigated and/or developed in the last 56 years have had significant drawbacks to their usage as the main energy supply for the needs of humanity.

Some of those alternative energy systems were nowhere near as efficient as the existing systems. Some of the alternative energy systems still introduced extra heat into the environment like the existing fossil fuel and nuclear energy systems. And others produced even more greenhouse gasses than the existing energy systems. Some of the new systems used food resources to produce combustible fuels which, consequently, reduced the food resources of the planet. Among the leaders in the new energy sources was, and is, nuclear energy which produces extra heat, toxic wastes and materials which can be used in nuclear weapons. Hydroelectric energy sources do not add heat to the ecosystem but they are not an inexhaustible resource as they depend upon rainfall which is diminishing as global warming increases. Wind energy resources do not add heat to the ecosystem but they are not constant and require expensive conversion and storage equipment.

The ideal energy source for mankind will not add heat to the planet's ecosystem, will not produce by-product greenhouse gasses; will not deplete our food and water resources; will not produce toxic wastes; however, it will be portable, self-replenishing and constantly available in real time anywhere on Earth and in useful quantities.

Our major source of natural energy on Earth is the Sun. Energy from the Sun enters the Earth's ecosphere by particle bombardment, radiated electromagnetic energy, gravitational variations and magnetic processes. Mankind has developed various methods of capturing energy from the Sun already. Silicon-based solar cells convert light in a narrow bandwidth into electron flows. These cells are, at most, only 50% efficient and only work when the Sun is shining on them at an optimum angle. Wind turbines only work when there is wind to power them and are, for the most part, not portable. Devices to convert wave action in the oceans only work when there are waves created by the wind and tidal effects caused by gravitational variations; and they are not portable enough to be used in common transportation devices.

I concluded therefore, that if mankind could find an inexpensive method of obtaining electricity from the Sun in some form which worked both day and night and which was already flowing into the Earth's ecosystem, we might be able to develop a clean and self-replenishing energy source which would add no extra heat to our ecosystem, would not alter our planetary albedo and might well be made in a portable form.
SUMMARY OF THE INVENTION

The Harmonic Energy Exchange Device (or “HEED”) offers an interim solution to Earth's fossil fuel resources. It utilises a previously untapped energy resource which exists throughout the known Universe. By the very nature of the invention, it only interrupts the flow of energy from the Sun and all the other cosmic sources of high-energy particles on their normal journey to the Earth by way of The Outer Layers.

The invention does not add energy to the normal thermodynamic equilibrium of the planet and its associated outer layers. The invention does not produce wastes - toxic or otherwise. It does not produce harmful gasses; and in some embodiments it could even assist in the rebuilding of our thinning ozone shield. Use of this invention will eventually remove mankind's dependence on fossil fuels and create new occupations. It will be cheap enough that homeowners will be able to install their own HEED and sell back energy to the grid until such time as every home has their own HEED and civilization has completely weaned itself from the use of fossil fuels and nuclear energy in its current form.

BRIEF DESCRIPTION OF DRAWINGS

![Figure 1](image)

**Fig.1**: Is the preferred embodiment of the circuit diagram of my invention incorporating references to external stimuli which are used to activate the circuit. It represents a parallel tuned circuit to store the energy.
Fig. 2: Is an illustration of the Earth and its immediate environment as a global capacitor where the outer layers form one plate and the Earth's surface form the other plate and both are separated by the troposphere as a dielectric medium.

Fig. 3: Is an alternative embodiment of the circuit diagram of my invention incorporating references to external stimuli which are used to activate the circuit. It represents the use of a series tuned circuit to store the energy.
DETAILED DESCRIPTION OF A PREFERRED EMBODIMENT OF THE INVENTION

Be it known that I, Harold Stanley Deyo, Jr, a citizen of both The United States of America and The Commonwealth of Australia, residing in the community of Pueblo West in Pueblo County, Colorado have invented a Harmonic Energy Exchange Device which converts dynamic pressures in the ambient media around Earth into controlled electric currents.

This invention as represented in Fig. 1 is unique in that it is designed to extract electricity from random pressure waves propagated in the Troposphere 14 by impacts of the solar wind and other cosmic particles with the Earth's "The Outer Layers" 22 of Fig. 2.

In Fig. 1, the Troposphere 14 in its rest state is represented by the line of "+" marks 14. The convergent or compression state 12 of the random waves in the Troposphere 14 is represented by the lower line of dots while the divergent or decompression state 13 of the random waves in the Troposphere 14 is represented by the upper line of dots. The preferred embodiment of my invention Fig. 1 is a method of coupling a parallel, resonant, electrical circuit to these random pressure waves to extract electricity from them.

As Dr John Trump's research and Onezime P. Breaux's U.S. Pat. No. 4,127,804 show, when one plate of a charged capacitor is moved closer to or farther from the other plate of that capacitor a voltage change appears on both plates of that capacitor. Furthermore, the electric field gradient between those plates changes as the plates are moved in this manner. Thus they have described a method of converting mechanical energy into electrical current by simply varying the plate spacing over time which can be expressed as ds/dt where "ds" is the change in spacing and "dt" is the change in time.

As illustrated in Fig. 2, The Outer Layers can be viewed as one plate of a capacitor comprised of the Earth's surface itself as one plate 21 and Earth's outer layers as the other plate 22 where the Earth's Troposphere 23 serves as the dielectric medium separating the two plates. There is a charge between these plates which varies extremely rapidly but not with a constant period. At any given instant, the vector product of all the impacts by the cosmic particles with The Outer Layers 22 will create a pressure wave in The Outer Layers 22 which will manifest in the Troposphere 23. Whatever that vector product is, it will alter the field gradient in the dielectric Troposphere 23. That alteration will either increase or decrease the effective spacing between "plates" 22 and 23.
In order to capture and convert the resulting voltage variations produced at or near the Earth's surface of Fig.2, this invention creates its own, localised stress field of Fig.1 established in the Troposphere of Fig.2 with a charged, conductive surface of Fig.1 which is encased in high-voltage insulation of Fig.1 and extending into the Troposphere of Fig.2.

In Fig.1, a series of high-voltage, starting pulses is applied across points 4 and 6 on opposite sides of a capacitor to create the localised stress field. As these high-voltage starting pulses are applied, the parallel resonant circuit formed by inductor coil 7 and variable capacitor 11 both referenced to ground is stimulated into resonance within the bandwidth determined by the values of these circuit components. Tuning of this circuit is effected through variable capacitor 11. The high voltage charge on conductive surface of Fig.1 is maintained by the parallel tuned circuit formed by inductor coil 7 and variable capacitor 11.

Then as the random, pressure waves propagate throughout the Troposphere of Fig.2, the localised stress field of Fig.1 is oscillated by the compression wave front and the decompression wave front (both in Fig.1) which creates voltage changes on capacitor.

In Fig.1, the resulting voltages changes on capacitor 5 will add energy to the parallel resonant circuit formed by inductor coil 7 and variable capacitor 11 which acts as a tank circuit to store the energy which has been passed to it. As energy builds in the parallel circuit the voltage of the circuit rises until a spark discharge occurs across the gap also referenced to ground. The current will only discharge in one direction as determined by diode. The circuit will work without diode but a diode is used here as one method to keep from draining all the energy from the tank circuit when a discharge occurs.

This resonant circuit can be tuned to various bandwidths to maximise the efficiency of the conversion process depending upon the location of the device, the time of day, temperature variations, relative humidity and other variables in the ambient Troposphere of Fig.2 around the conductive surface of Fig.1. A resistive load to extract power from the resonant circuit can be used instead of the spark gap of Fig.1.

This preferred embodiment uses a parallel, tuned circuit to access a wide range of frequencies usually to be found in the range of 4.5 to 7 MHz. This range encompasses the major, naturally-occurring, resonant frequencies found in the ionosphere.

A second embodiment of this invention as shown in Fig.3 replaces the parallel tuned circuit formed by inductor coil 7 and variable capacitor 11 in Fig.1 placed in parallel to each other and referenced to ground. This second embodiment forms a series-tuned circuit formed by inductor coil 7 and variable capacitor 11 in Fig.3 placed in series to each other and referenced to ground. It differs from the preferred embodiment only in the placement of variable capacitor 11 so that it is in series with coil 7.

This embodiment limits the frequency range and, hence, the energy which the system will store when compared to the preferred embodiment. It produces higher voltages across the spark gap than those produced in the preferred embodiment across the spark gap of Fig.1.

*****
What is said in this patent application adds some interesting factors to the TREC design of Lawrence Rayburn which pre-dates the Deyo patent by some years. His comment about replacing the spark gap with a resistive load suggests some alternative arrangements which might be tried out with the TREC system.

Also, somewhat along the same lines:

Translated from a Spanish-language original:

Many people think that it is not possible to get power from the Earth magnetic field because that field intensity is too low and so the energy levels aren't high enough for any form of useful application. This is not the case. I have built many coils and I get many kilowatts for useful purposes from Earth's magnetic field and here I present the basic concept and some formulas fundamental to all of this.

The influence of the Earth's magnetic field should not be ignored. In times of strong sun activity, the Earth's magnetic field oscillates and in any long power transmission line there are voltage surges and over-voltages which can cause technical troubles, breakdowns and stoppages of the electrical sources. The Faraday law for that induction is given for the following:

\[ V = 2 \pi f B A \]

Where:
- \( B \) is the Earth's magnetic field,
- \( f \) the frequency of the fluctuations, and
- \( A \) the surface area across which the field flows.

For calculation purposes we can approximate the Earth's magnetic field as being 1 Gauss (or \( 10^{-4} \) Teslas)

If we consider an ordinary, long transmission line of about 10 Km in length with the power lines spaced 1 metre apart, then we have:

\[ V = 6.28 \times 10^{-4} \times \frac{1}{10^4} \times f \]

which equals 6.28 x \( f \)

If the fluctuations are \( f = 10 \) Hz, that produces an over-voltage of 63 V. If the fluctuations are 100 Hz then the over-voltage is 630 V, etc....

So if the Earth's magnetic field is lower in intensity, the effect is considerable in a great surface and volume range.

For energy and power considerations, we can see that the Earth's magnetic field is lower than common permanent magnets, but the volume of space which it covers is very large. The energy in a magnetic field is not just the field intensity alone, but it depends also on the volume across which that field acts.

The energy stored in a magnetic field \( B \) across a space volume \( V \) is:

\[ U = \frac{1}{2 \mu_0} B^2 V \] .............. (1)

Where \( \mu_0 \) is the magnetic permittivity of the vacuum.

Common permanent magnets channel energy. If we can use them to get unlimited power like the Bearden's MEG, then the Earth's magnetic field across an air core coil can achieve the same result.

Now we can do a comparison between a permanent magnet and a coil oriented to the Earth's magnetic field to get the same energy levels.

Let's consider a powerful permanent magnet, as used in a MEG, of 5,000 gauss and dimensions of 50 mm x 20 mm x 10 mm. According to the equation (1) above, the energy stored in the permanent magnet will be:

\[ U = \frac{1}{8 \pi} \times (0.5)^2 \times (5 \times 10^{-2}) \times (2 \times 10^{-2}) \times (10^{-2}) \]

\[ U = 0.995 \text{ Joules} \] - that is to say, roughly 1 Joule of energy.

Devices like the MEG with permanent magnets don't get too many kilowatts, the reason is because that magnetic energy is constant. If we close that magnetic field in a core or magnetic circuit and we pulse that field we get 1
joule of energy at any desired time rate because the permanent magnet stores that energy unlimited and so if we want a power output of 1 KW as the power $P$ we calculate:

$$P = \frac{dU}{dt}$$

For $P = 1$ KW, we need pulse 1 joule of energy for only 1 millisecond.

In the same way, if we can get power of the same levels from Earth's magnetic field, we must calculate the volume of the air core coil. By using the same equation, we see that

$$(0.5)^2 \times (5 \times 10^{-2}) \times (2 \times 10^{-2}) \times (10^{-2}) = (10^{-4})^2 \times V$$

$V$ is the volume of the coil we need for get the same magnetic energy levels, and in this case, $V = 250 \text{ m}^3$

That is to say, a coil of 6.3 m diameter and 6.3 m length, placed parallel to the Earth's magnetic field, can store the same energy as that little 5,000 gauss permanent magnet which we considered for a MEG device.

But it is not necessary build a huge coil, we can use a smaller coil. The enclosed magnetic energy will be lower, but as $P = \frac{dU}{dt}$ we must raise the frequency of the pulses to obtain the same power level coming from a bigger coil. For example, an air core coil of 1 meter diameter and 1 meter length according to equation (1), stores an energy of:

$$U = 1 / (8 \times \pi \times 10^{-7}) \times (10^{-4})^2 \times \pi \times 1 / 4 \times 1 = 0.003 \text{ Joules}$$

If we pulse that energy level at 330 kHz, then we will get 1 kW, and at 660 kHz, 2 kW, etc., thus a higher frequency yields more power.

Then the question becomes, how can we pulse the constant magnetic field inside the coil? The answer is simple: by using an external source, we can cancel the Earth's magnetic field inside the coil. There must be power and energy amplification with respect to the external input source. To realise that power amplification, we must do the following:

Let the magnetic field variation inside the air coil be given by:

$$B(t) = Bo + Bf \times \sin(\omega \times t)$$

Where

$Bo$ is the constant of Earth's magnetic field,

$Bf$ is the magnetic field in the coil created by the external power source, and

$\omega$ is the angular frequency of the external source.

Replacing $B(t)$ from equation (1) we get the energy variation with time, $U(t)$, and then we can calculate the power as $P = \frac{dU}{dt}$ resulting in:

$$P(t) = Bf \times \omega \times V \times (Bo + Bf \times \sin(\omega \times t) \times \cos(\omega \times t)) / \mu_0 ...... (2)$$

Remember that $V$ is the volume inside the coil.

We see here that the output power depends on $Bo$, the Earth's magnetic field, just as in the case of Bearden's MEG it depends on the magnetic field intensity of the permanent magnet in the circuit.

So we can now calculate a COP value with $Bo$ and without $Bo$, or $Bo = 0$

Calculating the RMS power for both cases (not reproduced here because it corresponds to a case of basic differential calculus) and using the ratio, the result for the COP is:

$$\text{COP} = \left(1 + \left(2 \times \frac{Bo}{Bf}\right)^2\right)^{0.5}$$

We see then power amplification, and of course if $Bo=0$ and not a permanent magnetic field, the maximum COP is 1, input and output powers are equal. In the case of Bearden's MEG, the condition is $Bo = Bf$ for not degaussing the permanent magnet and in that case we have a COP = square root of (5), which is a value between 2 and 3 which corresponds to the practical results for this classic calculation.
But for the Earth’s magnetic field, we can get higher values because we can never cause a demagnetisation of the Earth’s magnetic field.

How many turns on the coil, pulsing frequency, coil diameter, coil length, etc., do we need?

The input power to cancel the Earth’s magnetic field inside the coil, or the condition $B_f = B_0$, we calculate using the RMS component of equation (2) above, setting $B_0 = 0$, so we have:

$$P = 0.05 \times f \times A \times L$$

where $P$ is in watts.

- $A$ is the section of the coil in m$^2$,
- $f$ the frequency in Hertz,
- $L$ the coil former length in metres

To cancel the Earth’s magnetic field inside the coil, the condition based on Ampere’s law is:

$$N \times i / L = 100$$

Where $N$ is the number of turns on the coil and $i$ is the current in amperes.

Finally, the induced voltage in the coil will be:

$$V = 2 \pi \times f \times N \times B_0 \times A$$

So, with the following values, we have for example:

- $N = 1000$ turns,
- $f = 100$ kHz,
- Coil diameter = 1 m,
- Coil length $L = 1$ m,
- $i = 100$ mA or 0.1 A,
- $B_0 = $ Earth’s magnetic field

This gives $V = $ approximately 4,000 Volts.

The input power for this example is about 4 kW, the output power for the COP factor will be a maximum of 12 kW. In closed-loop operation we provide the input 4 kW from the generated output and we get a self-powered generator producing 8 kW of output power. My practical results match these calculations.

How is a practical device built?

Using a large plastic pipe, we wind the primary input coil for use with the external source. For extracting the output power, we use another pipe placed inside the first pipe, and of approximately the same diameter and length with an adequate number of turns and wire size to step down the voltage, to, for example, 110 VAC. For the high voltage oscillator of the input source I use a resonant LC circuit taken from a ferrite power transformer.

It is very interesting to see this device work, and on days of geomagnetic storms, power levels go too high and I must use protective devices to prevent damage to the system and the loads connected to it.

Any questions to the following email: enertec2200@yahoo.es (which may not still be operational as this information is quite old).

**Electrostatic Generators**

Electrostatic generators are not at all unlike aerial systems in that a conversion to ordinary current is needed. The Swiss device designed by Paul Baumann (chapter 13) which has kilowatts of conventional electricity output power and which is self-powered demonstrates that very useful systems can utilise electrostatic charge. Paul’s design is built around a Wimshurst machine which is self-revolving due to the sloping charge-collection strips which form an electrostatic motor as well as collecting the charge which is passed on to the remainder of the circuit.
Quite a number of electrostatic generators have been designed and used. They generally use a small, low-power motor to repeatedly alter the capacitance between a series of metal plates and so, create alternating current flow. Some of these designs are really clever in the way in which they operate. For example, the following patent from Charles Goldie has an input voltage source which is generated by the device itself and the voltage used can be adjusted by the user, while the device provides two separate DC outputs in series, which can be used as a single higher voltage if desired.

The Le May patent shown below has useful techniques which raise the output power to more than five times what it would have been without the use of those techniques. The general impression of electrostatic generators is that they are cumbersome and generally ineffective. That may be the case for some of them, but it is certainly not the case for all of them. For example, the electrostatic generator design of William Hyde, shown in chapter 11, has a COP=10 performance where the electrical output is ten times greater than the mechanical power needed to make it operate, and I'm told that the generator output can be 10 kilowatts which is a more than respectable output.

A particularly clever design comes from Onezime Breaux (US 4,127,804) where a high-voltage charge is generated briefly, and then that same charge is shuttled backwards and forwards through the output load, without that charge ever being ‘used up’ (to put it in layman’s terms). As no system is ever 100% perfect, every ten minutes or so, the high-voltage charge is very briefly reinforced. A system of that type has to be capable of being a self-sustained generator. In a minimal prototype which was not perfectly constructed by any means, the power needed to spin the rotor was 0.8 watts, while the electrical output was 20 watts. This shows clearly, that electrostatic generators can be seriously useful, especially if built in the larger sizes.

The Charles Goldie Electrostatic Generator

SELF-EXCITED VARIABLE CAPACITANCE ELECTROSTATIC GENERATOR

This invention relates to electrostatic generators wherein the charge transfer mechanism makes use of capacitive effects between charged bodies and electrodes upon which charge is to be induced, and in particular, to the self-excitation of such generators.

The invention may best be understood from the following detailed description, having reference to the accompanying drawings in which:

Fig.1 is a diagram illustrating one form of a variable-capacitance electrostatic generator;
Fig. 2 is another diagram further illustrating the arrangement of Fig. 1:

Fig. 3 is a diagram illustrating a modification of the apparatus of Fig. 1 and embodying the invention; and

Fig. 4 is a diagram illustrating a portion of the apparatus of Fig. 3.
Looking at the drawings in more detail, Fig.1 shows a rotor 1 and a stator 2. The rotor 1 has a positive charge on it. A power supply 3 maintains the charge on rotor 1.

In Fig.2 it can be seen that the stator 2 is connected to ground by a resistive path 4 which is connected in parallel with at least one rectifier 5 so that current can only flow in one direction between the stator 2 and ground.

In the device shown in Fig.3 and Fig.4, the rotor serves as a capacitive link between a stationary charging electrode and a stator. A rotor 11 periodically passes close to a stator 12. However, instead of carrying it's own charge as in the device shown in Fig.1 and Fig.2, the necessary inducing charge on rotor 11 is itself induced on
rotor 11 by the charging electrode 13. So, when one end of rotor 11 is near the stator element 12, and the opposite end of rotor 11 is close to the charging electrode 13, a negative charge is induced on that portion of rotor 11 which is near the charging electrode 13 with the result that positive charge appears at the opposite end of rotor 11 since rotor 11 must itself be electrically neutral.

The invention will now be described with reference to the apparatus shown in Fig.3 and Fig.4, but it will be clear from the comments above, that the invention could equally well be used with a device of the type shown in Fig.1 and Fig.2. The principle advantage of the device shown in Fig.3 and Fig.4 is the fact that it eliminates the necessity of a brush on the rotor to supply it with charge, as the charge on the rotor is induced capacitively.

Referring back briefly to Fig.1 and Fig.2, it will be recalled that the invention is concerned with the construction of a self-excited generator with no external energy other than shaft power supplied. That is to say, the objective is a completely self-charging generator. Referring to Fig.1 and Fig.2, it will be seen that direct feedback of the output to the induction plate is ruled out by the polarity switch inherent in this type of machine. The difficulty is avoided by the two-section unit shown in Fig.3 and Fig.4. Here, a fraction of the output voltage of each section is fed to the induction plate of the other.

The action of the circuit is best understood by looking first at the lower section only. Rotor 11 is an electrically isolated, flat fan-like rotor mounted on an insulating shaft 14 which is driven by a suitable motor 15. As rotor 11 rotates, it periodically covers stator 2 and the charging electrode 13, both of which are insulated and sector-shaped. Charging electrode 13 is maintained at a positive DC voltage with respect to ground. As rotor 11 rotates into a position where it covers both the charging electrode 13 and the stator 12, the capacitance between the charging electrode 13 and stator 12 increases and negative charge is induced from the ground through diode 16 and on to stator 12. As rotor 11 rotates away from stator 12 and charging electrode 13, the capacitive coupling decreases and the voltage on stator 12 rises, negative with respect to ground. Diode 16 blocks any flow of negative charge from stator 12 and as the negative potential of stator 12 rises, current flows through a second diode 17 to the load 18. A fraction "V2" of this negative load voltage is applied to the charging electrode or induction plate 13' of the second or upper section by means of the variable resistor 19. The charging action of this second section is identical to that in the first section except for reversed polarities, and the output of the second section is correspondingly fed back to induction plate 13 of the first section via a second variable resistor 20. Variable resistors 19 and 20, control the output voltage and power by adjusting the feedback ratios.

The circuit is regenerative and so it is only necessary to supply a small reference voltage to start in the right direction. The use of stator and rotor materials with suitable contact potentials is one solution. Another solution is using a small battery 21 in one induction line. Suitable voltage-limiting devices 22 would be added either across induction plate 13, or across the load 18 to prevent excessive voltage build-up.

A number of features in this circuit are of interest. The usual slip rings and brushes are eliminated by the use of stator 12 and charging electrode 13 and an isolated rotor 11 rather than a single stator 2 and a rotor 1 mounted at constant induction potential as shown in Fig.1 and Fig.2.
In spite of the fact that the second section was added for the purpose of self-excitation, both output voltages are added together across the load 18, 18'. The arrangement shown in Fig.3 is merely for explanation of the self-excitation principle. The ground shown, for example, is not required and for higher voltages, the units may be cascaded with a common insulating drive shaft 14. For a given total voltage output, the number of rotor/stator sets is the same for this self-charge generator as for a generator requiring auxiliary charging supplies.

Two poles are shown for simplicity. In an actual machine a greater number would be more practical. The system applies equally well to other geometrical arrangements, such as the concentric or segmented drum design mentioned in US Patent application 829,823.

**The Le May Electrostatic Generator**

ELECTROSTATIC GENERATOR

The present invention relates to an energy conversion machine of the type in which a variable capacitor is cyclically driven while being charged and discharged in synchronism with the cyclic variations in capacitance.

There are several different types of electrostatic machines which, for example, function to generate electrical energy from kinetic energy or kinetic energy from electrical energy. One broad classification for these machines is based on whether conductive or non-conductive apparatus is used to transport electrical charge within the system. The present invention relates to the class of machines in which electrical charge is transported through conductive apparatus. More specifically, the present invention relates to electrostatic systems in which a form of variable capacitor is mechanically driven to provide a cyclically-varying capacitance which is charged during intervals of high capacitance and discharged at intervals of low capacitance, to provide electrical energy.

In general, previously-proposed variable-capacitor electrostatic generators (sometimes called electrostatic induction generators) have been capable of very high efficiencies and could be embodied in relatively light apparatus. These considerations result primarily from the fact that electrostatic fields may be sustained in air, vacuum, or other very light medium, while electromagnetic fields necessitate the use of heavy ferrous material. Further, the electrostatic fields are caused by charges carried on surfaces, rather than by currents in conductors, so that the relatively heavy copper requirements of electromagnetic machines may be avoided. It has been found that electrostatic machines operating in a vacuum, do not have the iron loss, copper loss or windage loss of electromagnetic machines, thereby achieving their extremely high efficiency.

However, other considerations have prevented these machines from coming into widespread use. Specifically, prior electrostatic machines of this class have normally been of large size relative to their power capacity. Furthermore, practical use of prior machines has normally required extremely high voltage operation. Both of these drawbacks result from the nature of the electrostatic field, it’s requirement of high potential gradients for field strengths comparable to electromagnetic fields, and the limitations on potential gradients imposed by the breakdown of the dielectric medium. Therefore, considerable insulation and safety equipment has been required in prior electrostatic systems, and operation at moderate voltages has not been practical. Still further, certain forms of electrostatic induction generators have necessitated rather complex switching systems to charge and discharge the capacitors; these systems have not been commercially feasible.

In general, the present invention comprises an efficient electrostatic induction system capable of economical operation which may be embodied in a unit that is small in size relative to power capability. The system includes two sets of rod-like members, one set of which is revolved relative to the other, so that certain of the relatively-moveable rods provide a variable capacitance. The other rods in the structure are then used to shape the electrostatic field in a manner which produces a greater difference between the minimum and maximum capacitance of the apparatus, resulting in increased power conversion capability for the size of the unit. The variable capacitance structure is connected to an electrical system which charges and discharges the capacitance in a cyclically-varying manner. Reactive elements are then coupled to the system to cause voltage phase shifts in the system relative to the variable capacitance, to increase the charge applied to, and taken from, the capacitance structure during the operating cycle, thereby further increasing the power-conversion capabilities of the system.

Another object of the present invention is to provide an improved electrostatic induction system.
Another object of the present invention is to provide an electrostatic induction generator or motor which has a higher power conversion capability relative to its physical size.

Still another object of the present invention is to provide an electrostatic energy conversion system which may be embodied economically in a relatively small size apparatus.

A further object of the present invention is to provide an electrostatic induction motor or generator in which energy is more effectively converted to another form by improving the shape of the electrostatic fields in the system.

Still a further object of the present invention is to provide an electrostatic induction generator or motor in which energy is effectively transformed to another form by the provision of reactive elements to tune the capacitive elements that are inherent in the system.

One further object of the present invention is to provide an improved system for efficiently converting energy from one form to another, wherein an electrostatic field is used to inter-couple the different forms of energy.

These, and other objects of the present invention will become apparent from a consideration of the following, taken in conjunction with the drawings, wherein:

**Fig. 1** is a schematic diagram illustrating the basic operation of a preliminary system to which the present invention may be applied;

**Fig. 2** is a perspective and diagrammatic representation of one form of variable capacitor which may be incorporated in an apparatus of the present invention;

Referring initially to Fig.1, there is shown a preliminary form of an electrostatic induction generator. A variable capacitor 20 is connected in a serial loop with a battery (or other source of voltage) 22 and a diode 24. A series circuit including a diode 26 and a resistor 28 is then connected across the diode 24. The diodes 24 and 26 are connected in a way which allows current flow in opposite directions through the battery 22. Variable capacitor 20 is driven by a motor to provide a cyclically-variable capacitance, with the result that the mechanical energy used to drive capacitor 20 is converted to electrical energy supplied to the load resistor 28.

Considering the operation of the system of Fig.1 in detail, capacitor 20 is driven to vary between maximum and minimum levels of capacitance. At a maximum level of capacitance, capacitor 20 is charged to a charge level “Q” by the battery 22 through diode 24. The voltage across capacitor 20 then equals Q/C where C is the capacitance of capacitor 20. Of course, this voltage coincides substantially with the voltage of battery 22 minus the voltage drop across diode 24.

As the capacitance C of capacitor 20 decreases towards its minimum value, the charge Q remains constant; therefore the voltage across the capacitor increases to accommodate the decrease in capacitance as V = Q / C. The increased voltage across capacitor 20 produces a current through battery 22, load resistor 28 and diode 26. This current tends to recharge battery 22 as well as providing energy to the load resistor 28.

In this manner, the mechanical energy used to drive capacitor 20 cyclically, is manifest in the form of electrical energy passed to the load resistor 28. Therefore, in general, this basic operation of the electrostatic generator is similar to an electromagnetic generator, except that the field which couples the mechanical input energy to the electrical output energy is electrostatic rather than electromagnetic.

A wide variety of structures may be used as the variable capacitor in an electrostatic generator. However, in the selected structure, it is normally desirable to reduce the ratio of the peak field voltage gradients to the average gradients by using rounded capacitor elements, e.g. tubes or bars, rather than capacitor plates with sharp corners. Two variable capacitor structures using these conductive bars are shown in Fig.2 and Fig.3 and will now be considered in detail.

The structure of Fig.2 is a radial-bar variable capacitor configuration where rows of radially-extending bars are mounted to be relatively moveable and so provide a variable capacitance between the rows. Specifically, a first row of bars 30 is mounted in a hub 32 which is carried on a fixed shaft 34. Similarly, another row of radially-
extending bars 36 is supported in a hub 38 which is mounted on fixed shaft 40, which telescopically receives a concentric shaft 42 which is coupled to motor 44 and which carries hub 46 supporting the row of bars 48 which is positioned between rows 30 and 36. The bars in each of the rows 30, 36 and 48 may be interconnected electrically by a conductor supported in the respective hubs. However, as the individual hubs 32, 38 and 46 are formed of insulating material, the separate rows are not interconnected electrically. Therefore, a variable capacitance exists between the individual rows 30, 36 and 48. This capacitance is somewhat similar to a common rotating plate capacitive structure, however, in order to reduce the peak field voltage gradients between the rows, the bars or capacitive elements are rounded to avoid sharp corners.

At a time when the row of bars 48 is in angular alignment with the bars in rows 30 and 36, the bars are closest and there is maximum capacitance. As the row 48 revolves it reaches a position of least alignment of the bars in rows 30 and 36 (as shown in the drawing) and there, the capacitance between the rows is at a minimum. Therefore as motor 44 rotates the bars in row 48, a cyclically varying capacitance is provided between these bars and the bars in rows 30 and 36. In the application of this structure to the present invention, certain of the bars may be used to shape the electrostatic field as described below, while the remaining bars provide the desired variable capacitance. Of course, the number of rows provided in a configuration of this type may be varied to increase the capacitance, as may the size of the bars. Of course, these considerations are determined by the particular application of the system.

---

**Fig. 3**

Fig. 3 shows another form of variable-capacitance structure which may be used in a system of the present invention. The structure shown in Fig. 3 includes two concentric cylindrical structures 50 and 52, which are mounted so that they rotate relative to each other. These two structures are similar except for their size. The smaller structure 50 is telescopically fitted concentrically into the larger structure 52. The smaller structure 50 includes a pair of insulating rings 54 and 56 which are held spaced apart by conductive bars 58 and are angularly offset in a circular configuration. A pair of insulating rings 60 and 62 of the structure 52 are concentrically mounted outside the rings 54 and 56 respectively and are held spaced apart by angularly offset conducting bars 64. The structure 52, comprising the rings 60 and 62 and the bars 64 is held fixed, while the structure 50, comprising the rings 54 and 56 and the bars 58, is revolved making bars 58 and 64 pass each other in parallel relationship. As a result of this movement, a variable capacitance exists between the bars of the two structures. As in the structure shown in Fig. 2, the individual bars in the separate structures may be interconnected electrically to provide a composite capacitance, or alternatively certain of the bars may be used for field shaping as described below. Thus the structure shown in Fig. 3, as well as the structure shown in Fig. 2, may be used as the cyclically-varying capacitance in the system shown in Fig. 1 to provide electrical energy from kinetic energy. In such a system, the energy would be provided by motors 44 or 66, however, the source of the kinetic energy is not important for the present invention.

In the operation of an electrostatic generator as shown above, the ratio of power conversion per unit size (and weight) of machine may be increased by increasing the maximum capacitance, or by decreasing the minimum capacitance of the variable capacitor. Of course, it is apparent that as the energy conversion is accomplished in systems of the present invention by a varying capacitor, the effectiveness of the conversion depends on the range over which the capacitor varies. In general, the efficiency of these systems is quite high even when operating with a small capacitive range, however, in such systems the energy conversion capability or power
rating of the system is low relative to its physical size. One major aspect of the present invention resides in a structure for increasing the range of capacitive change, and will now be considered in detail. For purposes of illustration, a moveable plate variable capacitor will be considered with reference to Figures 4a, 4b and 4c. The flat plate capacitor provides a good example of the universal principle to be described because of the simple electrostatic field present in such a structure.

Fig. 4a shows a pair of spaced-apart conductive plates 70 and 72 in face-opposing relationship and individually connected to the terminals of a battery 74 or other voltage source. The electrostatic field between plates 70 and 72 is indicated by lines of equal potential, and orthogonal flux lines which indicate the capacitance between the plates. Fig. 4b shows plates 70 and 72 in an offset position, displaced out of face-opposing relationship to result in reduced capacitance between the plates. Again, the electrostatic field between plates 70 and 72 is indicated by lines of equal potential and the orthogonal flux lines which indicate the capacitance between the plates.

As previously mentioned, any arrangement which can result in greater capacitance for the plates in the configuration shown in Fig. 4a, or reduced capacitance between the plates in the position shown in Fig. 4b, results in more effective energy conversion in an electrostatic generator. The system of the present invention includes a structure for shaping the electrostatic field between plates 70 and 72, to reduce the capacitance between these plates when these plates are in their position of minimum capacitance. This field-shaping is accomplished by adding extra conductors to influence the field between the plates.

Referring to Fig. 4c, plates 70 and 72 are again shown in their position of minimum capacitance, however, another plate 76 is shown in face-opposing relationship to plate 70. Plate 76 is connected to ground or other independent potential. As a result of this, and electrostatic field is provided between plates 70 and 76, altering the field shape and the potential gradients, as shown in Fig. 4c. The electric field and the capacitance between plates 70 and 72 is reduced substantially, while the maximum capacitance between these plates (when aligned in face-opposing relationship as shown in Fig. 4a) remains substantially unchanged.

These same considerations apply in a similar fashion to bar conductors or other configurations of variable capacitors. Of course, the grounded or field-shaping plates as the plate 76 may be provided in both the stator and the rotor of a variable capacitor, or may be carried by only one of these structures.

Referring now to Fig. 5, there is shown a system incorporating field-shaping electrodes and utilising capacitive structures comprising bars which may take the form generally illustrated in Fig. 2 and Fig. 3.
In Fig. 5, the stator bars are diagrammatically represented aligned in one row 78 and the rotor bars are similarly shown to be aligned in an adjacent row 82. Of course, either of the rows 78 and 82 may comprise a stator while the other comprises the rotor since relative motion is all that is necessary. However, in the prior art it has become somewhat common to term the rotor conductors as charge inductors while describing the rotor elements as charge conveyors.

In the system shown in Fig. 5, grounded field-shaping electrodes or conductors are provided in both the row 78 and the row 82, and are designated bars 78a and 82a shown shaded. The electrodes 82a are connected directly to ground, however the electrodes 78a are connected to ground through an inductor 86. The function of this coil will be discussed later.

The conductive bars serving as capacitance elements in the two rows are designated 78b and 82b respectively. The bars 78b (in the row 78) and the bars 82b (in the row 82) are connected in a circuit configuration somewhat as shown in Fig. 1. Specifically, the bars 78b are connected in a serial loop with a diode 88 and a battery 90. The junction point 91 between diode 88 and battery 90 is grounded, and a diode 92 serially connected with a load resistor 94 is connected across diode 88. A capacitor 96 is connected across the load resistor 94, and serves as a filter for the load current.

In the operation of the system, relative movement is provided between row 78 and row 82 producing a cyclically variable capacitance to cause the system to function as the system shown in Fig. 1. That is, during the interval of high capacitance between the rows 78 and 82 (as shown in Fig. 5), the capacitive structure is charged by battery 90 through diode 88. Then, as the bars are separated to reduce the capacitance, the voltage across them increases, causing a current to flow in the opposite direction through battery 90, the load resistor 94 and diode 92. As alternate bars in each of the rows 78 and 82 are grounded, the electrostatic field is shaped to reduce the minimum capacitance between the bars 78b and 82b as disclosed in Fig. 4. As a result, the capacitance variation is greater and more charge is transferred through the load during each electrical cycle.

In the operation of the system shown in Fig. 5 to convert mechanical energy into electrical energy, a generally capacitive electrical system is provided. Therefore the phase relationships within the system are generally those of a capacitive apparatus. In view of this, the present invention includes the provision of inductors to produce phase shifts and resonant voltage amplifications which increase the effective power-conversion capabilities of the system. In Fig. 5, such an inductance 86 is connected between the bars 78a and ground. The operation of the system of Fig. 5, including the inductor 86 is graphically illustrated in Fig. 6 which includes plots of capacitance, voltage and electrical current versus the position of the capacitive structure.
The upper family of curves are capacitance plots, in which, curve C1 is a plot of varying capacitance between the conductive bars 78b and 82b. The curve C2 is a plot of the capacitance between bars 78a and 82a, while the curve C3 is a plot of the capacitance between bars 78a and bars 82b. These curves are plotted against a uniform variation in relative positions between row 78 and row 82, the curves beginning at a point of minimum capacitance for the structure. Fig.5 illustrates the relative position marked as 3 in Fig.6.

The voltage curves in Fig.6 are plotted on the same base as the capacitance curves, and include a curve V1 which represents the voltage across coil 86, and a curve V2 which represents the voltage on the bars 78b relative to ground potential. The curve I, illustrates electrical current flow through inductor 86, and it is also plotted with respect to capacitative displacement.

Considering the operation of the inductance 86; in view of the capacitance between the grounded bars 78a and the capacitively-charged bars 82b (connected to battery 90) a charge is deposited on the bars 78a. Of course, in the absence of the inductance 86, this charge would be immediately passed to ground. However, by providing the inductance 86, the voltage of curve V1 is developed across this element. This voltage serves to produce further field shaping between the bars and results in more efficient power conversion. That is, the voltage of curve V1 appears on the bars 78a in phase with the capacitance C1 so that the field influence of bars 78a serves to increase the charge induced at or near the maximum of capacitance C1 and also serves, by reducing the field strength to reduce the minimum charge held on bars 78b and 82b at, or near the instant of minimum capacitance. Thus the variation in the electrostatic field causes the system to absorb more torque, resulting in increased power-conversion capability for the system.

In addition to the provision of inductor 86 as shown in Fig.5, other circuit configurations using inductors are to further affect resonant current surges which increase and decrease the field voltages in proper phase relationship with the capacitance variation, and so increase the amplitude of the capacitor alternating current. One such other variation is shown in Fig.7 which uses bars similar to those of Fig.5 and in which, like elements are similarly identified.
In the system shown in Fig.7, an inductor 98 is connected between diode 88 and the junction point 99 between diode 92 and the bars 78b. Furthermore, a capacitor 100 is connected across diode 88. In general, the added resonant circuit provides further current surges in the desired phase relationship with the variation of capacitance. Also, the resonance between inductor 98 and capacitor 100, tends to produce higher voltages in the electric field of the variable capacitor relative to the voltages across the excitation source 90 and the load 94. The capability of the machine to achieve high power from a small size of variable capacitor is thereby greatly improved.

A graphic indication of the improvement to a system resulting from the application of certain principles of the present invention may be seen in Fig.8 which includes several curves descriptive of various apparatus, and wherein speed is plotted along the horizontal axis versus specific power which is plotted along the vertical axis. Specific power is herein defined as the power output per unit of excitation voltage squared (P/E₀²) for a given size and configuration of machine.

The curve E1 is indicative of the operating characteristic of the simple system shown in Fig.1. The curve E2 (indicating a substantial improvement in performance) is indicative of the system shown in Fig.5. The curve E3 indicates the improvement of the system of Fig.7 (without the aspect described with respect to Fig.5), while the curve E4 indicates the operation of the system shown in Fig.7 as illustrated there.
It is apparent that the power conversion capabilities of the system of Fig. 7 (indicated by the curve E4) are greatly improved over the simple system which does not include these aspects of the present invention, particularly if the generator is operated at a fixed speed, or if means are provided to adjust the inductance or capacitance values of components 86, 98 and 100 to give the tuned peak power at whatever speed the machine is being operated.

Although various aspects of the present invention may be differently applied to electrostatic machines, to accomplish the desired results, one specific illustration of an operating machine is shown in Figures 9, 10, 11 and 12, and will now be considered in detail.

The system is mounted in a housing 110 which is sealed and maintained evacuated by a vacuum pump 112. By operating the cyclically-variable capacitor apparatus in a relatively high vacuum, insulation problems are reduced and windage losses are minimised. The housing 110 has a flat cylindrical form and consists of a circular plate bolted to a cup-shaped member 116 with an annular seal 118 provided at the junction between these members.

A mechanical shaft 120 passes concentrically through housing 110 and is journal led into bearings 124 and 126, which incorporate vacuum seals 124a and 126a. The shaft 120 has a rotor 128 coaxially fixed on it and is connected to a mechanical apparatus 130 by which the shaft is driven. Shaft 120 (made from insulating material) has a conductive section 132 formed in it, which electrically connects rotor 128 through a brush 134 and a lug 136 to one terminal of a battery 138, the other terminal of which is grounded.
In general, the basic electrical system is similar to that of Fig.7 with the stator elements being connected by lugs 146 and 148 to a junction point 150 which is connected through an inductor 152 and a capacitor 154 to ground. A diode 156 is connected in parallel with capacitor 154. The junction point 150 is also connected through diode 158 to a filter 160 which is in turn connected to a load 162. The field-shaping electrodes in the stator elements 140 and 142, are connected from lugs 164 and 166 through an inductor 168 to ground.

Considering the cyclically-varying capacitance apparatus in greater detail, the rotor comprises a pair of plates 170 and 172 (Fig.12), which are formed with angularly-offset radiating grooves 174 which are interconnected by spot welds 176 so that the grooves 174 essentially form radiating bars 175. In this structure, the rotor is entirely conductive material, e.g. metal, formed to comprise radiating tubes 175 (Fig.11) which are connected through the shaft conductor 132 and the brush 134 to the battery 138.

The stator components 140 and 142 are similar and comprise a plurality of tubes 180 (Fig.10) radiating in a plane from an axial location in the stator element and supported in a circular stator mounting 181 by being imbedded therein. Tubes 180 are formed of metal and the mounting 181 supporting the tubes is formed of insulating material as a casting of epoxy material. Alternate of the tubes 180 are designated 180a and are connected electrically to a terminal 184 which is contacted by one of the lugs 146 or 148 at a point 186.

The lugs 164 and 166 are connected to ground through inductor 168, with the bars 180a used as field-forming bars while bars 180b are the actual variable-capacitance elements. In this structure, only the stator is provided with field-shaping electrodes; however, it is to be understood, that in various other embodiments, field-shaping electrodes may be provided in both the stator and the rotor, or in only one structure, as taught with respect to Fig.5 and Fig.7. Also, in the system shown in Fig.9, only a single rotor plate is provided; however it is to be clearly understood that a large number of intermeshed rotor and stator plates may be provided in systems of the present invention, depending on the rated power conversion capability of the system.

In the operation of the system shown in Fig.9, rotor 128 is revolved relative to the stator elements 140 and 142 by the mechanical apparatus 130. Therefore, the tubular rotor bars are driven in and out of alignment with the radiating stator bars 180b. Therefore the connections to these elements (lugs 146 and 148, and brush 134) experience a cyclically-varying capacitance. The stator bars 180a extend the range of this capacitance in the manner described with respect to Fig.4.

During intervals of high capacitance, the cyclic capacitive structure is charged by battery 138 through inductor 152 and diode 156. As the capacitance of the structure decreases, the voltage therein increases, providing a current through diode 158, and filter 160 to the load 162. Thus, mechanical energy from the mechanical apparatus 130 is efficiently converted into electrical energy and supplied in that form to the load 162.

While the previous discussions have pertained primarily to electrostatic generators, it is to be understood that the important features of the present invention apply equally to electrostatic motors.

An important feature of the present invention resides in the structure disclosed in Fig.9, which may be economically manufactured and used in practical electrical systems.

Another important feature of the invention resides in the use of field-forming electrodes in the stator or rotor, or both the stator and the rotor to accomplish more effective energy transitions.

One other important feature of the invention resides in the provision of inductance elements to further increase the effectiveness of the system.

The Onezime Breaux Electrostatic Generator

ELECTROSTATIC ENERGY CONVERSION SYSTEM

This is an important design, but as the physical details in the patent seem rather limited, instead of reproducing the patent here, I will attempt to provide a description which should be more understandable for the average person.
The Principle

For there to be a greater energy output than the energy input required to make any generator operate, that extra energy must come from somewhere. There is no magic about any of these systems as we ourselves are immersed in a massive energy field. We do not notice this any more than we notice the radio waves which pass by, and through us, all the time. This energy field is very powerful as Thomas Henry Moray demonstrated many times by gaining fifty kilowatts of electrical power from just a simple aerial and a ground connection. We don’t know how he did that, but we would very much like to know how. Nevertheless, Moray demonstrated that there is massive power all around us – power which is free for the taking if we know how to do it. Unfortunately, most of the large number of people who do know how to extract this energy, refuse to share that information, leaving us to work out from basic principles, how to gain this free-energy. It should be noted in passing, that we already use this free energy when we use “mains electricity” as none of the energy supplied by the local Power Company actually comes out of your mains wall socket since all of the current supplied by the Power Company flows directly back to that company. All the Power Company does is to set up the conditions which cause some of the free-energy in your location to flow through the electrical equipment which you plug into that wall socket. What free-energy devices do, is to set up those same conditions to draw in electricity from our massive surrounding energy field, without the need for any help from the local Power Company.

The Design

When you try to start a car engine, you connect the car battery to an electrical Starter Motor which turns the engine over and causes sparks to be generated inside each of the cylinders of the engine. The current draw from the battery passes through the Starter Motor and is lost for ever. If the car engine starts, then some of the energy stored in the fuel burnt by the engine is used to replace the electrical current taken from the battery. If the car engine does not start, then after a fairly short time, all of the electrical energy stored in the car battery will be fed to the Starter Motor and the battery will no longer be able to supply any more current to turn the engine over.

The generator described here is a very clever design as any output power which it provides, it keeps and does not lose any of it. It is somewhat like that car Starter Motor returning the current to the battery, allowing any number of attempts to start the engine. The way that it operates is to pass current backwards and forwards between two capacitors. That current is made to pass through the primary winding of an output transformer, exactly mimicking the signal which the Power Company charges you for. However, with our generator, that current is never lost and can be used over and over and over again. A battery is used to create that initial current, and when the generator starts operating, it recharges the battery and if desired, the battery can be removed completely and the generator is then self-sustaining. The battery is only used to start the generator running and is not used at any other time.

The outline design is very straightforward and can be visualised as shown here:

Here, the motor marked M in the diagram, spins a metal shaft 23. The shaft is mounted on ceramic roller bearings (as used on skateboards) and nothing on the shaft touches any other part, which means that the shaft spins very freely and very little power is needed to spin it.

Shaft 23 has metal ‘vanes’ or plates 21 attached to it and these pass though somewhat similar metal vanes 25 which are fixed in place and do not move. These four sets of metal vanes form two separate variable capacitors.

The vanes 21 are arranged so that when one set reaches it’s maximum capacitance (being fully inserted into the non-moving vanes 25 as shown on the right of the diagram) then the other set of vanes is at it’s minimum capacitance being as far away as possible from it’s matching set of vanes 25.
Initially, at start-up, both of the sets of vanes marked 25 are fully charged to a high positive voltage by an electrical system (not shown here) and the output transformer is connected between these two sets of vanes, producing this arrangement:

The sets of vanes 21 are connected to a strongly Negative charge, passed to them through the metal shaft 23. When the negative plates 21 are inserted between the Positively charged plates 25, all of the positive charge on the unmeshed plates 25 gets sucked towards the negative charge on the meshed plates 21, but that charge is forced to flow through the output transformer on it’s journey. This arrangement causes the positive charge on the fixed plates to shuttle backwards and forwards through the output transformer, never getting ‘used up’ in the process. This means that the generator has an electrical output of 220 volts at 50 cycles per second and the only input power needed is the tiny amount required to spin the rotor shaft. The force needed to spin the rotor shaft is not affected in any way by the intensity of current drawn from the output transformer, which means that the generator is wholly independent of the load. While this is a very clever design, a number of practical construction details can be altered to improve the performance.

The Breaux patent shows a vane shape which doubles the frequency at which the drive motor spins and which is balanced on the shaft, producing no shaft vibration when spun rapidly. The vane shape is shown here:

You will notice that the rotor vanes (shown in grey), are positioned ninety degrees apart, providing even better shaft balance. All of the rotor vanes have the same shape and all of the stator vanes have the same shape, which is helpful for mass production. While just two rotor vanes and two stator vanes are shown in this introductory diagram, there can be as many pairs of rotor/stator plates as desired. Each additional pair of plates increases the output power of the generator.

This design calls for the vanes to be in a vacuum, which strongly suggests that this device was never prototyped as operating in a vacuum, unless all conducting surfaces have exceptional insulation, would be a major disaster.
as the coronal discharge would be massive – after all, that is how thermionic valves or ‘vacuum tubes’ are made and they carry large electrical currents through a vacuum. For this design to function properly, it needs to be operated in dry air.

The power output of a device of this nature increases with increasing vane area, and with decreased inter-vane gap and with increased voltage. Consequently, a working voltage considerably higher than 220 volts will be used when charging the vanes. This means that the output voltage will be much higher than is convenient. Generators of this type generally show a resistive load and only a resistive load. A practical implementation would require a step-down transformer on the output in order to reach a working AC voltage of 220V. It is generally thought that the inductive nature of the primary winding of any such transformer would create a major choking effect on the oscillating flow of charge between the vanes, due to the back-EMF of that winding. That is not the case if a Thane Heins style of transformer is used (as shown in chapter 3) as a transformer of that type does not have any significant back-EMF, making this a very interesting design, especially since the output current draw does not affect the input power which is solely used to spin the rotor shaft.

In theory, the static charge initially placed on the capacitor vanes is never depleted. However, in this world, perfect conditions never seem to be encountered. In this instance, there is a very slight loss of charge over time, and that charge is boosted very briefly after a substantial time has elapsed. A brief high-voltage pulse once every ten minutes is likely to be sufficient. There is no corona energy loss as corona streamers only form at high frequency and this generator does not exceed an absolute maximum of 60 Hz which is a very low frequency indeed, so there is never any corona discharge at all.

http://www.free-energy-info.com
http://www.free-energy-devices.com
We have been raised with the idea that it is necessary to burn a fuel to produce power which we can use. We are sold coal, coke, timber, paraffin/kerosene, petrol/gasoline, diesel, propane, etc. for us to burn in order to “get” energy. While it is perfectly true that burning these things will indeed result in energy in a form which we find convenient to use in heating, cooling, powering engines, etc. what is carefully avoided is the fact that it is not at all necessary to burn a fuel in order to run the things which we want to power. This ‘inconvenient’ fact has been concealed and denied for more than fifty years now (very surprisingly, by the people who want to sell us these fuels to burn – do you perhaps think that they may have some motive for this, other than our best interests about which they are no doubt, very concerned?).

This chapter is about ‘fuel-less’ motors. Strictly speaking, they are not self-powered but as they don’t burn a fuel of any kind, in everyday language they can be described as ‘self-powered’. In the same way that a solar panel in sunlight uses no fuel and yet puts out electrical power, these motors draw energy from the environment and provide us with mechanical power. In actual fact, power is never “used up” but just converted from one form into another. In the case of our trusty solar panel, some 17% of the radiation from the sun (mainly ultraviolet) is converted into electrical power and 83% goes in heating and other losses, but as we don’t have to supply the sunlight, and the solar panel pours out the electricity which we want without us having to do anything to make it happen, we really don’t care very much about its extremely low efficiency. As far as we are concerned, the electricity flowing from the panel is “free-energy”.

It is really amazing that we have been persuaded that we must burn a fuel in order to get power. Take the case of a heavy-displacement sailing yacht. The skipper can voyage using his inboard diesel engine:

This matches perfectly with the thinking that you need to burn a fuel in order to get power as the yacht is moving along, pushed by the engine which is powered by burning diesel fuel. But, what if the skipper decides to switch the engine off and set the sails?:

![Image of a sailing yacht](image-url)
Now, the same boat, weighing exactly the same with the same crew, is now continuing the voyage at the same speed, but no fuel is being burnt. The really interesting thing is that while we know this perfectly well, and we are aware that people have sailed right around the world in boats which do not have engines, it does not seem to occur to us that this shows conclusively that it is not necessary to burn a fuel to power some item of equipment or form of transport.

In the case of our yacht, the energy comes from the sun which heats the atmosphere unevenly, causing winds to blow and the yachtsman uses the sails to make those winds power his boat through the water. So, a sailing boat is actually powered by the sun although we don’t usually think about it that way.

There are many hydro-electric “power stations” where electricity is ‘generated’ by machines driven by water pressure. In actual fact, no power is ‘generated’ at all, but instead, the potential energy of the body of water is converted into electricity by having the water fall and spin the shaft of a machine. So, how did the water get up there in the first place? Well, it came from rain. And how did the rain get up there? It rose up there due to evaporation caused by the heat of the sun. So, the bottom line again is that hydro-electric ‘power’ stations are powered by the sun.

Windmills are also powered by the sun. But, and here is the really interesting thing, if I state that it is perfectly possible for a compressed-air engine to produce mechanical power without burning any fuel, then there is an immediate and strong reaction where people will say “Impossible – that is perpetual motion!!” They imply that perpetual motion is impossible but never supply any rational evidence to support that implication. The Earth has been spinning on its axis for millions of years, so when exactly do they expect it to stop? All the planets in the Solar System have been orbiting for millions of years, how long do they have to orbit before they can be considered to be in perpetual motion? Why then are people so opposed to the idea of perpetual motion? Presumably, because perpetual motion shows clearly that a fuel does not have to be burned to ‘produce’ power and that would not be good for people who sell fuels, and so, we are all told from an early age that perpetual motion is “impossible”.

Well, that does not matter here as we are going to look at compressed-air engines which run off the heat of the sun. That is, they are heat-pumps which are a well accepted engineering fact and they work on wholly accepted standard scientific principles. An ordinary refrigerator outputs three or four times as much heat power as the electrical power driving it, and it could be twice that efficient if it were used properly. This is a Coefficient Of Performance (COP) of 3 or 4, which is supposed to be “impossible” but unfortunately, all refrigerators work like this and you can’t exactly say that refrigerators don’t exist, just because their performance does not appear to fit in with some theories.

Actually, there is no magic involved here as the extra energy is being drawn from the heat content of the air in the immediate locality. The refrigerator is not operating in isolation and there is a heat exchange with the air surrounding it. This outside energy causes the COP>1 performance. In passing, all COP>1 devices operate by drawing energy in from an external source (usually the zero-point energy field) and none of them actually break the ‘rules’ of science. But, enough of that.
The people who don’t want self-powered engines used in the world today, pin their hopes on a continued ignorance of Engineering facts relating to heat pumps. A self-sustaining compressed-air engine is actually running off power from the sun just as sailboats, windmills and hydro-electric power stations do. Sorry folks, no magic here, just bog-standard Engineering. Admittedly, very few people know or realise the implications of this standard Engineering:

1. All work done in compressing air into a storage tank is converted into heat and then lost to the atmosphere, so the energy in the compressed air inside the tank is the same as that produced by atmospheric heating of that air, but as more of it is now in the tank, there is additional potential for work to be done. This extra energy was fed into the air by atmospheric heating before the air was compressed.

   The First Law of Thermodynamics states that where heat is converted into mechanical energy, or mechanical energy is converted into heat, the quantity of heat is exactly equivalent to the amount of mechanical energy. We then have the intriguing situation where all of the mechanical energy put into compressing air into a storage tank is lost as heat, and yet, the tank contents now has a higher potential for doing work. This information comes from Engineering textbooks.

2. If the expanded cold air leaving the engine is used to cool the intake air of the compressor, then there will be an added gain when it warms up inside the cylinder, pulling heat in from the local environment.

3. If the heat of compression is transferred to the air container feeding the engine and not given time to dissipate, then there is a further power gain for the engine.

4. If compressed air is allowed to expand rapidly, there is a marked drop in temperature. The Leroy Rogers engine design, shown later in this chapter, uses this fact to create air-conditioning for a car driven by a compressed-air engine.

OK then, in broad outline, the energy available from a tank of compressed air comes directly from the heat contained in the atmosphere, in spite of the fact that we always imagine that the energy in the tank was put there by our energetic pumping.

Let’s check this out by taking a look at some of the engines which use these principle to provide fuel-less operation, starting with the design of Bob Neal. The full patent for Bob’s design is included in the Appendix.

**Bob Neal’s Compressed Air Engine.**

Bob Neal’s design is a compressed-air operated engine and compressor where the operation of the engine keeps re-supplying the compressed air tank:
is a vertical transverse cross-section view through the compressor part of the engine. In his patent, Bob has avoided any direct mention of the fact that his engine design is fuel-less. That sort of statement is not popular with Patent Examiners even if it is perfectly true.

**Scott Robertson’s Compressor System.**
Bob Neal’s system could do with some further explanation, so here is an idea from Scott Robertson whose web site is [http://www.aircaraccess.com/index.htm](http://www.aircaraccess.com/index.htm), for a possible working compressor system using a leaf-blower:

While this looks rather complicated, in reality it really isn’t. Let’s take the different sections in order:
First, you have an ordinary air engine, supplied with compressed air from a pressure tank. This engine exhausts its (cold, expanded) air to the atmosphere. The engine powers two compressors which between them keep the tank full of compressed air.

The first compressor is a simple ‘leaf-blower’ type which produces a large volume of low-pressure air. The big question is “how do you get this large volume of low-pressure air into a tank which has high-pressure compressed air inside it?”. Well this seemingly impossible task is performed by the second compressor aided by a cunning, ultra-simple design:

Here, low-pressure air is fed into the low-pressure area marked in pink. Separating it from the high-pressure area is a metal plug marked in green. Set into this plug is a ring of five one-way air valves marked in red. These one-way valves let the low-pressure air into the high-pressure area because of a high-speed jet of air produced by the ‘jet-drive compressor’. At first glance, this seems impossible, but it is actually just an application of a standard Engineering technique. The high-speed air jet is directed through a specially shaped nozzle, creating a local low-pressure zone around the jet.
The low-pressure air at point “A” flows through the ring of five one-way valves into the disc-shaped low pressure area “B” and is blasted into the high-pressure area “C” by the high-power air jet ripping through the doughnut-shaped ring marked in yellow. The high-speed air jet causes the low pressure ring “B” by its rapid movement which creates a vortex due to the shape and positioning of the doughnut-shaped ring marked in yellow. This clever arrangement allows large volumes of low-pressure air to be drawn into a tank which contains high-pressure air.

You will also note that the two-stage compressor which generates this high-speed jet of air, has its working area actually inside the tank. This means that the heat of compression is used to heat the air inside the tank and raise its pressure, enhancing the operation further. It should be borne in mind that the new air entering the system has been heated by the sun and contains the energy which powers the system.

The Retro-fit Compressed Air Vehicle System of Leroy Rogers.

The Rogers motor shown here makes no claims to spectacular operation, but in spite of that, Leroy did admit in an interview that this motor does indeed have a greater output than the applied input, provided that the motor is not left just ticking over. This motor is like the US patent 3,744,252 “Closed Motive Power System Utilising Compressed Fluids” by Eber Van Valkinburg shown below. However, the Rogers patent shown here has the distinct advantage that it uses off-the-shelf motors and readily available hardware and there is nothing really exotic or difficult about the Rogers engine that a person couldn’t get from a valve supplier or get a metal fabrication company to construct.

However, while Leroy did state that his design was self-sustaining when going over 30 miles per hour, a key design feature is his very high performance compressor unit which he later patented as shown below. Present day vehicle engines are under-gearied and run at fairly low revs. These same engines operate much more efficiently at higher revs, if they are given different gearing. With the Rogers motor, the air contained in the high-pressure tank is sufficient to drive the pistons up and down. Air can be pumped back into the high-pressure tank by a compressor which has a much higher gearing and much lower capacity per piston stroke. The expanded air exiting from the engine is at much lower temperature than the surrounding air and if it captured in a buffer tank and used as the input of the compressor, then recharging the air tank is more efficient, provided that the tank absorbs heat from the surrounding environment, raising it’s temperature inside the tank and so giving an extra boost to the tank pressure, over and above the compression provided by the compressor.

One really nice feature of Leroy’s design is that he envisages it as being an adaption of an ordinary vehicle engine and he provides a considerable amount of practical detail as to how the adaption can be carried out.

Using a RotoVerter (as described in Chapter 2) to drive a compressor would lower the power requirements of the compressor drive to the extent that a motor adaption of this kind should be self-sustaining. The RotoVerter provides a major energy gain in its own right and is particularly suited to driving mechanical loads such as the compressor and it particularly ‘likes’ constant-load applications such as a compressor.

The adapted engine shown in the patent is like this:
This patent shows how the practical details of running an engine on compressed air can be dealt with. What it does not show is background details of the actual energy flows and the effects of compressing air and then letting it expand. These things are not normally encountered in our daily lives and so we do not have an immediate intuitive feel for how systems like these will operate. Take the effects of expansion. While it is quite well known that letting a compressed gas expand causes cooling, the practical effect is seldom realised.

Leroy's compressor patent is shown here:

**United States Patent 4,693,669  Supercharger for automobile engines**

**Inventor:** Rogers Sr., Leroy K. (Rte. 13, P.O. Box 815-DD, Briarcliff Rd., Fort Myers, FL, 33908)

**Publication Date:** 15th September 1987

**Abstract:**
A supercharger for delivering supercharged air to an engine, comprising a shrouded axial compressor, a radial compressor which is located downstream of the axial compressor and a housing. The housing is comprised of four sections, including a section which is a highly converging, 'frustoconical' transition duct which favourably directs the discharge of the axial compressor to the inlet of the radial compressor and a hollow, highly convergent, exhaust cone section immediately downstream of the radial compressor which converges into the exhaust port of the supercharger. An annular flow deflector is provided for directing the discharge of the radial compressor into the exhaust cone.

**Description:**
Superchargers impart additional pressure to the air or the air/fuel mixture of an engine so that the cylinders receive a greater weight per unit volume of air or air/fuel mixture than would otherwise be supplied. As a result, the volumetric efficiency and power output of the engine are improved.
According to prior practices, superchargers generally comprise a single air-blower which forces air or an air/fuel mixture into the cylinders of an engine. Typically, the air-blower is driven by a gear train which is connected to the crankshaft of the engine with a gear ratio of about 6 to 1. These prior types of superchargers have been used extensively in racing engines and radial aircraft engines. However, by reason of their high operating speeds and their gear trains, these superchargers have been considered too complicated, too heavy and too costly for use with mass production engines such as are found in cars and trucks.

Recently, some car manufacturers have been offering turbocharged engines which expand to exhaust gases of the engine through a turbine to drive a centrifugal compressor. Although turbochargers are advantageous in that the turbine can deliver large amounts of power to the compressor, their extreme operating speeds require special bearings, lubrication and maintenance. In addition, turbochargers require special ducting, such as by-pass arrangements, which only add to their cost and maintenance requirements. Consequently, turbochargers are only offered as expensive options in cars.

Further, there is current interest in a new type of car engine which operates from tanks of compressed gas to effect reciprocation of its pistons. An example of such an engine can be found in the U.S. Pat. No. 4,292,804 issued to the same inventor of the present invention. In the referenced patent, at least a portion of the partially expanded exhaust gas from the cylinders is directed to a compressor where it is recompressed and then returned to the storage tanks from whence it originally came. It would be desirable that at least some, if not all of the aforementioned recompression of the exhaust gas could be achieved with a belt-driven, rotary supercharger that is easily manufactured and maintained, yet is capable of providing ample recompression.

Objects of the Invention:
Accordingly, an object of the present invention is to provide a supercharger suitable for improving the performance of engines of cars, helicopters or the like, which supercharger is inexpensive to produce and easy to maintain.

It is another object of the present invention to provide a supercharger which provides sufficient boost without resort to extreme operating speeds and accordingly avoids the costly complications associated with high speed operation.
It is yet another object of the present invention to provide a relatively compact and lightweight supercharger which is inexpensive to manufacture and maintain.

Another object of the present invention is to provide a belt-driven supercharger having a design which provides supercharging compression at relatively low operating speeds.

It is still another object of the present invention to provide a supercharger which can be quite readily disassembled and reassembled for purposes of low cost maintenance and repair.

Still another object of the present invention is to provide a supercharger which can be constructed from mass producible parts to thereby reduce the cost of its manufacture.

It is still another object of the present invention to provide a belt-driven supercharger which provides supercharging compression without resort to a larger number of compressor stages.

Yet another object of the present invention is to provide a rotary supercharger for a gas operated engine, which supercharger is easily manufactured and maintained, yet capable of providing ample recompression of the recirculating drive fluid.
Summary of the Invention:
These and other objects are achieved by the present invention which provides a supercharger comprising a housing having an inlet and an outlet, a shrouded axial compressor and a radial compressor rotatably mounted within the housing, a highly convergent shallow, frustoconical transition duct for favourably directing the discharge of the axial compressor to the inlet of the radial compressor.

In accordance with a further aspect of the invention, the above-described supercharger further comprises an exhaust cone at a location downstream of the radial compressor and a flow deflector for directing the discharge of the radial compressor to the exhaust cone.

In the preferred embodiment, the housing itself comprises four sections: a cylindrical front housing section which defines an axially directed inlet; a second, cylindrical ducting section enclosing the axial compressor; a rear housing section defining the transition duct as well as the inlet and casing for the radial compressor; and the exhaust cone section which defines at its terminus the outlet of the housing. For driving the compressor shaft, a double-tracked pulley wheel is secured to the forward end of the common shaft, which pulley wheel is adapted to receive one or more drive belts from the crank-shaft wheel of the engine. A lateral opening in the front housing section accommodates the connection with the drive belts.

With the disclosed arrangement, compression can be achieved for supercharging purposes without resort to a large number of compressor stages or high operating speeds. Additionally, the design of the disclosed supercharger avoids the need for guide vanes between the axial compressor and the radial compressor. The exhaust cone section also favourably avoids the build-up of back pressure against the radial compressor. The design is also very simple and therefore inexpensive to manufacture and maintain.

Other objects, advantages and novel features of the present invention will become apparent from the following detailed description of the invention when considered in conjunction with the accompanying drawing.

Brief description of the Drawings:
A preferred embodiment of the present invention is described in greater detail with reference to the accompanying drawing wherein like elements bear like reference numerals, and where:
Fig. 1 is a cross-sectional side view of a supercharger constructed in accordance with the preferred embodiment of the present invention;

Fig. 2 is a side view of the supercharger of Fig. 1;
Fig. 3 is a frontal view of the impeller of the supercharger of Fig. 1;

Fig. 4 is a cross-sectional view taken along line 4--4 of Fig. 1;
Fig. 5 is a cross-sectional view taken along line 5--5 in Fig. 1;

Fig. 6 is a cross-sectional view taken along line 6--6 in Fig. 1;
**Detailed Description of the Preferred Embodiment:**
Referring to Fig.1 and Fig.2, a supercharger 10 is provided for supplying supercharged air to a car engine or the like, so that the engine receives a greater weight per unit volume of air or a fuel/air mixture than would be otherwise supplied. In accordance with a preferred embodiment of the present invention, the supercharger 10 comprises a housing 12 having an axially directed inlet 14 for receiving ambient air and an axially directed outlet 16 for delivering supercharged air to the intake of the car engine. Rotatably mounted within the housing 12 is a shaft 18 on which are secured an axial compressor 24 and a radial compressor 26, which is positioned downstream of the axial compressor. A pulley wheel 28 is secured to a forward end 30 of the shaft for receiving drive belts 31, which drive belts connect the shaft 18 to a pulley wheel on the crankshaft of the engine (not shown). The drive belts 31 deliver torque to the shaft 18 as required for driving the compressors 24 and 26 of the supercharger 10.

Housing 12 is constructed from four sections which are preferably bolted together at flanged connections in an end-to-end relationship. These sections include a front housing section 32, an axial compressor duct section 34, a rear housing section 36 and an exhaust cone section 38. The shaft 18 extends along the longitudinal axis of the housing 12.
The front housing section 32 is a hollow cylinder which extends forward of a front bearing support 40. The front housing section 32 encloses the forward end 30 of the shaft 18 and the associated pulley wheel 28. At its forward end, the front housing section 32 defines the inlet 14 for receiving air from an external source (not shown).

Referring particularly to Fig. 2, the front housing section 32 includes a lateral opening 44 on one side in order to accommodate the connection of the drive belts 31 to the pulley wheel 28. The front housing section 32 also includes a forward flange 46 for accommodating the connection of air filters, carburettors, air scoops or the like upstream of the supercharger 10 according to the particular engine layout.

It is to be understood that in the usual engine layout, the supercharger 10 receives air or a fuel/air mixture from an external source through its inlet 14, compresses the air or fuel/air mixture and then delivers it to the intake of the engine.

Referring again to Fig. 1, the pulley wheel 28 is interference-fitted upon the forward end 30 of shaft 18 and a key 134 is used to lock the pulley wheel 28 in place. The pulley wheel 28 is preferably a double-track design which is suitable for the attachment of twin drive belts, although a single-belt type pulley wheel would be adequate. The pulley wheel 28 is preferably sized so that the ratio of it's diameter with respect to the diameter of the drive wheel of the engine's crankshaft provides an effective gearing ratio in the range of approximately two and one-half to four and one-half. Thus at idle, when the car engine is running at approximately 700 rpm, the supercharger 10 is running at approximately 2,400 rpm, and at cruise, when the engine is running around 2,500 rpm, the supercharger 10 is preferably turning over in the range of 6,000 to 8,000 rpm. It is to be noted that although the diameter of the pulley wheel 28 may be substantially reduced in order to achieve a desired gearing ratio, the double-track wheel 28 presents a sufficient sum total of surface area to avoid slippage of the belts 31.

The next adjacent section of housing 12 is the axial compressor duct 34 which is a short cylinder coaxially disposed about the axial compressor 24. Preferably, the axial compressor duct 34 is constructed from cast aluminium, with the interior surfaces 48 machined to assure uniform clearance between the duct 34 and shroud 50 of the axial compressor 24. As with other sections of the housing 12, the axial compressor duct 34 is provided with flanges 52 and 54 for effecting connection to the adjacent housing sections. The axial compressor duct 34 guides air delivered from the front housing section 32 towards the axial compressor 24.
Referring now to Fig. 1 and Fig. 4, a front bearing support 40 is placed between the front housing section 32 and the axial compressor duct 34. The front bearing support 40 includes an outer annulus 56 and three radial arms 58. Between these arms are defined passages 60 for allowing air to pass through the bearing support 40. The outer annulus 54 is secured by bolts connecting a rear flange 64 of the front housing section 32 and the flange 52 of the axial compressor duct 34. By this arrangement, the front bearing support 40 is rigidly secured to the housing 12 so that loads and shocks to the shaft 18 can be transferred through the front bearing support 40 to the housing 12.

In the preferred embodiment, the outer annulus 56 of the bearing support 40 extends into the region of the inlet 14 of the front housing section 32 in such a way that it’s inner rim 68 coincides with the inner rim 70 of the shroud 50 of the axial compressor 24. In this way, the outer annulus 56 contributes to the guiding of the flow of air toward the axial compressor 24.

An outer raceway 74 of the front roller bearing assembly 76 is secured between the front bearing support 40 and a bearing retainer plate 78, which is secured by the removable bolts 80. In this preferred embodiment, the front bearing assembly 76 is of the sealed, high speed type. A suitable commercially available bearing assembly is marketed under the reference: model Fafnir 405KDD. Preferably, a lower raceway 82 of the front bearing assembly 76 is secured to the shaft 18 with an interference fit. A spacer 84 is provided on one side of the lower raceway 82, which spacer 84 also abuts a hub 86 of the axial compressor 24 in order to position the axial compressor 24 at a predetermined distance downstream of the bearing support 40. Similarly, a spacer 88 is provided on the other side of the lower raceway 84, and it abuts the pulley wheel 28 so as to space apart the pulley wheel 28 from the front bearing support 40 to ensure that there is sufficient clearance between them.

It should be appreciated that the bearing retainer plate 78 allows ready access to the front bearing assembly 76 for purposes of maintenance or repair. To service the front bearing assembly 76, a nut 90 and lockwasher 92 on the forward end 30 of the shaft 18 are loosened and removed together with the pulley wheel 28 and the spacer 88. Then bolts 42 and the bearing retainer plate 76 are removed, leaving the whole bearing assembly 76 exposed for servicing and/or removal.

The rear housing section 36 is connected by bolts to the downstream end of the axial compressor duct 34. Preferably, the rear housing section 36 is constructed from a single section of cast aluminium and includes external longitudinal ribs 94 for enhancing the structural rigidity of the rear housing section 34. The walls of the rear housing section 36 define three elements of the supercharger 10: a highly conical transition duct 96 which favourably directs the output of the axial compressor to an inlet 98 of the radial compressor 26; the inlet 98 of the radial compressor 26, itself; and a casing 100 for the radial compressor 26.

The transition duct 96 is a hollow, frustoconical portion having a half-apex angle (from the generatrix to the axis of symmetry) of approximately 35°. The angle is selected such that the inlet to the radial compressor 26 is as close as possible to the outlet of the axial compressor, without causing undue back-pressure. In the preferred embodiment, the transition duct 96 begins a short distance downstream of the axial compressor 24 and ends at the beginning of the inlet 98 of the radial compressor 26. The highly conical shape of the
transition duct 96 is believed to roll-in the higher volume of air being discharged from the more radially outward portions of the axial compressor 24. This rolling-in action is believed to promote a favourable flow regime at the inlet 98 of the radial compressor 26 so that there is no need for inlet guide vanes for the radial compressor 26. It is also believed that the highly conical shape of the transition duct 96 affects upstream flow conditions at the axial compressor 24 in such a way that its performance is improved. It has also been found that there is no need for a stator (or exit guide vane) for the axial compressor 24.

In essence, it is believed that the transition duct 96 performs the functions of the exit vanes of axial compressors and inlet guide vanes of radial compressors, but without the pressure losses commonly associated with them. Avoiding these pressure losses and the expected improvement in the performance of the axial compressor, allows the supercharger 10 to impart a higher overall pressure ratio than would otherwise be achieved without the transition duct 96. As a result, adequate compression is achieved at moderate operating speeds without resort to a bank of several axial compressors. It should be understood however, that when connecting the supercharger 10 to a relatively slowly reciprocating diesel or a very large engine, it may be desirable to include two or more axial compressors in order to boost the supercharger's overall pressure ratio. In such cases, the present invention would then include the placement of a transition duct downstream of at least the last axial compressor.

At the inlet 98 of the radial compressor 26, the walls of the rear housing 36 are cylindrical and coaxially positioned around shaft 18. It should be noted that in the preferred embodiment, the surface transition 102 from the transition duct 96 to the inlet 98 is rounded-off.

The casing portion 100 of the rear housing section 36 closely follows the contour defined by blade edges 104 of the radial compressor 26 in a close, substantially sealing manner as is well known in the art of radial compressors. The casing portion 100 of the rear housing section 78 channels air between the rotating blades of the radial compressor 26 so that the blades can impart work to the passing air. The casing portion 100 also defines a discharge outlet 106 for the radial compressor 26.

Just beyond the discharge outlet 106 of the radial compressor 26, the interior surfaces of the rear housing section 36 begin to curve immediately inwardly to provide a transition into the next adjacent section of the housing 12, the exhaust cone 38. In this fashion, the interior surfaces at the rear-most portion of rear housing section 36 and those of the forward portion of the exhaust cone 92 define internally a flow deflector 108. In the preferred embodiment, the flow deflector 108 is closely and concentrically positioned around outlet 106 of the radial compressor 26 so that the air being discharged from the radial compressor 26 does not have the opportunity to diffuse significantly prior to its arrival at the annular flow deflector 108. The annular flow deflector 108 directs the output of the radial compressor 26 into the exhaust cone 38 by providing a smooth surface transition from the interior of rear housing section 36 to the interior of the exhaust cone 38.

The exhaust cone 38 is a highly convergent, hollow, conical section placed immediately downstream of the radial compressor 26 for receiving the output of the radial compressor 26 from the annular flow deflector 108. In the preferred embodiment, the exhaust cone 38 is a single section of cast aluminium which is joined to the downstream end of the rear housing section 36 at a flanged joint 110. Preferably, the exhaust cone 92 converges according to a half-apex angle of approximately 35° and defines the exhaust port 16 at its terminus. A threaded section 112 at the exhaust port 16 allows the attachment of the appropriate external ducting (not shown) leading to the intake of the engine.

During operation of the supercharger 10, the space enclosed by the exhaust cone 92 prevents the build up of an elevated back pressure which might otherwise arise and detract from the operation and efficiency of the radial compressor 26. The enclosed space of the exhaust cone 92 is also of sufficient volume to absorb pulses and to average out unsteady flow conditions so to promote a smooth and continuous output from the supercharger 10.
Referring now to Fig.1 and Fig.6, the exhaust cone 38 includes a rear bearing support 114 which comprises members 116 which extend radially inwardly from the outer walls of the exhaust cone 38. At a radial inward location close to the shaft 18, the members 116 converge to form a cupped annulus which serves as a housing 118 for the rear bearing assembly 120. The housing 118 is open towards the rear face of the radial compressor 24 to facilitate disassembly of the supercharger 10. The rear bearing assembly 120 is the same type and size as the front bearing assembly 76. The inner race 122 of the bearing assembly 120 is set in place on the shaft 18 by spacers 124 and 126 in conjunction with a nut 128 and washer 130 on the rearward end 132 of the shaft 18. In this preferred embodiment, the members 116 are formed to be integral with the walls of the exhaust cone 38.

Referring to Fig.1 and Fig.5, upon rotation, the axial compressor 24 draws air through the inlet 14 and imparts an initial amount compression to the air as it forces the air into the transition duct 96 of the rear housing section 36. In the preferred embodiment, the axial compressor 24 comprises a hub 86, the shroud 50 and a series of ten (10) equally spaced, radial blades 136. Ideally, each blade 136 increases in cord from a root 138 to a tip 140 and includes a trailing edge 142 and a leading edge 144, where these edges are both...
slightly curved. The blades gradually increase in pitch from approximately 12° at the root to approximately 36° at the tips. However, the particular values of pitch and other geometrical aspects of the blades might be varied in accordance with different operating speeds or other parameters as would be apparent to one skilled in the pertinent art and familiar with this disclosure.

The axial compressor is preferably constructed from a single, cast aluminium section with the faces of the hub being machined for purposes of achieving accurate, axial positioning of the axial compressor on the shaft relative to the housing. The faces of the shroud are also machined flat. Additionally, the outer periphery of the shroud is machined to assure uniform clearance between the shroud and the adjacent interior surfaces of the axial compressor duct. Preferably, the axial compressor is secured to the shaft by an interference-fit on to a stepped portion of the shaft. The spacers axially position the axial compressor relative to the front bearing support and the radial compressor, respectively.

Dynamic balance test machines of the conventional type may be used to test the balance of the axial compressor prior to its installation. If an imbalance is detected, material can be removed at the outer periphery of the shroud so as to achieve proper balance.

Referring now to Fig.1, Fig.3, and Fig.7, the radial compressor is constructed from a single section of cast aluminium and includes a hub and curved blades. Interposed between each pair of blades are a second set of blades which terminate short of the intake so that the intake is not crowded by both sets of blades. Accordingly, the radial compressor features both a large total number of blades and an intake of relatively small diameter, and these features enhance the performance of the compressor. In the region of the intake, the blades present leading edges and undergo a twist into the direction of rotation so as to prevent a favourable angle of attack at the intake.

Preferably, the radial compressor is positioned upon the stepped section of the shaft with an interference-fit and locked against rotational slippage by a key. The spacer assures clearance between the rear face of the radial compressor and the rear bearing assembly. The shaft is constructed from a hardened steel and is threaded at both ends to receive nuts, respectively. In addition to the central stepped portion, the shaft also features stepped portions for receiving the front and rear bearing assemblies, respectively. The stepped arrangement of the shaft facilitates assembly and disassembly in that the stepped portions are greater than the diameter of the threading at ends.

Please note that the bearing supports are in a fixed position relative to the housing and that the compressors and the radial compressor are held in position between the bearing supports by spacers, which have predetermined lengths. Consequently, the placement of the compressors and relative to the longitudinal axis of the housing is fixed by the spacers and not by the axial location of the shaft relative to the housing. Please also note that the stepped portions of the shaft are each provided with extra lengths so that the respective components (the bearing assemblies and compressors) can each be situated over a relatively wide range of locations in the respective stepped
portions. Thus, the shaft 18 need not be positioned accurately along the longitudinal axis of the housing 12 in order to achieve proper assembly of the supercharger 10. For instance, if nuts 90 and 128 had been tightened differently than they appear in Fig.1, then shaft 18 might have been displaced slightly in the axial direction from where it is shown in Fig.1. However, the relative positioning of the various components on the shaft 18, i.e., the pulley wheel 28, the compressors 24 and 26 and the bearing assemblies 76 and 120, would have remained the same relative to themselves and the housing 12. This feature eases the process of manufacture and accordingly, reduces costs. It also reduces the amount of labour required for reassembly after repair.

In operation, the supercharger 10 is suitably connected at it’s outlet 16 to an intake of a car engine, with the drive belts 31 from the crankshaft of the engine being attached to the pulley wheel 28 of the supercharger 10. Then, as the engine is operated, torque is transferred by the drive belts 31 to the pulley wheel 28 for driving the compressors 24 and 26. Upon rotation, the axial compressor 24 draws air through the inlet 14, imparts an initial amount of compression to the air and discharges it into the transition duct 96 with a swirl. By reason of it’s design, the axial compressor 24 is believed to move a greater volume of air in the region of its blade tips 140 than at it’s more radially inward locations. Accordingly, there is a greater of mass of air situated at the outer annular region behind the axial compressor 24 than at the inner annular region. As the discharge from the axial compressor 24 is caused to leave the axial compressor duct 34, the highly convergent, transition duct 96 is believed to cause the outer annulus of air which is discharged from the axial compressor 24 to roll-in. This action is believed to have two favourable results. First, the roll-in action causes a flow regime to be established at the inlet 98 of the radial compressor 26 such that the need for a guide vane is wholly avoided. Secondly, and of equal importance, the rolling-in action, in conjunction with the large volume of space enclosed by the transition duct 96, is believed to affect the performance of the axial compressor 24 favourably, so that a higher pressure ratio is obtained from it.

Since the overall pressure ratio of the supercharger 10 is the product of the pressure ratios of the two compressors, it can be seen that the increase in performance of the axial compressor 24 results in a corresponding improvement in overall performance of the supercharger. It should also be noted that the deletion of inlet guide vanes for the radial compressor 26 and of exit vanes for the axial compressor 24 greatly simplifies the design of the rear housing section 36 and therefore provides savings in costs of manufacture. It also avoids the pressure losses associated with such guide vanes, which are often quite significant.

Upon leaving the transition duct 96, the pre-swirled flow of air enters the inlet 98 of the radial compressor 26 and then into the compressor 26 itself. In passing through the radial compressor 26, the air is turned and whirled such that the airflow is centrifugally discharged with a substantial radial velocity component, whereupon the resultant flow is abruptly turned by the annular flow deflector 108 and caused to enter the exhaust cone 38. As previously explained, the large volume of space enclosed by the exhaust cone 38 induces flow conditions behind the radial compressor 26 such that elevated back pressures are avoided, pressures which might otherwise impair the performance of the radial compressor 26. Pulses in the output of the radial compressor 26 are also moderated. The air is then delivered in a compressed state to the exhaust port 16 of the exhaust cone 38. The supercharged air then flows down the appropriate intake system of the engine until it reaches the cylinder or cylinders of the engine.
With respect to the application of the supercharger 10 to air-tank powered engines, such as disclosed in U.S. Pat. No. 4,292,804, the supercharger 10 functions in the same manner as described above, but is connected to the engine differently. In the air tank powered engine, at least one of the exhaust manifolds of the engines delivers partially expanded air to a line connected to the inlet 14 of the supercharger 10. Referring to Fig.8, in most of such applications, this line will be of a smaller diameter than the housing 12 at the inlet 14 of the supercharger, such that an adaptor 173 is needed. The adaptor 173 comprises an annular plate 174 having a threaded aperture 176 sized to receive a mating, threaded end 178 of the line 180. The plate 174 is secured to the flange 36 of the front housing section 32 by a plurality of bolts. Because the air coming from the line 180 is usually less than the full capacity of the supercharger, additional air is introduced through the lateral opening 44 along the side of the front housing section 32. In this application, the opening 44 thus serves as an air intake port as well as a means for accommodating the drive belts 31 and must therefore be sized upon the additional criteria that it not be so large as to upset the flow of the incoming air in the line 180. Upon the passage of the air through the supercharger, the air is directed through the exhaust port 16 and into a suitable line connected to it, which line may lead directly to the engine or to the storage tanks of the engine. If directed to the tanks, this recompressed air is used to supplement the required recharging of the storage tanks.

It is to be appreciated that savings in the cost of manufacturing the supercharger 10 are achieved by reason that the housing 12, the bearing supports 40 and 114, the axial compressor 24 and the radial compressor 26 are all constructed from cast aluminium parts and require only a minimum amount of machining. Moreover, the roller bearing assemblies 76 and 120 are commercially available components, and the supercharger 10 is easily assembled. These aspects further reduce the cost of manufacture and render the disclosed supercharger inexpensive to maintain and overhaul. More importantly, the supercharger 10, despite its simple design, provides supercharging at relatively low operating speeds. With it's lower operating speeds, the service life of the supercharger 10 is extended and the risk of it suffering mechanical failure is reduced. The need for special bearing designs and lubrication is also avoided. Accordingly, the supercharger 10 is highly suitable for mass production and for use in cars, trucks, helicopters or the like.

The Vortex Tube.
The web site http://www.airtx.com/how-does-a-vortex-tube-work.htm show “vortex tubes” which are completely passive devices with no moving parts:
This device does things which you would not expect. Compressed air at a temperature of, say, seventy degrees Centigrade is fed into the circular chamber where the shape of the chamber causes it to spiral rapidly as it exits the tube:

There is an energy gain in a vortex, as can be seen in a hurricane or tornado, but the really interesting thing here is the dramatic change in temperature caused by the change in pressure as the air expands. The ratio of heat gain to heat loss is controlled by the ratio of the sizes of the openings, which is why there is an adjustable nozzle on the small opening.

The air exiting through the large opening is much higher volume than the air exiting through the small opening and it expands very rapidly, producing a massive drop in temperature. The density of this cold air is now much higher than the air entering the vortex chamber. So there has been both a drop in temperature and an increase in density. These features of the expansion are made use of in the Leroy Rogers engine design, where some of the expanded air exhaust of the engine is compressed and passed back to the main air storage tank. While the compressor does raise the air temperature as it pumps the air back into the tank, it does not reach its original temperature instantly.
This results in the air temperature inside the tank dropping as the engine operates. But, the lowered tank temperature causes an inflow of heat from its immediate environment, raising the overall tank temperature again. This warming of the chilled air causes the tank pressure to increase further, giving an energy gain, courtesy of the local environment. It is important to understand that it takes less energy to compress air than the kinetic energy which can be generated by letting that compressed air expand again. This is a practical situation, courtesy of the local environment and is not a breach of the law of Conservation of Energy. It is also a feature which has not yet been exploited to any great degree and which is just waiting to be used by any adventurous inventor or experimenter.

**Eber Van Valkinburg’s Engine.**

Eber presents a custom engine based on these principles. His engine uses both compressed air and compressed oil to manipulate pressures within the system and provide an engine which is self-powered. In the Appendix is a slightly re-worded copy of the Eber Van Valkinburg patent, which remarks that “stored energy in a compressed elastic fluid is utilised in a controlled manner to pressurise an inelastic fluid and to maintain such pressurisation. The pressurised inelastic fluid is throttled to the impeller of a prime mover. Only a portion of the output energy from the prime mover is utilised to circulate the inelastic fluid so as to maintain a nearly constant volumetric balance in the system”.

**Richard Clem’s Motor.**

The Clem Engine is based on an entirely different principle, and one which is not spoken about very often. Hurricanes or “twisters” as they are sometimes called, are large rotating air masses of incredible power which develop in hot areas which are more than eight degrees North or South of the equator. The distance from the equator is essential as the rotation of the Earth is needed to give them their initial spin. They usually develop over water which is at a temperature of twenty-eight degrees Centigrade or higher as that allows the air to absorb enough heat energy to get started. That is why there is a distinct “hurricane season”
in these areas, since at certain times of the year the ocean temperature is just not high enough to trigger a hurricane.

What is not generally realised is that a hurricane develops excess energy due to its swirling circular movement. The generation of this extra power was observed and documented by Viktor Schauburger of Austria, who also used his observations to great effect. I think that what Schauburger says makes some people uncomfortable as they seem to think that anything “unorthodox” has to be weird and too peculiar to be mentioned. This is rather strange as all that is involved here is a simple observation of how our environment actually works. A hurricane is wider at the top than at the bottom and this concentrates power at the base of the swirling mass of air. This tapered rotation is called a “vortex” which is just a simple name to describe the shape, but any mention of “vortex power” (the power at the base of this rotation) seems to make many people uncomfortable which is most peculiar.

Leaving that aside, the question is “can we use this energy gain from the environment for our own purposes?”. The answer may well be “Yes”. Perhaps this principle is utilised by Richard Clem. In 1992, Richard Clem of Texas, demonstrated a self-powered engine of an unusual type. This engine, which he had been developing for twenty years or more, weighs about 200 pounds (90 kilos) and generated a measured 350 horsepower continuously over the full period of a nine-day self-powered test. Although this engine which runs from 1,800 to 2,300 rpm is especially suited to powering an electrical generator, Richard did install one in a car, and estimated that it would run for 150,000 miles without any need for attention and without any kind of fuel. Richard said that his prototype car had reached a speed of 105 mph. Just after receiving funding to produce his engine, Richard died suddenly and unexpectedly at about 48 years of age, the death certificate having “heart attack” written on it as the cause of death. Remarkably convenient timing for the oil companies who would have lost major amounts of money through reduced fuel sales if Richard’s motor had gone into production.

The motor is unusual in that it is a rotary turbine style design which runs at a temperature of 300°F (140°C) and because of that high temperature, uses cooking oil as its operational fluid, rather than water as the oil has a much higher boiling point. To a quick glance, this looks like an impossible device as it appears to be a purely mechanical engine, which will definitely have an operating efficiency which is less than 100%.

In broad outline, the oil is pumped through a pipe and into the narrow end of the cone-shaped rotor. The engine is started by being rotated by an external starter motor until it reaches the speed at which it generates enough power to be sustain its own operation. The rapid spinning of the cone, causes the oil to run along spiral grooves cut in the inner face of the cone and exit through angled nozzles placed at the large end of the cone:
The operating pressure produced by the pump is 300 to 500 psi. Richard did not attempt to patent his engine as US Patent 3,697,190 “Truncated Conical Drag Pump” granted in 1972 as a liquid-asphalt pump is so close in detail that Richard felt that there was insufficient difference for him to be granted a patent:

There appears to be considerable scope for anyone who wishes to build or manufacture this engine and it is capable of acting as a heater as well as device for producing mechanical power. This suggests that water purification could be an additional “extra” option for this engine.

Prof. Alfred Evert of Germany has produced an analysis of the operation of the Clem Engine and turbines in this general category. His website http://evert.de/indefte.htm has a good deal of information on the subject.

**Josef Papp's Inert Gas Engine Conversion.**

The Hungarian, Josef Papp, invented an unusual engine system which genuinely appears to be very nearly “fuel-less”. His design modifies an existing vehicle engine to operate on a fixed amount of gas. That is to say, the engine has no air intake and no exhaust and consequently, no inlet or exhaust valves. The engine cylinders contain a mixture of gases which have an Atomic Number below 19, specifically, 36% helium, 26% neon, 17% argon, 13% krypton, and 8% xenon by volume. The control system causes the contained gas to expand to drive the pistons down the cylinders and then contract to suck the pistons back up the cylinders. This effectively converts the engine into a one-stroke version where there are two power strokes per revolution from every cylinder.

A small amount of radioactive material is used in the engine, and I have seen it suggested that the engine should be screened to protect the user from radiation. I’m not sure that this is correct, but if it is, then it suggests that a matter to energy conversion is indeed taking place. It seems most unlikely that the minor amount of radioactive material in the engine itself could cause any significant radiation. The patent describes the material as “low-level” which suggests to me, material no more dangerous that the luminous paint that used to be used on the hands of clocks and watches.

Suitable engines must have an even number of cylinders as they operate in pairs. Josef's first prototype was a four-cylinder, 90 horsepower Volvo engine. He removed the intake and exhaust components and
replaced the engine head with his own design. During a thirty-five minute test in a closed room, the engine generated a constant 300 horsepower output at 4,000 rpm. The electrical power needed to run the engine was produced by the standard engine alternator, which was also able to charge the car battery at the same time. Interestingly, an engine of this type, quite apart from having zero pollution emissions (other than heat), is quite capable of operating under water.

Josef, a draftsman and ex-pilot, emigrated from Hungary to Canada in 1957 where he lived until his death in April 1989. There is solid evidence that Josef built an engine of over 100 horsepower (75 kilowatts) that was "fuelled" by a mixture of inert (or "noble") gases. With no exhaust or cooling system, it had huge torque even at low rpm (776 foot-pounds at only 726 rpm in one certified test). Dozens of engineers, scientists, investors and a Federal judge with an engineering background saw the engine working in closed rooms for hours. This would not have been possible if the engine had been using fossil fuel. There was absolutely no exhaust and no visible provision for any exhaust. The engine ran cool at about 60°C (140°F) on its surface, as witnessed by several reliable observers. All these people became convinced of the engine's performance. They all failed to discover a hoax. Ongoing research in the United States (totally independent of Papp) has proved conclusively that inert gases, electrically triggered in various ways, can indeed explode with fantastic violence and energy release, melting metal parts and pushing pistons with large pressure pulses. Some of the people performing this work, or who have evaluated it, are experienced plasma physicists. Contemporary laboratory work has established that inert gases can be made to explode.

In a demonstration on 27th October 1968 in the Californian desert, Cecil Baumgartner, representing the top management of the TRW aerospace corporation and others witnessed the detonation of one of the engine cylinders. In full public view, just a few cubic centimetres of the inert gas mixture was injected into the cylinder using a hypodermic needle. When the gas was electrically triggered, the thick steel walls of the cylinder were burst open in a dramatic way. William White, Edmund Karig, and James Green, observers from the Naval Underseas Warfare Laboratory had earlier sealed the chamber so that Papp or others could not insert explosives as part of a hoax. In 1983, an independent certification test was carried out on one of the Papp engines. Joseph Papp was issued three United States patents for his process and engines:

**US 3,680,431** on 1st August 1972 "Method and Means for Generating Explosive Forces" in which he states the general nature of the inert gas mixture necessary to produce explosive release of energy. He also suggests several of the triggering sources that may be involved. It appears that Papp is not offering full disclosure here, but there is no doubt that others who have examined this patent and followed its outline have already been able to obtain explosive detonations in inert gases.

**US 3,670,494** on 20th June 1972 "Method and Means of Converting Atomic Energy into Utilisable Kinetic Energy" and

**US 4,428,193** on 31st January 1984 "Inert Gas Fuel, Fuel Preparation Apparatus and System for Extracting Useful Work from the Fuel". This patent shown here, is very detailed and provides information on building and operating engines of this type. It also gives considerable detail on apparatus for producing the optimum mixture of the necessary gasses.

At the time of writing, a web-based video of one of the Papp prototype engines running on a test bed, can be found at [http://www.youtube.com/watch?v=N4li_z4Jpso](http://www.youtube.com/watch?v=N4li_z4Jpso) although it must be said that a good deal of the footage is of very poor quality, having been taken many years ago. The video is particularly interesting in that some of the demonstrations include instances where a transparent cylinder is used to show the energy explosion. Frame-by-frame operation on the original video shows energy being developed outside the cylinder as well as inside the cylinder, which does seem to suggest that the zero-point energy field is involved. I have recently been contacted by one man who attended some of the engine demonstrations run by Papp and he vouches for the fact that the engine performed exactly as described.

Papp's Patent US 4,428,193 is shown in full in the Appendix.
Josef never managed to get his engine design into commercial production before his death, primarily due to the opposition of vested interests. However, his design principles have been picked up and advanced by John Rohner and Haik Biglari.

The "Plasmic Transition Process" is the subject of various patents pending by PlasmERG Inc. of Iowa. John Rohner founded this company in 2008 to be the means to disseminate, develop and license this technology to other motor manufacturers for their own use. This process originally called the "Papp Engine" did run in 1982 and was then lost until John, and his partner Haik Biglari rediscovered it and applied modern science to the system to explain the process and filed their patents, presently pending. The original process was based on information originally patented by the late Joseph Papp, whose patents have now expired. John Rohner, a well known new-product design engineer, was originally contacted in 1979 by his brother Robert, with a schematic for the controller which Papp had designed. Unfortunately, John was busy with several other projects so he turned it over to his brother Tom.

PlasmERG has designed two motors for Own-Equipment-Manufacturers to use. One is an opposed, 2-cylinder, 120 cubic inch engine which produces some 300 horsepower. The second is a 6-cylinder 360 cubic inch engine which can produce around 1,500 horsepower. These motors are being co-developed with a sister company in Canada. John Rohner has personally provided the total investment for this development. As the company moves toward manufacturing, they are seeking investment partners by trading stock for investment. Their first commercial manufacturing plant will cost about 10 million dollars.

An alternative strategy is to create licenses for existing car and truck motor manufacturers until they can fund their own production. The current plan is to provide 500 to 1,000 test sites in underdeveloped nations for water pumping and power generation as "humanitarian" test sites. This should allow the time needed to get production understood and patents completed.

The expected run time of a motor from a single inert gas charge is over 3 months of continuous operation and gas re-charge should cost less than US $50. John stresses that the PlasmERG motor is not, (just as the original Papp engine was not), a "Pulsed Plasma motor". Plasma is not retained and "pulsed" as some people have supposed. What actually happens is that the plasma is recreated with each power stroke and then returns to a steady state gas on each return stroke, from which the name “Plasmic Transition” is derived.

The initial power and creation of plasma for expansion, is produced by a fusion event with a side-effect of a limited "chaotic" fission event causing a “plasmic transition” which is contained in a sealed 2-cycle rotating crankshaft motor.

There are two parallels to Plasmic Transition and power production of this motor. The first is natural lightning, which uses an almost identically similar Plasmic Transition process; and the second is steam which provides the same torque over rotational speed event characteristics. There is nothing in the ordinary internal combustion motor's operation that is comparable to either of these processes. The most crucial part of PlasmERG's motor operation is the Electronic Control System (ECS), comprising the following elements:

Programmable micro computers;
Radio frequency power generator;
HV spark coil initiation driver;
Various electromagnetic coil voltage switches providing base (resting) or variable (engine speed) voltages for all cylinder or reaction chamber electromagnetic coils;
On-controller DC to 12 volt DC converter;
Engine speed DC voltage (accelerator) to programmed variable voltage DC converter,
Inter controller communications port;
Instrument support for user panel and action port which receives commands from the user comprising by not limited to things like Run, Start, Throttle position, Hold speed, Brake application, Brake hard, various motor inputs and fuel container information.

The PlasmaERG’s website is at http://plasmerg.com/ but it needs Internet Explorer to display properly as it has major display problems when Firefox is used.

Robert Britt’s Inert Gas Motor.
Robert Britt designed a very similar engine to that of Josef Papp, and he was also awarded a US patent for an engine operating on inert gasses. William Lyne remarks that this engine design may be replicated using a Chevy “Monza” 6-cylinder engine or a VolksWagen 4-cylinder engine. The heads are removed and the new heads cast using the “pot metal” used for “pseudo chrome” automotive trim. That alloy contains aluminium, tin, zinc and possibly antimony and is particularly suitable as the insides of the cavities can be polished to the high reflectivity specified in the patents.

A full copy of Robert Britt’s patent US 3,977,191 is in the Appendix.
Heinrich Klostermann’s Air Plasma Motor.
Both Josef Papp and Robert Britt specified inert gas for operation, but Heinrich Klostermann points out that ordinary air is quite sufficient. His video is at https://www.youtube.com/watch?v=lNSAXbZfnbE at this time. His patent is:

US Patent 7,076,950    18th July 2006    Inventor: Heinrich Klostermann

Internal Explosion Engine and Generator Using Non-combustible Gases

Abstract:
An internal explosion engine and generator having an explosion chamber, a movable member forming one wall of the chamber, a charge of non-combustible gas sealed inside the chamber, means for repeatedly igniting the gas in an explosive manner to drive the movable member from a position of minimum volume to a position of maximum volume, means for returning the movable member from the position of maximum volume to the position of minimum volume, and means coupled to the movable member for providing electrical energy in response to explosion of the gas. In one disclosed embodiment, the movable member is a piston connected to a crankshaft, and it is returned to the position of minimum volume by a flywheel on the crankshaft. In another embodiment, two pistons are connected back-to-back in a hermetically sealed chamber to prevent loss of the explosive gas. In one embodiment, the electrical energy is produced by a generator connected to the crankshaft, and in the other it is produced by a coil positioned near a magnet which moves with the pistons.

Description:

BACKGROUND OF THE INVENTION

1. Field of Invention
This invention pertains generally to engines and generators and, more particularly, to an internal explosion engine and generator using non-combustible gasses.

2. Related Art
An internal explosion engine is generally similar in principle to an internal combustion engine except that it uses non-combustible gases such as air, oxygen, nitrogen or inert gas instead of the combustible gases.
which are used in internal combustion engines. Prior to operation, the gas for operating an internal explosion engine is placed in the explosion chamber of the engine, and the chamber is sealed. During operation, the gas in the explosion chamber is repeatedly compressed, ionised, explosively expanded and contracted to move a piston or rotor or other movable device to convert kinetic energy to mechanical or electrical energy. Once the gas has been loaded into the explosion chamber, the engine can operate for extended periods of time without additional fuel. There is no need for fuel intake on each cycle of operation, as in an internal combustion engine, and there is no exhaust. Examples of internal explosion engines of the prior art are found in U.S. Pat. Nos. 3,670,494 and 4,428,193.

OBJECTS AND SUMMARY OF THE INVENTION
It is, in general, an object of the invention to provide a new and improved internal explosion engine and generator. Another object of the invention is to provide an internal explosion engine and generator of the above character which overcomes the limitations and disadvantages of the engines and generators which heretofore have been provided. These and other objects are achieved in accordance with the invention by providing an internal explosion engine and generator which has an explosion chamber, a movable member forming one wall of the chamber, a charge of non-explosive gas sealed inside the chamber, means for repeatedly igniting the gas in an explosive manner to drive the movable member from a position of minimum volume to a position of maximum volume, means for returning the movable member from the position of maximum volume to the position of minimum volume, and means coupled to the movable member for providing electrical energy in response to explosion of the gas. In one disclosed embodiment, the movable member is a piston connected to a crankshaft, and it is returned to the position of minimum volume by a flywheel on the crankshaft. In another, two pistons are connected back-to-back in a hermetically sealed chamber to prevent loss of the explosive gas. In one embodiment, the electrical energy is produced by a generator connected to the crankshaft, and in the other it is produced by a coil positioned near a magnet which moves with the pistons.

BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 1 is a top plan view of one embodiment of an internal explosion engine and generator incorporating the invention.
Fig. 2 is a cross-sectional view, taken along line 2—2 in Fig. 1.

Fig. 3 is a cross-sectional view, taken along line 3—3 in Fig. 2.
Fig. 4 is a circuit diagram of the embodiment of Fig. 1.

Fig. 5 is a centreline sectional view of another embodiment of an internal explosion engine and generator incorporating the invention.
Fig. 6A and Fig. 6B are cross-sectional views, taken along lines 6A—6A and 6B—6B in Fig. 5.

Fig. 7 and Fig. 8 are enlarged centreline sectional views of valve and plug assemblies for the gas loading port in the embodiments of Fig. 1 and Fig. 5.

DETAILED DESCRIPTION
As illustrated in Fig.1 to Fig.3, the engine 11 includes a piston 12 in a cylinder 13, with rings 14 providing a seal between the piston and the inner wall of the cylinder. The upper or outer end of the cylinder is sealed by an end plate or head 16, and an explosion chamber 17 is formed between the cylinder head and the piston. An inlet port 18 is formed in the cylinder head for introducing a charge of gas into the explosion chamber, and the admission of gas through the port is controlled by a valve assembly 19. The piston is connected to a crankshaft 21 by a connecting rod 22, and the crankshaft includes a counterweight or flywheel 23. In operation, the piston is driven in a downward direction by the explosion of the gas in the chamber and returned to the firing position by energy stored in the flywheel. The lower end of cylinder 13 is closed by a crankcase housing 24. The crankshaft is connected to the shaft 26 of a generator 27 located outside the crankcase housing by a coupling 28. As discussed more fully hereinafter, the generator can also be driven as a motor for use in starting the engine.

In the embodiment illustrated, valve assembly 19 is a one-way check valve which allows gas to pass into but not out of the explosion chamber through inlet port 18. The valve assembly is shown in greater detail in Fig.7, and includes a body or bushing 31 with an axial bore or passageway 32. The inner end of the valve body is threaded into the port, and a cap 33 is threaded on to the enlarged outer end of the body. The cap includes a passageway 34, with communication between that passageway and passageway 32 being controlled by a ball 36 which is received in a seat 37 on the inner side of the cap. The ball is urged toward a closed position against the seat by a spring 38 which is constrained between the ball and a shoulder 39 at the inner end of the valve body. A gasket 41 provides a seal between the outer portion of the body and the head.

Electrodes are mounted in the head for igniting the gas in the chamber. A high frequency electrode 43 is positioned axially of the chamber and connected to a radio frequency generator 44 for ionising the gas to form a plasma. Electrodes 46–49 are spaced around electrode 43, with electrode 46 being connected to the secondary winding 50 of a spark coil 51 and electrodes 47–49 being connected to a capacitor 52. A contact pin 53 projects from the face of the piston in alignment with electrode 43.

Piston 12 and end plate or head 16 are made from a ferro-magnetic material such as Grade-416 stainless steel, and cylinder 13 is made of a non-ferrous material such Grade-303 stainless steel. A coil 54 is placed around the outer portion of the cylinder and coupled magnetically with the piston to form a reluctance generator.
Means is provided for detecting when the piston is in its top dead centre (TDC) or minimum volume position. This means includes a magnet 56 which is mounted on the counterweight or flywheel portion 23 of crankshaft 21 and a Hall-effect switch 57 which is mounted in a stationary position in the crankcase and actuated by the magnet when it comes into proximity to the switch.

Power for operating generator 27 as a motor to start the engine is provided by batteries 59 which, in the embodiment illustrated, are mounted inside the housing of a controller for the generator 61. The batteries are connected to the motor by a normally-open starting switch 62.

The batteries also provide power for the Radio Frequency generator 44 and for the electrodes 46–49 which ignite the gas in the chamber, with the energisation of those electrodes being controlled by a relay 63. The application of power to the Radio Frequency generator is controlled by an On/Off switch 64, and energisation of relay coil 65 is controlled by the On/Off switch and by the Hall-effect switch 57 which is connected between the on/off switch and the relay coil.

The relay has a first set of contacts 66 which switch capacitor 52 between the power source and the electrodes 47–49, and a second set of contacts 67 which connect the primary winding 68 of spark coil 51 to the power source. The batteries are charged with the current produced in coil 54 by the reluctance generator. That coil is connected to the input of a power rectifier 69, and the output of the rectifier is connected to the batteries.

Prior to operation, a charge of air is introduced into explosion chamber through check valve 19 and inlet port 18. To start the engine, on/off switch 64 is closed, thereby energising the Radio Frequency generator 44 and the primary winding of spark coil 51 and applying charging current to capacitor 52, and starter switch 62 is closed to energise generator 27 as a starting motor. The gas in the chamber is ionised by the RF power applied to electrode 43 to form a plasma.

As the piston makes its upward stroke, the air is compressed and heated, and toward top dead centre, the air is ionised by the. Radio Frequency power applied to electrode 43 to form a plasma. When the piston is at or near top dead centre, the Hall-effect switch 57 closes, energising relay coil 65. When the relay coil is energised, contacts 66 apply the charge which has built up on capacitor 52 to electrodes 47–49, and contacts 67 open to interrupt the current in the primary winding of spark coil 51, producing a high voltage discharge between spark electrode 46 and the contact pin 53 on the piston.

The spark from electrode 46 and the current from electrodes 47–49 flowing through the ionised air ignite the air, causing it to explode and produce a lightning-like pressure wave, with ultraviolet light, ozone and heat. That pressure wave drives the piston in a downward direction, turning crankshaft 21 and generator 27, storing mechanical energy in the flywheel and producing electrical energy from the generator.
After the piston reaches its maximum volume or bottom dead centre (BDC) position the mechanical energy stored in the flywheel causes the crankshaft to continue rotating, thereby driving the piston back toward top dead centre. The same charge of air is ignited over and over again for an extended period of time, and to the extent that any of the air is lost past the piston rings, it is automatically replenished by air entering the chamber through the check valve. Thus, with the piston on its down stroke, if the pressure in the chamber drops below the level set by spring 38, ball 36 moves away from its seat, allowing air to enter the chamber through the inlet port. During the upstroke, the pressure in the chamber holds the ball tightly against the seat, sealing the air in the chamber.

The embodiment of Fig. 5 includes a free piston engine 71 which has a pair of explosion chambers 72, 73 at opposite ends of a cylinder 74. This engine differs from the embodiment of Fig. 1 in that it has no crankshaft. However, the power producing mechanism is the same, and like reference numerals designate corresponding elements in the two embodiments. The outer ends of the cylinder are closed by end plates or heads 16, and the volumes of the two chambers vary in an opposite or complementary manner as a double ended piston assembly 76 is driven back and forth within the cylinder.

The piston assembly includes a pair of pistons 12 which are connected together in back-to-back fashion by a sleeve 77, with rings 14 providing a seal between the pistons and the cylinder. The pistons have central contact pins 53, and each of the explosion chambers has an inlet port 18 and electrodes 43, 46–49 for ionising and igniting the gas.

As in the embodiment of Fig. 1, piston 12 and end plates 16 are made of a ferro-magnetic material, and cylinder 74 is made of a non-ferrous material such as non-ferrous stainless steel or nickel plated aluminium. Sleeve 77 is made of a non-ferrous material such as aluminium. Coils 54 are placed about the outer portions of the cylinder and coupled magnetically with the pistons to form reluctance generators.

Sleeve 77 carries magnets 56 which actuate Hall-effect switches 57 mounted outside cylinder 74 to determine when the pistons are at or near their top dead centre (TDC) positions. A grounding contact 78 carried by sleeve 77 makes sliding contact with the wall of the cylinder to maintain the pistons and contact pins 53 at ground potential.

The piston assembly also includes a relatively large permanent magnet 81 which is carried by sleeve 77 midway between the pistons. A ferro-magnetic core structure 82 provides flux coupling between magnet 81 and stator coils 83, 84 which are located outside the cylinder.

The core structure includes a pair of generally C-shaped cores 86, 87, each of which has pair of relatively short inner arms 86a, 87a which abut against the upper and lower surfaces of cylinder 74 and an outer arm
which is spaced laterally from the cylinder. The ends of the inner arms which abut against the cylinder have a concave curvature which matches the convex curvature of the outer wall of the cylinder, and coils 83, 84 are wound about outer arms of the cores. The cores are formed in two sections, with a split across the outer arms to facilitate assembly.

Steel laminations 89 are embedded in the cylinder wall in contact with the short arms of the cores to complete the magnetic circuit. The laminations are hermetically sealed into the cylinder wall, and in one presently preferred embodiment they are stacks of silicon steel laminations with a thickness of 0.005 inch and a layer of nickel plating less than 0.001 inch thick sealing the stacks.

The stator coils can be used both as the windings of a motor for starting the engine and thereafter as the windings of a generator in which an electric current is produced as the piston assembly oscillates back and forth within the cylinder.

Since the cylinder is hermetically sealed, any gas leaking past the rings of the pistons will remain within the engine, rather than being lost to the outside environment as in the embodiment of Fig.1. In addition to air, suitable gases for use in the embodiment of Fig.5 include inert gases, oxygen, and mixtures of such gases.

With the gas hermetically sealed within the engine, it is not necessary to replenish the gas as often as it would be if the engine were not sealed, and inlet port 18 can be closed with the plug assembly 91 of Fig.8 rather than the valve assembly 19 of Fig.7, if desired. Alternatively, a source of gas can be connected to the inlet port via valve assembly 19 for automatic replenishment of the gas in the chambers as in the embodiment of Fig.1.

Plug assembly 91 includes a body or bushing 92 with a hollow interior 93 which is filled with a rubber insert 94. The inner end of the valve body is threaded into the port, and a cap 96 is threaded on to the enlarged outer end of the body to retain the insert in the plug. A gasket 97 provides a seal between the enlarged portion of the plug body and the end plate or head 16.

Operation and use of the embodiment of Fig.5 is similar to that described above in connection with the embodiment of Fig.1. A charge of the explosive gas is introduced into the explosion chambers through the inlet ports, and stator windings 83, 84 are energised to drive magnet 81 and the remainder of the piston assembly back and forth within the cylinder. As each of the pistons approaches its top dead centre position, the gas in the explosion chamber is compressed, then ionised and ignited so that it explodes and drives the piston assembly back toward the other end of the cylinder. As the magnet carried by the piston assembly moves back and forth within the gap in the core structure, the alternating flux it produces is coupled to coils 83, 84 to produce the output current in the generator windings.

The invention has a number of important features and advantages. It can use explosive fuel mixtures such as air, inert gases and other non-combustible gases which can be rapidly expanded and contracted multiple times to convert kinetic energy into electrical and/or mechanical power. The engine can have one or more explosion chambers with a piston forming a movable wall for changing the volume of each.

The operating gas is preloaded into the chambers, the inlet ports are sealed, and the engine can be operated with the same gas load over long periods of time and multiple explosive expansions and contractions at various frequencies, e.g. 30-60 cycles per second or more, without adding gas to the chambers.
In one disclosed embodiment, the loss of gas due to leakage is prevented by enclosing the engine in a hermetically sealed enclosure. In another, a check valve in the inlet port allows the gas in the chambers to be automatically replenished when the pressure in the chambers drops below a predetermined level. The hermetic sealing is particularly important and desirable if the engine is operated in environments such as outer space or underwater where replenishment gases may not be readily available.

The invention permits a wide range of design flexibility and can provide compact power supplies ranging in capacity from a few kilowatts to multiple megawatts, and it can be used in a wide variety of applications.

It is apparent from the foregoing that a new and improved internal explosion engine and generator has been provided. While only certain presently preferred embodiments have been described in detail, as will be apparent to those familiar with the art, certain changes and modifications can be made without departing from the scope of the invention as defined by the following claims.

Claims:
The invention claimed is:

1. An internal explosion engine and generator, comprising an explosion chamber, a movable member forming one wall of the chamber, a charge of air sealed inside the chamber, a one-way valve in communication with the chamber for admitting additional air to the chamber if the pressure in the chamber drops below a predetermined level, means for repeatedly igniting the air in the chamber in an explosive manner to drive the movable member from a position of minimum volume to a position of maximum volume, means for returning the movable member from the position of maximum volume to the position of minimum volume, and means coupled to the movable member for providing electrical energy in response to explosion of the air.

2. The engine and generator of claim 1 wherein the movable member is a piston.

3. The engine and generator of claim 2 wherein the means for returning the movable member to the position of minimum volume comprises a flywheel on a crankshaft connected to the piston.

4. The engine and generator of claim 3 wherein the means for providing electrical energy comprises a generator connected to the crankshaft.

5. The engine and generator of claim 1 wherein the means for returning the movable member to the position of minimum volume includes a second explosion chamber having a movable member connected to the first named member, a charge of air sealed inside the second chamber, and means for igniting the air in the second chamber in an explosive manner.

6. The engine and generator of claim 1 including a hermetically sealed housing enclosing the explosion chamber and preventing loss of the air from the chamber.

7. The engine and generator of claim 1 wherein the movable member is fabricated of a ferro-magnetic material, and the means for providing electrical energy includes a coil which is coupled magnetically to the movable member.

8. The engine and generator of claim 1 wherein the means for igniting the air includes means for applying RF energy to the chamber to ionise the air and form a plasma, and means for igniting the plasma.

9. The engine and generator of claim 8 including electrodes in the chamber for heating the ionised air.

10. An internal explosion engine and generator, comprising a cylinder, a piston movable within the cylinder to form an explosion chamber of variable volume, a charge of air sealed within the chamber, means for admitting atmospheric air to the chamber if the pressure in the chamber drops below a predetermined level, means for periodically, explosively igniting the air in the chamber to drive the piston between positions of minimum and maximum volume, a crankshaft driven by the piston, and a generator connected to the crankshaft for providing electrical energy in response to movement of the piston.

11. The engine and generator of claim 10 including a flywheel on the crankshaft.

12. The engine and generator of claim 10 wherein the means for igniting the air includes means for applying RF energy to the chamber to ionise the air and form a plasma, and means for igniting the plasma.
13. The engine and generator of claim 12 including a magnetically actuated switch responsive to the position of the piston for delivering the spark when the piston is at or near the minimum volume position.

14. The engine and generator of claim 10 wherein the means for admitting atmospheric air to the chamber includes a check valve.

15. The engine and generator of claim 10 wherein the piston is fabricated of ferro-magnetic material and is coupled magnetically with a coil positioned outside the cylinder.

16. The engine and generator of claim 10 including means for energising the generator as a motor for moving the piston to start the engine.

17. An internal explosion engine and generator, comprising a cylinder, a pair of pistons connected together for movement in concert within the cylinder to form a pair of explosion chambers of variable volume, a charge of non-combustible gas sealed within each of the chambers, check valves for replenishing the gas in the chambers by admitting additional gas into the chambers when pressure in the chambers drops below a predetermined level, means for alternately igniting the non-combustible gas in the two chambers in an explosive manner to drive the pistons between positions of minimum and maximum chamber volume, a magnet coupled to the pistons for movement with the pistons, and a coil positioned outside the cylinder near the magnet for producing electrical energy in response to movement of the pistons.

18. The engine and generator of claim 17 wherein the non-combustible gas is selected from the group consisting of air, inert gas, and combinations thereof.

19. The engine and generator of claim 17 wherein the means for igniting the gas in each of the chambers includes means for applying RF energy to the chamber to ionise the gas and form a plasma, and means for igniting the plasma.

20. The engine and generator of claim 19 including switches responsive to the positions of the pistons for igniting the plasma when the pistons are at or near the minimum volume positions.

21. The engine and generator of claim 19 including electrodes in the chambers for heating the ionised gas.

Michael Eskeli's Turbines.
In April 1989, Michael Eskeli was annoyed by a newspaper article published in the Dallas Times Herald which commented on the failure of science to come up with alternative power systems which do not rely on petroleum products to operate. Michael responded in a letter to the Editor, stating that he holds patents for fuel-less power generators, work-free heat pumps, and other related items, 56 patents issued in the mid-70s.

Michael does hold many patents, one of which is shown in Chapter 14, as a work-free fuel-less heater. However, as I am not aware of any working prototype being shown, I must recommend that you consider the following information as “an idea” rather than a proven fact. As far as I am aware, in the 1970s, the US Patent Office did not demand to see a working prototype before granting a patent, especially if the patent related to a device based on accepted Engineering principles.

However, as Michael’s claim is for self-powered devices, his claim seems too important to be ignored, prototype or no prototype, as competent people reading this may well understand the principles suggested and be in a position to build a self-powered device as a result. If that is the case, then I should really appreciate feedback information on any successful replications and the construction methods used.

As I understand it, Michael’s self-powered devices are Heat Pumps where the additional energy is flowing from the heat contained in the air, courtesy of the heating effects of sunshine. Standard engineering, but with a design which utilises this available energy to provide practical mechanical output power for vehicles and electrical generators.

The Eskeli patents which I have been able to locate are:
3,650,636  Rotary Gas Compressor
3,719,434  Rotary Ejector Compressor
3,748,054  Reaction Turbine
3,748,057  Rotary Compressor with Cooling

4,574,592  Heat Pump with Liquid-Gas working Fluid

And there are presumably 7 others not listed here, to raise the total to the 56 mentioned by Michael. I do not have the expertise to tell which of these may be self-powered just by reading the patent information, which generally does not mention anything along those lines, (the Patent Office staff not believing that COP>1 exists). Practically any of these patents might fit Michael’s description, so I will pick the following patents to reproduce here:

4,107,944  Heat Pump with Two Rotors (continuing 4,005,587 and 4,047,392)
4,012,912  Turbine, and
3,931,713  Turbine with Regeneration

*****************
HEAT PUMP WITH TWO ROTORS

ABSTRACT
A method and apparatus for generating heating and cooling by circulating a working fluid within passageways carried by rotors, compressing the working fluid in them and removing heat from the working fluid in a heat-removal heat exchanger and adding heat into the working fluid in a heat-addition heat exchanger, all carried within the rotors. The working fluid is sealed in, and may be a suitable gas, such as nitrogen. A working fluid heat exchanger is also provided to exchange heat within the rotor between two streams of working fluid. In one arrangement, the unit uses two rotors, both rotating; in an alternate arrangement, one of the rotors may be held stationary. Applications include air conditioning and heating applications.

Cross References to Related Applications
This application is a continuation-in-part application of "Dual Rotor Heat Exchanger" filed Nov. 18, 1973, Ser. No. 407,665, now U.S. Pat. No. 4,047,392.
This application also is a continuation-in-part of "Heat Pump" filed June 30, 1975, Ser. No. 591,881, now abandoned.
And this application also is a continuation-in-part of "Rotary Heat Exchanger with Cooling and Regeneration" filed Oct. 1, 1975, Ser. No. 618,456, now U.S. Pat. No. 4,005,587.

BACKGROUND OF THE INVENTION
This invention relates generally to devices for heat transfer from a lower temperature to a higher temperature by using a working fluid enclosed within a centrifuge rotor as an intermediate fluid to transport the heat.

Heat pumps have been known in the past but are complex and costly, and usually use a working fluid that is evaporated and condensed, which results in poor efficiency, and thus high energy cost.

SUMMARY OF THE INVENTION
It is an object of this invention to provide apparatus that is low in initial cost and has high thermal efficiency thus reducing cost of the power required to run it. It is further the object of this invention to provide a device and process wherein the losses that normally occur in bearings and seals, due to friction, are applied to the working fluid for its circulation, thus in effect eliminating the power loss due to such friction losses. Also, it is an object of this invention to provide the rotor with a working fluid heat exchanger to reduce needed rotor speeds.

BRIEF DESCRIPTION OF THE DRAWINGS
Fig. 1 is a cross section of the device.

Fig. 2 is an end view of the device.
Fig. 3 is an axial cross section of another form of the device.

DESCRIPTION OF PREFERRED EMBODIMENTS

Fig. 1 shows an axial cross section of the device, where 10 is the base, 11 is the first rotor, 12 is the second rotor, 13 is a seal and 14 is the bearing supporting shaft 15. 16 is fluid passage in the second rotor, 17 is the working fluid opening which may be a nozzle, 18 is the first heat exchanger for heat removal from working fluid, 19 is first heat transfer fluid conduit, 20 is working fluid heat exchanger, in this instance formed from sheet metal like bellows, 21 are vanes, 22 is second heat exchanger for heat addition to working fluid, 23 is bearing supporting shaft 24, 25 and 26 are entry and exit for second heat transfer fluid, 27 and 28 are entry and exit for first heat transfer fluid, and 29 is a vane in peripheral passage.
In Fig. 2, an end view of the unit shown in Fig. 1 is illustrated. Where 10 is base, 11 is first rotor, 17 are fluid openings, 12 is second rotor, 16 are second rotor fluid passages with vanes, 30 indicates direction of rotation, 24 is first rotor shaft, and 21 are vanes.

In Fig. 3, the rotors are arranged differently, but perform the same functions, approximately, as in the unit of Fig. 1. Where 40 is first rotor, 41 is first heat exchanger for heat removal from first fluid, 42 is first rotor shaft, 43 and 44 are entry and exit for first heat transfer fluid, 45 is conduit, 46 is working fluid heat exchanger, 47 are fluid openings which may be nozzles, 48 is second rotor, 49 is second heat exchanger for adding heat to the working fluid, 50 is bearing and seal, 51 is second rotor shaft, 52 and 53 are entry and exit for second heat transfer fluid.

In operation, the rotors are caused to rotate and the rotor cavities are filled with a suitable working fluid, which is usually a gas, such as nitrogen, air or other gaseous or vapour substance. Referring to Fig. 1, the second rotor rotates usually faster than the first rotor, and the working fluid is compressed by centrifugal force in passages 16, and in the first rotor to some extent, after which heat is removed in heat exchanger 18, with such heat then being transported by the first heat transfer fluid out of the device. The working fluid then passes along the peripheral passage 29 and releases heat in heat exchanger 20, after which the fluid is expanded against centrifugal force in vanes 21 and in heat exchanger 22 where heat is added to the working fluid. After expansion, the working fluid passes along centre passage and receives heat from heat exchanger 20, thus completing its work cycle.

The operation of the unit in Fig. 3 is similar, except that the second rotor usually rotates slower than the first rotor, and the second rotor may be kept stationary, if desired. Note that if the second rotor is held stationary, one may use dirty water as the second heat transfer fluid; normally, in rotating heat exchangers, the heat transfer fluid must be free of solids, which will collect in the heat exchanger due to centrifugal force, and block the heat exchanger, and by having a stationary heat exchanger, ordinary water may be used, such as water from a cooling tower.

In the unit of Fig. 1, the power input is normally to the second rotor, and the first rotor is allowed to rotate freely. In such usage, the rotor diameters are selected to provide, together with the friction loss in bearings, for the needed speed differential between the two rotors. With the second rotor rotating faster, necessary push for the working fluid is provided to keep the working fluid circulating. Alternately, the speed differential may be maintained by using a power transmission between the two rotors, such as a gearbox. In the unit of Fig. 3, the second rotor speed is slower than the speed of the first rotor, and where the rotor diameters are suitable, the second rotor may be held stationary, providing needed push for the working fluid for its circulation.

The working fluid heat exchanger 20 and 46, employ centrifugal force and varying gas density to obtain heat exchange between the two working fluid streams. Hot gas in the peripheral passage is lighter, and colder gas between the folds of the heat exchanger is colder, thus the cold gas is displaced by lighter gas by centrifugal force. Similarly, at the centre passage, cold gas at centre displaces hot gas between folds. Other types of heat exchangers may be used for the heat exchanger 20, including heat pipes, sheet metal discs, and finned tubing filled with a liquid.

The rotor may be encased within a vacuum tank, if desired, to reduce friction on rotor outer surfaces. The use of the working fluid heat exchanger 20 will reduce required rotor speeds to obtain required temperature differentials between the two heat transfer fluids, which then reduces friction losses on the rotor, which may eliminate the need for a vacuum tank.
Various modifications of this device may be made, and different types of heat exchangers used. Also, working fluid radial passages may be curved in various directions, one being the slope for vanes shown as item 21 in Fig. 2. By using vane slopes and sloped passages, one can adjust the amount of work exchange between the working fluid and the rotor. Nozzles 47 are usually positioned so as to discharge backwards, in order to generate some torque on the first rotor, and similar nozzles may also be used in passages 21 of the unit shown in Fig. 1. Further, the heat exchanger 22, of Fig. 1, may be mounted on a stationary member, if desired, in manner shown in Fig. 3, and heat exchanger 18 may be mounted within rotor 12, if desired. The various components of the units may be interchanged, as desired.

CLAIMS

1. In a heat pump wherein a compressible working fluid is circulated radially outwardly in a first fluid passage, said first passage contained in a first member, and radially inwardly towards centre of rotation in a second fluid passage, said second passage contained in at least one of said first and second members, said first and second members coaxially arranged, at least one of said members being supported by a shaft for rotation;

said first and said second radial working fluid passages communicatively connected at their respective outward ends by an outer passage and at their respective inward ends by an inner passage, said radial and outer and inner passages forming a closed loop extending at least partially through both of said members, a working fluid adapted to be circulating through said loop, means for compressing said working fluid by centrifugal force within said loop with accompanying temperature increase, first heat exchange means for cooling said working fluid after compression, said first heat exchange means being carried by one of said members, a second heat exchange means, carried by one of said members, for regeneratively exchanging heat between said working fluid within said inner and outer passages, and a third heat exchange means carried by one of said members for heating said working fluid after said heat exchange between said working fluid within said inner and outer passages.

2. The heat pump of claim 1 wherein a first heat transfer fluid is circulated within said first heat exchange means to remove heat with said first heat exchange fluid entering and leaving via conduits near the centre of rotation of said members.

3. The heat pump of claim 1 wherein a second heat transfer fluid is circulated within said third heat exchange means entering and leaving via conduits near the centre of rotation of said members.

4. The heat pump of claim 1 wherein both of said members are rotors.

5. The heat pump of claim 4 wherein the two rotors rotate at different angular speeds.

6. The heat pump of claim 1 wherein at least one of said members is a rotor.

7. The heat pump of claim 6 wherein said second heat exchange means includes a plurality of folds.

8. The heat pump of claim 7 wherein said second heat exchange means is of bellows configuration.

**********************

TURBINE

ABSTRACT

A method and apparatus for the generation of power wherein a working fluid is compressed within outward extending rotor passages, and then passed inward in other rotor passages with accompanying expansion and deceleration, with work being generated by the decelerating fluid. Heat may be added into the working fluid near the rotor periphery, and in closed rotors, heat is removed from the working fluid after expansion. A regenerator may also be used, mounted on the rotor, exchanging heat between two streams of the working fluid. During the deceleration, the working fluid passages are curved backwards, while the working fluid
passages for acceleration are usually radial. The working fluid may be either a liquid or a gas, and the heating fluid and the cooling fluid may also be either a liquid or a gas.

3,834,179 Turbine with Heating and Cooling Sept 1974 Eskeli
3,926,010 Rotary Heat Exchanger Dec 1975 Eskeli

**Cross References to Related Applications:**
This application is a continuation-in-part application of “Turbine,” Ser. No. 566,373, filed 4-9-75 now U.S. Pat. No. 3,949,557.

**BACKGROUND OF THE INVENTION**
This invention relates to power generators where a working fluid is circulated from a higher energy level to lower energy level, generating power.

In my earlier U.S. Pat. Nos. 3,874,190 and 3,854,841, I described a closed and open type turbines, and using centrifuge design. These turbines used forward facing nozzles within the rotor; in the apparatus disclosed here, such nozzles have been replaced by other methods.

**SUMMARY OF THE INVENTION**
It is an object of this invention to provide a single rotor centrifuge type turbine stage, where vanes or fins, with suitable contours, are used to extract power from the working fluid, using either an open type or a closed type rotor.

**BRIEF DESCRIPTION OF THE DRAWINGS**

*Fig. 1 is a cross section and*
Fig. 2 is an end view of a closed type rotor.

Fig. 3 is a cross section and
Fig. 4 is an end view of an open type rotor.

Fig. 5 is a cross section of a unit using a closed type rotor and also using a regenerator.

DESCRIPTION OF PREFERRED EMBODIMENTS
Referring to Fig. 1, there is shown a cross section of one form of the unit. Where 10 is the rotor which is supported by bearings 16 and 22, shaft 17 and base 21. 12 is a heat supply heat exchanger and 15 is cooling heat exchanger. 14 and 11 are vanes or fins, 18 and 19 are coolant entry and exit, 20 is a dividing wall, 23 and 24 are heating fluid entry and exit, and 13 is a working fluid passage which may be used to regulate the flow of working fluid within the rotor.

![Fig. 1](image)

Fig. 2 is an end view of the unit shown in Fig. 1. Where 10 is the rotor, 17 the shaft, 19 is a coolant passage, 21 is the base, 14 are vanes positioned so that they slope away from the direction of rotation as indicated by arrow 25, while simultaneously passing the working fluid inwards, 12 is the heating heat exchanger, and 15 is the cooling heat exchanger.

![Fig. 2](image)

In Fig. 3, a rotor for a unit using open cycle is used, where the working fluid enters and leaves the rotor. Here, 30 is the rotor, 31 is the vane situated in a passage which extends outwards, 32 is the fluid passage, 33 is a vane in the passage for inward bound working fluid, 34 is the working fluid exit, 35 is the rotor shaft, 36 is a rotor internal divider and 37 is the working fluid entry into the rotor.

![Fig. 3](image)
Fig. 4 shows an end view of the unit of Fig. 3 where 30 is the rotor, 35 is the shaft, 31 are vanes in the passages for outward bound fluid, and are shown here to be curved backwards, when the rotor rotates in the direction shown by arrow 38. After passing openings 32, the working fluid passes inwards guided by vanes 33, and then leaving via exit 34. Vanes 33 are curved as indicated, with the curvature being away from the direction of rotation, so the working fluid provides thrust against the rotor components as it decelerates when passing inwards toward the centre of the rotor.

In Fig. 5, a rotor with a regenerator is shown, and also the rotor shaft is arranged so that it can be kept stationary if desired. 50 is the rotor which is supported by bearings 56 and 63 and shaft 57. Vanes 51 may be radial or curved as desired, and vanes 54 are curved in a manner similar to vanes 33 in Fig. 4. 52 is a regenerative heat exchanger, exchanging heat between the working fluid streams flowing in passages 53 and 61. Heat supply heat exchanger 55 and cooling heat exchanger 62 are attached to the shaft, so that the shaft may be kept stationary or rotated at a different speed than the rotor 50. 58 and 59 are the entry and exit points for the heating fluid while 64 and 65 are the entry and exit points for the cooling fluid, and 66 is an opening.

When operating, the rotor rotates, and a working fluid within the rotor passes outwards in passage 11, and is compressed by centrifugal force, and accelerated to a tangential speed that may be the same as that for the rotor periphery. In a closed rotor such as is shown in Fig. 1, heat is added into the working fluid near the rotor periphery, and then the working fluid decelerated in the fluid passages 14 extending inwards toward rotor centre, with the passages being curved backwards away from the direction of rotation as shown in Fig. 2. As the working fluid is decelerated in the inward extending passages, the work associated by such deceleration is transferred into the rotor and this provides the thrust and torque to rotate the rotor. After deceleration and expansion, the working fluid is cooled in heat exchanger 15 and then passed to the outward extending passages thus completing its working cycle.

The operation of the unit of Fig. 3 is similar, except that the working fluid enters the rotor via opening 37 from external sources. For the unit shown in Fig. 3, the heat addition heat exchanger is omitted; for this unit, there is a pressure drop between entry 37 and exit 34. A heat exchanger similar to that shown in Fig. 1, item 12, may be used in the unit of Fig. 3, and then the entry and exit pressure for the working fluid may be the same, if desired.
The operation of the unit shown in Fig. 5, is similar to that described for the other units. The rotor rotates, and by centrifugal force, compresses the working fluid in passages 51, and then the working fluid gains heat in the regenerative heat exchanger, with the heat being supplied by another working fluid stream returning from the high temperature end of the unit. The working fluid is expanded and decelerated in passages 54 and heat is added in the heat exchanger 55. Then the working fluid passes through the regenerative heat exchanger and then is cooled in the cooling heat exchanger and then is passed into passages 51 thus completing its cycle.

The various components of the units shown can be exchanged to make additional forms of the apparatus. As noted, the unit of Fig. 3 may be provided with a heat exchanger similar to that shown in Fig. 1 for adding heat into the working fluid near the rotor periphery. Further, a regenerator may be provided with the units of Fig. 1 and Fig. 3, if desired, between the outward extending and the inward extending working fluid passages. Also, the cooling coil of Fig. 5, item 62 may be eliminated, and the working fluid taken into the unit from outside the unit, if desired.

The openings 32, 13 and 66 may be made into nozzles, if desired, and the nozzle oriented in different directions as desired. In particular, these nozzles may be positioned so as to discharge the working fluid tangentially backwards, if desired.

The regenerator of Fig. 5 is shown to be tapered. This taper may be as shown, or the taper may be made such that the regenerator portion diameter is smaller at the end which has the heat exchanger 55, than the end which has the heat exchanger 62. Also, the regenerator may be made without a taper.

Passages 53 and 61 are usually provided with vanes, as indicated in Fig. 5, to prevent tangential movement of the working fluid.

Applications for this power generator are those normally encountered in power generation.

The working fluid is usually a gas for units such as those shown in Fig. 1 and Fig. 5, but the working fluid may also be a liquid for a unit such as shown in Fig. 3. The heating and cooling fluids may be either gases or liquids, as desired.

The heat exchangers for heating and cooling are shown to be made of finned tubing. Other forms of heat exchangers for adding heat and for removing heat may be used. The regenerative heat exchanger is shown to be made of sheet metal; other forms of heat exchangers may be also used.

TURBINE WITH REGENERATION

ABSTRACT

A method and apparatus for generating power by passing a motivating fluid from a higher energy level to a lower energy level by compressing the fluid in a centrifuge-type first rotor and discharging the fluid via nozzles near the periphery of the first rotor, forwards in the direction of rotation to a second rotor which is an inward flow type reaction turbine, then passing the fluid through a regeneration type heat exchanger to transfer heat from the inward bound fluid into the outward bound fluid, after which the fluid is cooled in a heat exchanger to its original temperature and is passed outward again thus completing its cycle. Heat is added to the fluid near the periphery of the second rotor, or the heat may be added near the periphery of the first rotor, or both. Additionally, the fluid may be supplied to the unit from outside source, and returned to such outside source, and the cooling may thus be eliminated from the unit. Further, the fluid entering from an outside source may be at an elevated pressure. The fluids used may be gaseous, which is normal for a closed type unit, or they may be liquids at entry for the open type unit.

US Patent References:
This application is a continuation-in-part application of "Turbine with Dual Rotors," Ser. No. 405,628, filed 10/11/73, and uses material of a previous U.S. Pat. No. 3,834,179, "Turbine with Heating and Cooling".

BACKGROUND OF THE INVENTION

This invention relates generally to devices for generating power in response to a fluid flowing from a higher energy level to a lower energy level passing through a turbine for generating the power.

There have been various types of turbines previously, in some of which a fluid is accelerated in a single or multiple stationary nozzles and then passed to vanes mounted on a rotating rotor wheel, where the kinetic energy contained by the moving fluid is converted to power by deceleration of the fluid.

These conventional turbines normally have a high energy loss due to fluid friction, especially between rotor vanes and the fluid where the velocity differential is usually large. Also, these turbines often require complex shaped turbine vanes making the unit costly.

SUMMARY OF THE INVENTION

It is an object of this invention to provide a turbine for power generation in which heat is converted to power, in an efficient and economical manner, and with high thermal efficiency. It is also an object of this invention to provide a means for transferring heat from the motivating or working fluid, which is the first fluid, during its passage from rotor periphery to rotor centre into the first fluid which is passing from the rotor centre towards the rotor periphery. This heat transfer improves the efficiency of the turbine, and reduces the necessary rotational speed of the rotor, allowing less costly rotor construction.

BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 1 is a cross section of one form of the device, and
Fig. 2 is an end view of the unit shown in Fig. 1.

Fig. 3 is a cross section of another form of the device.

Fig. 4 is a detail of rotor nozzles.
Fig. 5 is a pressure-enthalpy diagram of the first fluid with working cycle illustrated for the first fluid.

**DESCRIPTION OF THE PREFERRED EMBODIMENTS**

![Diagram of turbine](image)

**Fig. 1** shows a cross section of one form of the turbine. In this form, the first fluid is sealed within the rotor with a second fluid which supplies heat to the first fluid, and a third fluid which cools the first fluid, being circulated from external sources.

The first fluid is accelerated and compressed within the first rotor, and after discharge from the nozzles of the first rotor, into the second rotor, where it receives heat from the second fluid, and after deceleration and expansion the first fluid passes in heat exchange relationship with the first fluid flowing outward so that heat is transferred from the inward bound first fluid to the outward bound first fluid. Cooling is then provided for the first fluid to bring the first fluid temperature to an initial predetermined value.

In **Fig. 1**, 10 is the casing, 11 is the first rotor, 12 is the third fluid heat exchanger, 13 is the vane which also serves as a heat exchange member, 14 is a heat-conductive wall, 15 is a vane, 16 is a nozzle, 17 is the second rotor, 18 is the second fluid heat-exchanger, 19 is a vane, 20 is the second-fluid conduit, 21 is a combined bearing and seal, 22 is a combined bearing and seal, 23 is a second rotor shaft for the delivery of power, and for support of the second rotor, 24 and 25 are supply and return for the third-fluid, 26 is a vent opening in the casing into which a vacuum source may be connected, 34 is a dividing wall, 27 are vanes serving also as heat-exchange members, 28 is a first-fluid passage, 30 is a combined bearing and seal, 31 and 32 are the second-fluid entry and exit points, and 33 is the first rotor shaft.
Fig. 2 shows an end view of the unit of Fig. 1 where 10 is the casing, 11 is the first rotor, 17 is the second rotor, 16 are the first-fluid nozzles, 18 is a heat exchanger, 19 are vanes, 20 is a conduit, 13, 14 and 27 form a heat exchanger for the first-fluid and 23 is the second rotor shaft.

Fig. 3 shows another form of the turbine, where the first-fluid is supplied to the turbine from outside sources thus eliminating the third-fluid heat exchanger. 50 is the first rotor, 51, 52 and 53 form a heat exchanger for the first-fluid, 55 and 58 are heating heat exchangers for adding heat to the first-fluid and may use a second-fluid at the same temperature or at a different temperature as the heating fluid, 54 are vanes within first rotor, 56 are first-fluid nozzles oriented to discharge forwards, 57 is the second rotor, 59 are vanes, 60 is a conduit for the second-fluid, 61, 62 and 72 are bearings, 64, 65, 69 and 70 are entries and exits for the second-fluid, 63 is the second rotor shaft, 71 is first rotor shaft, 66 is the base, while 67 and 68 are the exit and entry points for the first-fluid.
**Fig. 4** shows a detail of the first-fluid nozzles where 34 is wall on which nozzles 16 are mounted, 35 is the approximate direction of leaving of the first-fluid, and 36 indicates direction of rotation of first rotor.

In **Fig. 5**, a pressure-enthalpy diagram for the first fluid is shown, with the working cycle for the first-fluid where 80 is the pressure axis and 81 is enthalpy axis, 82 are constant entropy lines, 83 are constant pressure lines, and for the cycle, compression with heat removal, or without heat removal, occurs from 84 to 85, heat is added from returning first-fluid from 85 to 86, further compression is from 86 to 87, then expansion from 87 to 88 and 89, and heat removal to the first-fluid from 89 to 84, thus completing the cycle.

In operation, the rotors are filled to a desired pressure with a suitable first-fluid, and the first rotor is caused to rotate. The first-fluid is first compressed with heat removal, and then is passed in heat exchange relationship with the inward bound first-fluid with addition of heat, and after this the first-fluid is further compressed and accelerated and after this compression, the first-fluid is passed via nozzles mounted on the first rotor forwards in the direction of rotation, after which the first fluid enters the second rotor’s inward extending passages for deceleration, with heat being added to the first-fluid in the second rotor inward passages for reduction of density of the first-fluid. After passing inwards and decelerating, the first-fluid is passed in heat exchange relationship with the outward bound first-fluid, and after that, the first-fluid may be further decelerated, and then the first-fluid enters the outward extending passages of the first rotor thus completing the cycle.

The operation of the open turbine of **Fig. 3** is similar to that described, except that the first-fluid is supplied from external sources, and is then returned to said external source, with cooling then being deleted.

The work input to the first rotor is the work required to accelerate the first-fluid, and the work output by the second rotor is the work of deceleration received by the second rotor. The work output by the turbine is the work differential of these two rotors.

The rotational speed of the second rotor may be higher than the rotational speed of the first rotor. To provide for inward flow of the first fluid within the second rotor, the fluid density is reduced by adding heat to the first fluid either within the second rotor, or also within the first rotor.

The addition of heat from the inward bound first fluid to the outward bound first fluid increases the temperature of the first fluid during latter part of compression and during expansion, and thus has the effect of improving the thermal efficiency of the turbine. Also, another effect is the reduction in the needed rotational speed for the turbine rotors, thus reducing the required strength for the rotors, and making the rotors more economical to make and operate.

Working fluids for this turbine are usually gases for the first-fluid, and liquids for the second and third fluids. Gaseous second and third fluids may be also used, and the first-fluid may be a liquid in some instances. Also, the first fluid may undergo a phase change within the turbine, if so desired, when using a suitable fluid. Applications for this turbine include normal power generation service using various heat sources.

The first rotor shaft and the second rotor shaft are normally connected via a power transmission device so that a part of the power produced by the second rotor is used to rotate the first rotor. Starting of the unit is by a starting device.
The vanes of the rotors may be made curved if desired. In many instances, the first rotor vanes may be curved backward to increase compression of the first-fluid, and the vanes of the second rotor may be also curved, to improve performance, and to suit the design and fluid selected. In this connection, the fins for the heat exchangers are considered to be vanes.

The pressure-enthalpy diagram shown in Fig.5, is approximate only. This diagram may be varied, depending of the amount of heat added in the second rotor, or in the first rotor, and depending on the specific location of the second fluid and third fluid heat exchangers. In particular, heat may be added to the first-fluid during expansion to make the first-fluid actually increase in temperature; this will normally improve the overall thermal efficiency of the turbine. Also, heat removal by the third fluid may be conducted in places other than that shown in Fig.1, as desired.

It should be also noted that the heat addition to the first-fluid may be from sources other than the second fluid, and similarly, some other means may be used to cool the first-fluid other than the third fluid. Such heating sources may include electricity, or other rotors mounted in proximity to this turbine; these will not change the spirit of this invention.

The heat exchanger mechanism for transferring heat from the inward bound first-fluid to the outward bound first-fluid can also be located within the second rotor, and also the entry and exit for the first-fluid into the turbine may be within the second rotor. Such arrangements are not shown specifically in the drawings since they are considered to be within the capabilities of a skilled designer, in view of the descriptions given herein.

Much of this information on Michael Eskeli is taken, with the kind permission of Scott Robertson, from his web site http://www.aircaraccess.com.

James Hardy’s Self-Powered Water-jet Generator.
Repeated here from Chapter 2, a device which needs to be in this list of self-powered devices is the ultra simple water-jet generator. There is a video on Google which shows a self-powered electrical water-pump driven, electrical generator at the location: http://www.youtube.com/watch?v=zlinM1wAI5U

This is a very simple device where the jet of water from the pump is directed at a simple water-wheel which in turn, spins an electrical alternator, powering both the pump and an electric light bulb, demonstrating free-energy. What is of particular note is the utter simplicity of this device. It uses off-the-shelf parts almost exclusively and can be constructed by almost anyone.

It should be noted that the implementation shown in this video uses the most basic of turbine blades which must have a very low efficiency, and yet the output power generated is well above the level needed to sustain its own operation. Given well shaped conventional turbine blades of much higher efficiency would appear to raise the performance further, while one would think that using a Tesla Turbine with its simple discs should give a really spectacular performance. However, this may very well not be the case a the irregular, pulsed drive of the wheel will be leading-out additional energy as in the case of the Chas Campbell flywheel and the John Bedini flywheel. As it is, with its present form of construction, this device is already capable of producing additional power able to run other pieces of standard mains equipment.
This is clearly a development platform and it would benefit from having the areas which contain water, fully
enclosed, and the electrical diversion from mains power to the output alternator operated by a switch.

Initially, the generator is got up to speed, driven by the mains electrical supply. Then, when it is running
normally, the mains connection is removed and the motor/generator sustains itself and is also able to power
at least one light bulb. The generator output is normal mains current from a standard off-the-shelf alternator.
Power generation could hardly get any more simple than this.

The Heat Pump System of Arthur Cahill and John Scott.
Arthur Cahill and John Scott have patented a heat-pump system which draws heat energy from the
surrounding environment and uses that energy to produce mechanical and/or electrical energy for powering
a household. Why most people have a refrigerator they are generally not aware that it is a heat-pump and
moves three times as much heat from inside the refrigerator compared to the necessary input power
(COP=3 but could be up to COP=11 when used differently).

This heat-pump system appears to run without any form of energy input, but the energy comes indirectly
from the sun heating the surrounding environment and there is no magic involved. Mind you, when the
system runs and provides power, generally, without the need for any fuel, the user can be forgiven for
thinking of it as a fuel-less or self-powered system even though strictly speaking, that is not the case. The inventors have made allowances for unusual conditions where environmental conditions can't provide the temperature difference needed to make the system operate as intended. A liquid or gaseous fuel is provided along with a burner to provide the heat difference if those conditions are encountered.

Here is an extract from their patent:

**SOLAR ENERGY SYSTEM**

**ABSTRACT:**
A dynamic, self-sustaining and self-perpetuating device for the production of motive force by combining cryogenic and thermodynamic principles into one system, keeping the systems separated, two open to atmosphere, the other closed, sealed, pressurised and using special compounded fluids, which when alternately exposed to the heat of atmospheric temperature, then, to the coldness of a liquid or air-cooled condenser, first evaporates, then condenses. Rapid expansion during evaporation produces a high pressure vapour which operates an engine and a generator, which are an integral part of the closed system. Rapid condensation drastically reduces back pressure on the aft side of the engine, and the engine operates on the difference between the two pressures, producing electricity, or, the engine can be used as a direct drive for vehicles or equipment. Built-in safeguards and alternatives are a part of the systems, assuring continued operation despite adverse conditions.

**BACKGROUND OF THE INVENTION**

1. **Field of the Invention**
This invention relates to a closed-cycle, sealed, pressurised, energy producing system, utilising the sciences of thermodynamics and cryogenics to convert liquid into gas, then back to liquid.

2. **Description of the Prior Art**
There is no exact prior art, as cryogenics have been used primarily for air conditioning and refrigeration purposes, and thermodynamic efforts have been directed in the area of low efficiency ocean thermal energy conversion systems. A few attempts have been made to combine some form of cryogenics and thermodynamics, without notable success, mainly using sea water for evaporation and condensing. While using no fuel and requiring little in the area of labour, these ocean thermal energy conversion systems are of necessity, low pressure systems and require large sea going platforms to support the huge turbines and heat exchangers which are necessary to produce reasonable electrical power, resulting in excessive capital costs for minimal electrical output, since such stations only have the ability to service a small portion of the populace along the seaboards. None of these contrivances serve or benefit the populace as a whole, while the whole bears the burden of financing through taxes, or government grants.

Proposals to heat gases and cool gases in an endeavour to improve the efficiency of home heating and cooling systems, have been previously advanced, some operating on the heat pump principle. All such previous proposals and inventions have had one thing in common, they all plug into the Utility Company's electric line to obtain the electricity necessary to run the system.

In cryogenics the knowledge that certain liquids, when heated, change into a high pressure vapour, which is the heart of all air conditioning and refrigeration systems, has been known for many years. Thermodynamics were pioneered by the 19th century French physicist Nicholas Carnot. Attempts have been advanced during the years to harness one or the other and sometimes both, for the purpose of heating and cooling, resulting
in the invention of the heat pump in a much earlier year, but none of the systems yet devised for use by the general public have been able to operate without the use of an outside source of electricity, or, fuel, such as oil, or gas fired boilers, resulting in a considerable consumption of fuel and a cataclysmic effect on the earth's environment.

SUMMARY OF THE INVENTION

In accordance with the present invention, the device will operate in hot sunshine; on cloudy days without sunshine; during rainstorms; during snowstorms; during changes in temperature from day to night; during changes in seasons from winter, to spring, to summer, to fall; when it's cold, even below zero; for the power generated is that energy produced when a compounded fluid changes form, first to vapour, then back to liquid, by application of controlled temperatures within the sealed cycle. Thus, by combining cryogenics and thermodynamics into one system, keeping the two separated, one open to atmosphere and the other closed, sealed and pressurised, and by using fluids specifically compounded for the given area, or climate, these fluids, when exposed to atmospheric temperatures, in accordance with the kinetic theories of matter, gases and heat, provide the kinetic energy to operate an engine.

The condenser can be either liquid or air cooled, although for the embodiment depicted herein, the condenser is air cooled.

Generally speaking, there is up to an approximate 2.5 PSI increase associated with each degree of temperature rise in most cryogenic fluids and gases. However, using commercially available fluids, here are a few examples:

<table>
<thead>
<tr>
<th>Temperature F.</th>
<th>Fluid</th>
<th>Pressure in psi.</th>

You will notice that R-13 at 80° F. produces 521 psi., or 35.4 times atmospheric pressure and at 125° F. would produce thousands of psi. At 95° F. R-22 produces 185 psi., or a thrust on a five inch diameter piston of 3,633.4 pounds. Even at 30° F., with R-22 a thrust of 583.2 pounds is obtained. R-13 at 30° F. produces 263 psi. or 5,112.7 pounds of thrust on a five inch diameter piston. The pressures are there by using the Casco Perpetuating Energy System, utilising proprietary formulated liquids for the area and temperatures to be encountered. It is not intended that any of these mentioned fluids will be used in the present invention; the comparisons being made herein with popular and well known liquids, for comparison purposes only.

THE INVENTION

The present invention relates to a device to supply pollution free power to operate a generator for the producing of electrical power, or, to supply power as a direct drive to a shaft, transmission, clutch, differential or the such, the invention being independent of outside sources of power such as electricity supplied by a Public Utility Company. This is not to be considered perpetual motion, as will be explained later in the text.
Proprietary liquids, specifically compounded to produce the desired results in a given area, or climate, under pressure in the reservoir to keep them in a liquid state, will, when directed through tubes exposed to atmospheric temperature, change from a liquid state into a gaseous state (from here on referred to as steam), such conversion resulting in tremendous expansion, thus producing high pressure steam with which to drive the engine, or turbine.

It is a general object of this invention to provide a pollution free device for public utilisation, that will produce electrical power or, direct drive power. One object is to produce electrical power with which to heat, cool, cook, run electrical appliances and light a home. Another object of the invention is to provide industry with a pollution free means to not only heat, cool and light factories, but to supply electrical or direct drive power with which to operate factory equipment. A still further object of the invention is to provide a pollution free source of power to propel cars, trains, trucks, buses, equipment, steamships, aeroplanes, and other forms of transportation, without the use of fossil fuels as the primary power source. It is also an object of the present invention to provide the means whereby individuals can produce electrical power for their own use, and as a small power production, sell their surplus electrical power to the local electricity utility company. A further object of the invention is to provide a self-sustaining, small apparatus, that provides ample power from the engine to operate a car or other conveyance, or to supply sufficient electrical power to a home or factory, without having to plug the apparatus into a Public Utility electrical supply.

BRIEF DESCRIPTION OF THE DRAWING
Fig. 1 is a partially sectioned schematic view of the system:

DETAILED DESCRIPTION OF A PREFERRED EMBODIMENT

In the drawing, Fig. 1, the invention is shown in a preferred embodiment for home use. The liquid pump 39, pumps the cryogenic fluid from the pressurised liquid reservoir 38, into liquid line 40, where the fluid gravity feeds into flash boiler 8. Pump 39 also prevents back pressure from flash boiler 8 from entering the pressurised liquid reservoir 38, and since the pressure within steam line 10 and liquid line 40 are equal, the cryogenic fluid gravity feeds down liquid line 40 into steam line 10. The fins on flash boiler 8 are heated to atmospheric temperature by air stream 4, which converts the fluid within steam line 10, inside flash boiler 8 into high pressure steam. To maintain the pressure during the passage of steam to the engine 15, steam line 10 from flash boiler 8 is housed inside the oven 9, which is exhausted when necessary by discharge 12 from centrifugal blower 11. Constant temperature within oven 9 and flash boiler 8 is maintained by the admission of fresh atmosphere via air stream 4 passing through the finned flash boiler 8 and up through oven 9. Centrifugal blower 11 is thermostatically controlled to exhaust air within oven 9 which has cooled below a predetermined temperature. Any excess pressure within steam line 10 is by-passed through check valve 13 and bleed line 14 into the exhaust collector box 18, thus, a pressurised, closed system is maintained, which, once charged, unless an accident damages or ruptures a line, should not have to be replenished. Pressure within the exhaust collection box 18 will be less than the inlet pressure from steam line 10 to engine 15, because the condenser 24 is at a lower pressure, as is steam return tube 19, than PSI input to engine 15 from steam line 10, thereby creating a suction on the back of the exhaust collector box 18.

Airstream 29, which has been cooled by evaporator cooler 27, flows over the finned surfaces of condenser 24, instantly lowering the temperature of the steam within condenser 24 below a predetermined condensation point, thus turning the steam back to a liquid, such conversion and instant reduction of volume within condenser 24 causing a pressure reduction at the back of engine 15. This condensed liquid drains down into liquid coil return 35, where it is immediately pumped into the pressurised liquid reservoir 38 by liquid pump 36.

While under pressure in pressurised liquid reservoir 38, the fluid is maintained in a liquid state regardless of exterior temperature, until it is re-circulated back into the system by liquid pump 39, through liquid line 40 to flash boiler 8, where it again converts into steam.

The capacity of evaporator cooler 27 and packing 28 is sufficient to cool intake air stream 29 to a predetermined temperature below atmospheric temperature at any given time, even with humidity rise at night, or during rainstorms, or just during high humidity weather. This temperature differential is maintained as the atmospheric temperature rises and falls, with an anti-freeze liquid being added to the water in the evaporator cooler when temperatures drop below 32° F., to keep it from freezing.
Additional warm air to augment air stream 4 is obtained by directing the warm air exhaust collected in hot exhaust air collector 26, by centrifugal blower 41, through T-assembly 42. Air flow through T-assembly 42 is directed and controlled by the warm air control mechanism 44, which regulates flow-damper 43 to either exhaust through exit 45 into the atmosphere, or alternatively, recirculate air flow 29 through restricted-T 42, thereby compressing and further heating air flow 29 before injecting it through flash boiler 8. Warm air control mechanism 44 also controls fan 1 and louvers 3, selecting the optimum heat from either T-assembly 42 or variable-Venturi 2, to perpetuate the system.

The evaporator cooler 27 has an inlet water pipe 34 which supplies cold water from the normal house water supply, or well, (neither shown). The bottom water reservoir 33 is kept at a constant level of water by float valve 32. The water is pumped by pump 31 up tube 30 into the top water reservoir 25, where it runs through the perforated bottom of reservoir 25 down on to the packing 28, keeping packing 28 constantly wet, which cools air flow 29 as it is drawn through packing 28 and over the fins of condenser 24 by the partial vacuum in the hot air exhaust collector 26, such partial vacuum being created by centrifugal blower 41 exhausting the air from the hot exhaust air collector 26 slightly faster than air flow 29 can replace it.

As long as there is warmer air on the flash boiler 8 side of the system than the cooler condenser 24 side of the system, this device will continue to operate and produce electricity and/or power. The heat recirculating system and the use of three separate, distinct sub-systems within the system, one sealed, permits the system to perpetuate itself. As mentioned above, this device is not to be considered perpetual motion, for somewhere in the ranges of temperature differentials and weather conditions, there may be a no-man's land where the system could shut down, then the variable venturi 2, in conjunction with motor and fan 1 and louvers 3, will come into use automatically upon a signal from warm air controller 44 and 12 volt controller 23, and be used for a period of time. Motor and fan 1 forces an air stream 4 upward through the variable Venturi 2, with air stream 4 controlled by warm air controller 44 and 12 volt controller 23, adjusting louvers 3. As air stream 4 is forced through the restriction of variable Venturi 2, air stream 4 is compressed as it funnels up the narrowing walls of the variable Venturi 2, such compression causing the air to heat, thus overcoming possible deadlocked or identical temperatures between the condenser 24 and air flow 4. This slight temperature rise in air stream 4 will enable the system to perpetuate itself until the atmospheric temperature itself changes enough to permit a continued operation. Since fan and motor 1 is run by battery power from 12 volt supply 23, even though the batteries are constantly being charged during operation, the batteries may become exhausted because of an extended time the fan and motor 1 are run, then, or, if for any other reason the system starts to run down, a small burner 7, operating on liquid or gaseous fuel 6, through line 5 and valve 48, is ignited by spark mechanism 47 and supplies the heat necessary to support and perpetuate the system until atmospheric temperature and condensing temperature permits the system to operate normally. Fired clay heat retainers 46 are arranged on the grate within burner 7, to retain heat.

The cryogenic system is charged by filling with liquid under pressure through fill pipe 37. Re-charging, if necessary, is done the same way. Engine 15 turns drive shaft 16, which turns generator 17, producing electrical power (110V or 220V) via electric control system 20 which passes the electricity into three channels:

One: To 12-volt controller 23, to run the electrical parts of the system and keep the batteries charged.

Two: To the house 22, to supply the electricity with which to cook, run appliances, light, heat and cool the home.

Three: All remaining electricity is channelled through utility meter 21 into a local utility company's electrical line for sale and use elsewhere.

Chapter 9: Passive Systems

The Devices of Hans Coler.
A German naval captain called Hans Coler invented a COP>1 generator in 1925. He called this device the ‘Stromerzeuger’ and for a few watts from a dry battery it provided 6 kW continuously. He was refused development support because it was “a perpetual motion machine”.

Hans also invented a passive device which he called the ‘Magnetstromapparat’. His unit required very careful and slow adjustment to get it operating but when it started it continued on test in a locked room for three months of continuous operation. Nobody, including Hans, seems any too sure how this device works but it is presented here in case you wish to research it further. It comprises six bar magnets wound as shown here. Some are wound in a clockwise direction when looking at the North pole and these are called “Right” those wound in an anticlockwise direction are called “Left”:

![Diagram of six magnets arranged in a hexagon and wired as shown.](image)

*Note: There is paper insulation between magnet and coil*

These six magnets are arranged in a hexagon and wired as shown here:
And the schematic diagram is:

One extremely interesting feature of this passive device is that it has been witnessed producing 450 mV for several hours; it was capable of developing up to 12 Volts. The witnesses were quite sure that it was not picking up radio or mains input. So, what was it picking up? With magnets as the key component, it seems clear that it is the zero-point energy field which is being accessed, but clearly, the access represents a vanishingly small percentage of the actual power available.

To operate the device, the switch is left in the open position, the magnets are moved slightly apart and the sliding coil set into various positions with a wait of several minutes between adjustments. The magnets are then separated still further and the coils moved again. This process is repeated until at a critical separation of the magnets, a voltage is developed. The switch is now closed and the process continued more slowly. The voltage then builds up to a maximum which is then maintained indefinitely. The position of the apparatus in the room and the orientation of the device had no effect on the output.

The magnets were selected to be as nearly equal in strength as possible and the resistance of the magnet and coil were checked after winding to make sure they were as nearly equal as possible (about 0.33 ohms).

A very neat construction of the Coler ‘Magnetstromapparat’ by an unknown German experimenter is shown below - I’m afraid without permission as I have no idea who he is or how to contact him to ask his permission. The quality of workmanship is impressive and the result is a very professional looking device. Notice the sliding coil arrangement at the bottom left with one coil being positioned closely inside another and held in place where the experimenter chooses.

Recently, a construction video has come on offer at [http://www.kohlermagnet.com/](http://www.kohlermagnet.com/) and it shows step by step, one method of implementing this design. The website design screams ‘con artist’ and the final tuning is shown is such an apparently simple and quick way that it suggests that it could well be faked (by AAA batteries embedded in the underside of the very thick base board and wired in underneath), but the construction instructions make this a video which is worth watching. Scaling up the output from one tiny bulb to kilowatts of power is by no means the simple matter implied in the video, and I personally doubt that a passive device of this type could ever produce kilowatts of output power – at twelve volts you are looking at 165 amps of current requiring copper wire with a diameter of more than 7 mm to carry it.
Thomas Traweeger’s Electricity-Producing Pyramid.

One thing which is quite certain, and that is the fact that at this point in time, our technical know-how has not yet encompassed the zero-point energy field properly. It is by no means obvious how the Hans Coler device operates, and if we understood the technology properly, we would be able to say with certainty, exactly how and why it operates, and ways to improve it would be obvious. As it is, all we can do is look at it and wonder, possibly try a few experiments, but the bottom line is that we do not yet understand it. This is the normal situation in the early days of any new field of technology.

It is also quite usual for pioneers in any new field to encounter a good deal of opposition, mistrust, and generally disheartening treatment from other people. That is certainly the case for Thomas Traweeger from Austria, who has progressed well in the passive energy field. He has suffered repeated web-based attacks with his display material being destroyed and web sites being made inoperable.

So, what makes some people so afraid of Thomas? The answer is that he is experimenting with shapes. That doesn’t sound too terrible does it? Well, it certainly bothers some people, which suggests that he must be on the verge of uncovering a mechanism for drawing serious amounts of power from the zero-point energy field.
Thomas is by no means the first person to examine this area, but he is one of the first to consider drawing serious amounts of electrical energy from the local environment using shape and an appropriate detector. Obviously, this is the same area that Hans Coler was investigating, and it appears that Thomas has managed to tap a continuous 8 watts of electrical energy using a wholly passive device.

As we are not all that familiar with this type of technology, we tend to dismiss it as being a “crackpot” area, not worthy of investigation by serious scientists. It is actually, very far from being that in reality, and it just indicates our serious lack of technical understanding if we dismiss it out of hand. Two hundred years ago, the idea of a television set would definitely have been considered a “crackpot” pipe dream, far, far away from reality. Today, any schoolchild would be horrified at the thought of a TV set being considered “crackpot”. So, what has changed? Only our level of technology, nothing else. In another two hundred years time, when the zero-point energy field is fully understood, people will look back with a smile at the thought of people like us who didn’t know how to draw any amount of energy, freely from the environment, and they will laugh at the thought of burning a fossil fuel to produce energy from a chemical reaction. That, of course, does not help us at all in this time of our ignorance, and we still have to deal with the sort of people who thought that the horse-drawn cart would never be superseded.

The scientific method has been established for a long time now. Essentially, observations are made, experiments are performed and a theory is produced which fits all of the known facts. If additional facts are discovered, then the theory needs to be modified or replaced by another which includes all of the new facts. Established scientists find it difficult to adhere to the scientific principle. They are afraid of losing their reputation, their job or their funding and so are reluctant to investigate any new facts which indicate that some of their best-loved theories need to be revised. Fortunately, not being in the business, we can take new facts on board without any problem. In the light of what certain shapes do, this is just as well.

Let us see if we can put this in perspective. Consider an intelligent, well-educated person living several hundred years ago. Looking skyward at night, he sees the stars. At that time, the theory was that the stars were fixed to a ‘celestial sphere’ which rotates around the Earth. That was a perfectly good theory which matched the known facts of the time. In fact, the concept matches the observed facts so well that some people who teach Astro Navigation to sailors still find it to be useful in teaching the subject today. If you told the average person of those days, that the stars were not very small but very large indeed, that the Earth is orbiting around the Sun and in fact, the Sun is one of those ‘tiny’ stars, then you would have been considered one of the ‘lunatic fringe’.

Next, if you were to tell that person that there were invisible forces passing through the walls of his house and even through him, he would most certainly rate you as a bona fide member of the ‘lunatic fringe’. However, if you then took several compasses into his house and demonstrated that they all pointed in the same direction, he might start to wonder.

Now, just to really establish your membership of the ‘lunatic fringe’ you tell him that one day there will be invisible rays passing through the walls of all buildings and that these rays will allow you to watch things happening on the other side of the world. Finally, to complete the job, you tell him that there is a substance called uranium, and if he were to carry a piece around in his pocket, it would kill him by destroying his body with invisible rays.

Today, school children are aware of, the Solar System, magnetic lines of force, television and X-rays. Further, as the scientific theory has caught up, these children are not considered part of the ‘lunatic fringe’ but this knowledge is expected of them as a matter of course. The only thing which has changed is our understanding of the observed universe.

At the present time, we are faced with a number of observations which do not fit in with the scientific theories of some of the current educational establishments. If we consider these things seriously, we run the risk of being considered part of the ‘lunatic fringe’ until such time as scientific theory catches up with us again. So be it, it is better to examine the facts than to pretend that they don’t exist.

Present theory has worked well enough up to now, but we need to take on board the fact that since it does not cover all of the facts, it needs to be extended or modified. So, what observed facts are causing a problem? Well:

1. In Quantum Mechanics it has been found that some pairs of particles are linked together no matter how far apart they are physically. If you observe the state of one of the pair, the state of the other changes
instantly. This happens far, far faster than the speed of light and that does not fit neatly into present theory.

2. If a substance is cooled down to Absolute Zero temperature, it should be completely motionless, but that is not the case as movement can be observed. This movement is caused by external energy flowing into the frozen material. That energy, observed at Absolute Zero temperature is called ‘Zero-Point Energy’. So where does that fit into the theory?

3. There are several devices which are self-powered and which are capable of powering external loads. These things appear to act in defiance to the Law of Conservation of Energy.

4. The Aspden Effect (described below) indicates that current theory does not cover all of the facts.

5. It is now known and fully accepted by science that more than 80% of our universe is composed of matter and energy which we cannot see.

6. Even though our Sun is losing some five tons of mass per second, it radiates more energy than can be accounted for by the fusion of the amount of matter which would cause this loss of mass.

7. The inner core of the Earth is hotter than present theory would expect it to be.

These things indicate that there is something in our universe which is not properly covered by current theory. The present theory thinks of space as being a volume which contains no matter, other than perhaps, a tiny amount of inter-stellar dust. And while space can be traversed by radio waves and many other types of radiation, it is essentially empty.

This concept is definitely not correct. All of the odd observed facts suddenly fit in if we understand that there is an additional field which streams through all of space and passes unnoticed through all matter. This field is composed of particles so tiny that they make an electron appear enormous. These particles may in fact be the ‘strings’ of String Theory. What is sure, is that this stream of matter contains virtually unlimited energy.

It is the energy seen at Absolute Zero as it is continually streaming in from outside the cold area. It flows to us from every direction and the sun being a major source of it, augments the flow we receive during the daytime. This accounts for the variations seen by T. Henry Moray during the night when the energy he was picking up decreased somewhat.

This matter stream acts like a very dense gas except for the fact that effects in it have effectively zero propagation time. This accounts for the widely separated particles having what appears to be simultaneous reactions to a stimulus. Einstein’s idea of the speed of light being an absolute maximum is definitely wrong, as has been demonstrated in the laboratory.

In the early stages of investigating a new field, it can be quite difficult to work out how to approach it, especially if the field is entirely invisible and can’t be felt. The same situation was encountered in the early days of magnetism as lines of magnetic force are not visible and cannot be felt. However, when it was observed that iron was affected by magnetism, a mechanism was discovered for displaying where the invisible lines are located, by the use of iron filings. Interestingly, the presence of an iron filing alters the lines of magnetic force in the area as the lines “have a preference for” flowing through the iron. Also, the iron filings used in school demonstrations do not show the actual lines of magnetic force correctly as they themselves become tiny magnets which alter the lines of force which they are supposed to be showing.

We are still in the early stages of investigating the Zero-Point Energy field, so we have to consider anything which has an effect on this invisible field. One observed effect was found by Harold Aspden and has become known as the ‘Aspden Effect’. Harold was running tests not related to this subject. He started an electric motor which had a rotor mass of 800 grams and recorded the fact that it took an energy input of 300 joules to bring it up to its running speed of 3,250 revolutions per minute when it was driving no load.

The rotor having a mass of 800 grams and spinning at that speed, its kinetic energy together with that of the drive motor is no more than 15 joules, contrasting with the excessive energy of 300 joules needed to get it rotating at that speed. If the motor is left running for five minutes or more, and then switched off, it comes to rest after a few seconds. But, the motor can then be started again (in the same or opposite direction) and brought up to speed with only 30 joules provided that the time lapse between stopping and restarting is no
more than a minute or so. If there is a delay of several minutes, then an energy input of 300 joules is needed to get the rotor spinning again.

This is not a transient heating phenomenon. At all times the bearing housings feel cool and any heating in the drive motor would imply an increase of resistance and a build-up of power to a higher steady state condition. The experimental evidence is that there is something unseen, which is put into motion by the machine rotor. That “something” has an effective mass density 20 times that of the rotor, but it is something that can move independently and its movement can take several minutes to decay, while in contrast, the motor comes to rest in a few seconds.

Two machines of different rotor size and composition reveal the phenomenon and tests indicate variations with time of day and compass orientation of the spin axis. One machine, the one incorporating weaker magnets, showed evidence of gaining magnetic strength during the tests which were repeated over a period of several days.

Nikola Tesla found that uni-directional electric pulses of very short duration (less than one millisecond) cause shockwaves in this medium. These Radiant Energy waves passed through all materials and if they strike any metal object, they generate electrical currents between the metal and ground. Tesla used these waves to light glass globes which had just one metal plate. These lights do not have to be near the source of the Radiant Energy waves. He discovered many other features of these ‘longitudinal’ waves but one which is of particular interest is that when using his famous Tesla Coil, the waves produced visible streamers which showed what they were doing. What they were doing was running up the outside of the long inner wire coil, not through the wire, mark you, but along the outside of the coil, and when they reached the end of the coil, they continued on out into the air. Interestingly, Tesla believed that this flow of energy “preferred to run along the corrugations of the outside of the coil”. That is to say, somewhat like magnetic lines showing a preference for running through iron, this energy field shows a preference for flowing along certain physical shapes.

Thomas Henry Moray developed equipment which could tap up to fifty kilowatts of power from this field. There are two very interesting facts about Moray’s demonstrations: Firstly, the valves which he used to interact with the field, had a corrugated cylindrical inner electrode - an interesting shape considering Tesla’s opinion on the corrugated outer surface of his coil. Secondly, Moray frequently demonstrated publicly that the power obtained by his equipment could flow uninterrupted through sheet glass while powering light bulbs. Quite apart from demonstrating that the power was definitely not conventional electricity, it is very interesting to note that this power can flow freely through materials. I venture to suggest that Moray’s power was not flowing through the wires of his apparatus but rather it was flowing along the outside of the wires, or perhaps more accurately, flowing along near the wires.

Edwin Gray snr. managed to draw large amounts of power from a special tube designed by Marvin Cole. The tube contained a spark gap (like that used by Tesla) and those sparks produced Radiant Energy waves in the Zero-Point Energy field. He managed to collect energy from these waves, very interestingly, by using perforated (or mesh) cylinders of copper surrounding the spark gap. His 80 horsepower electric motor (and/or other equipment such as light bulbs) was powered entirely from energy drawn from the copper cylinders while all of the electrical energy taken from the driving battery was used solely to generate the sparks.

It is very interesting to note that Tesla, Moray and Gray all indicate that corrugated or rough-surface cylinders seem to direct the flow of this energy. Dr Harold Aspden also indicates that once the field is set in motion in any locality, it tends to continue flowing for some time after the influence which is directing it is removed.

Please remember that we are starting to examine a new field of science, and while we know a very limited amount about it at this point in time, at a later date, every schoolchild will be completely familiar with it and find it hard to believe that we knew so little about it, at the start of the twenty-first century. So, at this time, we are trying to understand how energy can be extracted from this newly discovered field. The indications are that the physical shape of some objects can channel this energy.

If you think about it, you suddenly realise that we are already familiar with shape being important in focusing energy. Take the case of a magnifying glass. When the sun is high in the sky, if a magnifying glass is placed in just the right position and turned in just the right direction, then it can start a fire. If the principles behind what is being done are not understood, then the procedure sounds like witchcraft:

1. Make a specially shaped object with curved faces, out of a transparent material
2. Discover the ‘focal-length’ of the object
3. Wait until Noon
4. Place some kindling on the ground
5. Position the object so that it looks directly at the sun
6. The kindling will catch light without you even having to touch it.

Sounds like something out of a book on magic, doesn’t it? Well, you need to know all about that if you want to pass any basic physics examination, and it comes in under the title of “Optics”. Please notice that the shape of the lens is vital: it must have a convex face on both sides. Also, the positioning is vital, the lens must be exactly its focal length away from the kindling material: a little too near or a little too far away and it just does not work. Magic? Well it may seem like it, but no, it is just scientific understanding of the nature of radiation from the sun.

Take the case of a satellite dish. This familiar object needs to be an exact shape to work well. It also needs to be made of a material which reflects high-frequency radio waves. Make one out of wood and it will look just the same but it will not work as the TV transmission will pass straight through the wood and not be reflected on to the pick-up sensor connected to the television set.

However, obvious and all as this is, it still did not cut any ice with the patent office in Czechoslovakia on the 4th November 1949. A radio engineer called Karel Drbal turned up with a patent application for a cardboard pyramid shape which kept razor blades sharp and was promptly told to get lost. The patent authorities demanded that he have a theory to show how the device worked. Karel was not particularly put out, and spent years investigating before he determined a theoretical basis for the device. He returned to the patent office, much to the disbelief of the Chief Patent Officer. He was granted his patent, not because his theory was compelling, but because the Chief Patent Officer took a pyramid home and tested it with his own razor blades. When his practical tests confirmed that the pyramid did exactly what Karel claimed, he was granted Patent No. 91304, “Method of Maintaining Razor Blades and the Shape of Straight Razors” and here is a translation:

Republic of Czechoslovakia
Office For Patents And Inventions
Published August, 1959
Patent File Number 91304

The right to use this invention is the property of the State according to Section 3, Paragraph G, Number 34/1957
Karel Drbal, Prague
Method of Maintaining Razor Blades and the Shape of Straight Razors.

Submitted 4 November, 1949(P2399-49)
Patent valid from 1 April, 1952

The invention relates to the method of maintaining of razor blades and straight razors sharp without an auxiliary source of energy. To sharpen the blades therefore, no mechanical, thermal, chemical or electrical (from an artificial source) means are being used. There are various mechanical sharpening devices being used up to now, to sharpen used razor blades. The blade is sharpened by crude application of sharpening material, which always results in certain new wear of the blade during the sharpening process. Furthermore, it is known that the influence of an artificial magnetic field improves the sharpening of razor blades and straight razors, if their blades are laid in the direction of the magnetic lines.
According to this invention, the blade is placed in the earth’s magnetic field under a hollow pyramid made of dielectric material such as hard paper, paraffin paper, hard cardboard, or some plastic. The pyramid has an opening in its base through which the blade is inserted. This opening can be square, circular, or oval. The most suitable pyramid is a four sided one with a square base, where one side is conveniently equal to the height of the pyramid, multiplied by \( \pi / 2 \). (which is \( \pi \) or 3.14 / 2). For example, for the height of 10 cm, the side of 15.7 cm is chosen. The razor blade of a straight razor is placed on the support made also of dielectric material, same as the pyramid, or other such as cork, wood, or ceramics, paraffin, paper, etc. Its height is chosen between 1/5 and 1/3 of the height of the pyramid, this support rests also on a plane made of dielectric material. The size of this support should be chosen as to leave the sharp edges free. Its height could vary from the limits stated above. Although it is not absolute necessary, it is recommended that the blade be placed on the support with its sharp edges facing West or East respectively, leaving its side edges as well as its longitudinal axis oriented in the North / South direction. In other words to increase the effectiveness of the device it is recommended lie in essence in the direction of the magnetic lines of the horizontal component of the earth's magnetism. This position improves the performance of the device, it is not however essential for the application of the principle of this invention. After the blade is properly positioned, it is covered by the pyramid placed in such a way that it’s side walls face North, South, East, and West, while its edges point towards North-West, South-West, South-East, and North-East.

It is beneficial to leave a new blade in the pyramid one to two weeks before using it. It is essential to place it there immediately after the first shave, and not the old, dull one. But it is possible to use an old one, if it is properly resharpened. The blade placed using the method above is left unobstructed until the next shave. The west edge should always face West. It improves the sharpening effect.

Example: When this device was used, 1778 shaves were obtained using 16 razor blades, which is 111 shaves per blade on the average. The brand used was "Dukat Zlato" made in Czechoslovakia. The lowest count was 51, the highest was 200. It is considered very easy to achieve up to 50 shaves on the average. (for a medium hard hair).

The following shows how the invention could save both valuable material and money. One of the razor blades mentioned above, weighs 0.51 grams. We will consider 50 shaves on average when placed in the pyramid against 5 shaves when it is not. It is obvious that the number of shaves, degree of wear, and the ability to regenerate the dull edge depends on the quality of the material, quality of sharpening process, and hardness. ...given that the numbers are averages and could be in fact much better. In the course of the year one therefore uses 73 razor blades without the aid of the pyramid while only eight razor blades while using the pyramid. The resulting annual saving would be 65 razor blades or 33.15 grams of steel per person.

Only the pyramid shape has been used for this invention, but this invention is not limited to this shape, as it can cover other geometric shapes made of dielectric material that was used in accordance with the invention. And that this shape also causes regeneration of sharp edges of shaving blades by lowering of stresses and reducing the number of defects in the grids of crystal units, in other words recovering and renewing the mechanical and physical properties of the blade.

This is interesting, as it confirms by independent test that a pyramid shape produces an effect, even if it is not possible to say with absolute certainty what exactly the effect is and how exactly the pyramid shape manipulates that energy.

Thomas Trawoeger has produced a video of a pyramid which he constructed. The video commentary is in German and it shows a computer fan being operated when connected to his pyramid which looks like this:
Sceptics will immediately say that as there are wires connected to the device, that the power for the fan is being fed through those wires, even though they appear to be connected to monitoring equipment. This is possible, but in my opinion, it is not actually the case. The pick-up used is shown here:

It should be remembered that these pictures are quite old and all inventors keep working on their inventions in an effort to improve their operation and to investigate the effects caused by alterations. At the close of 2007 the design has progressed considerably and now features a number of most unusual things ranging from construction to orientation. The [http://www.overunity.com/index.php/topic,695.300.html](http://www.overunity.com/index.php/topic,695.300.html) forum is working on replicating this design thanks to the generosity of Thomas Trawoeger who speaks German and the exceptional work of Stefan Hartmann who has produced an English translation and who hosts the web site.

The following is an attempt to present the basic information from that forum in a clear and concise manner, but I recommend that you visit and contribute to the forum if you decide to experiment with this design.
The frame of the pyramid is not the same shape as the well-known Egyptian pyramids and has a sloping face some 5% longer than those in Egypt. The materials used in constructing the pyramid are very important. The frame is made of 20 mm x 20 mm x 2 mm square-section steel tube. While the exact size of the pyramid is not critical, the exact proportions are critical. The base must be exactly square, with each side of the base being exactly the same length, 1 metre in this case. The sloping sides are exactly the same length as the base pieces being 1 metre long also. Eight one-metre lengths of steel section will therefore be needed for building the frame.

The sides of the pyramid need to be covered with a rigid sheet and here again, the material used is critical, with only gypsum/paper boards (plasterboard with no foil) being satisfactory - other materials just don’t work. If no sides are added, then the pyramid is very difficult to adjust to get proper operation. When the frame has been constructed, it is positioned in a most unusual way being forty-five degrees away from the conventional positioning of a pyramid. This sets this pyramid so that one pair of corners face North - South, and the frame should be connected to a good electrical ground as shown here:

The pick-up is constructed from 12 mm outside diameter copper pipe and fittings and is hard soldered together. It has an overall size of 120 mm x 100 mm hard soldered together as shown here:
This frame of copper piping is not assembled as shown straight off as there is a requirement for a long graphite rod, 2 to 3 mm in diameter, to be positioned vertically inside each vertical leg of this frame and that can’t be done after assembly. So the bottom section is assembled as one piece, and the top section is assembled separately with the graphite rods sticking down out of the T-sections, held in place by their wires and insulating plugs. The graphite rods can be bought from art materials supply shops.
The very fine filter-grade quartz sand filling for the tubes is inserted and the graphite rods carefully positioned so that they do not touch the side walls of the vertical copper tubes, and the two parts joined by hard soldering:
The left hand side hole in the copper pipe is used to inject a 5% salt / water solution, using a hypodermic syringe, until the water starts to come out of the hole at the right hand side. The right hand side hole is 5 mm lower down than the one on the left.

Next, the wires are bent around to produce a 9-turn coil with a 25 mm diameter, around the vertical copper pipes. The windings are in opposite directions on the opposite sides of the frame:

Next, a ten-plate capacitor is made from copper sheets 1 mm thick. As copper is very expensive, the copper plates can be produced from spare lengths of copper pipe, cut along the axis and flattened careful to produce a smooth, unmarked surface 70 mm x 35 mm in size. The plates are stacked and accurately aligned, and a hole is drilled 1 mm off-centre. Then each alternate plate is turned around to produce two sets of plates bolted together with a 6 mm diameter plastic bolt, 1 mm thick plastic washers and a plastic nut. A plastic threaded rod and a plastic nut can be used instead of a plastic bolt. Because the hole is not quite central, the plates stick out at each end, giving clearance for attaching the plates together with the copper wire coming out of the copper pipe framework:

**Capacitor Construction**

[Diagram of capacitor construction]
The capacitor is positioned inside the copper pipe frame and held in place by the strength of the 2.5 mm thick copper wire coil around the vertical pipes in the frame:

The pick-up sensor is now attached to the pyramid frame. Using a non-conductive cord, it is suspended by the top lug and its orientation controlled using the lower two lugs. The positioning in the pyramid is unusual, being North-East to South-West, as is shown here:

Next, a second capacitor is constructed from 1 mm thick copper sheet. Again, sections of copper pipe can be used after being cut along their long axis and carefully opened out and flattened. This capacitor is just two plates 140 mm x 25 mm spaced 1 mm apart (one inch = 25.4 mm).
A voltmeter can be used to check the exact alignment of the pyramid. There is a video (with a commentary in German, at http://www.secret.tv/player_popup.php?id=1307723&movieid=1308850 showing an earlier version of this pyramid set-up driving an electrical fan taken from a computer). If this device interests you, then you should join the enthusiast research and development forum mentioned earlier.

In June 2011, Thomas issued instruction videos which show how to construct, use and troubleshoot his newer design of pyramid. These videos are in English and they are very detailed and instructive. One person has split those two very long videos and placed them on YouTube as a series of thirteen smaller videos. In them, he states that the salt water in the design above is actually counter-productive and should not be used.

I will not attempt to show the construction details described in those videos as the information is very extensive, but a few comments may be appropriate here. Thomas refers to a ‘wheel’ but unless I am mistaken, he means a solid plastic rod of circular cross-section. The coil wire which he uses is 1.5 mm diameter copper wire with plastic insulation. With an inner coil of 104 turns, that can produce 1.5 amps at 14 volts, which is 21 watts, and with no input power being provided by the user, that is a COP of infinity. However, if I understand what he is saying, he positions his pyramids North-South (unlike the design above) and more importantly, at a particularly good point on what he calls a ‘water-line’ which I take to be a ley line located by a dowser. That may be due to the fact that he lives in a village in Austria which is a long way from the Equator, which, according to Joseph Cater’s analysis of pyramids, reduces their effectiveness.

In this new design, Thomas uses 20 watts of power from a Citizen’s Band radio transmitter, boosted by an amplifier, and applied to his detector tube while he fills it very slowly with fine-grain, high-quality quartz sand. This signal orientates most of the quarts grains and probably replicates most of Thomas Henry Moray’s detector which allowed such high power extraction from a simple aerial. In this design of Thomas’ no earth wire is needed for operation. An earth wire is provided, but this is for the protection of the user and is not part of the energy gathering system. Thomas agrees with Joseph Cater, that the energy being tapped flows out of the top of the pyramid.
Thomas’ website which is in German is [http://www.comshop.tv/](http://www.comshop.tv/)

Thomas picks a fairly small size of pyramid for his demonstration tutorial. It is made using eight pieces of steel channel, each piece being exactly one meter long. He welds these together but remarks that bolting them together is perfectly all right provided that each piece makes good electrical contact with the pieces which it touches as the whole frame acts as a single component in his design.

Thomas also talks about ‘welding’ the inner copper pipe to one end cap, but what he means is ‘soldering’ the joint as he spreads resin on the join, heats it with a gas torch and then runs plumber’s solder around the join.

Thomas’ video series was removed from the web but has been replaced here:

**********

Antoine Bovis’ Discoveries.

Confirmation of the dehydrating effect of a pyramid was provided by the Frenchman Antoine Bovis who went on holiday to Egypt in the 1930s and visited the Great Pyramid which was constructed exactly in the North-South direction (almost certainly not by accident) and built to an accuracy of 0.01% or better. He discovered that a number of small animals had wandered into the pyramid, got lost and starved to death. The really interesting point was that all of these animals had been mummified through dehydration and none of the bodies had rotted away. When he returned home, he built a model pyramid with base edges three feet long.
He found that his pyramid duplicated the dehydration effect. He, and others who followed him, investigated the effect of pyramids. They found:

1. The best shape is that which matches the dimensions of the Great Pyramid, whose faces slope at an angle of 51 degrees, 51 minutes and 10 seconds. Pyramids with other slopes will work, but not quite as well. If you would like to make one yourself and test the effects, then each of the four sides can be cut from stiff cardboard to these proportions:

So if the base length is to be 20 units, then the height at the mid point of the base will be 16.18 units.
If the base length is to be 25 units (mm, cm, inches, or whatever), then the height should be 20.22 units.
If the total base width is to be 30 units, then the height at it’s mid point should be 24.27 units.
If the total base width is to be 35 units, then the height should be 28.32 units, and so on.
The right-angled triangles formed have a height of 1.618 (the "golden ratio") times the base width.

Just cut out four of the triangles and tape the edges together. It would be a good idea to add a square base piece (or triangular gussets) to ensure that the base is exactly square and not skewed.

Thomas Trawoeger states that the exact angle is not particularly important and his latest designs have angles of about sixty degrees.

2. There is no need for the pyramid faces to be solid, provided that there are four base sides and four sloping edges. Having solid sloping faces gives a slight improvement and Thomas considers that at least three of the sloping faces should have panels, the material type being important.

If building a framework pyramid, then the dimensions for the four base pieces and the four sloping edges would be:
Base: 20, length of the sloping edges: 19
Base: 25, length of the sloping edges: 23.76
Base: 30, length of the sloping edges: 28.52
Base: 35, length of the sloping edges: 33.27 and so on.

3. The best material from which to construct the pyramid is copper, but as it tends to be rather expensive, almost any other material can be used: plastic piping, timber laths, steel alloy pipes, wire, etc. Giving the pyramid a sheet-copper cap which runs down about 5% of the face length, giving a short solid face on the open framework also gives a slight improvement. Les Brown states that the best material is sheet iron plated with gold, though that sounds very expensive.

So, what can a pyramid do? Well, nothing, actually, except for directing and possibly concentrating and focusing the Zero-Point Energy field. Perhaps the question should be ‘what effects are caused by using a pyramid?’.

Well, as seen above, Flavio Thomas Trawoeger has managed to get a continuous electrical output via a pyramid for a period of at least thirty days. I understand that he uses a magnet just as an on-off switch, but having a magnet as part of the pick-up makes a lot of sense as the magnetic dipole of any magnet has a distinct effect on the zero-point energy field. The low-tech investigators have noted that an effect caused by a pyramid may be repeated for maybe nine times in a row, and then inexplicably, one day it will not work. They surmise that the effect may be caused by magnetic variations due to solar flares or the like. They may well be right in this as they are not using a magnet but just simple cardboard, or more frequently, simple
frame pyramids. This area is wide open to investigation with very low-tech apparatus and passive electronic components.

What has been found repeatedly:

**James Brock’s Experiments.**

1. Living things placed under a pyramid shape are boosted in health and growth. You can test this easily for yourself by taking two identical plants or animals and keeping one under a pyramid and one outside the pyramid. An example of this is given on the website: http://www.motherearthnews.com/Sustainable-Farming/1977-11-01/Raising-Rabbits.aspx where James Brock of Texas reports on tests he has run on a group of rabbits. It would be incredibly easy to fake this kind of information, so you need to make up your own mind on the validity, and ideally, run some simple tests of your own. James states that he built a pyramid-shaped hutch with 4-foot long sloping edges out of timber, and a rectangular hutch:

![Pyramid and Rectangular Hutch](image)

Each of the hutches had a transparent door. He then borrowed eight rabbits aged about 20 days old, taken from two different litters and placed them in matched groups of four in each hutch, and fed them equally, weighing them every four days.

By the end of the experiment, 57 days later, the rabbits which had been housed in the pyramid hutch weighed an average of 46.5 ounces, compared to an average of 34.5 ounces for those in the rectangular hutch. That is, the rabbits in the pyramid hutch were nearly 35% heavier and side by side they looked like this:
James presents the results like this:
James invites you to run this test for yourself to verify that this does indeed occur. It should be noted that as the test ran over a period of 57 days, any days lost through magnetic variation would not have been detected by him.

2. Pyramid users also state that they find the following effects on a consistent basis (provided that the pyramid is kept away from strong electromagnetic fields, so do not put a pyramid on top of a TV set or a refrigerator):

(a) Fruit is preserved. When a purchase of fresh fruit or vegetables is made, if they are placed under a pyramid for about an hour and then stored as they normally would, it is said that they stay fresh for at least twice as long as normal and the flavour is enhanced. It is believed that unhelpful micro-organisms are killed by the pyramid. If the fruit and vegetables are kept indefinitely under the pyramid they eventually dry up instead of rotting.

(b) Food quality is enhanced. If frozen meat, fish or fowl is thawed out under a pyramid, the quality of the meat is said to be noticeably improved.

(c) Coffee quality is improved. If a cup of coffee is left under a pyramid for about twenty minutes, it is said to gain a much more mellow flavour. Leaving ground coffee or a jar of instant coffee under a pyramid overnight is also said to change it so the coffee made from it is of a much higher quality.

(d) A glass of wine placed under a pyramid for twenty minutes is said to undergo a distinct change with great improvement seen in both the taste and the aroma. Other alcoholic drinks are also said to be improved by this process.

(e) A twenty to thirty minute treatment of fruit juices is said to reduce the acidic “bite” of the drink, and in many cases, alter the colour of the juice.

(f) Any item pickled in vinegar, such as olives and pickles, gain a greatly enhanced natural flavour and are greatly mellowed by the process.

(g) The rapid growth of mould on Cheddar cheese can be overcome by the cheese being kept under a pyramid at normal room temperature. It is recommended that the cheese be wrapped in plastic to reduce the rate at which it dries out.

(h) Rice and wheat can be kept in open jars under a (twelve-inch open frame wire) pyramid for at least four months without any form of deterioration or infestation by insects or flies - which are repelled by the energy inside the pyramid. A test was run outdoors with a six-foot base pyramid with food placed in the centre to attract ants. It was found that ants heading for the food followed a curved path out of the pyramid without ever reaching the food.

(i) Water left under a pyramid is altered. Cut flowers placed in it tend to last 30% longer than normal while growing plants watered with it grow more strongly and are harder. The water appears to hold the
energy indefinitely, a glassful takes twenty minutes, a quart (two pints) takes one hour and larger amounts should be left over night. Animals given the choice of pyramid water or untreated water almost always choose the treated water.

3. In the 1940s, Verne Cameron of America discovered that the beneficial pyramid energy could be transmitted. He placed a pyramid at each end of a row of plants, connected a wire to the apex of each pyramid and ran the wire underneath the plants. He placed a clump of steel wool on the wire under each plant. The pyramids were, aligned North--South and he found that even better results were obtained if the row of plants was also aligned in a North--South direction.

4. There are reports of instances where dogs suffering from old age, lameness and hair loss have been cured and rejuvenated in about six weeks by the use of a pyramid.

I suggest that the Great Pyramid in Egypt was most definitely not built as a burial place but that the chamber inside it was used to treat people with large amounts of the energy picked up by the shape of the pyramid. It is also likely that the pyramid was used as a communications device, but that is outside the scope of this document.

The really important thing is that there is clearly an energy field (perhaps the ZPE field) which flows continuously, is very beneficial to life and which can be tapped to produce unlimited motive power without the need for any kind of input from us. Just like the early discovery days of radio waves, TV signals, X-rays, Gamma rays, etc. we are in the discovery days of the Zero-Point Energy field. You, personally, have as much chance of being successful in harnessing this energy as any large research laboratory with unlimited financial resources. Remember that Flavio Thomas can drive an electrical fan using equipment which costs next to nothing. A cone shape with the same face slope as a pyramid is also an effective shape, and no matter how you position it, it always has a face pointing North--South. May I also remark that it might be worth experimenting with the “pancake” coil (called a bi-filar series-connected coil) patented by Tesla because he found that it was particularly effective in picking up Zero-Point Energy:

The Patent of Peter Grandics.
Other people have also investigated pyramid and cone shapes and they confirm that there is indeed a considerable effect from these shapes. Peter Grandics has been awarded US patent 6,974,110 for the collection of electrical energy from a pyramid shape. He tested the system both with an applied high voltage and without any applied voltage, and discovered electrical pick-up in both cases. Here is a digest of part of his patent:

**SUMMARY OF THE INVENTION**

This invention describes a simple technique to convert the energy of a DC electrostatic field into an alternating current by wrapping a coil around a pyramid. The resulting AC current can be rectified and used for practical purposes. A pyramid-shaped capacitor can also be used in an inverse mode of operation for the generation of propulsive force.

Accordingly, one embodiment of the present invention is a method for converting DC electrostatic energy into usable electrical energy, the method comprising the steps of:

(1) Providing a capacitor of pyramidal shape;
(2) Placing an insulated coil on the surface of the capacitor, the coil having leads;

(3) Attaching a rectifier to the leads of the coil, the rectifier having leads; and

(4) Attaching a capacitor or a battery to the leads of the rectifier so that DC electrostatic energy is converted into usable electrical energy.

**DESCRIPTION OF THE PREFERRED EMBODIMENT**

This invention describes a novel method of converting DC electrostatic energy into an AC current which can be rectified and used for practical purposes. The shape of the capacitor and the body of such device is designed to convert the DC electrostatic energy into the AC current for maximum effect.

![Diagram](image)

A pyramidal or conical shape is preferred for one of the capacitor electrodes. In Fig. 1, a detector coil 102 is provided that which connected to an oscilloscope 104. The coil surrounds the metallic pyramid 100. In the experimental set-up shown, the field is established between a top plate 106 and the pyramid 100 by using a ground 108 connected to a source of DC electrical energy 110. When a high voltage DC field (30 kV) is established on such capacitor, a regularly repeating, clock-like signal is detected in the coil placed on the pyramid's surface (Fig. 2). This is an unexpected observation as corona discharges are irregular by nature.

The alternating current from the coil can be rectified and used for practical purposes. If a suitable DC electrostatic field could be found in nature, this principle would be useful in tapping the energy of such field. To test for this possibility, I have measured the rectified signal from the coil without an external power source. The rectified coil output was collected in a capacitor and voltage measured at intervals of one hour. The voltage measured is significantly higher if the capacitor electrode is pyramid-shaped as opposed to a box-shaped electrode of the same height and volume. When the pyramid is placed inside a Faraday cage, the signal is excluded (see details in the Example). The data have demonstrated in principle that with this experimental set-up, electrical energy can be extracted from the Earth's electrostatic field. The Earth's surface and the ionosphere substitutes for the two charged electrodes, which exhibit negative and positive polarities, respectively.

**EXAMPLE 1**

Demonstration of the pyramid generator: For the experiments, I have selected a one-foot base length foam pyramid from a pyramid vendor (The Pyramid Project, Ft. Wayne, Ind.). The outside of the pyramid was covered with aluminium foil. The pyramid was placed on a 2 foot × 2 foot insulating polyethylene platform equipped with an adjustable height 2 foot × 2 foot size aluminium top plate, 1/16" thick. The height of the aluminium plate was adjusted as needed and a gap of 1.25" between the plate and the tip of the pyramid was used in the experiments. In some experiments, an aluminium pyramid was used with a wall thickness of 1/16".

A high voltage (HV) CRT power source producing 30 kV DC was taken from a colour monitor. I have assumed that an actual energy-producing pyramid should be relatively high in order to obtain a large voltage drop from its tip to the ground. Therefore, assuming a height of 100-150 m for a life-size pyramid and a voltage drop of 200-300 V/m near the surface of the Earth, the 30 kV is in the range of the voltage-drop expected for the height of a life-size pyramid.
The positive pole was attached to the top aluminium plate. This simulated the positive charge of the atmosphere. One corner of the pyramid was attached to the negative pole of the high voltage power source, while the opposite corner of the pyramid was grounded. This set-up served as a model for the electrostatic field distribution around a potential life-sized pyramid. As controls, either a 1 foot × 1 foot sheet of aluminium foil or an aluminium foil-covered box, having the main dimensions of the test pyramid (1' × 1' × 7.625"), was used as a negative pole. The detector coils were made by winding 20 turns of 24 gauge enamel-coated magnet wire, approximately 8 cm in diameter. A Tektronix high-frequency oscilloscope, Model no. 2236 was used for signal analysis.

The first sets of experiments were control measurements with a box of the same height and base length as the test pyramid. The detector coil was placed on the top of the box. Measurements were taken with or without the high voltage applied. One corner of the box was attached to the HV power source (negative pole) and the opposite corner to the ground. The same arrangement was used for the flat square (1'×1') foil. The peak-to-peak signal amplitude for the box was 8 mV and the signal frequency was 2 MHz. For the flat foil sheet, the signal amplitude was 12 mV with a frequency of 1.43 MHz. The signal form was of a decaying sine wave.

When high voltage was applied to these shapes, signal amplitude of 14 mV was obtained for the flat sheet and of 16 mV for the box. The signal frequency was 1.54 MHz for the flat sheet and 2 MHz for the box. The waveforms were of decaying sine waves in all these experiments.

When the pyramid was tested without HV, the peak-to-peak signal amplitude was measured at 60 mV with a frequency of 2 MHz. When the high voltage was applied, the signal amplitude increased up to 180-200 mV, while the frequency remained at 2 MHz. The pyramid produced signal intensity significantly higher than the controls. The signal is regularly repeating, clock-like in nature (Fig.2). When a metal (aluminium) pyramid of the same size (wall thickness 1/16" inch) was tested in the same high voltage field using the same detection coil, a voltage of 1 to 1.5 V was detected at the frequency of 2 MHz.

To collect energy from the coil, a bridge rectifier (1000 V peak voltage at 6 A) was attached to the leads of the coil. The rectified current was fed into a capacitor (1500 microfarad, 250 V DC max.), and a direct current of 45 V was obtained. This has demonstrated a simple method to convert electrostatic energy into a continuous direct current. An 8-turn coil having an output of 200-300 V AC (peak-to-peak) was also used for energy conversion. The rectified current from the 8-turn coil powered a 0.186 W light bulb (Fig.3). Ideally, the bridge rectifier is made of fast-recovery diodes.

Even in the absence of an externally applied voltage, current is always present in the circuit. Charge builds up in the capacitor and 1 V was obtained overnight using the 20-turn coil set-up. Over 48 hours, a voltage of 5 V was measured. Faraday shielding practically prevented the phenomenon.

The preferred shape of the pyramid as a charge collector was again demonstrated in further experiments using the 8-turn coil-bridge rectifier-capacitor (1,500 microfarad) assembly placed on the 1 ft base length aluminium pyramid. A same-volume and height aluminium box was used as control. Charging times of 1-2 hours were used under fair-weather conditions. For the pyramid, 550 mV was measured on the capacitor while on the box 100 mV was obtained. This demonstrated the superiority of the pyramidal shape in capturing atmospheric electrostatic energy. It also demonstrated that we could tap into the electrostatic field of the atmosphere and draw electric energy. For the collection of energy, a battery could substitute for the capacitor.

You should also check out the pyramid aspects of the cutting-edge work of Paulo and Alexandra Correa as detailed in Chapter 11.

The Pyramids of Les Brown.

Les Brown experimented extensively with pyramids and related devices. It should be stressed at this point that while various facts have been observed, the action caused by a pyramid is not fully understood at this time and no "laws" have yet been deduced. We have to work here on the basis of "this is what was done, and these are the results". Because of this, the following extract from the work of the late Les Brown is reproduced here and you must decide for yourself if what he says is true and whether or not it might be worth your while trying out some of what he says:

In conducting pyramid experiments you should look daily for signs of change and note them meticulously, and above all be patient. Don't plant a seed one day and expect to have a plant six feet high the next. A plant takes just as long to develop inside a pyramid as it does outside,
but in time you will see the tremendous difference in size. Also, don’t keep moving plants around inside your pyramid during an experiment; leave pots stationary so you can see what the results are.

Here, you will see how to make your own pyramids for experimentation; they can be constructed entirely from inexpensive materials equally as well as from costly ones. Cardboard, wire, plywood or anything rigid enough to retain the pyramid shape will suffice. The pyramid does not necessarily have to be solid; in many experiments just the outline shape is sufficient, provided that it is jointed at all corners and at the apex.

An "energiser" array of small pyramids can be made from cardboard and positioned at the corners of a large pyramid to enhance its operation. An array might have 5 rows of four little pyramids or perhaps twelve rows of six pyramids. Individual small pyramids can be made from cardboard and then assembled on a base to form the array. The following template could be used for this, just ensure that the base is square:

A pyramid energizer has multiple uses. The one shown above consists of 72 small cardboard pyramids and a top plate of cardboard covered with foil. By placing the top plate on top of the pyramids and orienting the entire energizer to magnetic north, you can use the energy generated for such purposes as mummification, energizing water, or as a beneficial surface on which to place growing plants for outstanding growth.
Remember that with all types of pyramids, positioning is all-important. One of the sloping sides must at all times be facing towards magnetic North - not a corner but the flat face of the pyramid must face magnetic North. Use a compass to determine the direction of magnetic north which will be nearly in line with the Pole star, (but not quite). In this respect, a pyramid is like a radio. For maximum performance you must tune it in properly, pointing it right at the transmitter. Similarly, several pyramids with one face towards magnetic North and stacked on top of each other will produce increased energy, cell activity and growth.

Using pyramids, I sincerely believe that I can grow 36 times more and better plants in a given area than any farmer or market gardener can in the same area, using conventional methods.

All kinds of shapes contain energy, the very nature of the shape itself determines the degree of energy which it contains, that is, the shape determines how receptive it will be to energy flows. By shapes I refer mainly to cubes, spheres, triangles, pyramids and the like. Each shape has potential, but they all have different limits and we should seek the one which offers the most potential. Of all shapes, the pyramid gives us the best performance because it receives the greatest amount of energy. It must be four-sided, of specific measurements and correct angles, and it must have the correct compass orientation. There are dangers in using a pyramid blindly without knowledge of its functions and its great potential. When all four sides are put together you must have a pyramid which is leaning in at 51 degrees, 51 minutes, 14 seconds.

The energy inside the pyramid is said to come down through the peak and continues coming in until it reaches a certain intensity, or the limits of safety, at which point the pyramid releases all the energy and begins collecting it again. The pyramid is said to release 80% of its energy through the peak and the other 20% via the four base corners. Only a pyramid performs this way, and even then the maximum performance is obtained only by a perfect pyramid. So, when you start to build one, aim at perfection. The nearer you can get to a perfect pyramid, the more you will benefit.

You can grow bumper crops with the use of a pyramid. Anything growing beside an iron fence will be bigger and better than one nowhere near metal. The reason is that the iron fence picks up static or magnetic energy and feeds it to the plant. I remember my mother and grandmother placing large nails in the soil of their potted house plants because plants thus treated always grew bigger and better. They had no idea why. In fact, if you asked them, the standard answer was that, as the nail rusted, the plant fed on it. This reasoning is fallible, however, because for one thing, plants can only absorb minerals in liquid form and for another, the rust would kill some plants. Rather, the nails picked up the magnetic energy and boosted the house plants' growth. When a plant receives an extra dose of energy to that already floating free in the atmosphere, that dose acts as a stimulant and causes better growth. What really happens is that the living cells are increased in size, and naturally when each cell is larger, since there are still the same number of cells, the final plant is a lot larger than normal.

If you grow a plant in a pyramid, it absorbs energy at a much higher intensity than that produced by the nails in the plant pots, and so the end result is enormous growth. When this is applied to vegetables and fruits, the plants, as well as their products, are immensely oversized. My own experiments have convinced me that this energy creates a special reaction in living cells of plants, resulting in larger blooms, leaves and fruits on whatever plants are propagated within the pyramid.

The normal life cycle of lettuce, for instance, from seed to maturity, is six to eight weeks. Grown under a pyramid the life cycle is still the same, but the plant is considerably larger. If one allows the vine type of tomato to mature to six or seven trusses under a pyramid while simultaneously allowing an identical plant to do the same outside the pyramid, giving both plants precisely the same feeding and watering, a startling difference in yield occurs. I should mention that if you put your outside plant too near the pyramid, it will reach for, and receive, some of the pyramid's energy, so keep it well away to get a fair test. The outside tomatoes would weigh out at approximately 10 to 14 pounds per plant, whereas the plant grown in the pyramid would produce between 50 and 60 pounds of tomatoes. Not every type of plant grown under a pyramid will produce this increase; this is the average that I have come to expect from tomatoes.

A few more averages I have obtained repeatedly were: lettuce two to three times larger than average; beans 25 inches long by 1.25 inches wide; cabbage - when controls were three pounds each, the pyramid-grown plants were 12 to 13 pounds per head; radishes that normally would be the size of a quarter were four inches in diameter; controlled cucumbers that averaged 14 inches in length and weighed up to one pound normally, were 21 inches long and weighed up to four pounds when grown in the pyramid and the pyramid also warms your whole house and cleanses the air which you breathe.

Energised air in the pyramid also appears to repel small insects; though, there is no need for pesticides to be
used within its glass walls. Pest-free plants grow to maturity inside, with none of the setbacks plants subject to normal attack from pests suffer in the garden outside. This also means that pyramid-grown vegetables need no washing upon harvesting. The mere appearance of such plants is more appetising than that of those grown normally. Greens are more vivid, and many leaves have a sheen which is noticeably absent from plants in kitchen gardens. Artificial fertilisers will never be used in my pyramid. Since many fertilisers apparently are becoming short in supply themselves, the ability to grow plants without their use is a double blessing for all mankind. I will use natural farmyard manures, the best way to regain the succulent taste and nutrition which are missing from plants grown with chemical fertilisers.

An egg broken out of its shell and left within the confines of the pyramid will gradually congeal and become like plastic, as the interior energy works on its cells - harmlessly. The cells do not die nor induce putrefaction. After a period of even weeks or months these congealed eggs can be reconstituted in water to the point where they can be eaten with complete safety, and they taste even more delicious than eggs produced in the usual way.

One peculiar phenomenon which I have observed under my large pyramid is the formation of dew on the plants inside it. This happens early in the morning. During all my years of experience with greenhouses, I never noticed dew forming on any plants in conventional greenhouses. This dew gently dissipates as the sun grows stronger, exactly as it would outside. Also, after a recent thunderstorm, my pyramid cucumbers grew two to two and a half inches in a matter of a few hours.

I built a pyramid purely for research purposes. For large-scale production, one which is much greater in size would be needed. When building the prototype, I encountered and overcame, virtually all the problems one can expect to meet in a construction of this type. Building a pyramid is nothing like building a house, and while a slight difference in measurements can be overcome when building a house, it is not possible to make a mistake in a pyramid and just carry on building. The particular piece containing the error must be pulled out and replaced correctly, as any mistake is transferred all the way around the pyramid.

My test pyramid is 30 feet high along a perpendicular line from ground to peak. The sides from base corner to peak measure 44 feet 4.5 inches, with a baseline of 46 feet 10.5 inches. It contains two additional floors above the ground level, and the sum of the areas of these two floors equals or is greater than that of the ground floor. Thus, the two additional floors virtually double the growing area. My first floor is 12 feet above the ground, and there is a reason for this. I calculated that when the sun was at its highest point the first floor would have to be positioned at 12-feet high so as to allow the sun to shine on to the back north edge of the ground floor. The 12-foot height was perfect, its achievement resulting from a mixture of good judgement and a bit of luck. However, I would not need to build a growing level at this height again because there are as many plants that grow well in shade as there are those that prefer growing in the sun. In future, my floors will all be eight feet apart, and I will put my sun-loving plants in the southern half and my shade-loving ones in the back northern half.

By placing the floors at eight-foot intervals there is much more growing area available than there is in placing the first floor at a 12-foot height. In addition, choosing this lower height allows the upper floors to decrease more slowly in size than they would if placed farther apart. Obviously, as the peak of the pyramid is approached, the floors decrease in area. One of the benefits obtained with these extra floors is that since heat rises, there are higher temperatures on each floor nearer the top of the pyramid. This allows a wide range of crops to be grown.

To illustrate the temperature difference, if the ground floor were 75°F, then the second floor would reach a temperature of 90°F, and the third floor would be around 105°F to 115°F, each floor having higher humidity. This means that anything from cool to tropical crops can be grown within one pyramid. The ground floor is perfect for such crops as radishes, lettuce, carrots, beets, tomatoes, etc., while the second floor is ideal for cucumbers, squash, peppers, and plants which like it hotter and more humid than the first floor. The top floor can be used for lemons, oranges, figs and especially, orchids.

The pyramid draws in its own water on the ground floor; I have never had to water that level being built directly on the ground. It never draws too much or too little water, always just the right amount for growth. Naturally, I have to pump water to the upper floors, but because the first floor provides its own water supply, at least half of my pyramid is watered for nothing automatically. I grow right in the ground the pyramid stands on, but upstairs I have placed wooden planting troughs all around the floors, leaving room to walk, and I grow plants in these. It is a major job getting the soil to the upper floors initially, but it is only a one-time task. The troughs are 16 inches deep and 14 inches wide, and contain a bottom. There is a run all around the
allowing passage from one run to the other.

Space in the pyramid is used to the utmost. At the perimeter of the low areas, I plant the kind of plants that need little headroom, and then plant bigger crops toward the middle. This is a matter of common sense, but using vine type tomatoes and stringing them up, one can work between the rows better, and if the lower leaves are removed, there is sufficient space to grow lettuce, cabbage or any low-lying crop in between the tomato plants. The trusses may be left on the tomatoes; they will not shade the low-lying plants. To ensure a steady supply of food, it is wise to plant only a few plants of each variety at intervals, which means that in the beginning it will take several weeks to reap a full harvest, but subsequently there will be a continuous yield.

By planting in such a manner, the grower will reap about six full crops each year. This method applies only to an enclosed pyramid, which would also require heating in the winter. The means of heating is up to the individual. Personally, I use a wood stove because I have my own wood supply. However, a wood and oil combination is best because it allows one to be away for a couple of days when necessary. If the wood fire gets low, then the oil burner takes over.

As for growing potentials of the floors of the pyramid, I have found that the second floor is the best place for germinating new seeds. I find that I can get germination in three days on that floor, whereas it usually takes five days otherwise. Thus far I have described the pyramid from the growing aspect only to the point of showing you how and where to grow crops, but let's take a look at a few statistics on production. Your garden, for instance, will only give one crop a year, but the pyramid through the means I suggest will give you six crops per year. Now let's compare two pieces of ground, both the same size, one with a pyramid on it. Say the garden is 50 feet square and the pyramid is 50 feet square. The upper floors inside the pyramid give you approximately 2,500 square feet of growing area upstairs to go along with your ground floor area of 2,500 square feet, and you are getting six crops per floor as opposed to one, or twice times six, the equivalent of 12 times your garden yield. Nor is that all of the advantage. Recall my discussion of the increase in size of the plant cells; this itself gives an average of three times the size of a normal crop. Multiplying the 12 times by the size of the crop, you are 36 times better off than with a single garden.

In addition to food growth, the pyramid also has application in food preservation. I have read statistics stating that 40 percent of all food grown in my home country of Canada is lost to putrefaction, whether at the place of storage, in transport, in wholesale and retail, or finally in the home. Regardless of how this spoilage occurs, this state of affairs can be remedied. The energy of the pyramid which grows plants so amazingly well, can also be used for the purpose of mummification of food, which can be dehydrated and kept in storage for an indefinite period without losing any of its taste or nutritional properties. There are absolutely no ill effects on any food stored in a pyramid. In fact, in many instances it is far better when reconstituted than it was in the first place. It has the water taken out of it; but it also repels bacteria and as a result, nothing will rot in a pyramid. For instance, I cannot make a compost heap inside my pyramid; I have to do it outside; otherwise the ingredients in the compost all remain in good shape and will not break down. For further proof, the grain grown in Manitoba today is a direct descendant of the grain found in the Great Pyramid, grain that had been there for centuries and had kept perfectly.

Earlier I mentioned mummifying eggs. I conducted an experiment in mummifying an egg, using a pyramid energizer instead of a single wire pyramid. The energizer consisted of a small batch of one-inch-high pyramids, 20 in all, positioned in a group. Using such a grid of pyramids provides quicker results than using just one pyramid. I broke an egg into a dish, placed the dish on top of the energizer and observed what happened in the ensuing days. In about six hours I noticed the lower perimeter of the yolk turning a pale yellow, and this continued through each day, the pale colour gradually moving up to the top of the yolk. In the meantime, the white was becoming less fluid, thickening, so to speak. In two weeks the whole egg was just like glass; the yolk was hard and the white was now in crystal form. At no time would flies or any insect approach it, even though it was open to them. Flies were as prevalent as usually, but they would not go near the egg. There was never any smell present from start to finish.

I left the egg in this state for about three months and showed it to many of my visitors, but then it was time to reconstitute it and try it for taste. I added some water (an egg loses about 30 grams of water in such a period) and left it 24 hours. It then boiled some water with the intention of poaching the egg. When the water was ready, I tipped the egg in, and immediately the albumen turned snowy white and the yolk a perfectly natural yellow colour. Had I dropped the egg before reconstituting it, it would have shattered, but now it was simmering away, looking just like a fresh egg. After cooking the egg I put it on a plate, salted and peppered it, then cut the yolk through with my knife, and it flooded across my plate. I admit I was not in too big a hurry.
to eat it, but if I was going to prove something, I had to taste it. I smelled the egg, and it was no different from normal, so I ate it. I can honestly say it was one of the nicest eggs I have ever tasted; it seemed to have more flavour than usual.

I do not know of any food that cannot be treated in such a manner. I have tried preserving every food I can think of, and it all keeps indefinitely, with no refrigeration necessary.

Since publicity was first given to my large, wooden pyramid some three years ago, I have been inundated with letters, phone calls and personal visits. People from all walks of life and many different places in North America and Europe and indeed a few from further afield - Australia, Africa and the East Indies - all have expressed an interest and have given me kind encouragement. Many of these letters, calls and visits have had as their objective the gathering of practical information on the building of pyramids and the problems likely to be encountered.

My pyramid is made from rough sawn timber, cut on and near my own property and milled by a neighbour. But it is not necessary for pyramids to be made of wood. They can be made of any rigid material which will support permanent glazing: cardboard, strong wire, sheet steel or metal, angle irons, logs - anything which will not curve and that can be precisely measured and fitted.

Nor do pyramids have to be solid for many uses; open-sided shapes will do, so long as all corners are joined and the angles are correct. My present pyramid is made of timber and covered with heavy-gauge plastic sheet. Future ones will be sheathed in fibreglass, acrylic or glass. They will be closed pyramids solely because I propose to grow food during the depths of Canada's frigid winters.

My pyramid frame is built mainly of wood measuring two inches by four inches and two inches by eight inches rough sawn (not planed all over). Pyramids can be built to any scale as long as the proportions are correct.

There is a video of Les Brown on the web at this time. It shows him describing some of his experiences with pyramids. It is at http://www.youtube.com/watch?v=P7VN6B2GjVI and in it, Les describes an experiment which he carried out on his very large agricultural pyramid. First, he constructed a helical coil using co-axial cable which he sketches this way:
The coil was then placed on a 1/4" (6 mm) thick sheet of plywood and the end of the wire in the centre of the coil was inserted through the plywood and the central conductor pushed into the ground. The other end of the wire was bent up to act as an aerial, and the board itself was stapled through with two inch long wire staples driven into the ground and acting as further grounding for the coil, as he sketched here:

Les then climbed up a ladder and fastened another coil under the apex of the pyramid. This coil he wound out of multi-stranded copper wire. The wound it in the shape of an inverted cone with the wire going in a counter-clockwise direction and he spread the top strands out like an aerial array. He drew it this way:

He then decided to connect the two coils together using a strand of natural wool, so he tied it to the bottom of the coil at the apex. He climbed down the ladder and standing on the ground, he took hold of the piece of wool and was thrown several feet away by the energy flowing through the wool. This frightened him so much that he took the pieces apart and never investigated that type of arrangement ever again. He believes that it was because he was grounded when he grasped the wool, that there was such an energy flow through him. If you decide to try this with a smaller pyramid, then I suggest that you connect the wool to the lower coil first, making the earth connection that way, before tying it to the upper coil. However, let me stress again that we just don't know what is happening in and around the pyramid, so any experiments which you choose to carry out are entirely your responsibility and at your own risk. Although a good deal of practical information is given here, it must not be construed as being a recommendation that you make or use any of the devices described in this document as the presentation is for information purposes only.

Les Brown mentions other uses for the devices which he has developed. He says: My wife, who suffered from migraine headaches, had a severe attack for a week; and during that time she took an abundant supply of pills, which proved to be of no benefit. She placed a pyramid on her head in the early hours of the night, and in about 20 minutes had been relieved of all pain. She said nothing of this to me, but two weeks later suffered another headache. Instead of suffering for a lengthy period, she used the pyramid again, and without the use of pills the headache vanished again in about the same length of time. She told me about this second episode. About a week later she suffered an ordinary headache and repeated the performance, with the same result. She now has gone three years with no headaches at all. Around this time, I had been working all day in the hot sun, and the back of my neck became quite painful. I tried placing a small pyramid on the back of my neck while I sat still for a while. It produced the same relieving results for me. I believe it increases blood circulation to the affected part.

After about ten minutes I could feel the pain being drawn out upwards. At the same time my head felt cold on top, not cold to the touch, but simply felt cold to me. I mentioned this to my wife, and she said she had
had the same sensations of coldness but was waiting for me to remark about them first. I am not suggesting that this treatment will do the same for everyone, but merely mentioning that it worked for us.

The elderly mother of a friend of mine, her hands badly crippled with arthritis, was persuaded to place her hand on an energiser. A wire pyramid was put over both hand and energiser for one hour. She continued this treatment for a few days, experiencing a diminution of pain and a loosening of her fingers each time. Before she returned to her home in England she actually sat and played the organ. She played haltingly and rustily, it is true, but she had been unable to play at all for several years prior to using the pyramid. Significantly, her hands returned to their crippled state shortly after she returned to England as her pyramid was stolen at London Airport.

We also find that when we are feeling low and depressed, my wife and I sit for an hour or so, each with a small pyramid on our head, facing North, our depression lifts and we feel quite rejuvenated. My wife and I regularly drink pyramid-treated water. If we are feeling low we have a snifter of pyramid water and in a short time we feel a marked lift. On the other hand, if we find ourselves in what used to be described as a choleric state and sit with the pyramid on our head - but facing south -our irritability rapidly leaves and is replaced by a state of calm.

A prominent acquaintance of mine who does not wish to be named, always drives with a pyramid under his car seat. He claims he feels less “bushed” after a long drive than he did before using a pyramid. Many investigators have found that by putting a pyramid or an energiser over, or under, their beds, they experience better and more refreshing sleep, some of them claiming they need far less sleep than they required before using a pyramid for this purpose.

The real keynote when trying these pyramid experiments is persistence. As with many other experiences, pyramids do not always “work” the first time you apply one to a situation, and a person must “stay with it” and make subtle corrections until the desired results are obtained. Putting energized water into a vase containing tulips caused them to last for about three and a half weeks. Not only did they last this phenomenal length of time, but they grew about nine inches during that period! I have never before seen flowers grow after having been cut.

Many people claim that insect stings stop itching after the application of energised water; this has been our own experience. On one occasion I had a nasty cut on my hand. Immediately after washing it with pyramid water, the pain stopped and when it was fully healed, I had no scar. The cut also healed much more quickly than is “normal” for me.

Please be aware that the energy channelled by pyramids and the Joe Cell described below is very powerful and more than capable of running a vehicle without the use of any kind of visible fuel. Dealing with this power is not an established science and we are just blundering around the edges of a science which has not been properly investigated, so at this time it is a case of discovering what tests have been carried out and analysing the results to see if there is a solid pattern leading to repeatable tests which can be performed by anyone.

We are at about the same place as the Wright brothers were in 1903 just after their successful powered flight at Kitty Hawk. They took their "Flyer" back to Dayton, Ohio and discovered that it wouldn't fly. The problem was not immediately obvious to them. Being down at sea level and in an uncomfortably high wind, was essential for their device to be able to get off the ground, but understanding why and how to overcome the problem was not immediate as the theory of practical heavier-than-air flight was not established at that time. The same situation applies today to pyramid power.

**Joseph Cater’s Pyramid Analysis.**

There has been a good deal of disagreement between people in different locations, on how effective or otherwise, a pyramid is in day to day use. A very astute scientist by the name of Joseph H. Cater explains that this is due to the pyramid being powered primarily by energy flowing from the Sun, and so, people who live near the Equator will find a pyramid much more effective than people living in high latitudes.

Mr Cater explains exactly how a pyramid operates, but to understand his explanation fully, you will probably need to read the extract from one of his books, which is included in Chapter 15., to discover what “soft particles” are, where they come from and what effect they have on everything around us.

Mr Cater says that the energies concentrated inside a pyramid have been shown to be extremely beneficial to humans. Soft particle bombardments from outer space and especially from the Sun, concentrate inside
the pyramid. Some, passing through the surface of the pyramid are slowed down to such an extent that the Earth’s gravitational field, repelling the negative charges, tends to keep them inside until collisions with other particles drives them out.

Most of the particles collected by the pyramid, concentrate along the edges as would be expected, since electricity on any charged body tends to do much the same thing, with concentrations at points and along edges. In fact, pyramid frames have been found to be nearly as effective as the closed pyramid, if, and only if, there is a continuity in the framework and no breaks in any of the joining parts.

The soft electrons collected on a pyramid frame or closed pyramid, soon reach saturation point and continued bombardment causes the excess to drop down inside the pyramid. This, coupled with the gravity-repelling forces, causes a high concentration inside the pyramid. The proportions of the pyramid are apparently a factor in it’s performance. If the sides are too steep, many of the soft electrons will move along the edges into the ground outside instead of being forced inside the pyramid. If the sides are not steep enough, not many particles will be collected as they strike the material at nearly a right angle which causes only a small reduction in velocity. If they strike at a sharper angle, there is a greater tendency for them to be retained by the material.

If two side of the base are aligned with magnetic North, it is allegedly more effective. Pyramids can be rendered more potent by lining the interiors of a non-metallic enclosed pyramid, with metal foil such as aluminium or copper. The foil allows a greater quantity of soft electrons to accumulate around the non-metallic outer portion because the soft particles do not pass through the metallic substance as easily, causing a back-up of soft particles. During the process, the foil absorbs large quantities of soft particles before many of them can enter the pyramid. Pyramids also radiate soft electrons upwards from the peak.

Many of the soft particles which are stopped briefly on the outside of the pyramid, are repelled upwards by the Earth’s gravitational field, and as well, by soft electrons attached to the pyramid. This produces a funnelling effect which ejects soft electrons from the apex of the pyramid. The Earth’s gravity accelerates soft particles at a far greater rate than it does ordinary matter as soft particles are associated with ethers.
which are much closer to those of the gravity-inducing particles than is the case for ordinary matter. After the pyramid becomes saturated, a greater quantity of soft particles than ever, will concentrate inside. The foil will continue to radiate a high concentration of soft particles during the night when the number of particles bombarding the pyramid is considerably reduced.

It is found that pyramids work better during the summer than at any other time of the year. They are also more effective in the lower latitudes because most of the energy concentrated by the pyramid comes from the Sun. There are conflicting opinions as to the effectiveness of pyramids because of this as there is little understanding of the principles involved. For example, those who experiment with pyramids in Canada may claim that they don’t work while those in Southern California will contradict them. A pyramid does not increase the flow of soft particles through the area covered by the pyramid as the same concentration flows outside the area. What a pyramid does, is impede the general flow of soft particles and produce a back-up of particles inside and below the pyramid, and consequently, a higher concentration of soft electrons in these regions. The material used in a pyramid is of great importance. This was demonstrated when a wealthy man in the Midwest built a pyramid-shaped house five stories high, which was then covered with gold-plated iron. The phenomena produced were completely unprecedented. For example, ground water was forced to the surface and flooded the first floor. This was because the soft particle concentration inside and below the pyramid was so great that ground water was impregnated with such an abnormal concentration of negative charges that it was repelled upwards by the Earth’s gravity.
